The so-called male kola is essentially distinct from kola, being said to be the fruit of a small tree, Garcinia Kola (fam. Guttiferae Heck.), and containing no caffeine. The fruit is oblong, about one and a half to three inches long and from three-quarters to one inch broad; it is trigonal in section, with a readily removable thin testa of a reddish-yellow to dark brown color, covered by markings which resemble those on the seed coat of the nutmeg. It is bitter and astringent. In the section the microscope reveals a number of resinous masses surrounded by cells rich in starch.

The seeds of Lucuma mammosa Griesbach (Fam. Sapotaceae), sometimes mixed with kola nuts, are recognized at once by their strong odor of prussic acid. Heekel and Schlagdenhauffen have observed the seeds of Heritiera litoralis Dryand (fam. Sterculiaceae) mixed with kola nuts. These false kola nuts contain no caffeine, and are nearly orbicular and flattened in shape, one of the fleshy, purplish-brown cotyledons being only half the size of the other. (A. J. P., 1887, 446.)

**Kosam Seeds.** Fructus Bruceae, Pharm. Nederland.—The seeds of the Brucea sumatrana Roxb. (Fam. Simarubaceae) indigenous in China and Southern Asia. Schlagdenhauffen found in them saponin, and Physalis and Bertrand a glucoside, kosamin. They are asserted to be useful in menorrhagia, also in dysentery and diarrhea. (P. J.; lxiv, p. 463.) According to Power and Salway (Year-book of Pharmacy, 1907), the B. antidysenterica has similar properties and is largely used in Abyssinia.

**Kossala.**—An Abyssinian remedy against tape worm. (Proc. A. Ph. A., xxvi.) It is said, however, to produce gastric irritation.
"Krameria Root is the dried root of Krameria triandra, Ruiz and Pav. (Peruvian Rhatany), and also of another species of Krameria, probably Krameria argentea, Mart. (Para Rhatany)." Br. "The dried root of Krameria triandra Ruiz et Pavon, known in commerce as Peruvian Rhatany, or of Krameria Ixina Linne, known in commerce as Savanilla Rhatany, or Krameria argentea Martins, known in commerce as Para or Brazilian Rhatany (Fam. Leguminosae), without the presence of more than 5 per cent. of stems or other foreign matter." N. F.

The genus Krameria was named in honor of J. G. H. Kramer, a physician and botanist of Temesvar, Hungary.

Krameria was dropped from the U. S. P. IX but retained in the British Pharm., 1914, and in the N. F.

Krameria triandra is a shrub, having a long, much-branched, spreading root, of a blackish-red color; with a round, procumbent, very dark colored stem, divided into numerous branches of which the younger are leafy and thickly covered with soft hairs, giving them a white, silky appearance. The leaves are few, sessile, oblong-ovate, pointed, entire, presenting on both surfaces the same silky whiteness of the young branches. The flowers are lake-colored, and stand singly on short peduncles at the axils of the upper leaves. The stamens are three. The nectary is of four leaflets, the two upper spatulate, the lower roundish and shorter. The fruit is globular, of the size of a pea, surrounded by stiff reddish-brown prickles, and having one or two seeds. It is a native of the Peruvian Andes, growing in dry argillaceous and sandy places. It flowers at all seasons, but is at the height of its bloom in October and November. The root is dug up after the rains, and, according to Tschudi, it is especially obtained in the southern provinces of Peru. Closely allied to it is K. Ixina L., which yields Savanilla Rhatany. It is, however, distinguished by having four stamens, and occurs in Guiana and Northern Brazil. The name rhatany is said to express in the tongue of the Peruvian Indians the creeping character of
the plant yielding the root.

Para or Brazilian Rhatany was described by Berg in 1865, and is believed to be the root of the K. Argentea. It closely resembles the Savanilla variety. Two forms of rhatany which Cotton has described as Black and Brown Antilles rhatany because produced in these islands have been pronounced by Fluckiger (P. J., July, 1870, p. 84) to be identical with the Para Rhatany. According to the studies of Dunwoody (A. J. P., 1890) this rhatany contains the same active principles as the root of K. Triandra, but in slightly less quantity.

The British Pharmacopoeia recognizes two varieties of rhatany, which are described as follows: "Peruvian Rhatany is nearly cylindrical, slightly flexuous, reddish-brown; length variable; thickness not exceeding fifteen millimetres. Cork scaly; fracture splintery; wood yellow. In transverse section, bark bright reddish-brown and occupying about one-third of the radius of the section. Para Rhatany is cylindrical, nearly straight, dark purplish-brown or almost black, and marked with deep transverse cracks. Fracture short; wood pale reddish-brown. In transverse section, bark dark reddish-brown and occupying about one-half of the radius of the section. Both varieties inodorous; taste of the bark astringent, of the wood scarcely perceptible. Ash not more than 4 per cent."

The N. F. description is as follows:

"Peruvian Rhatany.—It consists of a knotty, several to many-headed crown with numerous branching roots, the latter rarely attaining a length of 50 cm. and usually less than 1 cm. in thickness, cylindrical, somewhat tapering, and flexuous or wavy; externally light reddish-brown or brownish-red, more or less marked with dark scaly cork, especially in the upper portion, otherwise nearly smooth, somewhat longitudinally wrinkled and devoid of transverse fissures, fracture of bark slightly fibrous, of wood tough and splintery, the pinkish-brown bark less than one-third of the radius, the wood yellowish or pinkish-white and finely radiate. Inodorous, wood nearly tasteless, bark astringent.

"Savanilla Rhatany and Para Rhatany.—Roots usually separate, less flexuous and tapering than those of Peruvian Rhatany, and usually not exceeding 12 mm. in thickness; externally purplish-brown or
chocolate-brown and marked with numerous transverse fissures; fracture less tough than that of Peruvian Rhatany; internally the bark and wood darker, the bark about two-fifths or more of the radius and more astringent than that of Peruvian Rhatany. Inodorous, wood nearly tasteless, bark astringent. Powdered Krameria is reddish-brown; starch grains simple or two- to four-compound, the individual grains spherical, ellipsoidal, or plano-convex, and sometimes with a central, radial or star-like cleft, from 0.003 to 0.035 mm. in diameter; bast fibers more or less wavy in outline with very much attenuated ends and with non-lignified walls; trachea with simple or bordered pores associated with numerous wood fibers which are narrow-spindle shaped and with thick, porous, slightly lignified walls; numerous cellular fragments with yellowish or reddish-brown walls; calcium oxalate in monod clinic prisms, from 0.01 to 0.1 mm. in length, few or frequently absent. Macerate 2 Gm. of powdered Krameria with 10 mils of alcohol, with occasional stirring for one hour, and filter. The deep reddish colored filtrate obtained yields a dark brownish-red precipitate and a deep orange-red filtrate upon the addition of an excess of alcoholic lead acetate T.S.; this latter filtrate yields no precipitate upon the further addition of a drop or two of alcoholic lead acetate T.S., and yields an olive-brown solution having a purplish fluorescence upon the addition of a drop or two of ferric chloride T.S. Krameria yields not less than 9 per cent. of aqueous extractive and not more than 5 per cent. of ash.

A. rhatany appeared not long since in the London market from Guayaquil. It is described as a large woody root from 1 to 5 cm. in diameter. The bark is of a reddish-brown color with blackish streaks, is thin in comparison to the pith, is of a fibrous texture, and is somewhat striated on the surface and dotted over with small warts. It has a very astringent taste, but no marked odor. E. M. Holmes thinks that it is not the product of the genus Krameria. According to the analysis of Passmore, Guayaquil rhatany contains a larger quantity of tannin than the Peruvian drug, but less than the Para or the Savanilla rhatany. (P. J. 1903, lxxvi, 878.) A spurious rhatany of unknown botanical origin has appeared in the English market coming from Peru. The root is tapering and varies from two to three and a half inches in length, and a quarter to five-eighths of an inch in diameter. The bark is reddish-brown, rough, scaly and longitudinally grooved. The root has a short fracture and a meditullium of about 24 wedge shaped bundles, is odorless and of an astringent taste. For detailed macro- and microscopical descriptions, see P. H. Marsden, P. 3., 1901, 618.
According to an analysis made in the University of Wisconsin, the Krameria lanceolata Torrey, of North America, yields 34.5 per cent. of extract and 17 per cent. of tannin, and is therefore richer than the official drug. When treated with iron it strikes a deep-purple color, and is thus easily distinguished from Para rhatany, which gives a dirty brown color, and from Savanilla rhatany, which gives a violet color.

As the astringency is much stronger in the cortical than in the ligneous portions, the smallest pieces are preferable, as they contain the largest proportion of the bark. The powder is of a reddish-brown color. The starch grains occur single or two- to four-compound, the individual grains being spherical, ellipsoidal, or plano-convex, and sometimes with a central, radial, or star-like cleft, from 0.003 to 0.035 mm. in diameter. The bast fibers are more or less wavy in outline with very much attenuated ends and with non-lignified walls. The tracheae possess simple or bordered pores associated with numerous wood fibers which are narrow-spindle shaped and with thick, porous, slightly lignified walls. There are also numerous cellular fragments with yellowish or reddish-brown walls. Calcium oxalate may occur in monoclinic prisms, from 0.01 to 0.1 mm. in length. Macerate 2 Gm. of powdered Krameria with 10 mils of alcohol, with occasional stirring for one hour, and filter. The deep reddish colored filtrate obtained yields a dark brownish-red precipitate and a deep orange-red filtrate upon the addition of an excess of alcoholic lead acetate T.S.; this latter filtrate yields no precipitate upon the further addition of a drop or two of alcoholic lead acetate T.S., and yields an olive-brown solution having a purplish fluorescence upon the addition of a drop or two of ferric chloride T.S. Krameria should yield not less than 9 per cent. of aqueous extract and not more than 5 per cent. of ash.

The virtues of the root are extracted by water and alcohol, to which it imparts a deep reddish-brown color. From the researches of Vogel, Ghnelin, Peschier, and Trommsdorff, it appears to contain tannic acid, lignin, and minute quantities of gum, starch, saccharine matter, and an acid which Peschier considered as peculiar and named krameric acid. The tannic acid of rhatany (krameria-tannic or ratanhia-tannic acid) is separated by treating the ethereal extract of the bark with alcohol, and evaporating the alcoholic solution. It gives a dark-green precipitate with ferric chloride, a flesh-colored one with gelatin, and none with tartar emetic. (Gmelin.) The tannin of rhatany, in the presence of
melted potassium hydroxide, is transformed into protocatechuie acid and phloroglucin, and with diluted acids gives glucose and a peculiar red coloring principle called ratanhia red, \( \text{C}_{26}\text{H}_{22}\text{O}_{11} \). (J. P. C., Jan., 1868, p. 73.) The proportion of red astringent matter obtained by Vogel was 40 per cent. The mineral acids and most of the metallic salts throw down precipitates with the infusion, decoction, and tincture of rhatany, and are incompatible in prescription.

In examining a specimen of extract of rhatany from America, Wiittstein discovered an alkaloid, which he thought to be identical with tyrosine. A somewhat different result was obtained by Ruge, who, after an examination, showed that the new alkaloid is not identical with tyrosine, for it has the formula \( \text{C}_{10}\text{H}_{12}\text{NO}_{3} \), while that of tyrosine is \( \text{C}_{9}\text{H}_{11}\text{NO}_{3} \), but is rather homologous with it. Like tyrosine, it is an amido-acid, and forms salts equally with mineral acids and with strong bases. It was called ratanhine by Ruge. Goldschmidt has since shown (D. C., 1914, 17) that the formula of rhatanin is \( \text{C}_{49}\text{H}_{43}\text{NO}_{3} \), and that it is a homologue of tyrosine. It is identical with angelin, geoffrayin, and andirin, which have been described in various plants. He obtained it in crystalline needles, melting at 280° C. (536° F.). (See A. J. P., 1875, p. 266.)

Cold water extracts all the astringency of rhatany, forming a clear deep-red infusion, which upon careful evaporation yields an almost perfectly soluble extract. The root yields its virtues also to boiling water by maceration, but the resulting infusion becomes turbid upon cooling, in consequence of the deposition of apotheme taken up by the water when heated. By boiling with water a still larger proportion of the apotheme is dissolved, and an insoluble quantity of the pure tannin becomes insoluble in cold water, and medicinally inert, either by combining with the starch which is also dissolved, or by conversion into apotheme through the agency of the atmosphere. The decoction is, therefore, an ineligible preparation, and the extract resulting from its evaporation, though greater in weight than that from the cold infusion, contains much less soluble and active matter. Alcohol dissolves a larger proportion of the root than water, but this is owing to the solution of apotheme, and the alcoholic extract contains little if any more of the astringent principle than that prepared by cold water, while it is encumbered with much inert matter. (See Extractum Krameriae.)
A very delicate test for the presence of rhatany is given by Gucksmann (Ph. Post, 1912, 65), who states that if an extract containing it be diluted with water until almost colorless, the addition of 0.5 Gm. of sodium bicarbonate to 10 mils of the liquid will produce a rose red color.

**Uses.**—Rhatany is an active astringent, and may be advantageously given in chronic diarrhea. It has long been used in Peru as a remedy in bowel complaints, as a corroborant in cases of enfeebled stomach, and as a local application to spongy gums. Ruiz, one of the authors of the Peruvian Flora, first made it known in Europe. In the form of infusion, tincture, or extract, rhatany has been used locally in fissure of the anus, prolapsus ani, and leucorrhea.

Dose, of the powder, twenty to thirty grains (1.3-2.0 Gm.).

F.; Trochiscus Krameriae (from Extract), Br.; Trochiscus Krameriae et Cocainae (from Extract), Br.; Fluidextractum Krameriae, N. F.; Fluidglyceratum Krameriae, N. F.; Pulvis Gambir Compositus, N. F.; Syrupus Kramerise, N. F.
[This was the last era in pharmacy when plant drugs were widely prepared, both for Regular School, Eclectic and Irregular physicians, and the Dispensatories were the major reference works used by pharmacists to prepare these products. Official plant drugs and preparations are in larger case, unofficial plant drugs and preparations are in smaller case. I have extracted all plant drugs and preparations, excluded non botanicals and those most reasonably used only by physicians...Opium, Digitalis, etc. Michael Moore]

**Lac.** Lacca. Resina (Gummi) Lacca. Laque, Gomme lacque, Fr. Lack, Oummilack, G.—A resinous substance obtained from several trees growing in the East Indies, particularly from Croton laccifera L. (Fam. Euphorbiaceae); several species of Ficus, especially F. religiosa L. and F. indica L. (Fam. Artocarpaceae), and, according to Valentine Ball, Schleichera trijuga Willd. (Fam. Sapindaceae), Butea frondosa Roxb., of the Fam. Leguminosae, and Zizyphus jujuba Lam. (Fam. Rham-naceae). Stillman states that Acacia Greggii A. Gray (Fam. Leguminosae) and Covillea tridentata (DC.) Vail. (Larrea mexicana Moric.) (Fam. Zygophyllaceae), plants growing in Arizona, Colorado, and the Western territories, furnish both shellac and lac dye. (A. J. P., 1880, 409.) Lac is found in the form of a crust, surrounding the twigs or extreme branches, and is generally supposed to be an exudation from the bark, owing to the puncture of an insect belonging to the genus Coccus, and designated C. lacca. By some it is thought to be an exudation from the bodies of the insects themselves, which collect in great numbers upon the twigs, and are embedded in the concreted juice, through which the young insects eat a passage and escape. Several varieties are known in commerce. The most common are stick-lac, seed-lac, and shellac.

Stick-lac is the resin as taken from the tree, still encrusting the small twigs around which it originally concreted. It is of a deep reddish-brown color, of a shining fracture, translucent at the edges, inodorous, and of an astringent, slightly bitterish taste. Its external surface is perforated with numerous minute pores, as if made by a needle, and when broken it exhibits many oblong cells, often containing the dead insect. When chewed it colors the saliva red, and when burnt, diffuses a strong, agreeable odor. It is in great measure soluble in alcohol.

Seed-lac consists of minute irregular fragments, broken from the twigs and partially exhausted by water. It is of a light or dark brown color, inclining to red or yellow, feebly shining, almost tasteless and capable of imparting to water less color than the stick-lac, sometimes scarcely coloring it at all. It is occasionally mixed with small fragments of the twigs.

Shellac is prepared by melting the stick-lac or seed-lac, previously deprived of its soluble coloring matter, straining it, and pouring it upon a flat smooth surface to harden, or pulling it out by hand into large thin sheets, which are broken up after cooling.
A variety of lac is mentioned by writers, in the form of cakes, called cake-lac or lump-lac (lacca in placents); but this is at present rare in commerce.

According to John, lac consists of resin, coloring matter, a peculiar principle insoluble in alcohol, ether, or water, called laccin, a little wax, and various saline matters in small proportion. The resin, according to Unverdorben, consists of several distinct resinous principles differing in their solubility in alcohol and ether. The laccin is nearly or quite wanting in shellac, which also contains scarcely any of the coloring principle. Hatchett found in stick-lac 68 per cent. of resin, and 10 of coloring matter; in seed-lac 88.5 per cent. of resin, and 2.5 of coloring matter; in shellac 90.9 per cent. of resin, and 0.5 of coloring matter. The other constituents, according to this chemist, are wax and gluten, besides foreign matters. R. E. Schmidt (Ber. d. Chem. Ges., 1887, 1285-1303) has prepared the lac dye in a pure crystallized state. He gives it the formula $C_{16}H_{12}O_8$, and calls it laccaic acid. It was obtained crystallized from ethereal solution. Caustic alkalies dissolve it, giving a magenta color. Baryta water forms a violet lake. Laccaic acid shows some analogy to carminic acid, but the colors they give on wool and silk are different. Laccaic acid is decomposed on heating with concentrated hydrochloric acid to 180° C. (356° F.), as well as on fusing with caustic potash.

Japanese lac from Rhus vernicifera was examined by A. B. Stevens. (See Proc. A. Ph. A., 1905, 311.)

The importations of gum shellac for the year 1914 was 16,824,130 lbs., valued at $2,686,480; and for 1915, 24,308,145; lbs., valued at $3,018,296.

Lac in its crude state is slightly astringent, and was formerly used in medicine, but at present it is not employed. Shellac is wholly inert. It is sometimes used in alcoholic solution as a glaze for confectionery. The use of such insoluble resinous glaze for a food product is prohibited in some states partly on account of its indigestibility per se and partly because in its preparation for varnish or pigment purposes arsenical compounds are used to heighten the color and many instances are on record where confectionery which had been coated with such glaze contained appreciable amounts of arsenic. A bleached form of arsenic-free lac has recently appeared in commerce, which would seem to be free from many of the objections previously urged against lac in coating confectionery. Stick-lac and seed-lac are used on account of the coloring principle which they contain. Shellac, as well as the other varieties, deprived of their coloring matter, is applied to numerous purposes in the arts. It is the chief constituent of sealing wax. The best red sealing wax is made by melting together, with a very gentle heat, 48 parts of shellac, 19 of Venice turpentine, and 1 of balsam of Peru, and mixing with the melted mass 32 parts of finely powdered cinnabar. But common rosin is often substituted in part for the lac, and a mixture of red lead and chalk for the cinnabar. For methods of detecting adulteration with rosin see J. Soc. Chem. Ind., 24, 1905; also Chem. Ztg., 1910, 991. The best black sealing wax consists of 60 parts of lac, 10 of turpentine, and 30 of levigated bone black; the best yellow sealing wax, of 60 parts of lac, 12 of turpentine, and 24 of lead chromate. (Berzelius.) Lac is also used as a varnish, and forms an excellent cement for broken porcelain and
earthenware. It may be dissolved in alcohol, oil of turpentine, benzin, or naphtha. For a method of preparing a colorless varnish from lac the redder is referred to P. J., 1864, 338. Lac has been highly recommended as an adhesive material for the dressing of wounds, ulcers, etc. It is prepared for use by dissolving, with the aid of a gentle heat, in alcohol contained in a bottle, sufficient lac to give it a gelatinous consistence, and then closing the bottle. It is used by spreading it on the bandages. For details of the preparation of shellac, see U. S. D., 19th ed., p. 1543.

**LACTUCARIUM. U. S.**

**LACTUCARIUM Lactucar.**

"The dried milk-juice of Lactuca virosa Linne (Fam. Compositae)." U. S.

Lactucarium Anglicum, Lactucarium Germanicum; Strong-scented Lettuce, Green Endive; Lactucarium, Fr. Cod.; Gifflattichsaft, G.; Lactucario, Sp.

The plants of this genus yield when wounded a milky-juice, to which, indeed, they owe their generic name. The juice from L. sativa, L. virosa, and L. altissima Bieberstein has been supposed to possess narcotic properties.

Lactuca sativa or garden lettuce is an annual plant. The stem, which rises above two feet, is erect, round, simple below, and branching in its upper part. The lower leaves are obovate, undulate and rounded at the summit; the upper are smaller, sessile, cordate, and toothed; both are shining, and of a yellowish-green color. The flowers are pale yellow, small, and disposed in an irregular terminal corymb. Before the flower-stem begins to shoot, the plant contains a bland pellucid juice, has little taste or odor, and is much used as a salad for the table, but during the period of inflorescence it abounds in a milky juice, which readily escapes from incisions in the stem. The juice is more abundant in the wild than in the cultivated plants. The original native country of the garden lettuce is unknown. The plant has been cultivated from time immemorial, and flourishes equally in hot and temperate latitudes. Some botanists suppose that L. virosa of the old continent is the parent of all the varieties of the cultivated plant.

Lactuca virosa, the acrid or strong-scented lettuce, is biennial, with a stem from two to four feet high, erect, prickly near the base, above smooth and divided into branches. The lower leaves are large, oblong-
ovate, undivided, toothed, commonly prickly on the under side of the midrib, sessile, and horizontal; the upper are smaller, clasping, and often lobed; the bracts are cordate and pointed. The flowers are numerous, of a sulphur-yellow color, and disposed in a panicle. The plant is a native of Europe.

It is lactescent, and has a strong disagreeable odor like that of opium, and a bitterish, acrid taste.

Lactucarium is cultivated in Scotland, Germany, Austria and France. According to Fairgrieve (P. J., 1873, iii, p. 972) the plant cultivated in Scotland is the *L. virosa*, var. montana. From May to August, or even as late as September, the collectors spread over the field cutting the head of each stalk and scraping the flow into their vessels. This is repeated several times daily until the plants are exhausted. The method of cultivation in the Mosel Valley, Germany, is described by Kieffer (Ph. Zeit., i, p. 143), who states that the drug of Germany is shipped to England and later imported into the United States via San Francisco, where it is supposedly used in the adulteration of opium. The cultivation in France is described by Van Italic (J. P. C., 1913, viii, p. 449).

For various plans which have been suggested for collecting the drug, see 14th ed., U. S. D.

Lactucarium, as brought from England, is in small, irregular lumps, about the size of a pea or larger, of a reddish-brown color externally, and of a narcotic odor and bitter taste. As prepared near Edinburgh, it is commonly in roundish, compact, and rather hard masses, weighing several ounces. (Christison.) A variety known in our market as German lactucarium is in pieces about 4 cm. long by 2.5 cm. in thickness, four-sided, with one side convex and the three others flat, or slightly concave from shrinking, as if quarter sections of a saucer-shaped cake which had been divided before it was quite dry. The color on the outer or convex surface is darkish brown, that of the out surfaces light yellowish-brown. From experiments by Parrish and Bakes, the German appears to be inferior to the English, as 44 per cent. of spirituous extract was obtained from the latter, and only 36 per cent. from the former, while the two extracts were about equal in their sensible properties. (A. J. P., 1860, p. 226.) French lactu-cariuna resembles the German, except in being in circular cakes about 4 cm. in diameter. The official description is as follows: "Usually in quarter sections of hemispherical
masses, or in irregular, angular pieces; externally dull reddish- or
grayish-brown; fracture tough, waxy; internally light brown or
yellowish; somewhat porous; odor distinctive, opium-like; taste bitter.
Lactucarium is partly soluble in alcohol and ether and, when triturated
with water, it yields a turbid mixture. Treat Lactucarium with boiling
water and filter; the filtrate is clear while hot; on cooling it becomes
turbid but clears upon the addition of ammonia water or alcohol; it is
not colored blue by iodine T.S. (starch). An alcoholic solution of
Lactucarium gives no more than a faint green color upon the addition
of a drop of ferric chloride T.S. (tannin). The powder is grayish-brown to
dark brown, consisting almost entirely of irregular fragments without
any cellular structure: when mounted in hydrated chloral T.S., the
fragments become clear, showing granular fragments, and from this
deposit, numerous rod-shaped crystals and broad monoclinic prisms as
well as aggregates of these, all of which polarize light. In the
preparation of powdered Lactucarium, dry the crude drug at a
temperature not exceeding 70° C. (158° F.). Lactucarium contains not
more than 15 per cent. of moisture, and yields not more than 10 per
cent. of ash." U. S.

The thridace of Francois, at one time supposed to be identical with
lactucarium, is in all probability nothing more than the inspissated
expressed juice of lettuce, and, indeed, was directed as such in the
French Codex of 1837, the leaves being rejected, and the stalks alone,
near the flowering period, being subjected to pressure.

The drug of commerce usually has a growth of mold on the surface. If it
has penetrated the drug to any extent it reduces its quality. Occasionally specimens are met with that are moldy throughout, and
these should be rejected. In color, taste, and odor, lactucarium bears
considerable resemblance to opium, and has sometimes been called
lettuce opium. It does not attract moisture from the air. It yields nearly
half its weight to water, with which it forms a deep-brown infusion. It is
partly soluble in ether and alcohol. From its resemblance in some of its
properties and to opium, it was conjectured to contain morphine, or some
analogous principle, but this conjecture is false. There is no doubt as to
the complexity of the composition of lactucarium, but so feeble are its
properties that it has largely gone out of active use, and its chemistry is
of little practical importance. Buchner, Aubergier, and Walz claim
severally to have discovered the active principle, which has been named
lactucin, but the substances obtained by these different chemists are
not exactly identical in properties, and the lactucin of Walz and Aubergier is considered by Lenoir as owing its bitterness (to impurities, separated from which it is without taste and inert. For a full account of the earlier analyses of lactucarium, see 16th edition, U. S. D. Ludwig found, in 100 parts, 48.63 of substances insoluble in water, and 51.37 of substances soluble in water. Of the insoluble matter 42.64 parts were of lactucerin or lactucon, in snow-white aggregated granules, dissolving in strong hot alcohol which deposits it on cooling, readily soluble in ether but insoluble in water, incapable of saponification by potassium hydroxide, and therefore not properly a fat, and in alcoholic solution faintly reddening litmus paper. On the other hand, Hesse states that lactucon which, according to Massner, has the composition C$_{26}$H$_{44}$O$_2$, is a mixture of esters, of which one, C$_{36}$H$_{58}$O$_2$(C$_2$H$_3$O)$_2$, is a diacetyl ester yielding, when saponified, a-lactucerol, C$_{36}$H$_{60}$O$_2$, and acetic acid, while the other is a mono-acetyl ester, C$_{36}$H$_{59}$O$_2$(C$_2$H$_3$O). Of the 51.37 parts soluble in water, 6.98 were albumen, 1.75 lactucerin, held in solution by other substances, 27.68 bitter extract soluble in water and in alcohol, and 14.96 aqueous extract insoluble in alcohol of 0.830. The former of these extracts was found to contain a peculiar acid substance called lactucic acid, and the lactucin of Aubergier. Lactucic acid is of difficult crystallization, light yellow, strongly bitter, without sour taste, of an acid reaction, and readily soluble in alcohol and water. It has as much claim as any other discovered substance to be considered the active principle of lactucarium.

The assertion sometimes made that Lactuca virosa contains a mydriatic alkaloid has been denied by J. C. Braithwaite and H. E. Stevenson, P. J., 1903, 148. Farr and Wright (P. J., 1904, p. 16) claim, however, to have definitely established the presence of a mydriatic alkaloid, giving alkaloidal reactions with Mayor's and Threshes reagents, and producing a powerful mydriatic effect upon the eye.

Kromayer (Ann. Ch. Ph., cv, p. 3) found also lactucopikrin, C$_{44}$H$_{32}$O$_{21}$, a brown, amorphous, and very bitter substance of weak acid reaction. It is easily soluble in water and alcohol. Ludwig's lactucic acid Kromayer considers to be an oxidation product of lactucopikrin.

Hesse (Handworterbuch, iv, p. 8) prepared lactucerin, and finds it to crystallize in white needles, fusing point 210° C. (410° F.), soluble in hot ligroin, chloroform, and benzene. On fusion with potassium hydroxide it
yields acetic acid and lactuceryl alcohol, C₁₈H₃₀O, which forms white needles, fusing at 162° C. (323.6° F.), and is easily soluble in ether, chloroform, and hot alcohol. Hesse has since (Ann. Ch. Ph., 234, p. 243) determined that lactucarium contains the acetates of α- and β-lactucerol, C₁₈H₃₀O. These compound ethers are saponified with alcoholic potash and water added, which precipitates α- and β-lactucerol. These are washed, dried in the air, and taken up with boiling alcohol. On cooling, α-lactucerol separates out first and can be purified by recrystallization, while the β-lactucerol is obtained from the mother liquor. The acetate of α-lactucerol fuses at 210° C. (410° F.), while that of β-lactucerol fuses at 230° C. (446° F.). For an examination of Russian lactucarium, by L. Schiperovitch, see Ph. Z. R., or D. C., 1886.

**Uses.**—The ancients believed that lettuce had soporific properties, and many years ago J. R. Coxe, of Philadelphia, first proposed the employment of the inspissated milky juice as a medicine. It was chiefly, however, through the recommendation by Duncan, Sr., of Edinburgh, that the medicine came into use and was adopted as official in various pharmacopoeias. It is claimed for it that it has, although in a very much inferior degree, the anodyne and calming properties of opium, without its disposition to derange the digestive organs. It has been employed in this country to some extent to allay cough and quiet nervous irritation, but we believe that the general experience is in accord with our own in finding it to be almost devoid of narcotic properties. We have never been able to obtain any good results from its use. Water distilled from lettuce (eau de laitue) is used in France as a mild sedative, in the quantity of from two to four ounces. The fresh leaves boiled in water are sometimes employed in the shape of cataplasm. It is said that in Egypt a mild oil is derived from the seeds, fit for culinary use. (See Syrupus Lactucarii.)

Dose, ten to twenty grains (0.65-1.3 Gm.), but much larger quantities may be given without obvious effects.

**Lamium.** Lamium album L. White Dead Nettle. (Fam. Labiatae.)—A perennial herb introduced from Europe and found on roadsides and waste places in the United States. Hemo-styptic properties were long since attributed by Lusitanus and by Florain to the flowers of this plant, and, according to the more recent researches by Kalabin (Cb. G. T., xx. No. 12), their decoction produces a rise of the arterial pressure
due to contraction of the peripheral vessels. The extract was found to cause firm, lasting contraction of the uterus, and the saturated tincture, in doses of twenty-five to forty minims (1.6-2.5 mils) every two or three hours, to be useful in hemorrhagic metritis and metrorrhagia. Its effects in puerperal hemorrhage were not pronounced.

**Lantana.** Lantana brasiliensis Link. Yerba Sagrada. (Fam. Verbenaceae)—This Brazilian plant contains, according to Negrete, an alkaloid, lantanine, which is actively antiperiodic in doses of from fifteen to thirty grains (1.0-2.0 Gm.) in the twenty-four hours, given directly after the paroxysm. It is also claimed to be an intestinal antiseptic. (T. G., 1885.) Lantana camara L., known in the West Indies as sagetree or wild sage, contains an alkaloid, lantanine, said to resemble quinine in its action.

The stem of the burdock is succulent, pubescent, branching, and three or four feet in height, bearing very large, cordate, denticulate leaves, which are green on their upper surface, whitish and downy on the under, and stand on long footstalks. The flowers are purple, with heads globose, and in terminal panicles. The involucre consists of imbricated scales, with hooked extremities, by which they adhere to the clothing of man and the coats of animals. The achemes are oblong, somewhat compressed and three-angled, ribbed, truncate. Although a native of Europe, burdock is abundant in the United States, where it grows on the roadsides, among rubbish, and in cultivated grounds. There are three recognized species of Arctium in North America—viz., A. tomentosum (Lam.) Schk. (Woolly or Cottony Burdock); A. Lappa L. (Burdock, Clotbur or Great Bur); and A. minus Schk. (Common, Burdock).

It is described by the N. F. as "nearly simple, fusiform, of variable length from 5 to 20 mm. in diameter near the crown; frequently split or in broken pieces; externally grayish-brown, longitudinally wrinkled, the crown somewhat annulate, sometimes surmounted by a woolly tuft of leaf remains; fracture somewhat horny; a dark cambium separating the thick brownish bark from the yellowish porous and radiate wood, centrally hollow or containing a white, pith-like tissue. Odor slight; taste mucilaginous, sweetish, and slightly bitter. The powder is light brown and, when examined under the microscope, exhibits parenchyma cells of the cortex; the medullary rays and wood containing amorphous masses or sphere-crystals of inulin; yellow resin cells occur in the cortical parenchyma of young roots; wood fibers few; no starch and no calcium oxalate. Lappa yields not more than 6 per cent. of ash." N. F.

Inulin has been found in it by Guibourt, and sugar by Fee, while F. E. Hendershot believes that it contains a glucoside, besides arabin and pectin and. extractives. (Proceedings of Mich. Pharm. Assoc., 1887.) Trimble also obtained from the root a bitter, crystalline glucoside. (Ph. Era, 1888, p. 133.) Thos. Donaldson (A. J. P., 1890, p. 123) found 8.6 per cent. of yellow fixed oil and about 1 per cent. of white waxy
matter. A small quantity of volatile oil (0.065 per cent.) has been found in burdock root according to Haensel's Report, Oct., 1902. The inulin usually exists in parenchymatous cells in a different state, but if sections of the green root be dehydrated by soaking in 95 per cent. alcohol, the inulin will be found in spheroidal form.

An interesting account of burdock and its use as an edible vegetable in Japan, by Inazo Nitobe, may be found in A. J. P., 1897, 416.

Uses.—Burdock root has been employed as a diuretic and diaphoretic alterative, especially useful in the gouty, scurvy, and syphilitic and scrofulous diatheses; also in various chronic skin diseases, especially in psoriasis, prurigo, and acne. (M. S. Rep., 1868.) The fresh leaves have been employed both externally and internally in cutaneous eruptions and ulcerations. There is no sufficient reason, however, to believe it has any medicinal virtue. This fluidextract is recognized by the N. F. (see Part III).

Dose, thirty to ninety grains (2.0-5.8 Gm.).

**Larch Bark.** Laricis Cortex. Br. 1885. Ecorce de Mèleze, Fr. Larchenrinde, G.—The bark of Larix decidua Mill. (Larix europaea DC.) (Fam. Pinaceae) was found by Aldridge to contain gum, starch, resin, and tannic acid of the kind which precipitates the salts of iron olive-green. John Stenhouse has obtained from it a peculiar volatile acid, larixinic acid (larixine). For method of separation, see 16th edition, U. S. D. Larixinic acid occurs in beautiful white, lustrous crystals, often more than an inch long, of a peculiar somewhat empyreumatic odor, and a slightly bitter and astringent taste, inflammable, volatilizing at 93° C. (199.4° F.) and melting at 153° C. (307.4° F.), soluble in 87.88 parts of water at 13.3° C. (56° F.), very soluble in boiling water, soluble in cold but much more so in hot alcohol, and sparingly soluble in ether. It readily crystallizes from its solutions. A very singular and characteristic property is that of forming, when added, in strong solution, in excess, to baryta water, a bulky, transparent, gelatinous precipitate, occupying the whole measure of the liquids if concentrated. The probable formula of the acid is $C_{10}H_{20}O_{5}$. The inner larch bark possesses astringent and gently stimulant properties, and is supposed to have a special tendency to the mucous membranes. It has been found particularly efficacious in purpura and other hemorrhagic affections, especially hemoptysis, and has been given in bronchitis with copious expectoration, and in diseases of the urinary passages. It has been used also, mixed with soap and glycerin, as a local remedy in psoriasis, chronic eczema, and other cutaneous affections. Of the extract from three to five grains (0.20-0.32 Gm.), of the tincture from thirty minims to a fluidrachm (1.8-3.75 mils) or more may be given every three or four hours.

**Larkspur Seed.** N. F. IV. Delphinium. Lark's claw. Knight's spur.—It is described by the N. F. as "the dried seeds of Delphinium Consolida Linne or of Delphinium Ajacis Linne (Fam. Ranunculaceae), without the presence of more than 5 per cent. of foreign matter. Irregularly tetrahedral, or by pressure somewhat triangulate, acute at one end, obtuse or rounded at the other, about 2 mm. in length and equally broad or
slightly narrower, surface black or blackish-brown, deeply and narrowly furrowed, the furrows intersecting so as to give a sharply tuberculate appearance to the surface, with serrate edges; testa crustaceous; kernel whitish, fleshy; embryo small, in fleshy endosperm. Odor very faint; taste bitter, afterward biting and acrid. Larkspur Seed yields not more than 7 per cent. of ash. N. F. Thomas C. Hopkins, of Baltimore, found in the seeds of Larkspur, delphinine, C₂₂H₃₅O₆N, volatile oil, fixed oil, gum, resin, chlorophyll, gallic acid, and salts of potassium, calcium, and iron. (A. J. P., xi.) Rochebrune (Toxicol. Africaine, i) has separated alkaloids believed by him to be identical with delphinine from D. peregrinum L. and D. mauritanicum Coss. From the expressed juice of the larkspur aconitic acid was obtained by W. Wicke. (J. P. C., 1854.) Moreover, the seeds of the indigenous D. exaltum Ait. are stated to have a physiological action similar to that of the larkspur. Larkspur is a common weed in the Western States, where it occasions death among grazing cattle. It is said to lose its toxicity during the flowering period. It is a showy annual, which has been introduced from Europe into the United States, where it has become sparingly naturalized, growing in old grain fields and flowering in June and July. The flowers are bitter and acrid. The seeds are the only part of the plant which is official. In large doses the seeds produce violent vomiting and purging, and are said to be diuretic. A tincture is official in the N". F. and has been used in spasmodic asthma and dropsy, but is mainly employed as a parasiticide in a manner similar to the preparations of staphisagria. Dose, ten minims (0.6 mil), gradually increased. Brett has found that D. peregrinum L., when growing, is very effective in the destruction of grasshoppers. (P. J., vol. xxi, 1891. See Staphisagria in Part I.)

Lathyrus. Lathyrus sativus L. (Fam. Leguminosae). Jarrosse, Gesse, Kasari (Ind.).—The White or Chickling Vetch, the seed of which is used in Europe as a food both by man and animals, under the name of "mutters," produces, when taken too freely, a condition known as lathyrismus. Horses which have been fed on the plant for a considerable period drop while performing the lightest work, in consequence of paralysis of the hind extremities, and in many cases death has followed from bilateral paralysis of the recurrent laryngeal nerves and consequent asphyxia. This laryngeal affection does not occur in the human subject, and death very rarely takes place. In man the muscles of the lower extremities below the knee are apt to be especially affected, the abductors more than the adductors. The muscles of the face, neck, and upper extremities are very rarely, if ever, attacked. The reflexes and the general sensibility are usually not influenced; but Giorgieri has seen the tendon reflexes increased. According to Cantani, the galvanic contractility of the paralyzed muscle is altered, and the transverse markings of the muscles are nearly obliterated by fat globules. In fatal cases the spinal cord has been found normal. Astier obtained from the seeds a poisonous alkaline volatile liquid. According to him, this, being volatile, is not present in preparations such as pressed cakes made at a high temperature, which are consequently not poisonous. If, however, such cakes have been prepared at low temperature, they exhibit toxic properties, owing to the retention of the toxic principle. This is in conformity with the experience of the peasants in some parts of Europe, who mix the ground white vetch seeds with wheat flour, and boil the mixture for food. E. M. Holmes states that these seeds should not be used in foods in any proportions, as they are poisonous. (P. J., 1913, 795.)
LAUROCERASI FOLIA. Br.

CHERRY-LAUREL LEAVES

"Cherry-Laurel Leaves are the fresh leaves of Prunus Laurocerasus, Linn." Br.

Cherry Bay; Laurier-cerise, Fr. Cod.; Kirschlorbeer, G.; Lauroceraso, It.; Lauroceraso (Hoja de), Sp.

Prunus Laurocerasus is a small evergreen tree, rising 15 or 20 feet, with long, spreading branches, which, as well as the trunk, are covered with a smooth, blackish bark. The leaves are oval-oblong, petiolate, from five to seven inches in length, acute, finely toothed, firm, coriaceous, smooth, beautifully green and shining, with oblique nerves, and yellowish glands at the base. The flowers are small, white, strongly odorous, and disposed in simple axillary racemes. The fruit is an oval drupe, very similar in shape and structure to a small black cherry. The cherry-laurel is a native of Asia Minor, but is cultivated in Europe, both for medicinal use and for the beauty of its shining evergreen foliage. Almost all parts of it have more or less of the odor of hydrocyanic acid.

In their recent and entire state cherry-laurel leaves have scarcely any odor; but, when bruised, they emit the characteristic odor of the plant in a high degree. Their taste is somewhat astringent and strongly bitter, with the flavor of the peach kernel. They are officially described as "thick, coriaceous, on short, strong petioles, oblong or somewhat obovate, from twelve to eighteen centimetres long, tapering towards each end, recurved at the apex, distantly but sharply serrate and slightly revolute at the margins; dark green, smooth and shining above, much paler beneath; midrib prominent, with one or two glandular depressions on the under surface near its base. Inodorous, but emitting when bruised an odor resembling that of prussic acid." Br.

Cherry-laurel leaves are sometimes substituted by the leaves of other species of Prunus. These are readily distinguished in that they do not possess the characteristic glandular hairs which occur on the basal portion of the leaves and petioles of P. Laurocerasus. (B. P. G.) 1907, p. 325.)
Cherry-laurel leaves yield a volatile oil containing benzaldehyde and hydrocyanic acid by distillation with water, which they strongly impregnate with their flavor. One pound, avoirdupois, of the fresh leaves yields 40.5 grains of the oil. (Ph. Cb., 1855, 205.) The oil resembles that of bitter almonds, for which it is said to be sometimes sold in Europe, where it is employed to flavor liquors and various culinary preparations, but, as the glucoside of cherry-laurel leaves is decomposed more slowly than ordinary crystallized amygdalin, it is liable to hold hydrocyanic acid, and hence to be poisonous. The glucoside referred to has been termed laurocerasin, or "amorphous amygdalin." It is decomposed by emulsin into hydrogen cyanide, benzaldehyde, and sugar, but more slowly than ordinary amygdalin. Its optical activity also differs from that of ordinary amygdalin. (Jacobsen, Die Glykoside, 25.) That the oil exists already formed, to a certain extent, in the fresh leaves, is rendered probable by the fact, stated by Winckler, that they yield it in considerable quantity when distilled without water. (J. P. C.) xxv, 195.) The fresh leaves are used to flavor milk, cream, etc., and more safely than the oil, though they also are poisonous, when too largely employed.

**Uses.**—The leaves of the cherry-laurel possess properties similar to those of hydrocyanic acid, and the water distilled from them is much employed in various parts of Europe for the same purposes as that active medicine. But it deteriorates by age, and therefore, as kept by pharmacists, must be of variable strength. J. Broker, a Dutch pharmacologist, has satisfied himself, by numerous experiments, that the proportion of hydrocyanic acid in the leaves varies with the season, the age of the plant, the character of the soil and of the weather, and thinks that, in consequence of this variability, they are inferior for medicinal use to bitter almonds, which in this respect have a more uniform composition. He found the proportion of the acid in the leaves greatest in July, and least in February. (B. F. M. R., Oct., 1868, p. 517.) It is not, therefore, to be regretted that the want of the plant in this country has prevented the general introduction of so variable a remedy as the distilled water. (See Aqua, Laurocerasi.)

**Off. Prep.**—Aqua Laurocerasi, Br.

**Laurus.** Laurus nobilis L. Sweet Bay. Laurier commun, Fr. Lorbeër, G.—The sweet bay is an evergreen tree of the Fam. Lauraceae, inhabiting the countries bordering on the Mediterranean. The leaves are alternate, on short petioles, oval-lanceolate or
oblong, entire, pellucid-punctate, of a firm texture, smooth, shining, deep green upon their upper surface, paler beneath. They have a fragrant odor, especially when bruised, and a bitter, aromatic, somewhat astringent taste. They yield by distillation a greenish-yellow volatile oil. The volatile oil, of which the fruit yields 0.23 per cent., has a sp. gr. 0.88, and is solid at 0° 0. (32° F.). It is largely composed of oxygenated compounds. The constituents thus far recognized are myrcene, phellandrene, methylchavicol, citral, methyl-eugenol, chavicol, and eugenol. (Schim, Rep., April, 1897.) Water distilled from the leaves has their peculiar odor. The berries when dried are black and wrinkled, and contain two oval fatty seeds within a thin, friable envelope; or they may be considered as drupes, with a kernel divisible into two lobes. They have the same aromatic odor and taste as the leaves, but are more pungent. Besides an essential oil, they contain a fixed oil, which, as obtained by expression from the fresh fruit, is of a greenish color, and aromatic odor from retained volatile oil. One of its chief constituents is the ether of lauric acid, the so-called laurostearine, $C_3H_5(H_{12}H_{23}O_2)_3$, which fuses at 45° C. (113° F.). The free acid may be obtained from this by saponification. It cannot be distilled without decomposition. Another constituent of the crude fat is laurin, $C_{22}H_{30}O_3$, which can be extracted by alcohol. It forms neutral, easily fusible prisms without odor or taste. Lard, impregnated with the odorous principle of the berries, and colored green by chlorophyll or sometimes by indigo and turmeric, is said to be often substituted for the genuine expressed oil. This may be detected by boiling alcohol, which dissolves the true oil. The leaves, berries, and oil are excitant and narcotic, but are rarely used internally as medicines, and in this country are scarcely employed in any manner. E. M. Holmes, however, states that the berries have been used in Europe to promote miscarriages. (P. J., 1910, 52.) Their chief use is to communicate a pleasant odor to external remedies. The leaves are also used for culinary purposes in communicating their aromatic flavor to soups, stews, etc. They come into commerce frequently as the packing around stick licorice extract from Mediterranean countries.

**Lavender Flowers.** Lavandula. U. S. 1880. Lavandula vera DC. (L. officinalis Chaix, L. spica L.) Lavender. Flores Lavandulae, P. G. Lavande, Fleurs de Lavande, Fr. Lavandelblumen, Lavandelbluthen, G. Lavandola, It, Espliego, Alhucema, Sp.—Lavender is a small labiate shrub. The plant is a native of Southern Europe, and covers vast tracts of dry and barren land in Spain, Italy, and the south of France. In England and America it is very largely cultivated. For method of culture and detailed descriptions of the various varieties that have been educed, see B. M. S. J., Aug., 1873, 165. The cultivation of lavender has become an important industry and attempts are being made to cultivate the finer qualities of lavender in the United States.

For details of lavender culture, see U. S. D., 19th ed., p. 1546.

Lavender flowers have a strong fragrant odor, and an aromatic, warm, bitterish taste. They retain their fragrance long after drying. Alcohol extracts their virtues, and a volatile oil upon which their odor depends rises with that liquid in distillation. Hager obtained from a pound of the fresh flowers from half a drachm to two drachms of the oil. The flowers are frequently sold for packing away with clothing as a moth
preventive. Lavender is an aromatic stimulant and tonic, but is seldom given in its crude state. The products obtained by its distillation are much used in perfumery, and the volatile oil is official. (See Oleum Lavandulae.)

**Lawsonia.** Lawsonia inermis L. (L. alba Lam.) Henna Plant. Mehndi.—This is a shrub of the Fam. Lythraceae, growing in the Levant, Egypt, Persia, and India, and well known as the source of a dye-stuff denominated henna, much used throughout the Mohammedan countries of the East. It is largely cultivated in Egypt. The flowers have a strong, pungent odor, and a distilled water prepared from them is used as a cosmetic. The fruit is thought to have emmenagogue properties. The powdered leaves, under the name of henna, are used to stain golden yellow the feet and hair of women of the harem. Abd-el-Aziz of Cairo, Egypt, found in it a brown substance, of a resinoid fracture, having the chemical properties which characterize the tannins, and therefore named by him hennotannic acid. Henna has been employed both internally and locally, in jaundice, leprosy, and affections of the skin.

**Ledum.** Ledum palustre L. Marsh Tea. Rosmarinus Sylvestris. Marsh Cistus. Wild Rosemary. Ledon, Romarin sauvage, Fr. Porsch, Sumpfporsch, Wilder Rosmarin, G.—A small evergreen ericaceous shrub, growing in awamps and other wet places in the northern parts of Europe, Asia, and America, and in the mountainous regions of more southern latitudes. The leaves have a balsamic odor, and an aromatic, camphorous, bitter taste, and contain, among other ingredients, volatile oil and tannin. For the properties of the volatile oil, see J. P. C., 4e ser., xx, 244; also Proc. A. Ph. A., xxxv, 154. It contains ledum camphor, a stearopten, together with valeric and other volatile acids, and ericinol, C_{10}H_{16}O. The tannin has been named leditannic acid, C_{15}H_{20}O_{8}. On boiling with dilute mineral acids it is decomposed, and ledixanthin, C_{30}H_{34}O_{13}, separates as a yellowish or reddish powder. (Thal, Ph. Z. R., 1883, 268.) Thai also extracted ericolin, C_{34}H_{56}O_{21}. This is a glucoside, which on heating with diluted sulphuric acid decomposes into sugar and ericinol, C_{10}H_{16}O, a colorless, peculiar-smelling oil, which turns brown in the air, owing to oxidation. The leaves are thought to be narcotic and diaphoretic, and have been employed in dysentery and in various cutaneous affections, particularly leprosy and scabies. In complaints of the skin they are used both internally and externally, in the form of decoction. In Germany they are sometimes substituted for hops in the preparation of beer. Ledum groenlandicum Oeder (L. latifolium Ait.), or Labrador tea, which is a larger plant than the preceding, is a native of North America, growing in damp places in Canada and the northern part of the United States. The leaves have an agreeable odor and taste, and are esteemed pectoral and tonic. They are said to have been used as a substitute for tea during the war for independence.

**Leek.** Porrum. Porreau, Fr. Lauch, G.—The bulb of Allium Porrum Don. (Fam. Liliaceae) The leek, which is the national emblem of the Welsh, is a biennial bulbous plant, growing wild in Switzerland, and cultivated in the gardens of Europe and this country for culinary purposes. All parts of it have an offensive, pungent odor and an acrid taste, dependent on an essential oil, of which allyl sulphide, (C_{3}H_{5})_{2}S, is the main ingredient. The bulb, which is the medicinal portion, consists of concentric
layers, like the onion, which it resembles in medicinal properties, though somewhat milder. It is generally stimulant, with a direction to the kidneys. Dose, of expressed juice, a fluidrachm (3.75 mils).

**Leonotis.** Leonotis Leonurus R. Br. Wild Daggar.—This handsome tropical labiate is said to possess purgative and emmenagogue properties. (See P. J., May, 1885.) The leaves of this plant are smoked by the Hottentots like tobacco. It is asserted that in overdose it has a narcotic effect. It is used by the South African aborigines as a cathartic, and in the treatment of snake bite. A decoction is also employed externally for various skin eruptions. (P. J., 1907, lxxix.)

**Leonurus.** Leonurus Cardiaca L. Motherwort. Agripaume, Cardiaire, Fr. Herzespénn, Wolfstrapp, G.—An aromatic perennial labiate herb, growing wild in this country in waste places, around dwellings, etc., whose infusion of decoction is sometimes used in amenorrhea and sudden suppression of the lochia.

**Lepargyraea.** Shepherdia argentea Nutt. Buffalo Berry. Bull Berry. Grains-de-Bœuf, Fr.—The acidulous fruit of this plant, of the Fam. Elaeagnaceae, produced in great profusion in the region of the upper Missouri, is largely used as an article of food. According to Henry Trimble, it contains a little more acid than currants. (A. J. P., Dec., 1888.)

**Leptandra.** N. F. IV [U. S. P. VIII]. Culver's Root. Culvers' Physic. Black Root. Racine de Leptandra, ou de Veronique de Virginie, Fr. Leptandra-Wurssel, G.—"The dried rhizome and roots of Veronica virginica Linne (Fam. Scrophulariaceae), without the presence of more than 5 per cent. of stems or other foreign matter." N. F. Veronica virginica, commonly called Culver's root, or Culver's physic, is an herbaceous perennial, with a simple, erect stem, three or four feet high, smooth or downy, furnished with leaves in whorls, and terminating in a long spike of white flowers. The leaves, of which there are from four to seven in each whorl, are lanceolate, pointed, and minutely serrate, and stand on short footstalks. A variety was seen by Pursh with purple flowers, which was described and figured as a distinct species by Rafinesque, under the name of L. purpurea. The plant flowers in July and August. It grows throughout the United States east of the Mississippi, affecting mountain meadows in the South and rich woods in the North, and is not unfrequently cultivated. The National Formulary describes leptandra as follows "Rhizome usually of horizontal growth, nearly cylindrical, somewhat branched; branches readily separable from the main rhizome, from 4 to 10 cm. in length and from 4 to 13 mm. in diameter; externally grayish-brown to dark reddish-brown, annulate from circular scars of bud-scales, upper surface with short stem remnants, occasionally with buds, and numerous circular stem-scars; from the under and lateral portions arise numerous coarse roots; fracture very tough and woody; internally, bark rather thin, dark brown and resinous, wood about the same thickness as the bark, light brown and porous, pith large, more or less hollow, the color being similar to that of the bark. Roots from 1 to 10 cm. in length and from 1 to 2 mm. in diameter; externally dark brown to purplish-brown, smooth and faintly longitudinally wrinkled; fracture short; internally with a thick, brownish-black bark and small, light brown central cylinder. Nearly
odorless; taste very bitter and acrid.

"The powder is brown to yellowish-brown; odor strong, penetrating; consisting of numerous irregular fragments, many of them being colored pink or violet upon the addition of hydrated chloral T.S.; starch grains numerous, mostly in the parenchymatous cells, the individual grains nearly spherical or more or less polygonal, and from 0.002 to 0.008 mm. in diameter; tracheae with spiral thick-enings or with simple or bordered pores; wood fibers with thick lignified walls, with simple pores or with bordered pores, resembling tracheids; fragments of parenchyma containing a light brown or brownish-black resin, the latter frequently closely coherent with the starch grains in the cells thus preventing the separation of the individual starch grains; mounted in hydrated chloral T.S., occasional elongated cells with a lemon yellow, oily substance are observed. Leptandra yields not more than 12 per cent. of ash." N. F. For a microscopical description of leptandra, by A. P. Breithaupt, see A. J. P., 1897, 235.

Water and alcohol extract the virtues of the root. According to E. S. Wayne, of Cincinnati, it contains a peculiar crystalline principle, leptandrin, to which the virtues of the medicine may be ascribed. F. F. Mayer confirmed the presence of the crystalline principle, and classed it as a glucoside, but Power and Rogerson (Tr. Chem. Soc., 1910, xcvi) were unable to find any such principle. The resinous matter obtained by making a tincture of the root and precipitating this with water has been improperly called leptandrin, and considered the active principle. Subsequently Wayne obtained from the root a saccharine principle having the properties of mannite (A. J. P., 1859, p. 557.) G. Steinmann (A. J. P., 1887, p. 229) obtained pale lemon-yellow crystals of a peculiar agreeable odor and a very bitter taste. They were not precipitated from solution by Mayer's reagent or by tannin, and did not yield glucose on being boiled with diluted sulphuric acid.

The recent root is said to act violently as a cathartic, and sometimes as an emetic. In the dried state it is much milder, but less certain. The practitioners calling themselves eclectics consider it an excellent chologogue, and use both the impure resin, which they call leptandrin, and the root itself as a substitute for mercurials. Rutherford, in his experiments upon dogs, found leptandrin to act rather feebly upon the liver. The powdered extract and fluidextract are recognized by the N. F. (see Part III). Dose, fifteen to sixty grains (1-3.9 Gm.); of the impure resin, two to four grains (0.13-0.26 Gm.).

Levisticum. Radix Levistica, P. G. Liveche, Ache de Montague, Fr. Liebstockel, G.—Several species of this umbelliferous genus are employed as domestic remedies. The stout perennial herb, Levisticum officinale (L.) Koch, or lovage of the south of Europe, is extensively cultivated for its aromatic fruits. It is aromatic in all its parts, but only the roots and fruits are used. The fruits are small, ovate-oblong, somewhat flattened, curved, strongly ribbed and of a yellowish-brown color. Lovage is a stimulant aromatic, and has been employed as a carminative, diaphoretic, and emmenagogue. The best form for administration is that of infusion. The coloring principle has been isolated by M. J. Nickles, who gives it the name of ligulin, and
suggests an important application of it that may be made in testing drinking water. If a drop of its alcoholic or aqueous solution is allowed to fall into distilled water, it imparts to the liquid its own fine crimson-red color, which undergoes no change; but if limestone water be substituted, the red color disappears in a few seconds, and is followed by a beautiful blue, due to the alkalinity of the latter. (J. P. C., 1859, 329.)

The root of Ligusticum sinense, under the name of kao-pen, is largely used by the Chinese. In the Northwestern United States the large aromatic roots of Ligusticum filicinum S. Wats., Osha Colorado cough-root, are used to a considerable extent as stimulating expectorants. (See A. J. P., 1890 and 1891.)

**Lewisia.** Lewisia Rediviva Pursh. Spathum. Chita. Bitter Root.—The roots of this plant, of the Fam. Portulacaceae, abundant in the Northwestern United States, are very widely used by the Indians as an article of food. For analysis and description, see A. J. P., 1889.

**Liatris.** L. spicata (L.) Willd. Gay-feather. Devil’s Bite Colic Root. Button Snakeroot.—An indigenous perennial composite plant growing in natural meadows and moist grounds from Southern Ontario and Minnesota, southward. It has a tuberous root, and an erect annual stem, which terminates in a spike of beautiful, purple, compound flowers, appearing in August. The root is said by Schoepf to have a terebinthinate odor, and a warm, bitterish, terebinthinate taste; to be possessed of diuretic properties; and to be useful as a local application in gonorrhea and sore throat. The leaves of the allied Trilisa odoratissima, (Walt.) Cass. (Liatris odoratissimus Willd.), or Vanilla leaf, are very largely employed in the Southern United States to flavor ‘tobacco, and to preserve clothing, etc., from moths. As a preservative it is worthless. The agreeable odor is due to coumarin, C_{9}H_{6}O_{2}, which may be frequently noticed in crystals upon the surface of the smooth spatulate leaves. (A. J. P., March, 1875; Sept., 1881; xlvi, 116; N. R., 1882, 66.) The roots of L. scariosa Willd. (Lacinaria scariosa Hill) and L. squarrosa Willd. (Lacinaria squarrosa Hill) (rattlesnake's master) have been employed to cure the bite of the rattlesnake. According to Wm. P. C. Barton, all the tuberous-rooted species of Liatris are active diuretics.

**Ligustrum.** L. vulgare L. Troene, Fr. Rain-weide, Hartriegel, G. Privet or Prim.—A shrub of the Fam. Oleaceae, from four to ten feet in height, growing wild both in Europe and the United States, usually in hedges and by the roadside. The leaves, which have an astringent, bitter taste, and the flowers, which are small, snow-white, and of an agreeable odor, have been used in the form of decoction in sore throat and aphthous and scrofulous ulceration of the mouth. The berries are black, have a sweetish bitter taste, and are said to possess purgative properties, and to color the urine brown. They are sometimes used for dyeing. Death in a child between two and three years old is recorded by James Cheese (P. J., 2d ser., viii, 607), as due to the eating of privet berries. The bark was analyzed by M. G. Polex, who found a peculiar substance, which he denominated ligustrin, insoluble in ether and absolute alcohol, but soluble in water and diluted alcohol. Strong sulphuric acid gives with ligustrin a deep indigo-blue color. Kromayer (A. Pharm. (2), cxviii, 19) proved that Polex's ligustrin was only impure syringin, C_{19}H_{28}O_{10} + H_{2}O. The large white crystals become anhydrous at 115° C. (239° F.), and fuse at 212° C. (413.6° F.). He found in
addition (see Kromayer, A. Pharm., (2) ci, 281) mannite, sugar, muco-saccharine matter, starch, chlorophyll, bitter extractive, bitter resin, tannin, albumen, and salts. (A. J. P., xii, 347.) Kromayer found besides the syringin a crystallized bitter principle, fusing at a little over 100° C. (212° F.), which he named ligustron.

**Lilium.** Lilium canadidum L. (Fam. Liliaceae) Common White Lily.—This well-known plant is a native of Southern Europe from Corsica to Asia Minor, but has been long cultivated in gardens. The bulb, which consists of imbricated fleshy scales, is without odor, but has a peculiar, disagreeable, somewhat bitter, and mucilaginous taste. It contains much mucilage, and a small proportion of an acrid principle. In the recent state it is said to have been employed with advantage in dropsy. Vomiting, purging, drowsiness, etc., are said to have been produced in a little girl by the pollen of the tiger lily, L., tigrinum Andr. (Jeffries Wyman, Am. J. M. S., 1863.)

**LIMONIS CORTEX. U. S., Br.**

**LEMON PEEL** Limon. Cort.

"The outer rind of the fresh ripe fruit of Citrus medica Limonum (Risso) Hooker filius (Fam. Rutaceae)." U. S. "Lemon Peel is the fresh outer part of the pericarp of the fruit of Citrus medica, Linn., var. ß Limonum, Hook. f." Br.

Limonis Pericarpium; Ecorce (Zeste) de Citron, de Limon, Fr. Cod.; Cortex Citri Fructus, P. G; Citronenachale, Limon-enachale G.; Scorza di Limone, It.

For some general remarks on the genus Citrus, see Aurantii Cortex.

Citrus medica, or lemon tree, closely resembles Citrus Aurantium, before described. The leaves, however, are larger, slightly indented at the edges, and stand upon footstalks which are destitute of the winged appendages that characterize the other species. The flowers, moreover, have a purplish tinge on their outer surface, and the fruit is different in appearance from the orange. There are several varieties of Citrus medica, which some botanists consider as distinct species, but which scarcely differ except in the character of their fruits. Those particularly deserving of notice are the citron, lemon, and lime.

1. In the citron, C. medica genuina (Bentley & Trimen, p. 53), the fruit is very large, sometimes six inches in length, ovoid, with a double rind, of which the outer layer is yellowish, thin, unequal, rugged, with innumerable vesicles tilled with essential oil; the inner is white, very
thick and spongy. It is divided in the interior into nine or ten loculi, filled with small oblong vesicles, which contain an acid juice precisely like that of the lemon, and used for the same purposes. The rind is applied to the preparation of conserves, to which it is adapted by its thickness. The fruit is called cedrat by the French.

2. The lemon, C. medico,, var. Limonum (Citrus Limonum of Bisso) (Bentley & Trimen, p. 54) is smaller than the preceding, with a smoother and thinner rind, a pointed nipple-shaped summit, and a very juicy, acid pulp. In other respects it closely resembles the citron, to which, however, it is usually preferred in consequence of the greater abundance of its juice.

3. The lime is still smaller than the lemon, with a smoother and thinner rind, oval, rounded at the extremities, of a pale-yellow or greenish-yellow color, and abounding in a very acid juice, which renders it highly useful for the purposes to which the lemon is applied. It is the product of C. medica acida. According to E. M. Holmes the West India limes are much richer in acid than are those produced in the South of Europe; the juice of the spineless variety was found to contain 37.73 grains per ounce; the ordinary West India lime 36.15 grains per ounce; the Sicily lime 30.32 grains per ounce. Lime juice is recognized by the N. F. IV under the name Succus Citri.

The Citrus medica, like the orange-tree, is a native of Asia. It is now known to grow wild in Northern India, and was introduced into Europe from Persia or Media. It was first cultivated in Greece, afterwards in Italy, as early as the second century, and has now spread over the whole civilized world, being raised by artificial heat where the climate is too cold to admit of its exposure during winter to the open air.

Properties.—The exterior rind of the lemon has a fragrant odor, and a warm, aromatic bitter taste, somewhat similar to that of the orange, though less agreeable. It is usually found in narrow, thin bands, with very little of the spongy, white, inner layer adhering to it, and is officially described as follows: “The outer, lemon-yellow or dark yellow layer, recently separated by grating or paring and consisting of an epidermal layer, numerous parenchyma cells containing yellow chromoplastids, and large oil reservoirs with globules of the volatile oil; odor highly fragrant, distinctive; taste pungent, aromatic. Under the microscope, sections of the rind, mounted in a fixed oil, show an
epidermal layer composed of small tabular cells, a hypodermal layer containing numerous plastids, a mesocarp with colorless, thin-walled parenchyma and large, elliptical oil reservoirs; parenchyma cells containing a layer of granular protoplasm adhering to the walls and occasionally membrane crystals of calcium oxalate, which are irregularly polygonal in shape, and from 0.015 to 0.025 mm. in diameter." U. S.

"Outer surface pale yellow and more or less rough; with only a small amount of the white spongy part of the pericarp on the inner surface; in transverse section numerous large oil-glands below the epidermis. Strong, characteristic and fragrant odor; taste aromatic and bitter." Br.

It contains a bitter principle, and yields, by expression or distillation, an essential oil, which is much used for its flavor. Both this and the rind itself are recognized in the Pharmacopoeias. (See Oleum Limonis.) When the white, spongy portion of the rind is boiled in water, and the decoction evaporated, crystals are deposited of a substance called hesperidin. This is a glucoside, and has the formula $C_{22}H_{26}O_{12}$, and is decomposed by dilute acids into hesperetin, $C_{16}H_{14}O_{6}$, and glucose, $C_{6}H_{12}O_{6}$. It turns dingy black when gently warmed with alcoholic solution of ferric chloride. It is bitter, but as it is found most largely in the spongy and comparatively tasteless part of the rind, it may be doubted whether it is entitled to be considered as the active bitter principle. (See A. J. P., xxvi, 553.) Lemon peel yields its virtues to water, wine, and alcohol. E. G. Clayton (An., xix, 134) calls attention to the distinction between lemon peel and orange peel when moistened by strong hydrochloric acid. Orange peel under these circumstances changes in color from a yellow to a rich dark green color, while lemon peel retains its hue or assumes a dingy yellowish-brown tint.

The German Pharmacopoeia under the title of Cortex Citri Fructus requires that the lemon peel be derived from the completely developed but not fully ripe fruits of Citrus medico, L.

**Uses.**—The rind of the lemon is sometimes used to qualify the taste and increase the power of stomachic infusions and tinctures.

Linaria. Linaria vulgaris Hill. Antirrhinum Linaria L. Common Toadflax. Butter and Eggs. Ramsted. Snapdragon. Linaire commune, Fr. Leinkraut, Flachskraut, Lowenmaul, G.—This is a perennial herbaceous plant of the Fam. Scrophulariaceae very common in America, Europe, and Asia. It should be collected when in flower, dried quickly, and kept excluded from the air. When fresh it has a peculiar, heavy, disagreeable odor, which is in a great measure dissipated by drying. The taste is herbaceous, weakly saline, bitter, and slightly acrid. Its constituents are stated to be two glucosides, linarin and pectolinarin (P. J., lxxix, p. 316), with limarosnin, linaracrin, antirrhinic, tannic and citric acid. This plant is said to be diuretic and cathartic, and has been used in dropsy, jaundice, and cutaneous eruptions. It is most conveniently employed in infusion. The fresh plant is sometimes applied, in the shape of poultice or fomentation, to hemorrhoids, and an ointment of the flowers has been employed for the same purpose, and also locally in diseases of the skin. The flowers are used in Germany as a yellow dye.

LINUM. U. S. (Br.)

LINSEED [Flaxseed]

"The ripe seeds of Linum usitatissimum Linne (Fam. Linaceae), without the presence or admixture of more than 3 per cent. of other seeds or foreign matter. Preserve it in tightly-closed containers and add a few drops of carbon tetrachloride or chloroform from time to time to prevent attack by insects." U. S. “Linseed consists of the dried ripe seeds of Linum usitatissimum, Linn." “.

Off. Prep.—Lini Semina Contusa, Br.; Species Emollientes, N. F.

Linum catharticum L. Purging Flax.—Purging flax is an European annual of the Fam. Linaceae, six to eight inches high. The whole plant is very bitter and somewhat acrid, and imparts its virtues to water, which acquires a yellow color. It appears to owe its activity to a peculiar drastic principle, which has received the name of Unin, and which is afforded most largely by the plant after the flower has fallen. Schroeder (N. R. Pharm., xi, 11) obtained it in lustrous, white, silky crystals, which are neutral in reaction and have a strong persistent bitter taste in alcoholic solution. Purging flax has enjoyed some reputation in Europe as a gentle cathartic, useful in muscular rheumatism, catarrhal affections, and dropsy with disease of the liver. Dose, of the extract, from four to eight grains (0.26-0.5 Gm.); of the powder, one drachm (3.9 Gm.).
LINI SEMINA CONTUSA. Br.

CRUSHED LINSEED

"Crushed Linseed is Linseed reduced to a coarse powder. It should be recently prepared."

Linum Contusum, Br. 1898; Crushed Flaxseed.

Common flax is an annual plant, with an erect, slender, round stem, about two feet in height, branching at top, and, like all other parts of the plant, entirely smooth. The leaves are small, lanceolate, acute, entire, of a pale-green color, sessile, and scattered alternately over the stem and branches. The flowers are terminal, and of a delicate-blue color. The calyx is persistent, and composed of five ovate, sharp.. pointed, three-nerved leaflets, which are membranous on their border. The petals are five, obovate, striated, minutely scalloped at their extremities, and spread into funnel-shaped blossoms. The filaments are also five, united at the base, and the germ, which is ovate, supports five slender styles, terminating in obtuse stigmas. The fruit is a globular capsule, about the size of a small pea, having the persistent calyx at the base, crowned with a sharp spine, and containing ten seeds in distinct cells. This highly valuable plant, now almost everywhere cultivated, is said by some to have been originally derived from Egypt, by others from the great elevated plain of Central Asia. It flowers in June and July, and ripens its seed in August.

The flax plant was cultivated for its fiber by the American colonists soon after the landing of Columbus. Soon thereafter it was grown for its seed and already in 1792 the United States exported nearly 300,000 bushels of flaxseed. Very early the linseed oil industry was developed in the United States and in 1810 there were nearly 300 linseed oil mills in the 14 states, more than half of them being in Pennsylvania. It is estimated that at the present time 12,000,000 bushels of seed are crushed annually for the oil. "The annual crop of flaxseed in the United States approximates 30,000,000 bushels. A large quantity of seed is annually exported as well as oil-cake, the latter being extensively used as a cattle food."
Properties.—The official description of flax-seed is as follows: "Ovate or oblong-lanceolate, flattened, obliquely pointed at one end, from 3 to 5 mm. in length; externally chestnut-brown, very smooth and shiny, the raphe extending as a distinct, light-yellow ridge along one edge; easily cut with the finger-nail; internally olive-green; oily; odor slight; taste mucilaginous and oily. Under the microscope, transverse sections of Linseed when mounted in hydrated chloral T.S. show an epidermis with a mucilaginous layer from 0.01 to 0.03 mm. in thickness, covered by a very thin layer of cutin which is often more or less broken; two layers of parenchyma which overlie a continuous ring of stone cells having yellowish, porous walls and rather large lumina; a pigment layer, the cells having a reddish-brown content; an endosperm consisting of from 6 to 10 rows of cells surrounding the two large plano-convex cotyledons; the cells of both the endosperm and the cotyledons contain a fixed oil and aleurone grains, the latter being from 0.003 to 0.02 mm. in diameter." U. S.

"Seeds small, brown, glossy, nearly flat; from about four to six millimetres long; ovate, somewhat obliquely pointed; surface glabrous and minutely pitted. Internally yellowish-white, with a narrow oily endosperm and two large oily cotyledons. Epidermal cells filled with mucilage which swells and dissolves in water. No odor; taste mucilaginous, oily." Br.

The linseeds in commerce have been divided by E. M. Hohnes into two groups. The first group, characterized by the seeds being of sufficient size for six or seven to weigh a grain, contains Bombay, Bold Calcutta, Sicilian, and Ionian seed; in the group of small seeds (10 to 12 to the grain) are English, Dutch, Russian, and ordinary Calcutta varieties. An important practical point noticed by Holmes is that much of the drug of commerce is adulterated with weed seeds, which are nearly always smaller than the linseeds, and can therefore be separated by the sieve. When linseed meal is to be made for medicinal use, this separation should always be insisted upon, as many of the weed seeds are from Cruciferae, and are irritating. For detailed information as to varieties of linseed, weed seeds, etc., the reader is referred to Holmes's paper. (P. J., July, 1881; also N. R., 1881.)

The ground seeds are found in commerce under the name of flaxseed meal. This is of a dark-gray color, highly oleaginous, and when mixed with hot water forms a soft adhesive mass, much employed for luting by
practical chemists. "The powder of flaxseed is lemon-yellow or light brown, consisting chiefly of large, oily globules and irregular fragments of endosperm and seed-coat; the seed-coat is characterized by the tabular pigment cells filled with a reddish-brown, insoluble content and the somewhat elongated stone cells with yellowish walls; mounts made from material from which the fixed oil has been removed show aleurone grains from 0.003 to 0.02 mm. in diameter, both free and in the cells of the endosperm and embryo. Linseed Meal or Flaxseed Meal is light olive-brown with reddish-brown fragments; the latter being very coarse and the cellular tissues are the same as those of the powder. Powdered Linseed or Flaxseed and Linseed Meal or Flaxseed Meal must be free from any unpleasant or rancid odor. The powder, upon extraction with purified petroleum benzin, yields not less than 30 per cent. of a fixed oil, at least 98 per cent. of which is saponifiable. Boil 1 Gm. of the fat-free Linseed or Flaxseed Powder or Meal, with 50 mils of water, cool and filter; the filtrate gives not more than a faint blue color, on the addition of iodine T.S. Linseed yields not more than 6 per cent. of ash." U. S.

Crushed flaxseed is "a coarse, brownish-yellow powder, with readily visible fragments of the brown seed-coats. Bland, not pungent or rancid, odor when mixed with warm water, Yields not less than 30 per cent. of oil when exhausted by carbon disulphide; the oil thus obtained responds to the tests described under. 'Oleum Lini'; the residual powder exhibits no starch grains when examined under the microscope. Ash not more than 5 per cent." Br.

The average composition of linseed oil cake is thus given by Schaedler (Technologie der Fette und Oele, 1883): moisture, 10.56 per cent.; oil, 9.83 per cent.; non-nitrogenous fiber, 44.61 per cent.; ash, 6.5 per cent.; proteid matter, 28.5 per cent.

Much of the linseed meal of commerce is simply cake meal, which was, indeed, official in the former Br. Ph., but such meal is unfit for medicinal use, not only because it contains very little oil, but also because the oil which is in it has, through rupture of the cells and partial expression, been so exposed to the air as to become rancid. Linseed meal is sometimes adulterated with corn meal, or other meals containing starch, whose presence is at once revealed by the iodine test. It is sometimes found in the market adulterated with petroleum or other mineral oil, doubtless made by powerfully pressing the pure linseed meal and substituting for the linseed oil the less expensive product, petroleum. (A.
The absolute value of a sample of crushed linseed can be determined by analysis. It should contain from 25 to 35 per cent. of oil, not more than 8 or 8.5 per cent. of husk, and less than 8 per cent. of ash. The following test is said to be sufficient for practical purposes: "Put half an ounce of the meal into a glass vessel, pour six ounces of boiling water over it, stir well, and allow it to stand for twelve hours. If first-class, it should absorb all the water, and show a thin scum of white glutinous liquid on the top, which will adhere closely to a glass rod or a wooden pencil dipped into it. If the meal does not absorb nearly all the water, it is of inferior quality. The amount of inferiority must be judged by the amount of water not absorbed, and by the character of the fluid on the top of the solution. If it is thin and non-glutinous, the meal is of inferior quality."

Meyer found in linseed fixed oil, wax, resin, extractive, tannin, gum, nitrogenous mucilage, starch, albumen, gluten, and various salts. Meurein could find no starch, but detected phosphates, which had escaped the notice of Meyer. (J. P. C., 3e ser., xx, 97.) For some years there has been a discussion concerning the reaction for starch which is sometimes ascertained in commercial flaxseed. Apparently starch grains are not usually present, although it is stated that they may occur in appreciable quantities in the unripe seed. (Ph. Ztg., li, p. 658.) Certain tissues of the seed coat beneath the mucilaginous epidermis may give a starch reaction, and it is stated that even the cells may contain starch. (Proc. A. Ph. A., 1907, lv, p. 326.) Their investing coat abounds in a peculiar gummy matter or mucilage, which is readily imparted to hot water, forming a thick viscid fluid, that lets fall white flakes upon the addition of alcohol, and affords a copious dense precipitate with lead subacetate. The viscid mucilage of linseed cannot be filtered until it has been boiled. It contains in the dry state more than 10 per cent. of mineral substances; when freed from these and dried at 110° C. (230° F.), it has, like althcea mucilage, the formula $C_{12}H_{20}O_{10}$. The seeds by exhaustion with cold or warm water afford about 15 per cent. of this mucilage. By boiling with nitric acid, it yields crystals of mucic acid; by diluted mineral acids, it is broken up into dextrogyrate gum, sugar, and cellulose. (Kirchner and Tollens, Ann. Ch. Ph., clxxv, 215.) For further information on the histology and pharmacognosy of the flaxseed, see Winton and Moeller, "The Microscopy of Vegetable Foods;" Kate B. Winton, Bot. Gaz., lvii, p. 2445; Collin, J. P. C., 1909, xxix, p. 369.
Jorissen and Hairs (Drogues Simples, t. ii, 685) obtained from the young plant a gluco-side, to which they gave the name of linamarin, which crystallizes in colorless needles, melting at 134° C. (273.2° F.), without odor, but possesses a fresh and bitter taste. It differs from amygdalin in not being decomposed by emulsin, but diluted acids decompose it into sugar, hydrocyanic acid, and a third product which is volatile and possesses certain of the characters of the acetones. No benzaldehyde is formed. Linseed contains about 4 per cent. of nitrogen, corresponding to about 25 per cent. of proteid substances. After expression of the oil these substances remain in the cake, so that the latter contains 5 per cent. of nitrogen and constitutes a very important article for feeding cattle and is termed cake meal. The interior of the seed, or nucleus, is rich in a peculiar oil, which is separated by expression, and extensively employed in the arts on account of its drying properties. (See Oleum Lini.)

Uses.—Flaxseed is demulcent and emollient. The mucilage obtained by infusing the entire seeds in boiling water, in the proportion of half an ounce to the pint, is much and very advantageously employed in catarrh, dysentery, nephritic and calculous complaints, strangury, and other inflammatory affections of the mucous membrane of the lungs, intestines, and urinary passages. The whole seed is occasionally given in tablespoonful doses as a laxative. By decoction, water extracts a portion of the oleaginous matter, which renders the mucilage less fit for administration by the mouth, but superior as a laxative enema. The meal mixed with hot water forms an excellent emollient poultice.

Lippia.—A number of the species of this genus (Fam. Verbenaceae) contain aromatic oils, and several have been used in popular medicine. The L. citriodora, H. B. K., yield verbena oil, and is commonly known as Lemon verbena. From the L. mexicana, Podwissotzki (Proc. A. Ph. A., 1886) separated an essential oil somewhat resembling that of fennel, as well as a camphor-like substance which he named lippioil. According to Maisch (A. J. P., xxlvii, p. 330), however, the plant used by Podwissotzki was probably the Cedronella mexicana (Bentli.). Power and Tutin (A. Pharm., 1907, cxxiv, p. 337) found in the L. scaberrima (Sender), a native of South Africa, where it is popularly known as Beuless boss, an essential oil somewhat resembling lavender in its odor, a peculiar crystalline substance, which they named lippialol, having the qualities of a mono-hydric alcohol, and a number of other substances not peculiar to the plant.

Liquidambar. Liquidambar Styraciflua, L. Sweet Gum.—An indigenous tree (Fam. Hamamelidaceae), growing in different parts of the United States from Connecticut to Florida, and flourishing also in Mexico and Central America, where, as well as in our
Southern States, it sometimes attains a great magnitude. In warm latitudes a balsamic juice flows from its trunk when wounded. This has attracted some attention in Europe, where it is known by the name of liquidambar or copalm balsam, and is sometimes, though erroneously, called liquid storax. It is not afforded by the trees which grow in the Middle Atlantic States, but is obtained in the Western States bordering on the Ohio, and southward as far as Central America. It is a liquid of the consistence of thin honey, more or less transparent, of a yellowish color, of a peculiar, agreeable, balsamic odor, and a bitter, warm, and acrid taste. By cold it becomes thicker and less transparent. It concretes also by time, assuming a darker color. It is sometimes collected in the form of tears, produced by the spontaneous concretion of the exuded juice. According to Bonastre, it contains a colorless volatile oil, a semi-concrete substance which rises in distillation and is separated from the water by ether, a minute proportion of benzoic acid, a yellow coloring substance, an oleoresin, and a peculiar principle, insoluble in water and cold alcohol, for which Bonastre proposed the name of styrracin. The styrracin of Bonastre has since been found to be cinnamyi cinnamate \((C_9H_{10})C_9H_7O_2\), which is found together with the ethyl, benzyl, and other esters of cinnamic acid. Examined by W. P. Creecy, of Mississippi, it was found to contain cinnamic acid as the prominent acid ingredient, besides a volatile, odorous principle melting at 65° C. (149° F.), and smelling of vanillin, and 30 per cent. of a hard resin (according to W. von Miller, storesin, \(C_{36}H_{55}(OH)_3\)). If the storesin be repeatedly extracted with diluted potassium hydroxide solution, it is separated into a-storesin, which is amorphous and melts at from 160° to 168° C. (320°-334.4° F.), and b-storesin, which forms white flocks melting at from 140° to 145° C. (384°-393° P.). Of these, the b-resin is first extracted, while the residue is nearly pure a-resin. The volatile oil mentioned above contains a hydrocarbon, styrol, styrene or cinnamene, \(C_8H_8\), which changes on heating into the polymeric metastyrol, a colorless, transparent solid. The results of W. L. Harrison, confirmed by Maisch (A. J. P., xlvi, 160, 165), seem to prove that the American drug is identical with storax, except in containing no water mechanically mixed with it.

Another product is said to be obtained from the same tree by boiling the young branches in water, and skimming off the fluid which rises to the surface. It is of thicker consistence and darker color than the preceding, is nearly opaque, and abounds in impurities. This also has been confounded with liquid storax, which it resembles in properties, though derived from a different species of Liquidambar. It is said to be used in Texas in coughs. (Gammage, N. O. M. S. J., xii, 836.) For an account of the collection of American storax, see Ph. Rund., 1895, 57.

Liquidambar may be employed for the same purpose as storax, and is so used in the Southern United States, but it is almost unknown in the Northern States. The concrete juice is said to be chewed in the Western States in order to sweeten the breath. The bark of the tree is used with asserted great advantage in the Southern and Western States in diarrhea and dysentery, especially in children. It is taken in the form of syrup, which may be prepared from the bark in the same manner as the syrup of wild cherry bark, according to the U. S. Pharmacopoeia. The dose is a fluidounce (30 mils) for an adult, repeated after each stool. (Ann. J. M. S., N. S., xxxii, 126.)
Liquidambar Altingia (Altingia excelsa), a tree which inhabits a very wide region in Southern Asia, yields a storax-like substance varying in color from white to red. (See P. J., viii, 243.) According to Tschirch and van Itallie, it differs from storax in the presence of benzoic and cinnamic aldehydes, the absence of ether and the small quantities of cinnamic acid in it. Liquidambar storesin is said also to be known in Eastern markets.

**Liriodendron.** Liriodendron Tulipifera L. Tulip Tree. American Tulip-poplar Tree. (Fam. Magnoliaceae). White Tulip Bark. Ecorce de Tulipier, Fr. Tulpenbaumrinde, G.—The tulip poplar is a large tree which is abundant in rich soil in the forests from Southern Ontario to Wisconsin and extending into the Southern States, the timber being commonly known as Poplar or White Wood. Its formerly official bark was taken for use indiscriminately from the root, trunk, and branches, though that of the root is thought to be the most active. Deprived of the periderm, it is yellowish-white, the bark of the root being somewhat darker than that of the stem or branches. It is very light and brittle, of a feeble, rather disagreeable odor, strongest in the fresh bark, and of a bitter, pungent, and aromatic taste. These properties are weakened by age, and we have found specimens of the bark, long kept in the shops, almost insipid. Emmet believed the active principle to be the substance discovered by him and named liriodendrin. It is white, crystallizable, brittle, insoluble in water, soluble in alcohol and ether, fusible at 82.2° C. (180° F.), volatilizable and partly decomposed at 132.2° G. (270° F.), of a slightly aromatic odor, and a bitter, warm, pungent taste. It does not unite either with acids or alkalies, and the latter precipitate it from the infusion of the barks by combining with the matter which renders it soluble in water. Water precipitates it from its alcoholic solution. It is obtained by macerating the root in alcohol, boiling the tincture with magnesia until it assumes an olive-green color, then filtering, concentrating by distillation until the liquid becomes turbid, and finally precipitating the liriodendrin by the addition of cold water. (A. J. P., iii, 5.) J. U. Lloyd believes that the active principle is the alkaloid tulipiferine, discovered by him in 1886, and this, according to Bartholow, appears to possess toxic properties. (Ph. Rund., 1886, 169.) The virtues of the bark are extracted by water and alcohol, but are injured by long boiling.

Liriodendron is a stimulant tonic, with diaphoretic properties, and has been used in chronic rheumatism and dyspepsia. Dose, of bark in powder, from half a drachm to two drachms (2.0-7.7 Gm.); of saturated tincture, a fluidrachm (3.75 mils).

**Lithospermum.** Lithospermum officinale L. Common Gromwell. Milium Solis.—A European perennial, also found along roadsides and pastures of Canada and the northern United States, of the Fam. Boraginaceae, the seeds of which are ovate, of a grayish-white or pearl color, shining, rather larger than millet seeds, and of a stony hardness, from which the generic name of the plant originated. They were formerly used as stimulant diuretics, but are nearly inert.

**Lithraea.** Lithraea venenosa Miers. (Fam. Anacardiaceae).—The leaves of this Chilian, plant are said to act upon the skin in a manner similar to Rhus toxicodendron,
and to contain a resin and an ethereal oil. The tincture of the fresh leaves has been used as a counter-irritant.

**Litmus.** Lacmus. Turnsole. Tournesol. Lacca Coerulea. Lacca Musica. Laquebleu, Fr. Lackmus, G.—Three purple or blue coloring substances are known in commerce, obtained from lichenous plants. They are called severally litmus, orchil, and cudbear. Litmus is yielded by numerous species of lichens which, under the French name of orseille, are brought into commerce from the coasts of Sweden and Norway; from the Alps, the Pyrenees, and other European mountains; from the European and African coasts of the Mediterranean; from the Canaries, Madeira, and various other rocky islands, especially from Mozambique, Madagascar, and Angola, and from California. The speciea of lichens concerned represent various genera; at present the two most important of the lichens are said to be the RocellaMontagnei of Mozambique and the Dendrographaleucophoea of California. In the north of Europe Lecanora tartarea Ach., or Tartar oan moss, and on the Mediterranean coasts the Roccellatinctoria Ach., or orchilla weed, at one time furnished the great bulk of the orseille of commerce. The chromogenous ethers which constitute the coloring matter of the lichens may be readily detected in situ by reagents. ([P. J., Nov. 19, 1904.]) In some of the lichens these coloring principles are chiefly situated in the cortex; in others they are especially abundant in the gonidial layer.

The principles in these plants upon which their valuable properties depend are themselves colorless, and yield coloring substances by the reaction of water, air, and ammonia. They are generally acids or acid anhydrides, and are named lecanoric, orsellic, erythric, etc., according to their origin. Lecanoric (diorsellinic) acid, C_{16}H_{14}O_{7}, the original constituent of most of these plants, when boiled with water or alkaline solutions, is changed into orsellinic acid, as follows:

\[
C_{16}H_{14}O_{7} + H_{2}O \rightarrow (C_{8}H_{9}O_{4})_{2}
\]

**Orsellinic acid,** C_{6}H_{2}\left\{CH_{3}, (OH)_{2}, fuses at 176\degree C. COOH\right\}

(348.8\degree F.), and decomposes into orcin, C_{6}H_{3}(CH_{3})(OH)_{2}, and CO_{2}. The same decomposition is readily effected by distillation with milk of lime. Orcin combines with ammonia gas to form C_{6}H_{8}O_{2}NH_{3}, the solution of which exposed to the air becomes colored reddish by the formation of orcein, C_{7}H_{7}NO_{3}. This latter compound forms the basis of the commercial orseille extract (orchil or archil).

Kane described a deep red crystalline substance, erythrolitmin, and a brownish-red coloring principle, azolitmin, C_{7}H_{7}NO_{4}. This latter is considered as the distinctive coloring matter of the commercial litmus, and is now found in commerce under that name and is used as an indicator. It is nearly insoluble in cold water or benzene, but dissolves in alcohol with red, and in ether with yellow color. It appears to have the characters of a weak acid, the salts of which are blue and the potassium and calcium compounds of which exist in litmus.

To test the value of the plants as dye-stuffs, they may be macerated in a weak...
solution of ammonia, or a solution of calcium hypochlorite may be added to their alcoholic tincture. In the former case a rich violet-red color is produced; in the latter, a deep blood-red color appears, but soon fades,

Lacmus or litmus is prepared chiefly if not exclusively in Holland. The process consists in macerating the coarsely powdered lichens, in wooden vessels under shelter, for several weeks, with occasional agitation, in a mixture of urine, lime and potash or soda. A fermentation ensues, and the mass, becoming first red and ultimately blue, is, after the last change, removed, mixed with calcareous or silicious matter to give it consistence, and with indigo to deepen the color, and then introduced into small molds, where it hardens. It is said that ammonia may be substituted for urine in the manufacture of litmus, but that the reactions necessary for the production of the coloring matter of the litmus are due to the action of the enzyme which is found in the lichens. Litmus occurs in rectangular cakes, from a quarter of an inch to an inch in length, light, friable, finely granular, of an indigo-blue or deep violet color. It has the combined odor of indigo and violets, tinges the saliva a deep blue, and is somewhat pungent and saline to the taste. From most vegetable blues it differs in not being rendered green by alkali. It is reddened by acids, and restored to its original blue color by alkalis. For a method of purifying commercial litmus by Foerster, see Nat. Drug., 1904, 460.

Its chief use in pharmacy is as an indicator. For this purpose it is employed either in infusion or in the form of litmus paper. The infusion, formerly called tincture of litmus, may be made in the proportion of one part of litmus to twenty of distilled water, and two parts of alcohol may be added to preserve it. Litmus paper is prepared by first forming a strong clear infusion with one part of litmus to four of water, and dipping slips of white unsized paper into it, or applying it by a brush to one surface only of the paper. The paper should then be carefully dried, and kept in well-stoppered vessels, from which the light is excluded. It should have a uniform blue or slightly purple color, neither very light nor very dark. As a test for alkalis the paper may be stained with an infusion of litmus previously reddened by an acid, care being taken to avoid all excess. By gas light it is said that the change of color cannot be determined by the eye exactly, as the blue of litmus becomes mauve; but this may be obviated by watching the process through a green glass, by which the faintest trace of blue becomes discernible. For the official method of preparing litmus paper, see Tests, Teat Solutions, etc., PART III.

Orchil, or archil, as prepared in England, is in the form of a thickish liquid, of a deep reddish-purple color, but varying in the tint, being in one variety redder than in another. The odor is ammoniacal. It is made by macerating lichens in a covered wooden vessel, with an ammoniacal liquor, either consisting of stale urine and lime, or prepared by distilling an impure salt of ammonia with lime and water. (Pereira.) For details as to the method of preparation, see Chem. News, 1874, 143. It is occasionally adulterated with the extracts of colored woods, as logwood, sappan-wood, etc. A mode of detecting these adulterations is given by F. Leeshing in the Chem. Gaz. of June 1, 1855, 219. A sulphonated derivative of orchil is much used in coloring food-stuffs under the name of "vegetable red."

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - L - Page 30
The Southwest School of Botanical Medicine http://www.swsbm.com
Cudbear is a purplish-red powder procured in the same manner as orchil; but the mixture, after the development of the color, is dried and pulverized.

The point in which the preparation of these coloring substances differs from that of litmus appears to be, that potassium or sodium hydroxide is added, in the latter, to the ammoniacal liquid used. Orchil and cudbear are employed as dye-stuffs and for coloring purposes, and sometimes, in like manner with litmus, as indicators (see Cudbear). For chemical constituents of lichens, see A. J. P., 1898, 455.

**LOBELIA. U. S., Br.**

**LOBELIA Lobel.**

"The dried leaves and flowering tops of Lobelia inflata Linne (Fam. Lobeliaceae), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." U. S. "Lobelia is the dried flowering herb of Lobelia inflata, Linn." Br.

Lobelia inflata, often called Indian tobacco, is an annual or biennial indigenous plant, usually a foot or more in height, with a fibrous root, and a solitary, erect, angular, very hairy stem, much branched about midway, but rising considerably above the summits of the highest branches. The leaves are scattered, or alternate, petiolate, the upper sessile, ovate, or oblong, about two inches (5 cm.) long, irregularly toothed, pubescent, pale green. The flowers are numerous, small, disposed in leafy terminal racemes, and upon short axillary footstalks. The calyx is five-toothed and much inflated in fruit. The corolla, which is of a delicate blue, has a labiate border, with the upper lip divided into two, the lower into three segments. The united anthers are curved, and enclose the stigma. The fruit is an oval, striated, inflated capsule, crowned with the persistent calyx, and containing, in two cells, numerous very small, oblong, reticulated brown seeds.

Lobelia inflata is a very common weed, growing in the roadsides and in neglected fields throughout the Eastern United States and Canada. Its flowers begin to appear towards the end of July, and continue to expand in succession until the occurrence of frost. All parts of it are medicinal, but, according to Eberle, the root and inflated capsules are most powerful. The plant should be collected in August.
Lobeline Sulphate.—This occurs as very deliquescent yellow friable pieces soluble in water and alcohol. It is asserted to be a very valuable anti-spasmodic drug, being of especial use in the treatment of asthma. Its incompatibilities are the same as those of alkaloids in general and it is a very active poison, emetics and tannin followed by systemic stimulants being the antidote. Dose, one-third to one-half grain (0.02-0.03 Gm.).

Loco Plants. Crazy Weeds.—These are plants growing in the far Western States, the eating of which by horses and cattle is believed to produce loss of flesh, disordered vision, delirium, convulsive movements, or stupor and death. The chief local plants are Aragallus Lamberti, commonly known as rattlweed or whiteloco, extending from Alaska southward. A plant of more limited range is the purple loco, woolly loco or Texas loco (Astragalus mollissimus Torr.). There are quite a number of other plants causing heavy losses to stock men of the West.

Isaac Ott found a plant, which he believed to be A. mollissimus, to act as a violent spinal poison and mydriatic (N. R., Aug. 1882), and, according to Carl Ruedi, the decoction produces in the rabbit great hilarity, excitement, and even ferocity, and contains an alkaloid, locoine, and an acid. (Tr. Col. State Med. Soc., 1895.) On the other hand, O'Brien, of the State Agricultural College of Colorado, was not able to obtain any active chemical substance from six U. S. species of the genus, including the two previously mentioned, while in a very careful study of a plant which was neither in flower nor in seed, but whose identification as A. mollissimus was clear, H. C. Wood found that it was not poisonous to rabbits or dogs, a result which has been confirmed by Ingersoll (Proc. A. Ph. A., 1890) and O'Brien (Bulletin 25, Agricultural Experiment Station of Colorado) and others. It would appear that A. mollissimus is not a poisonous plant. Other species of the genus, especially A. Hornii A. Gray, A. Bigelovii A. Gray, and A. Caryocarpus Ker., Gawl, have had poisonous properties attributed to them, and in the fruit of the last-mentioned species G. B. Frankforter believes he has demonstrated the presence of an alkaloid. In 1908 Crawford brought forward the interesting theory that the poisonous effects of the loco weed were due to barium, but Alsberg and Black (Bull. 246, U. S. Bureau of Plant Industry, 1912) have shown that many other plants in the same localities contain equal quantities of barium, but do not produce the characteristic symptoms, and that the barium is in such an insoluble form as to render improbable that it would be absorbed in the intestinal tract. There can be no doubt that domestic animals are destroyed in the West in very large numbers from an affection which is known as “loco,” and hundreds of thousands of dollars have been spent in bounties by the State of Colorado for the extirpation of the supposed poisonous astragalus. It is probable that many of the deaths attributed to loco have been from other causes. Thus, Ingersoll of the Colorado State Agricultural College, found in a large number of locoed sheep masses of Taenia expansa, which he believed to be the cause of death. It is a probable explanation that the phenomena of loco disease are due to the fermentation of an astragalus or other plant in the intestines of the animals, and the production of one or more poisons which are
absorbed and produce narcotic symptoms. If this be correct the loco disease is parallel in its etiology and nature to the lathyrismus of Europe. See Lathyrus sativus; also N. Y. M. J., 1889, xlix. Similar effects are produced in horses by the pods of the mesquite (Prosopis juliflora DC.), when eaten too freely.

According to Haeckel (Die naturlichen Pflansen Familien), the Russian grass Stipa capillata L. frequently kills sheep, not, however, by a direct poisonous action, but by its glumes working through the skin into the vital organs; and Stipa Vaseyi, which is said in some parts of New Mexico and Texas to be known by the name of "sleepy grass," is believed by some ranchers to be the cause of loco disease. Lescohier (M. R., 1911, xx, p. 273) finds that the sleepy grass is an active respiratory poison, and also has some depressant action upon the heart muscle. He suggests that the apparent narcosis produced by the injection of it into the lower animals, is due to partial asphyxiation. This explanation, however, seems improbable in light of the symptoms which are reported in animals which have eaten the grass. Gillespie (B. M. J., 1908, ii, p. 1059) reports that the drug is not only a narcotic, but also a diuretic and sudorific.

**Lolium.** Lolium temulentum L. Darnel. Bearded Darnel. Ivraie, Fr. Lolch, Taumelkorn, G. —This grass, which has spread over the world wherever wheat is cultivated, is rarely found in the United States. It owes its importance to its growing especially with wheat, so that its ground seeds are eaten in the flour. From ancient times its seeds have been believed to produce an intoxication similar to that of alcohol; hence its specific Latin name and the French name, Ivraie. In the sweetish seeds, P. Antze (A. J. P., 1891, 568) believed that he found a solid alkaloid, temulentine, and a volatile one, loline, but Hofmeister (A. J. P., 1892, 611) determined that the volatile alkaloid was an impure ammonia, while the temulentine was a mixture which contained a nitrogenous acid and an uncrystallizable alkaloid, temuline, of which the hydrochloride has the formula C$_7$H$_{12}$N$_2$O.$2$HCl.

It is alleged that lolium seeds produce vertigo, dizziness, headache, somnolence, and general intoxication in man, as well as in dogs, sheep and horses, while they are innocuous to hogs, cows, and poultry. Riviere and Maiziere (J. P. C., 1863, 280) have recorded death as occurring from the use of bread containing large amounts of darnel. P. Antze found that both loline and temulentine are poisonous, causing violent gastro-intestinal irritation, dyspnea, and general depression. (Cb. G. T., 1891.) M. P. Guerin believes the poisonous properties of darnel are due to the presence of a fungus. (Morots Journ. de Bot., 1898.)

**Lonchocarpus.** Lonchocarpus violaceus (J acq.) H. B. K. Stinkwood.—The wood of this papilionaceous tree is said to be used by the natives of Surinam as a fish poison. (Ph. Cb., xxxix, 282.)

**Lonicera.** Lonicera Caprifolium, L. Honeysuckle. "American" or Italian Woodbine. (Fam. Caprifoliaceae)—The flowers of the common honeysuckle are sometimes used in perfumery, and a syrup of the fruit has been commended in asthma. The fruit of all the species of Lonicera is said to be emetic and cathartic (Merat and De Lens), and that of L. xylosteum L. to have caused serious poisoning. (J. P. C., 4e ser., xviii, 65.)
Lotus. Lotus arabicus L.—According to W. R. Dunstan and T. A. Henry, the leaves of this leguminous plant contain a yellow crystalline glucoaide, lotusin, C_{22}H_{19}NO_{10}, and an enzyme, lotase, by which lotusin is converted into prussic acid and a yellow substance, lotoflavin. (Proc. Roy. Soc., lvii, 224.)

Lucuma.—This Brazilian genus of the fam. Sapotaceae yields a number of species, which are used in Brazil as medicines or articles of diet. For an account of them, see Ph. Rund., 1888. See also Monesia.

Luffa. Luffa cylindrica (L.) Rom. Vegetable Sponge. Wash-rag Sponge. Gourd Towel.—A cucurbitaceous genus, indigenous to Arabia and Egypt, furnishing a gourd-like fruit, which presents upon the removal of the epidermis a durable skeleton of interwoven woody fibers, which are used in place of sponge. Reinhard J. Weber has furnished the following description of Luffa cylindrica as grown in this country: It is a large climbing vine, with a thin but very tough light green, succulent stem, attaining a length of from 10 to 30 feet. The leaves are alternate and palmately-lobed, of a light green color, and almost destitute of taste. The flowers are monoecious, petals five, united below into a bell-shaped corolla; anthers cohering in a mass; ovary two-celled, style slender, stigmas three. The fruit is elliptical-ovate, fleshy and dehiscent, with a green epidermis, longitudinally marked with black ridges, varying from ten to fifteen in number; under each of these ridges is found a tough, woody fiber. The seeds are numerous and almost flat, broadly-ovate, three-eighths of an inch long. (A. J. P., 1884, 6.) The fruit of L. echinata Roxb., of India, is a violent irritant poison, from which C. J. H. Warden has separated a principle allied to, if not identical with, colocynthitin. (P. J., June, 1890.)

Lupinus. Lupinus albus L. Lupin. Lupin, Fr. Feigbohne, Wolfsbohne, Gr.—A plant belonging to the Leguminosae, and a native of Europe and Western Asia, which is sometimes cultivated in our gardens. Other species are also met with—L. hirsutus L., L. luteus L., L. polyphyllus Lindl., L. densiflorus Benth. The last two are indigenous to the Pacific slope and the West. The bitter principle lupinin, C_{29}H_{32}O_{16}, is a glucoside, and its solution in alkalies is of a dark brownish-yellow color. On boiling with dilute acids it is decomposed into lupigenin, C_{17}H_{12}O_{6}, and a fermentable, dextro-rotatory glucose. The bruised seeds of white lupin, after soaking in water, are sometimes used as an external application to ulcers, etc., and internally are said to be anthelmintic, diuretic, and emmenagogue. An instance has been recorded where a decoction used as an injection in the rectum caused symptoms which suggested a poisonous character for the drug. An alkaloid, lupanine, C_{15}H_{24}ON_{2}, has also been discovered in L. angustifolium. It is a pale, yellow, syrupy fluid of an intensely bitter taste and showing a green fluorescence. Two alkaloids, lupinine, C_{21}H_{40}O_{2}N_{2}, and lupinidine, C_{8}H_{15}O_{2}N, have been isolated from the seeds of Lupinus luteus and L. niger, the former a crystalline powder and the latter a syrupy liquid. Steiger (J. Soc. Chem. Ind., 1886, 385) has also studied a carbohydrate analogous to dextrin, which Baeyer and Eichborn discovered in Lupinus luteus. He finds that it is not changed by yeast, that
nitric acid converts it into mucic acid, and that diluted sulphuric or hydrochloric acid
converts it into galactose.

According to Schwartz (W. K. R., 1906) the seeds of the Lupinus arabicus contain
calcium-anhydro-oxydiaminephosphate, to which he has given the name of magolan
and which is a useful remedy in diabetes mellitus. It occurs in crystals which yield a
green precipitate with copper acetate. The dose of magolan is three grains (0.2 Gm.).
several times daily.

**Lycium.** Lycium halimifolium Mill. Matrimony Vine. (Fam. Solanaceae)—Different
species have been used in various parts of the world for supposed medicinal virtues.
Lycium vulgare, which is indigenous in the south of Europe and in Asia, is a thorny
shrub, with long flexible branches, and is cultivated for hedges and arbors. Huse-
mann and Marme found in the leaves and stem an alkaloid, lycine, \( C_5H_{11}O_2N \). (A. J.

.., 1864, 226.) It is very deliquescent, and is soluble in both water and alcohol, but
nearly insoluble in ether. It is crystallizable, of a sharp but not bitter taste, and forms
crystallizable salts with the acids. Husemann believes that lycine does not exist in
the plant, but is formed during the process of extraction, and also that it is identical
with betaine, \( C_5H_{11}NO_2 \), the alkaloid obtained from beet juice by Scheibler, and with
the oxyneurine of Liebreich. (A. J. P., xlvii, 209.) E. Schmidt found in Lycium vulgare
traces of mydriatic alkaloids, resembling those of belladonna. (Ap. Ztg., 1890, 511.)
The young shoots of one of the species of Lycium are eaten in Spain as asparagus,
and its leaves as salad, and the aborigines of Colombia used another species against
erysipelas. The leaves of L. vulgare, as well as the fruit, are said to be used by the
physicians of Japan. (Merat and. De Lens.)

**LYCOPODIUM. U. S.**

**LYCOPODIUM Lycopod.**

“The spores of Lycopodium clavatum Linne (Fam. Lycopodiaceae),
without the presence or admixture of more than 2 per cent. of
impurities." U. S.

Club Moss, Stag's horn. Semen Lycopodii, Pulvis Lycopodii, Sulphur Vegetabile;
Vegetable Sulphur; Lycopode, Fr. Cod.; Souire vegetal, Fr.; Lycopodium, P. G.;

Lycopodium clavatum, commonly called club moss, has a trailing,
branching- stem, several feet long, and thickly beset with linear-awl-
shaped, flat, ribless, smooth leaves, tipped with a fine bristle, curved
upward, and of a light green color. The fructification is hi terminal
spikes, single or in pairs, with crowded ovate, entire, pointed scales,
bearing in the axil a transversely oval sporangia which splits nearly to the base and contains the narrow reticulate spores. The plant is a native of Europe, Asia, and America, being especially common in the dry woods northward.

The spores are collected in Switzerland and Germany. Lycopodium is "a light yellow, very mobile powder, nearly inodorous and tasteless. It is not wetted by water but floats upon it; when boiled with water it sinks; when thrown into a flame it burns with a quick flash. Under the microscope, the spores of Lycopodium are spherical tetrahedrons, from 0.025 to 0.04 mm. in diameter; in section they vary from plano-convex to triangular, the outer wall or exosporium being extended in the form of slight irregular projections, giving the surface of the spore a reticulate appearance, the reticulations being polygonal and formed of straight sides; when viewed so that the rounded surface of the spores is on the under side, the upper surface is characterized by a distinct, triangular marking, being the edges of the three straight surfaces, extending from the center of the Spores to near the outer edge. Lycopodium shows very few, if any, pollen grains of species of Pine, the latter being from 0.04 to 0.07 mm. in diameter, and consisting of three parts, in which a central, convex, generative cell separates the two spherical cells or wings which are blackish, due to the inclusion of air. Lycopodium yields not more than 3 per cent. of ash." U. S.

Fluckiger by thoroughly comminuting the spores of lycopodium with sand, obtained 47 per cent. of a bland oil of bright yellow color and sp. gr. 0.925, which does not congeal even at -15° C. (5° F.). A. Barkowski obtained from the spores of Lycopodium 48.5 per cent. of a neutral non-drying oil, very similar to almond oil. This oil contains 2 per cent. of a fatty acid called lycopodic acid (**C**₁₈**H**₃₆**O**₄), 80 per cent. of oleic acid, a minute quantity of a vegetable cholesterin similar to that obtained by Hesse from Calabar beans, 8.2 per cent. of glycerin and 3 per cent. of arachidic, palmitic and stearic acids. The lycopodic acid crystallizes in silky needles, it is doubly refracting like quartz, and appears to be isomeric with dioxy stearic acid. (D. C., 1891, 155; see also A. Pharm., 1908, 246.) Stenhouse found volatile bases to be present in very small amount. The ash amounts to 4 per cent. It contains alumina and 1 per cent. of phosphoric acid, and is not alkaline. (Pharmacographia, 2d ed., 732.) Lycopodium is sometimes admixed with pine pollen which is probably to be looked upon as an accidental contamination. In the same way, it may contain small quantities of talcum and starch. It is
sometimes adulterated with a resinous compound made from rosin, ferruginous earths, shellac, sulphur, turmeric, talcum, dextrin or the cereal starches.

In Nashville, Tenn., a specimen came into the possession of Benj. Lillard which was found to contain one-half of its bulk of dextrin. (Ch. Ph., Sept., 1873.) Folleto recommends two reactions to detect pollen: one by adding to a syrupy solution of zinc chloride, potassium iodide and iodine to saturation; the pollen is colored yellow by this reagent, lycopodium is not colored; the other reagent is methyl-green, which colors pollen green, but does not color lycopodium. (Ph. Centralh., 1896, 527.)

Uses.—Lycopodium is used as an absorbent application to excoriated surfaces, especially those which occur in the folds of the skin in infants. In pharmacy it answers the purpose of facilitating the rolling of the pilular mass, and of preventing the adhesion of the pills when formed. The moss itself has been esteemed diuretic and antispasmodic; its decoction has been employed in rheumatism, diseases of the lungs and kidneys, and in the removal of plica Polonica, but it has fallen into complete desuetude. One of the ingenious uses for lycopodium in microscopy is to mix a little of it with an unknown powder or on a slide on which a mount is made. The spores are easily recognizable and distinguishable from other elements and give an excellent idea of the approximate size of the elements which are being observed, as the spores are almost uniformly 40 microns in size.

Lycopodium Saururus Lain. Piligan.—In this Brazilian lycopod Adrian has found an actively poisonous alkaloid, piliganine. (C. R. A. S, June, 1886; see also B. G. T., cxi, 174.)

Lycopus. U. S. 1870. Lycopus virginicus L. Lycope de Virginie, Fr. Virginischer Wolfsfuss, G.—The bugle-weed is a labiate which grows throughout the greater part of the Eastern United States. The whole herb is used. Jos. L. Weil found 0.41 per cent. of fat melting at 50° C. (122° F.), 0.68 per cent. of a granular wax melting at 70° C. (158° F.), 0.43 per cent. of a crystallizable resin soluble in ether, a crystallizable glucoside, and a small quantity of gallic acid and tannin. (A. J. P., 1890, 72.) It has a peculiar odor and a nauseous slightly bitter taste, which it imparts to boiling water.

Lycopus europoeus L., a native of Europe, growing in waste places from Massachusetts to Virginia, is said to be frequently collected and sold for L. virginicus. The former may be distinguished by its acutely quadrangular stem, its Farrow lanceolate leaves, of which the lower are somewhat pinnatifid, its more crowded flowers, and the acute segments of its calyx, armed with short spines. It has been
employed in Europe as a substitute for quinine.

According to A. W. Ives, the bugle-weed is a mild narcotic and an astringent, useful in pulmonic and other hemorrhages. Dose of decoction (one ounce to one pint of boiling water), from one to four fluidounces (30-120 mils).

**Lycoris.** Lycoris radiata Herb. (Fam. Amaryllidaceae)—According to Morishima (A. E. P. P., 40), this plant contains two alkaloids, lycorine, C\textsubscript{32}H\textsubscript{32}N\textsubscript{2}O\textsubscript{9}, which occurs in large colorless poly-hedric crystals, and is physiologically very active, resembling emetine in its action, and sekisa-nine, C\textsubscript{34}H\textsubscript{34}N\textsubscript{2}O\textsubscript{9}, which occurs in colorless, anhydrous columns and is quite inactive physiologically.

**Lythrum.** L. Salicaria L. Spiked Loosestrife Purple Willow-herb. Salicaire Fr. Rother Weiderich, G.—This is an elegant perennial plant of the fam. Lythraceae, a native of Europe, but naturalized from Quebec to Delaware. The dried herb is inodorous, and has an herbaceous, somewhat astringent taste. It has been used as a demulcent astringent in diarrhea and chronic dysentery. The dose of the powdered herb is about a drachm two or three times a day. A decoction of the root, prepared by boiling an ounce in a pint of water, may be given in the dose of two fluidounces (60 mils).
[This was the last era in pharmacy when plant drugs were widely prepared, both for Regular School, Eclectic and Irregular physicians, and the Dispensatories were the major reference works used by pharmacists to prepare these products. Official plant drugs and preparations are in larger case, unofficial plant drugs and preparations are in smaller case. I have extracted all plant drugs and preparations, excluded non botanicals and those most reasonably used only by physicians...Opium, Digitalis, etc. Michael Moore]

**Mace.** Macis. N. F. IV.—" The arillode of the seed of Myristicafragrans Houttuyn (Fam. Myristicaceae)." N. F. IV. Mace was official in the U. S. Pharmacopoeia 1890, but was omitted in subsequent editions. It has very properly been admitted to the National Formulary IV. It is described as follows: "In narrow bands, 25 mm. or more in length, somewhat branched and lobed above, united into broader bands; yellowish to brownish-orange, and oily. Odor fragrant; taste warm and aromatic.

"The powder is orange-buff to orange-brown. Mounted in water and examined microscopically, the powder exhibits elongated epidermal cells; parenchyma containing very small amylodextrin granules, which are colored red-brown by iodine T.S.; large oil cells the contents of which are not greatly changed in color on the addition of alkali.

"Powdered false Mace or Bombay Mace is yellow-brown to deep-brown in color and deficient in odor and taste. When mounted in water and examined microscopically it exhibits flattened, thick-walled epidermal cells and oil cells much more numerous than in true Mace and containing an orange-red resinous substance which is dissolved by alkalis forming a blood-red liquid.

"Moisten Mace with hydrochloric acid; no greenish color is produced (difference from and absence of the arillode of Myristica malabarica Lamarck or Bombay Mace).

"Add potassium chromate T.S. to an alcoholic extract of Mace (1 in 10); the precipitate formed is yellow and does not change to red on standing, nor does the solution develop a red coloration (difference from and absence of Bombay Mace).

"Saturate a piece of filter paper with an alcoholic tincture of Mace (1 in 10), and add one drop of potassium hydroxide T.S.; no blood-red coloration is produced (difference from and absence of Bombay Mace).

"Mace yields not less than 8 per cent. of volatile ether extract, and not less than 20 per cent. nor more than 30 per cent. of non-volatile ether extract.

"Mace yields not more than 3 per cent. of ash which is almost completely soluble in hydrochloric acid." N. F. IV. Mace is inferior when it ia brittle, less than usually
divided, whitish or pale yellow, or with little taste and odor. The presence of starch granules or other microscopic particles different from those spoken of in powdered mace is proof of adulteration. Mace contains from 7 to 9 per cent. of a volatile oil, the greater portion of which consists of pinene, along with which is some myristicin, \( \text{C}_{12}\text{H}_{14}\text{O}_3 \). Wallach separated two odorous fixed oils; one yellow, soluble in ether, insoluble in boiling alcohol; the other red, soluble in alcohol and ether in every proportion.

**Mackay Bean.**—This is the seed of *Entada scandens* Benth. (Fam. Leguminosae), of Queensland, which has the reputation in the colony of being strongly poisonous, and in which John Moss found saponin. (P. J., vol. xviii, 242.)

**Magnolia.** U. S. 1880. *Magnolia Bark.*—Three species of magnolia, were formerly official as follows: *Magnolia virginiana* L., Small or Laurel Magnolia, *M. acuminata* L. or Cucumber-tree, and *M. tripetala* L., commonly known as Umbrella-tree (Fam. Magnoliaceae). In the latter Wallace Procter found in the fruit a neutral crystalline principle, magnolin. When pure, this is without odor and has at first little taste, in consequence of its insolubility in the liquids of the mouth, but after a time produces an irritant effect on the fauces. It is nearly insoluble in cold, but slightly soluble in hot water, very soluble in alcohol or ether. Procter considered it analogous to the liriodendrin obtained by Emmet, but quite distinct. It has been also found in other species. (See A. J. P., 1872, 145; also Lloyd's paper in Ph. Rund., 1866, 224.) W. F. Rawlins (A. J. P., 1889, 7) obtained from the leaves of *M. glauca* a small quantity of a volatile oil of bright green color, with an odor resembling fennel or anise, but more pleasant. From the ethereal solution of this oil small crystals deposited. Indications were also obtained of a bitter glucosidal principle.

The bark and fruit of all the species of Magnolia are possessed of similar medicinal properties; but the bark only was official, and that of the root has been thought to be most efficient. "The bark from young wood is quilled or curved, thin, externally orange-brown and glossy, or light gray, with scattered warts and somewhat fissured, internally whitish or pale brownish and smooth; fracture short, in the inner layer somewhat fibrous; inodorous; taste somewhat astringent, pungent, and bitter. The bark of old wood, deprived of the cork, is whitish or brownish, fibrous, and less pungent." U. S., 1880. The aromatic property, which resides in a volatile principle, is diminished by desiccation, and entirely lost when the bark is long kept. The bitterness, however, remains. The bark is destitute of astringency.

Magnolia is a gently stimulant aromatic tonic and diaphoretic. It has been used in malaria and in rheumatism. The dose of the recently dried bark in powder is from half a drachm to a drachm (2.0-3.9 Gm.), frequently repeated.

**Malambo or Matias Bark.**—A bark received from South America by Alex. Ure, under the name of matias bark, was found to have the characters of the malambo bark, which is held in high esteem in Colombia, where it is produced. According to H. Karsten, it is derived from a hitherto undescribed species of Croton, which he names *Croton Malambo* Karst. (Fam. Euphorbiaceae). (See Florae Colombiae Terrarumque
adjacentium Specimina Selecta.) This is a small tree or shrub, growing on the coast of Venezuela and Colombia. (P. J., 1859, 321.) It has an aromatic odor and a bitter, pungent taste, and yields these properties to water and alcohol. Its active ingredients appear to be a volatile oil and a bitter extractive matter. According to Mackay, it has been used successfully in intermitents, convalescence from continued fevers, hemicrania, dyspepsia, and other cases in which tonic remedies are useful, and also as an adjuvant to diuretics. It is probably nothing more than an aromatic tonic. Ure has administered it with good effect as a substitute for Peruvian bark. (P. J., iii, 169.)

Under the name of Winter's bark, a considerable quantity of malambo bark was at one time imported into the United States from South America.

**Mallow Leaves.** N. F. IV. Malvae Folia. Malva sylvestris L. Common Mallow. Flores Malvae Folia Malvae, P. G. High Mallow. Cheese Cake Flower or Pancake Plant.—It is described by the N. F. as the "the dried leaves of Malvasylvestris Linne and of Malva rotundifolia Linne (Fam. Malvaceae). Reject leaves showing brown fungous growths of Puccinia Malvacearum Montagne." N. F. This is a perennial, herbaceous, European plant of the Fam. Malvaceae. Almost all the species of the genus are possessed of the same properties. M. rotundifolia, L., known as cheeses, one of the most common, as well as M. sylvestris, are both used in medicine. The leaves often show a fungus growth," Leaves of Malvasylvestris, petiolate with petioles up to 10 cm. in length, orbicular or reniform, slightly truncate or cordate at the base, from 10 to 11 cm. in length, and from 15 to 20 cm. in width, with three to seven shallow, angular or rounded lobes, venation palmate, margins crenate-dentate, pubescent on both sides. Leaves of Malvarotundifolia, with petioles up to 20 cm. in length, obicolar up to 8 cm. in width, base deeply cordate, five to seven shallow rounded lobes, venation palmate, margins with rounded blunt teeth, pubescence more scant than in M. sylvestris. Intermixed with the leaves are frequently found dark purple flowers and glabrous reticulated carpels (M. sylvestris) or pale bluish flowers and pubescent rounded carpels (M. rotundifolia). Inodorous; on chewing it becomes very mucilaginous, taste bland. When examined under the microscope, sections show an epidermis containing mucilage cells; numerous stomata, on both surfaces, each with three or four neighboring cells; trichomes of three distinct types, small, short-stalked glandular hairs, single, large, one-celled curved hairs with thick walls and compound or stellate hairs in groups of two- to six-cells (the latter especially numerous in M. sylvestris); palisade tissue of one or two rows of cells, the mesophyll of three or four rows; the parenchyma containing calcium oxalate in rosette crystals and numerous mucilage cells which are distributed in the tissue of the veins; veins with collateral bundles. The powder is light green and, when examined under the microscope, exhibits the characteristic hairs, mucilage cells, epidermis with stomata, and rosette crystals of calcium oxalate. Mallow Leaves yield not more than 16 per cent. of ash." N. F. The herb and flowers have a weak, herbaceous, slimy taste, without odor. They abound in mucilage, which they readily impart to water, and the solution is precipitated by lead acetate. The infusion and tincture of the flowers are blue, and have been used as indicators, being reddened by the acids and rendered green by alkalies. The roots and seeds also are mucilaginous. Common mallow is emollient and demulcent. The infusion and decoction are sometimes employed in catarrh, dysentery, and nephritis
complaints, and are applicable to all other cases which call for the use of mucilaginous
liquids.

**Malouetia.** Malouetianitida Spruce. Gauchamaca. (Fam. Apocynaceae)—This plant, of
Venezuela, contains an alkaloid, guachamacine, which Kobert believes to be identical with curarine. (A. J. P., 1885, 560.)

**Manaca.** Vegetable Mercury.—This is a portion of the root and stem of Brumfelsia
Hopeana Benth. (Francisca uniflora Pohl), a Brazilian plant belonging to the Fam. Solanaceae. It occurs in pieces from a few inches to one foot in length, and about one-half inch in diameter, very tough and woody, with a yellowish center and a dark, very thin outer bark. The stem portion has a very small yellowish pith. H. B. Parsons (Am. Chem. J., vol. i, No. 6) came to the conclusion that it contains no alkaloid, but E. Lenardson (In. Dis., Dorpat, 1884) asserts that he has found in it an alkaloid, manacine besides a peculiar fluorescent substance supposed to be identical with gelseminic acid. Some investigators report failure to find any alkaloidal principles. E. P. Bruer (T. Q., 1882), as the result of experiments made upon the lower animals arrived at the conclusion that manaca acts upon the spinal cord, first stimulating, and then abolishing, the activity of the motor centers, the action being shared in by the respiratory centers. All the glands, especially the kidneys, were stimulated by it. In large doses he found it to produce in man lassitude, perspiration, and loose, greenish alvine discharges. Manaca has been very strongly recommended in the treatment of chronic or subacute rheumatism and syphilis. The dose of the fluidextract is from ten to thirty minims (0.6-1.8 mils) three times a day.

**Mandragora.** Mandragora autumnalis Bertol. Mandrake. Mandragora. (Fam. Solanaceae)—A perennial, European plant, with spindle-shaped root, which is often forked beneath, and is therefore compared, in shape, to the human figure. In former times this root was supposed to possess magical virtues, especially when collected at certain times, and was used as an amulet to promote fecundity, etc., and the superstition is still cherished in some parts of Europe. The plant is a poisonous narcotic, somewhat similar in its properties to belladonna, to which it is botanically allied. See a paper by Ekert for the history of this drug. (S. W. P., 1913, 425.) Crouzel isolated an alkaloid, mandragorine, which he found similar in properties to atropine. (P. J., 1885, 1067.) It has since been more thoroughly studied by F. B. Ahrens. (Ber. d. Chem. Ges., 1889, 2159-2161.) Mandragorine is colorless, inodorous, deliquescent, melts at from 77° to 79° C. (170.6°-174.2° F.), and has the formula C_{17}H_{23}NO_{3}. It seems to be iso-meric with atropine, but is not converted into it by alkalies. The sulphate and the hydrochloride are crystalline and deliquescent. A second alkaloid in much smaller amount was also extracted, of which the gold and platinum double chlorides were formed. Both alkaloids had a mydriatic action. It was much used by the ancients as a narcotic, and as an anesthetic agent before surgical operations. (J. P. C; xv, 290.) Morion or death-ioine, said to have been administered previous to the torture, was made from it. Its physiological action has been partially investigated by B. W. Richardson. (B. F. M. R., 1874, 242.)

**Mangosteen.**—The pericarp of the fruit of the Garcinia Mangostana L. (Fam. United States Dispensatory - 1918 - Botanicals Only - M - Page 4
The Southwest School of Botanical Medicine http://www.swsbm.com
Guttiferae). It is sometimes substituted for bael fruit (see Belae Fructus, Br., Part I). It is an active astringent, and has been used as such locally in various catarrhs, and also in diarrhea and in leucorrhea. Ambrose has used the toasted and pulverized rind of mangosteen in the treatment of tropical dysentery with asserted benefit. He gives doses of one drachm (4 Gm.) every two hours. The activity of the drug appears to reside in the neutral principle mangostin. Dose, of fluidextract, from half to one fluiddrachm (1.8-3.75 mils).

**MANNA. U. S.**

**MANNA**

"The dried saccharine exudation of Fraxinus Ornus Linne (Fam. Oleaceae)." U. S.

Manne, Fr. Cod.; Manna, P. G., It.; Mana, Sp.

Manna is said to be obtained from several other trees besides Fraxinus Ornus, among which F. rotundifolia, F. excelsior, and F. parvifiora have been particularly designated. Many saccharine substances, generally exudations from plants, have, from their resemblance to this substance, obtained the name of manna, and attracted more or less attention from writers. The term "manna" has been applied to certain substances which have no relation to true manna, notably to the lichen Lecanora esculenta, which at times has suddenly fallen like rain over immense tracts of country, from Persia to the African Sahara. It occurs in the form of small roundish lumps, from the size of a pin's head to that of a pea, yellowish or grayish externally and whitish within, hard, inodorous, and insipid. It has been affirmed that this lichen does not contain starch, but it is really used as an article of food, and good bread is said to have been made out of it. (Nature, Jan., 1891.) It is probable that it is the manna of Scripture.

The proper false mannas, exudations from various trees, are best considered under the headings of the countries which yield them:

European False Manna, or Briancon Manna, an exudation from the common European larch (Larix europaea, or Pinus Larix), differs chemically from ordinary manna in containing no mannite. Berthelot found in it a peculiar sugar, which he named melezitose (See A. J. P., 1859, p. 61.) To this the formula C\textsubscript{18}H\textsubscript{32}O\textsubscript{16}+2H\textsubscript{2}O is given showing that
it belongs to the class of the saccharides.

American False Manna.—A substance resembling manna, of a sweet, slightly bitter and terebinthinate taste, and actively purgative, exudes from incisions in Pinus lambertiana, of Oregon, and was used by the natives. Berthelot has extracted from this product a peculiar saccharine principle, which he calls pinite. It is very sweet, but does not undergo the vinous fermentation. (See A. J. P., xxviii, 157.) Pinite was for a long time classed among the sugars, but the latest researches seem to show that it is a hexahydric phenol derived from hexahydro-benzene. The formula is \( C_{17}H_{14}O_6 \), and it is a methyl derivative of inosite.

California Manna, or Father Picolo's Manna.—Proust (Ann. d. Chim, 1806, 145) alludes to a manna mentioned by Father Picolo as being deposited on a species of grass in California. J. U. Lloyd (A. J. P., 1897, 337) believes Picolo's manna to be a saccharine deposit, caused by aphides on Phragmites communis. It is apparently still collected by the Indians.

African False Mannas.—Turkish Manna is a sweet product obtained from Echinops persica Fisch., and is obtained by treating the cocoons of a coleopterous insect (Larinus maculatus) with hot water, filtering and crystallizing the sugar. From it Berthelot obtained a new variety of sugar, trehalose, \( C_{12}H_{22}O_{11}+2H_2O \). (Gaz. Med. de Paris, 1857.) Pinus Cedrus, of Mount Lebanon, yields a similar product, which has some repute in Syria as a remedy in phthisis. (P. J., xiii, 411.) In the neighborhood of Diar-bekir, in Asiatic Turkey, a saccharine substance, known as Diarbekir manna, is found on the leaves of dwarf oaks, from which it appears to be exuded. (P. J., Nov., 1862, p. 546.) The manna of the oak of Kurdistan, spoken of by Flicikiger, is probably the same as that of Diarbekir, which may be its entrepot. According to Flicikiger, this consists chiefly (90 per cent.) of a crystallizable sugar. It deviates to the right the plane of polarized light, and reduces in the cold the solution of copper oxide in soda and glycerin. This manna contains a mucilage, but no cane sugar or dextrin. (J. P. C., April, 1873, p. 335.) Quercus Vallonea Kotschy, and Q. persica Jaub. et Spach, yield "oak manna," through insect agency, while certain species of Echinops (probably E. persica Fisch.) yield the singular manna-like substance that is known as Trehala in Syria, and as Shukkar Tigal in India. Pyrus glabra yields a manna which is collected by the people of Luristan, in Persia. It has long been known that Salix fragilis and probably other species of
willow yield to the Persians a manna-like exudation. According to Raby (L’Union Pharm., May, 1889), there are two varieties, chirkhest and bidenguebin, which contain respectively, according to the analysis of Ludwig, chirkhestite (C₆H₁₄O₆), allied to sorbite, and bidenguebinose (C₁₂H₂₂O₁₁), allied to melezitose. "Whether these mannas are really distinct from those sold in the Indian bazaars as coming from Afghanistan and Persia seems uncertain. Of these bazaar mannas the most important is the Shirkoit or Oriental manna. By Haussknecht it is referred to Atraphaxis spinosa; but J. E. T. Atchison states that it is yielded by the Cotoneaster nummularia Fisch. et Mey., a tall, stout shrub, whose smaller branches in July become covered with an exudation, which is eaten as a sweetmeat, and exported in quantity to Russia and India. The second variety, Taranjabin, is yielded by the camelthorn, Alhagi Camelorum Fisch., in Persia and Afghanistan, and probably by Alhagi Maurorum of De Candolle, a leguminous thorny shrub abundant in India—if indeed the two species be distinct. According to A. Villiers, it* is nearly pure melezitose. (P. J., 1876, 3d ser., vii, 917.) Another kind of manna is Gazangabin, or Gazanjabin, yielded by Tamarix gallica Linn., var. mannifera; a fourth kind is obtained from the Salsola faetida DC. (P. J., Dec. 11, 1886, 467.) The tamarisk of Northern Africa (Tamarix gallica Ehr.), which produces the small tamarisk galls of Mogador, containing 40 per cent. of tannic acid (A. J. P., 1878, p. 27; also N. R., 1877, p. 41), according to Burckhardt also gives origin to a species of manna that is used by the Bedouin Arabs near Mount Sinai with their food. This substance, however, according to Mitscherlich, contains no mannite, but consists wholly of mucilaginous sugar. Berthelot found a manna from Sinai to consist of 55 per cent. of cane sugar, 25 of levu-lose and glucose, and 20 of dextrin and analogous substances. (Ann. Ch. Phys., lxvii.)

Persian Manna, or Gez, has been identified (C. D., 1894, 790) as being derived from Astragalus anisacanthus, and is found in the districts of Khonsar, Feridan and Chahar Mahal, and Ispahan. In the form of sweetmeat, having the appearance of flour, it is sent all over Persia and much esteemed.

Australian Mannas.—A manna-like exudation on the Eucalyptus viminalis Labill., growing in New South Wales, contains a saccharine matter called melitose, different in properties from mannite and from all the varieties of sugar, though isomeric with glucose. It is susceptible of the vinous fermentation. (See A. J. P., xxviii, 157.) Lerp is produced
upon the leaves of Eucalyptus dumosa, when very small, and sometimes appears spread over large extents of country like a kind of snow. The natives use it for food. It is a complex body, containing an unfermentable sugar, eucalin, gum, starch, inulin, and lignin. (J. P. C., xvi, 240.) It is said to be a secretion from an insect, formed into minute cells, each of which is the abode of one of the insects. (See A. J. P., 1862, p. 547.) Myoporum platycarpum R. Br., the sandalwood or dogwood-tree of Australia, exudes an exceedingly sweet and pleasant manna, which is much used as an article of food. The product is identical with the official manna, containing nearly 90 per cent. of mannite. F. W. Passmore obtained from Eucalyptus Gunnii Hook., a sugar termed melitriose (P. J., 1891, 718.)

New South Wales Manna.—According to R. T. Baker (Journ. and Proc. Boy. Soc. New South Wales, xxx, 1897), this manna is produced in the form of nodules at the nodes of the stems of the blue grass Andropogon annulatus. It contains numerous crystals of mannite, amounting, according to the analysis of H. G-. Smith, to 50 per cent.

Fraxinus Ornus, or the European flowering ash is a tree of moderate height, usually from twenty to twenty-five feet, very branching, with opposite, petiollate, pinnate leaves, composed of three, or four pairs of leaflets, and an odd one at the end. The leaflets are oval, acuminate, obtusely serrate, about an inch and a half in length, smooth, of a bright green color, and supported on short footstalks. The flowers are white, and usually expand with the leaves. They grow in close panicles at the extremities of the young branches, and have a very short calyx with four teeth, and four linear-lanceolate petals.

Fraxinus Ornus is native of Sicily, Calabria, and Apulia, and is cultivated in Sicily. It yields manna after the eighth year, and continues to yield it for ten or twelve years, when it is usually cut down and young sprouts are allowed to grow up from the root. (Stettner, A. Pharm., liii, 194.) During the hot months the juice exudes spontaneously from the bark, and concretes upon its surface, but, as the exudation is slow, it is customary to facilitate the process by making deep longitudinal incisions on one side of the trunk. In the following season these are repeated on the other side, and thus alternately for the whole period during which the tree yields manna, extending sometimes, it is said, to thirty or even forty years. Straw or chips are frequently placed so as to receive the juice, which concretes upon them. The manna varies
in its character according to the mode of collection, the nature of the season, and the period of the year at which the exudation takes place. That procured in Sicily is said to be the best. Daniel Hanbury travelled through the old manna region, and satisfied himself that the collection of manna for commercial purposes is confined almost exclusively to Sicily. (P. J., Nov., 1872, 421.) For information on manna collection in Sicily, see notes by J. S. Ward. (P. J., 1893, 381;) For an interesting description of California mannas by J. U. Lloyd, particularly Picolo's manna, see A. J. P., 1897, 329.

In commerce three varieties are distinguishable:

1. FLAKE MANNA, or manna canulata (cannellata), is the purest variety, and is chiefly obtained from Palmero. It exudes spontaneously, or from incisions, during the hottest and dry-est weather in July and August. According to Stettner, it is furnished by the upper incisions upon the trunk, while the lower incisions yield the inferior varieties. It is in irregular, unequal pieces, often several inches' long, resembling stalactites, rough, light, porous, brittle, whitish or yellowish-white, and frequently concave on the surface by which they were attached to the trunk, and which is often soiled by impurities, sometimes by adherent fragments of the bark. When broken, these pieces exhibit a crystalline or granular structure. This variety is sometimes in small fragments, generally less than an inch in length.

2. COMMON MANNA—manna communis, or the manne en sorte of French pharmacy—is next in quality, and is collected in Sicily in September and the beginning of October, when the heat of the weather has begun to moderate. The juice does not now concrete so readily, and a portion, falling on the ground at the root of the tree, becomes more or less mixed with impurities, and forms imperfectly solid masses, which require to be further dried in the sun. Common manna consists of whitish or yellowish fragments, similar to the pieces of flake manna, but much smaller, mixed with a soft, viscid, uncrystallized brownish matter, identical with fat manna.

3. FAT MANNA, or Manna (pinguis) sordida, is collected in the latter part of October and November, when the weather is cooler and rains are more common. The juice is now still less disposed to concrete, and flowing down the trunk is received in a small excavation at its base. As found in commerce, it is in the form of a soft, viscous mass, containing
few crystalline fragments, of a brown or yellowish-brown color, and full of impurities. The U. S. Pharmacopoeia directs that such manna should be rejected.

Fictitious Manna.—Attempts have been made to counterfeit manna, but the facility of detection renders such frauds unprofitable, and they are not often practised. R. P. Thomas described (A. J. P., xxiv) a sophisticated manna which differed from the genuine drug both in sensible and in chemical properties, not even containing mannite. Baume describes a method in which common manna is purified so as to resemble flake manna. It consists in dissolving common manna in a little water, allowing the liquid to settle, decanting it in order to separate the impurities, then inspissating it so that it will congeal on cooling, and immersing threads in the inspissated liquid, several times successively, in the manner practised by candle makers. It may be still further purified by the use of animal charcoal. Thus prepared, it contains less mannite than flake manna, and less of the nauseous principle, but is said not to operate less effectively as a laxative. A fictitious manna is described by Edmond Histed (P. J., April, 1870) as having been taken from Paris to London, which bears a close resemblance to flake manna, for which it might be mistaken upon a hasty notice. The resemblance was, moreover, increased by the fact that it contains man-nite, of which Histed obtained 40 per cent., while fine natural flake manna yielded him 70 per cent. Closely examined, it is found to differ essentially from genuine flake manna, showing no crystals of mannite when broken, not having the taste and smell characteristic of good manna, and, besides, being cleaner, lighter-colored, more solid, and making a clearer solution in water. (See A. J. P., 1870.) This may have been a specimen of artificial flake manna, prepared from the inferior or common manna.

Properties.—Manna is officially described as « irregular, more or less elongated, flattened, 3-sided pieces; externally yellowish-white; friable, somewhat waxy; internally nearly white, porous and crystalline in appearance; odor slight, but characteristic; taste sweet, slightly Bitter and faintly acrid. Manna also occurs in irregular masses, consisting in part of brittle or soft, resin-like fragments; from yellowish-white to yellowish-gray in color. The quantity of the yellowish-white fragments must not be less than 40 per cent. of the whole. Add 5 Gm. of Manna. to 100 mils of alcohol, heat to boiling and filter; on cooling, the filtrate rapidly deposits crystals of mannite." U. S.
Manna has a slight, peculiar odor, and a sweet taste, which in the impure kinds is also very nauseous, but in the finest flake manna scarcely so much so as to be disagreeable. Its sp. gr. is 0.834. It melts with heat, and takes fire, burning with a blue flame. When pure it is soluble in three parts of cold and in its own weight of boiling water. From a boiling saturated aqueous solution it separates in partially crystalline masses on cooling. Alcohol also dissolves it. Boiling alcohol will dissolve 15 parts of manna, and upon cooling deposit beautiful crystals of mannite.

Ebert (Zeit. Oest. Apoth. Ver., xlvi, p. 427) has contributed a very able paper, containing citations of all the literature up to 1908, regarding the origin and pharmacognosy of the different varieties of manna. Probably the most comprehensive monograph on the ash manna is that of Tschirch in his large work entitled “Handbuch der Pharmakognosie.” Band II, p. 103.

Fourcroy and Vauquelin found manna to consist of (1) a peculiar sweet principle, mannite, which constitutes 75 per cent.; (2) a variety of sugar; (3) a yellow nauseous matter, upon which the purgative property is thought chiefly to depend; and (4) a little mucilage. Leuchtwiess obtained from 105 parts of manna, 11.6 of water, 0.4 of insoluble matter, 9.1 of sugar, 42.6 of mannite, 40.0 of a mixture of mucilaginous matter containing mannite, resin, organic acid, and a nitrogenous substance, and 1.3 of ashes. In manna canellata in fragmentis he found 37.6 per cent. of mannite, and in manna Calabrina 32 per cent. (Pflanzenstoffe, 2d ed., p. 180.) Buignet discovered in manna a considerable proportion of dextrin. He appears to have been led to this discovery by observing a very energetic dextrogyrate power in flake manna, which could not be owing to the saccharine matter it contained, because the same power continued after all the sugar had been destroyed by fermentation. Dextrin forms about one-fifth part of flake manna, and a much larger part of the inferior kinds. Tanret (Bul. Soc. Ch., 1902, p. 947) finds manna to contain several new carbohydrates and reports the composition as follows: mannitol, 40 to 55 per cent.; levulose, 2.5 to 3.4 per cent.; dextrose, 2.2 to 3.0 per cent.; manneotetrose (C_{24}H_{42}O_{21} + 4H_{2}O), 12 to 16 per cent.; manneotriose (C_{18}H_{32}O_{16}), 6 to 16 per cent., with small amounts of resin and ash.

Fluckiger found in all samples of mannite examined a small amount of a dextrogyrate mucilage, which is precipitated by neutral lead acetate,
and yields mucic acid when boiled with strong nitric acid. The greenish color of certain pieces of manna is produced by fraxin, \( C_{16}H_{18}O_{10} \), a glucoside closely resembling aesculin. Fraxin crystallizes in colorless prisms, easily soluble in hot water and in alcohol, and has a faintly astringent and bitter taste. By diluted acids it is resolved into fraxetin, \( C_{10}H_{8}O_{5} \), and glucose, \( C_{6}H_{12}O_{6} \). Even its diluted solutions are fluorescent. (Pharmacographia, 2d ed.)

Mannite (mannitol) is white, inodorous, crystallizable in semi-transparent needles, of a sweetish taste, soluble in five parts of cold water, scarcely soluble in cold alcohol, but readily dissolved by that liquid when hot, and deposited when it cools. Its composition is \( C_{6}H_{14}O_{6} \), and it is considered as belonging to the class of hexatomic alcohols. If mixed with chalk and cream-cheese and kept for some weeks at the temperature of 40° C. (104° F.), it yields alcohol largely, with the disengagement of carbonic acid and hydrogen and the production of lactic acid. No fungus is produced, as in the ordinary fermentation of sugar. (Berthelot, J. P. C., xxx.) With lime, barium and strontium oxides, it forms definite compounds, soluble in water, and precipitable from their aqueous solutions by alcohol. (Ibid., Jan., 1860.) It does not reduce an alkaline solution of copper oxide; and a test of its purity is thus presented. (A. J. P., Jan., 1861, p. 26.) It is optically inactive except after the addition of borax. It is then found to be dextrorotatory. Emil Fischer has shown that there are three mannites obtainable; the ordinary mannite is the dextrorotatory variety, and is always obtained in the reduction of a-mannose with sodium amalgam; a levorotatory variety is obtained by the reduction of l-mannose; and an inactive mannite is obtained from the inactive mannose. These three physical isomers differ slightly in their fusing points and crystalline form. The native variety may be obtained by boiling manna in alcohol, allowing the solution to cool, and redisolving the crystalline precipitate; pure mannite is now deposited. Another method is to dissolve flake manna in water, precipitate by solution of lead sbacetate, filter, throw down the excess of lead by sulphuric acid, evaporate the solution, and mix with alcohol. On cooling*, the mannite is deposited. (Bonsall, A. Pharm., cxxxiv, 70.) This principle has been found in numerous vegetables. It is said to be gently laxative in the dose of from one to two ounces (31-62 Gm.).

Manna, when long kept, acquires a deeper color, softens, and ultimately
deliquesces into a liquid, which on the addition of yeast, undergoes the vinous fermentation. This is probably owing to its conversion into sugar by the absorption of enough oxygen to cause it to pass over into some variety of glucose or fermentable sugar. That which is driest resists this change the longest. It is said that manna recently gathered is less purgative than it afterwards becomes.

**Uses.**—Manna is a gentle laxative, usually operating mildly, but in some cases producing flatulence and pain. It is usually prescribed with other purgatives, particularly senna, rhubarb, magnesia, and the neutral salts, the taste of which it conceals, while it adds to the purgative effect. It is usually given dissolved in water or some aromatic infusion; but the best flake manna may be administered in substance. Manna forms a combination with iron, which it preserves against oxidation. (See P. J., March, 1873.) Under the name of dulcinol a mixture of mannite and common salt has been recommended by Sternberg (D. M. W., 1906, p. 1707) as a sweetening agent in diabetes.

Dose, half to one ounce (15.5-31 Gm.).

**Off. Prep.**—Infusum Sennae Compositum, U. S.; Syrupus Mannae, N. F.

**Manzanillo.** Manchineel. Hippomane Mancinella L.—According to A. Betancourt, the milky juice of this euphorbiaceous tree, growing in the West Indies, is a violent irritant, acting as a vesicant when applied to the skin, and when taken internally in doses of twenty drops causing a fatal gastro-enteritis. In doses of two drops it acts as a powerful and very certain cathartic; it is also diuretic. In Cuba it has much repute in tetanus. (L.M.R., Feb., 1889.)

**Maranta.** Arrowroot. Arrowroot Starch. (Fam. Marantaceae)—Under this name the U. S. Pharmacopoeia, 1870, recognized the fecula or starch obtained from the rhizome of M. arundinacea, L.

The arrowroot plant is a native of the West Indies, where it is largely cultivated for the sake of its fleshy, irregularly cylindrical rhizomes whose cells are gorged with starch granules. It is cultivated also in the East Indies, Ceylon, Sierra Leone, and south of Africa, and formerly in our Southern States, especially Georgia and Florida. The plant is easily propagated by cuttings of the root. An analysis by Macdonald (J. Soc. Chem. Ind., 1887, 336) gives the following as the composition of the St. Vincent root: Starch, 27.07 per cent.; fiber, 2.82; fat, 0.26; albumen, 1.56; sugar, gum, etc., 4.10; ash, 1.23; water, 62.96; total, 100.00. An analysis of the arrowroot starch from the same locality by Macdonald gave: Starch, 83.70 per cent.; fiber, 0.04; fat, 0.07; sugar, gum, etc., 0.18; ash and sand, 0.14; water, 15.8.7; total, 100.00. The fecula is
prepared in the following manner. The rhizomes are dug up when a year old, washed, and then beaten into a pulp, which is thrown into water, and agitated so as to separate the amylaceous from the fibrous portion. The tissues are removed by the hand, and the starch remains suspended in the water, to which it gives a milky color. The milky fluid is strained through coarse linen, and allowed to stand that the starch may subside, which is then washed with a fresh portion of water, and afterwards dried in the sun.

The Bermuda arrowroot was formerly the most highly esteemed, but the production of it in the island has almost ceased. The Bermuda arrowroot of the American, and probably largely also of the English, markets, is of various sources, the name seemingly being applied to any superior product. For a list of other sources of arrowroot of commerce during different periods, see U. S. D., 19th ed., p. 1561.

Attempts have been made to substitute finely prepared potato starch for arrowroot, and there is no doubt that, in nutritive properties it is quite equal, but patients complain of an unpleasant taste of the potato which it is likely to retain. Arrowroot is in the form of a light, white powder, or of small pulverulent masses, without odor or taste. It is firm to the touch when pressed between the fingers, and produces a faint creaking sound when rubbed. It is a pure starch, corresponding in chemical properties with that of wheat and the potato. It is liable to become musty, and should then be rejected. The odor and taste are the best criteria of its quality. It should be perfectly free from odor and unpleasant flavor.

The microscope offers the best means of distinguishing the different varieties of fecula sold as arrowroot, or used for its adulteration. The granules of Maranta arrowroot are rarely oblong, somewhat ovate-oblong, or irregularly convex, from 10 to 70 microns in diameter, with very fine lamellae, a circular hilum which is fissured in a linear or stellate manner. (Pereira.)

Arrowroot affords a light, very mild, and easily digested article of diet, well adapted for the sick and convalescent, and peculiarly suited, from its demulcent properties, to bowel complaints. It is prepared by dissolving it in hot water or hot milk, with either of which it forms a pearly, gelatinous solution, and, if in sufficient quantity, a jelly-like mass on cooling. A tablespoonful will communicate sufficient consistence to a pint of water. It should first be formed into a perfectly smooth paste with a little cold water or milk, and the boiling water then gradually added with brisk agitation. The preparation may be rendered more palatable by lemon juice and sugar, or by wine and spices.

**Marrubium.** Hoarhound. Horehound. Herba Marrubii. Marrube Blanc, Fr. Cod. Andornkraut, Wässer Andorn, G. Marrubio, It., Sp.—Under the title of marrubium the U. S. P. formerly recognized "The dried leaves and flowering tops of Marrubium vulgare Linne (Fam. Labiatae)." U.S. VIII. Whitehoarhound haa a perennial, fibrous root, and numerous annual stems, which are quadrangular, erect, very downy, and from twelve to eighteen inches high. The leaves are about 2.5 cm. long, roundish-ovate, dentate or deeply serrate, obtuse, wrinkled, veined, downy above, hoary on the
under surface, and supported in pairs on strong foot-stalks. The flowers are white, and in crowded axillary woolly whorls. It contains a volatile oil, resin, tannin, lignin, and a bitter principle called marrubiin by Mein. This marrubiin is slightly soluble in cold water, crystallizes from alcohol in prismatic and from ether in tabular crystals, is not precipitated by tannin, and has a very bitter and somewhat acrid taste. The fusing point of the crystals is 160° C. (320° F.), according to Kromayer. Marrubiin was afterwards obtained by Harms (A. Pharm., cxxvi, 141), by Hertel (A. J. P., June, 1890), and by Morrison (A. J. P., July, 1890). It has also been studied by Matusow (A. J. P., 1897, 201). He gives to it the formula C_{39}H_{43}O_{6}, and states the melting point of the purified substance to be from 154° to 155° C. (309.2°-311° F.). According to him, it is not a glucoside.

Hoarhound is tonic, and in large doses laxative. It was formerly considered a valuable deobstruent, and was recommended in chronic hepatitis, and various cachetic affections, but it exerts no specific influence over any of them, and has passed mainly from the hands of physicians into domestic use, where it is used in the form of a confection for sore throat. It is employed occasionally in bronchitis with copious expectoration. The infusion, made in the proportion of an ounce of the herb to a pint of boiling water, may be given in wine-glassful doses. Geo. M. Beringer gives the following process for Syrup of Hoarhound: Hoarhound in No. 20 powder, 200 Gm.; sugar, 750 Gm.; glycerin, 125 mils; water, a sufficient quantity to make 1000 mils.

Mix the glycerin with 375 mils of water and moisten the drug thoroughly with sufficient of the mixture, then pack lightly in a percolator and add enough menstruum to saturate and leave a layer above the drug and macerate for twenty-four hours. Then percolate slowly, using the balance of the menstruum and then warm water till extracted. Reserve the first 500 mils of percolate and evaporate the remainder to 100 mils, then add the reserve and dissolve the sugar in the liquid, using a slight heat if necessary. When cold add sufficient water to make the preparation measure 1000 mils and strain. Syrup of hoarhound so made is clear, brown in color and possesses the characteristic bitter and aromatic taste of the drug and after keeping for more than six months has shown not the least tendency to change. (Proc. N. J. Pharm. Assoc., 1909, 45-46.)

Dose, thirty grains to a drachm (2.0-3.9 Gm.).

Massoi Bark. Lawang.—In Eastern commerce certain aromatic barks occur under the name of masspi barks. Of these, three are believed by F. Hekmeyer to be the products respectively of Cinnamomum xanthoneurum Blume, Cinnamomum Burmanni Blume (C. Kianis Nees), and Massoja aromatica Becc. (Sassafras goesianum Teijsm. and Binn.), all of the Fam. Lauraceae. For a description of these barks, by E. M. Holmes, see P. J., 1888, 465. The massoi bark which comes from New Guinea, and from which Messrs. Schimmel have distilled an oil resembling that of nutmeg and cloves, probably has a different origin from the true massoi bark which has a cocoanut-like odor. (Y. B. P., 1912, 473.)

G. Almaciga, Mastic, Sp. Sakes, Turk. Arah, Arab. —" A concrete resinous exudation from Pistacia Lentiscus Linne (Fam. Anacardiaceae)." N. F. IV. Mastic was deleted from the U. S. P. VIII because the official pill of aloes and mastic was dropped; the National Formulary IV has, however, admitted mastic and the pills containing it. The mastic tree, which is also called lentisk of lentiscus, is a shrub or small tree, seldom more than twelve feet in height, much branched towards the top, and furnished with petiolate, abruptly pinnate leaves. The flowers are dioecious, and very small. The tree is a native of the countries bordering upon the Mediterranean. The fruit yields by expression a fixed oil, of a deep green color, and liquid at about 32.3° C. (90° F.), which the Arabs of North Africa use both as an article of diet and for light. A resinous exudation from the stem and branches is the official part, but it does not appear to be collected in all places where the tree flourishes. Under the name of Bombay mastic there occur in India masses of oleoresin said to be derived from the Pistacia Terebinthus, having the general appearance of true mastic with a deeper color, but lacking fragrance, and dissolving in hot alcohol. For an account of the collection of mastic from P. Terebinthus growing in the island of Cyprus, see C. D., 1897, 273.

Mastic is obtained chiefly from the island of Scio, or Chios, in the Grecian Archipelago, where the tree is cultivated for this product. Incisions are made in the trunk and principal branches, from which the juice slowly exudes, and either hardens in tears upon the bark, or drops on the ground, where it is received upon cloths or the bare earth, and concretes in irregular masses. The tears are most esteemed, and are the only form recognized by the N. F. They are of various sizes, oval or roundish, often compressed, smooth, semi-transparent, of a pale-yellow color, of a shining fracture, friable, and usually covered with a whitish powder, occasioned by their friction against each other. They are brittle, but become plastic when chewed. The masses consist of yellowish agglutinated tears, with others of a darker color and less translucent, and often fragments of wood, bark, or earthy matter intermingled.

The N. F. describes it as "in subglobular, lenticular, elongated or pear-shaped tears, about 3 mm. in diameter, pale yellow or greenish-yellow, transparent, having a glass-like lustre, the surface sometimes very slightly dusty; brittle, becoming plastic when chewed; odor slight, balsamic; taste mild, terebinthinate. Mastic is completely soluble in ether and almost completely soluble in alcohol. The acid number, determined as directed by the U. S. P. (Test No. 10, Part III), is not less than 65." N. F. IV.

According to J. Leon Soubeiran the valuable tears are produced by spontaneous exudation from the branches. But the greater part of the resin comes from longitudinal incisions in the stem, made with a knife, close together, and extending from the root to the branches. In fifteen or twenty days the resin has concreted, and is collected in little panniers of white paper or cotton cloth. (Proc. A. Ph. A., 1897, 563.)

Mastic is nearly inodorous, unless rubbed or heated, when it becomes fragrant. Its taste is weak, but agreeably terebinthinate, and, after long chewing, very slightly acrid. It is at first friable 'undw the teeth, but soon becomes soft and ductile, and acquires a white, opaque appearance. Its sp. gr. is 1.074. It is fusible and inflammable by heat. Alcohol dissolves about 90 per cent. of it, leaving a viscid
substance which becomes brittle when dried, and for which the name of masticin or beta-resin of mastiche has been proposed. This substance, though not dissolved by alcohol, softens and swells up in it, as gluten does in water. Häsiwetz gives $C_{20}H_{31}O$ as the formula of the resin. The portion dissolved by the alcohol is called by Johnston alpha-resin of mastiche or mastichic acid because of its acid properties, and has the formula $C_{20}H_{32}O_2$. (Handwörterbuch der Chemie, iv, p. 280.) Mastic is wholly soluble in ether, chloroform, and oil of turpentine, scarcely soluble in the fixed oils, and insoluble in water. It consists chiefly of resin, with masticin, and a volatile oil. Fluckiger, through Schimmel & Co., of Leipzig, ascertained that this volatile oil is present in mastic to the extent of 2 per cent. He found it to be a terpene of the composition $\text{C}_{20}\text{H}_{31}$.

Schimmel & Co. (Schim. Rep., April, 1897) state that mastic resin yields from 0.9 to 2.5 per cent. of a powerful balsamic essential oil of the same odor as the raw material, a sp. gr. of from 0.855 to 0.87 at 15° C. (59° F.), and an optical rotation (100-mm. tube) of from +22° to +27°. Tschirch and Reutter (A. Pharm., 1904, 104) examined mastic carefully; they found approximately 42 per cent. of free resin acids. These are: the isomeric α- and β-masticinic acids, $C_{23}H_{36}O_4$, masticolic acid, $C_{23}H_{36}O_4$ (slight amount), amorphous α-masticonic acid, $C_{32}H_{48}O_4$ (20 per cent.), and β-masticonic acid, $C_{32}H_{48}O_4$ (18 per cent.). Besides this, mastic contains 30 per cent. α-masticoresin, $C_{35}H_{36}O_4$, soluble in alcohol; 20 per cent. of β-masticoresin (masticin), insoluble in alcohol, and 2 per cent. of an ethereal oil, possessing a pale yellow color and a somewhat camphoraceous odor. Finally, there is also a bitter principle, which could not be isolated in pure form. For a chemical investigation of Egyptian mastic by Eeutter, see S. W. P., 1913, 537. Mastic is occasionally adulterated with olibanum, sandarach, and other resinous bodies, and, in seasons of scarcity, with sea salt.

Mastic was formerly thought to possess properties analogous to those of the turpentines, and was used in debility of the stomach, hemoptysis from ulcerations, leucorrhea, chronic diarrhea, etc., but its virtues were overrated, and it is at present scarcely ever given internally. In the East, however, an aqueous infusion is said to be still used in cholera infantum, and the Greek employ cataplasms made by mixing it with bread and red wine, which they apply to the lower abdomen. (Landerer.) It is sometimes employed temporarily to fill the cavities of carious teeth, for which purpose it is well fitted by its softness. In Turkey it is habitually chewed by the women, under the impression that it sweetens the breath and preserves the gums and teeth. Dissolved in alcohol or oil of turpentine, it forms a brilliant varnish. A solution made by macerating half an ounce of mastic and fifteen grains of caoutchouc in two fluidounces of chloroform, and filtering in closed vessels, forms a valuable varnish for microscopic work. The following mode of applying it to carious teeth has been recommended. Dissolve four parts of mastic in one of ether, in a bottle well stoppered. With the solution thus formed, which is yellow and of an oily consistence, saturate a small piece of cotton of the size of the carious cavity, and, having well cleansed and dried the cavity, introduce the cotton, without painful pressure, so as to fill it exactly. The resin attaches itself to the diseased surface of the tooth, which it protects from the air, and from the food taken into the mouth. Dose, thirty grains (2 Gm.). It has been highly recommended by various surgeons as a dressing for wounds. Its use is chiefly for the purpose of preventing bacteria upon the surrounding skin.
getting into the wound. Voos (M. M. W., 1911) paints the skin up to the edges of the wound without previous washing, with a solution of mastic in benzol and then cleanses the wound in the ordinary manner and applies an aseptic dressing. A special solution for this purpose is upon the market under the name of mastisol. Another formula for mastic varnish which has been used is 20 Gm. of mastic, 30 mils of chloroform, and 1 mil of linseed oil.

**Matico.** N. F. IV (U. S. P. VIII). Matico Leaves. Feuilles de Matico, Fr. Cod. Maticoblatter, G.—"The dried leaves of Piper angustifolium Ruiz et Pavon (Fam. Piperaceae), without the presence of more than 5 per cent. of stems, flower spikes, or other foreign matter." 2V. F. IV. The genus Piper, according to Engler and Pranti, includes nearly six hundred species, which are distributed throughout the tropics of the Old and New World, being particularly numerous in tropical America and of relatively less number in Africa.

Piper angustifolium is a shrub with a jointed stem about twelve feet in height. The plant is a native of Peru, where the fruit, under the name of thoho-thoho, is employed in the same manner as cubeb. This species is also found in other parts of South America. The commercial drug matico is furnished, according to G. Dethan and E. Bertault (J. P. C., 1897, 537), by two varieties of Piper angustifolium—viz., a-cordulatum (Artanthe elongata Miq.), and ß-ossanum, which differ somewhat in the shape of the leaves. The former has the leaves larger, shorter, and broader, with an oblique cordate base. The midrib of a-cordulatum is much less convex below than in the other variety. In 1864 Bentley (P. J., Jan., 1864) described a false matico from Central America believed to be yielded by the Piper aduncum L. It is distinguished by the want of the reticulations on the upper and the down on the under surface which characterize true matico. (See also Thorns, Arbeiten a. d. Pharm. Institut d. Universitat, Berlin, 1910, p. 70.)

The drug is described in the N. F. as: "Usually in compressed, matted masses with leaves more or less broken; leaves sub-sessile, lanceolate, from 10 to 20 cm. in length and from 2 to 5 cm. in breadth; summit tapering and acute; base slightly unequal, cordate; margin finely crenulate; upper surface dark green, tesselated; lower surface pale green, reticulate with prominent yellowish-brown midrib and veins forming small quadrangular meshed clothed with matted pubescence. Odor distinct, aromatic; taste pungent, pepper-like. Sections, when examined under the microscope, exhibit the epidermis of the upper side composed of regular polygonal cells and of the lower side of somewhat irregular and undulate cells, especially where covering the veins; numerous stomata with large neighboring cells on the lower side; the hypodermis of one row and palisade cells in two or three rows; mesophyll loose, spongy tissue; midrib in cross section oval, outer layer of thick-walled cork cells; secretion cells filled with yellow oil; upper surface with papillae and few bristly hairs; hairs of the lower surface of two kinds, the one nine to ten cells in length, pointed, bent and matted, having thick walls and astrigate cuticle; the other bristle hairs of one stem cell and a head cell; calcium oxalate crystals few in parenchyma tissue of the venation, in the form of raphides or monodiclinic prisms. The powder is greenish-yellow and, when examined under the microscope, exhibits the characteristic hairs, polygonal epidermal cells, and secretion...
cells of the leaf. Matico yields not more than 18 per cent. of ash.

Fluckiger found it to contain 2.7 per cent. of the volatile oil, which was slightly dextrogyrate and boiling in large part at 180° to 200° C. (356°-392° P.). In the winter-time it deposited large crystals of a camphor, according to Kugler (A. J. P., 1884, 477). Schimmel & Co. (Schim. Rep., Oct., 1898, p. 37) and Thorns (A. J. P., 1904, p. 584) state that the newer matico oils do not contain this camphor but contain asarol (propenyl-trimethyltrioxybenzene). Matico also affords, according to Marcotte, a crystallizable acid named artanthic acid, with some tannin. (Pharmacographia, 2d ed., p. 590.)

Matico is said to be employed in Peru in arresting hemorrhages and as a local application to ulcers, and has been used in European practice in the treatment of diseases of the genito-urinary organs, such as those for which cubeb is commonly prescribed. It has also been praised as a remedy in dysentery and diarrhea and especially as a local hemostatic, in which it probably acts in part mechanically in the same manner as does agaric. The powder is sometimes used, but the fluidextract (see Part III), is preferable for internal administration. Dose, forty-five to seventy-five grains (3-5 Gm.).

MATRICARIA. U. S.

MATRICARIA Matricar. [German Chamomile Wild Chamomile]

"The dried flower-heads of Matricaria Chamomilla Linne (Fam. Compositae), without the presence or admixture of more than 5 per cent. of stems or foreign matter. Preserve it in tightly-closed containers and guard against attack by insects." U. S.

Flores Chamomillae Vulgaris; Horse Gowan, Dog's Camovyne; Camomille commune (d'Allemagne), Fr. Cod.; Flores Chamomillae, P.G.; Kamillen, Kamillenblumen, G.; Camomilla comune, It.; Manzanilla (Flor de), Sp.

Matricaria Chamomilla is an annual plant, with a branching stem a foot or two in height, bearing alternate leaves, the lower being tri-pinnate, the upper bipinnate or simply pinnate, and all of them very green, and nearly or quite smooth. The leaflets are linear and very small. The flower-heads appear singly at the ends of the stem and branches. The bracts of the involucre are obtuse, green in the middle, and whitish, membranous, and translucent at the margin. The ray-florets are pistillate white, at first spreading, and ultimately reflected. The disk is of a deep yellow color, at first flat, but in the end convex, and in some cases somewhat conical. The plant is a native of Europe.
and western Asia, and is occasionally cultivated in our gardens. It is also naturalized in North America and Australia. Mitlacher gives the results of methods of cultivating matricaria in Zeit. Oest. Apoth. Ver., 1, p. 410. Meyer has suggested (Pharm. Zeit., Iviii, p. 790) the practicability of scientifically collecting matricaria from the wild grown plants. All parts of it are active, but the flowers only are official. These are gathered from May to August, shrink in drying, so that they are scarcely half as large as in their recent state. Those found in commerce are imported from Germany.

Properties.—Matricaria is officially described as follows: "Flower-heads composed of a few white ray-florets and numerous yellow disk-florets on conical, more or less hollow receptacles, the latter being from 3 to 10 mm. in breadth; disk-flowers tubular, perfect, and without a pappus; ray-flowers from 10 to 20, pistillate, corolla white, 3-toothed and 4-veined, usually reflexed; involucre hemispherical, composed of from 20 to 30 imbricated, oblanceolate, and pubescent scales; peduncles light green to brownish-green, longitudinally furrowed, more or less twisted and attaining a length of 2.5 cm.; achenes somewhat obovoid and faintly 3-to 5-ribbed; pappus none, or only a slight membranous crown; odor pleasant, aromatic; taste aromatic and bitter. Matricaria yields not more than 13 per cent. of ash." U. S.

"The similar flower-heads of Anthemis arvensis L., and Maruta Cotula De Candolle (Fam. Compositae), have conical, solid, and chaffy receptacles." U. S. VIII.

In addition to the above it is sometimes admixed with the flower-heads of other European species of Anthemis. Sometimes the flower-heads of the common daisy (Chrysanthemum Leucanthemum L.) as well as other species of Chrysanthemum are present in the drug of commerce.

The dried flowers of matricaria are considerably smaller than those of common chamomile, and exhibit a larger proportion of the disk-florets compared with those of the ray. They have a strong, peculiar, rather unpleasant odor, and a disagreeable, bitter taste. Their active constituents are volatile oil and bitter extractive, which are readily taken up by water and alcohol. The oil, which is obtained by distillation with water, is thick, somewhat tenacious, of a fine deep blue color becoming green and brown by age, and almost opaque in mass. Though supposed by Gerhardt to be identical with the oil of chamomile
Anthemis nobilis, it has been shown to be distinct. (P. J., Feb., 1862, p. 429.) It congeals at -20° C. (-4° F.), has the sp. gr. 0.93, and contains a terpene, C_{10}H_{16}, and a colorless oil, C_{10}H_{16}O. Schimmel & Co.'s Report for April, 1897, states that the German chamomile oil contains a paraffin hydrocarbon, which was obtained as a snowy white solid melting at 53° to 54° C. (127.4°-129.2° F.). The blue color is due to a volatile principle called azulene by Pie'sse, and caerulein by Gladstone and others; also found in oil of absinthe, yarrow and some other blue volatile oils. This, when distilled with potassium, yields a terpene, (C_{10}H_{16})_{3}, and with phosphoric oxide a hydrocarbon, C_{10}H_{14}. (Kachler, Ber. d. Chem. Ges., iv, 36.)

**Uses**—Matricaria is a mild tonic, very similar to chamomile in medicinal properties, and, like it, in very large doses an emetic. It is considered also in Europe to be antispasmodic and anthelmintic. It is much employed in Germany, but in this country scarcely at all, unless by German practitioners. It may be given for the same purposes and in the same manner as chamomile.

Dose, half an ounce (15.5 Gm.).

**Off. Prep.**—Species Emollientes, N. F.

**Medeola.** Medeola virginiana L. (Gyromia virginiana L.) Indian Cucumber.—An indigenous perennial herb of the Fam. Liliaceae, growing in all parts of the United States. The tuber, which in shape and flavor bears a strong resemblance to a small cucumber, is said by Pursh to be eaten by the Indians, and by Barton to be useful as a diuretic in dropsies.

**MEL.**

**U. S. HONEY**

"A saccharine secretion deposited in the honey-comb by the bee, Apis mellifera Linne (Fam. Apidae).” U. S.

From the nectaries of various flowers the bee and other insects extract a
thin, aqueous fluid, nearly without flavor and insipidly sweet, usually known as nectar. As honey is made out of this substance it is very much affected by the character of the nectar, so that the nature of the plants which predominate in the vicinity of the hive is a matter of great importance to the bee culturist, not only in regard to the flavor of the honey which is yielded, but even to its freedom from poisonous qualities, cases having been reported from time to time of poisoning produced by the eating of honey which had not been tampered with after extraction from the hive. In the United States honey made by the bee from the flowers of the Mountain Laurel (Kalmia) is especially poisonous. See N. J. M. K., 1852, 46; "Poisonous Honey," by L. F. KEBLER, Proc. A. Ph. A., 1896, 167; H. Bley, Ph. Ztg., Nov., 1885. The latter states that Datura Stramonium and Gelsemium are for honey making especially dangerous plants. The nectar when taken in by the bee is chemically changed by secretions from glands in the head and thorax, levulose, dextrose, and rarely sucrose being formed. The finest honey is that which is allowed to drain from the comb. If obtained from hives that have never swarmed, it is called virgin honey. An inferior kind is procured by submitting the comb to pressure, and if heat be employed previous to expression, the product is still more impure. The honey which is most highly esteemed is that made from the nectar of the white clover blossom. Equally valuable is the honey derived from raspberry blossoms and basswood flowers. The honey made late in the summer from the flowers of the buckwheat is darker in color. The largest producer of honey in the United States is California. The United States is said to be the greatest honey producing region on the globe, the annual production being between 60,000,000 and 75,000,000 pounds annually. Nearly 2,000,000 pounds of wax are also produced in this country.

Propolis is a resinous substance, deposited by bees at the base of the hive, and in other parts which require protection from the outer air, of a nature entirely different from that of wax or honey, and supposed to be intended for the protection of the comb from injurious agencies. H. O. Hitchcock (Chicago Med. Journ., 1867) considers it one of the best remedies in diarrhea and dysentery. It is of a dark reddish or yellowish-brown color, of a shining fracture, an aromatic taste and odor, quite insoluble in water, nearly so in ether, but readily dissolved by alcohol and solution of potassium hydroxide. Hitchcock used a tincture (two drachms of propolis and four fluidounces of alcohol) in doses of from thirty minims to a fluidrachm (1.8-3.75 mils).
Bee bread is the name given to a material found in some of the cells of the comb, consisting mainly of the pollen of plants. (Chicago Med. Examiner, Sept., 1865.) Jas. S. Whitmire found that in the dose of a drachm (3.9 Gm.) three times a day it caused great increase of the urinary secretion. No disagreeable affects followed its use, except a slight flatulency and looseness of the bowels. It is entirely palatable and inoffensive to the stomach. (A. J. P., 1866.)

Eucalyptus Honey, or Black Honey.—This honey, a detailed description of which may be found in U. S. D., 16th ed., appears to have been not a natural but a sophisticated article.

In the recent state honey is fluid, but on being kept it is apt to form a crystalline deposit, and to be ultimately converted into a soft granular mass. In commerce it is found of every consistence, from that of a viscid liquid, like thin syrup or oil, to that of lard or soft suet. Its color is sometimes white, but usually yellowish, and occasionally of a brownish or reddish tinge. It has a peculiar agreeable odor, varying somewhat with the flowers from which it was collected, and a very sweet, feebly aromatic taste, which is followed by a slight prickling or sense of acridity in the fauces. Cold water dissolves it readily, alcohol with less facility. "Honey is a thick, syrupy liquid of a light yellowish or yellowish-brown color, translucent when fresh, but gradually becoming opaque and crystalline; having a characteristic odor, and a sweet, faintly acid taste. It is slightly acid to litmus and is laevorotatory. Dilute Honey with twice its weight of water; the resulting liquid is only moderately turbid, not stringy, and has a specific gravity of not less than 1.099 at 25° C. (77° F.) (corresponding to a specific gravity of not less than 1.370 for the original Honey). Incinerate about 1 Gm. of Honey, accurately weighed, in a platinum crucible, in small portions at a time; not more than 0.3 per cent. of ash remains. Separate portions of 5 mils each of a filtered aqueous solution of Honey (1 in 5) acidified with nitric acid, are not rendered more than slightly opalescent by the addition of a few drops of silver nitrate T.S. (chlorides), nor more than slightly cloudy by a few drops of barium chloride T.S. (sulphates). Boil about 2 Gm. of Honey with 10 mils of distilled water; the resulting solution, when cold, is not rendered blue, green or reddish on the addition of iodine T.S. (starch or dextrins). The color of an aqueous solution of Honey (1 in 2) is not changed at once when mixed with an equal volume of ammonia water (foreign coloring matter); 5 mils of an aqueous solution of Honey (1 in
2) does not at once acquire a red or rose color on the addition of a few drops of hydrochloric acid (azo dyes). A solution of 10 Gm. of Honey in 50 mils of distilled water requires not more than 0.5 mil of normal potassium hydroxide V.S. for neutralization, phenolphthalein T.S. being used as indicator. Triturate about 1 Gm. of Honey with 20 mils of ether in a mortar, filter it into a porcelain dish or crucible, allow the filtrate to evaporate and add to the residue one drop of resorcinol T.S. At most only a pink color may be produced, which disappears in half a minute, but not an orange," cherry, or brown-red color (artificial or added invert sugar).” U. S.

It is essentially a strong aqueous solution of mixed dextrose and levulose, amounting generally to from 70 to 80 per cent. According to Win. A. Selser, who separated wax from honey on a large scale, the proportion of wax in the honey comb averages 1 per cent.; from 1500 pounds he obtained 14¹/₄ pounds of wax by actual experiment. (A. J. P., 1904, 267.)

A large number of samples of genuine honey analyzed in 1897 for the Department of Inland Revenue, Canada (Bull. 47), showed the following variations:

Direct polarization, -2.4 to -19.
Invert polarization, -10.2 to -28.
Sorose (by Clerget), 0.5 to 7.64 per cent.
Invert sugar, 60.37 to 78.8 per cent.
Water, 12 to 33 per cent.
Ash, 0.03 to 0.50 per cent.

Neufeld in Der Nahrungsmittelchemiker als Sachsverstandiger, Berlin, 1907, p. 275, gives the following limits for pure honey of European origin:

Water ........... 8.30 to 33.59 per cent.
Protein ........... 0.03 to 2.67 per cent.
Invert sugar ..... 49.59 to 93.96 per cent.
Sucrose ........... 0.10 to 10.12 per cent.
Dextrin ........... 0.99 to 9.70 per cent.
Formic acid ....... 0.03 to 0.21 per cent.
Ash ............... 0.02 to 0.68 per cent.

Browne has published a comprehensive article on American honey (U. S. Dept. Agric., Bur. of Chem., Bull. 110, 1908) of which the tabular analyses are given in Leach, Food Inspection and Analysis, 3d ed., p. 635.
The honey sugar may be obtained by treating granular honey with a small quantity of alcohol, which, when expressed, takes along with it the other ingredients, leaving the crystals nearly untouched. The same object may be attained by melting the honey, saturating its acid with calcium carbonate, filtering the liquid, then setting it aside to crystallize, and washing the crystals with alcohol. Inferior honey usually contains a large proportion of uncrystallizable sugar and vegetable acid. Diluted with water, honey undergoes the vinous fermentation. In warm weather, honey, itself, if not very pure, sometimes ferments, acquiring a pungent taste and deeper color. The presence of dextrin in pure honey seems to be established. G. L. Spencer (A. J. P., 1895, 27) has found as much as 4 per cent. of dextrin, and Haenie (Zeit. An. Chem., xeiv, 99) has found that honey from Coniferae always contains dextrin. Kunnmann and Hilger (A. J. P., 1896, 570) state that dextrin is present in all honey, whether dextro-rotatory or laevo-rotatory, and claim to have identified it as achroo-dextrin. Miillenhoff believes that the honey is preserved in the sealed cells of the comb by the secretion with it of a minute quantity of formic acid, and has found by experiment that the addition of one part of 25 per cent. formic acid is sufficient to keep permanently 250 parts of honey, but in this connection it should be remembered that the absence of contact with the air would account for the preservation of honey in the comb. Starch is said to be occasionally added to the inferior kinds to give them a white appearance. The adulteration may be detected by adding water, which dissolves the honey and leaves the starch at the bottom of the vessel. Dilution with water may be suspected from the greater thinness of the honey and its want of disposition to crystallize.

Honey is sometimes adulterated with artificial glucose. This cannot be detected by the official tests with certainty, but the safest method is to employ the polariscope. (See Leach, "Food Adulteration and Analysis."

According to Oscar Haenie, glucose can also be detected by first dialyzing thoroughly and then polarizing, under which circumstance, if glucose be present, rotation to the right occurs; if the honey be pure the light is not affected. Undialyzed honey ordinarily polarizes to the left, but unadulterated conifer honeys are dextrogyrate. (P. J., xxi.)

Honey has been frequently adulterated with artificial invert sugar. This is best detected by the official method given above.
Uses.—Honey possesses the same medicinal properties as sugar, but is more disposed to affect the bowels. Though largely consumed as an article of food, it is seldom employed medicinally, except as a vehicle. Its taste and demulcent qualities render it a useful addition to gargles, and it is sometimes employed as an application to foul ulcers.

Off. Prep.—Mel Depuratum, U. S., Br.

MEL DEPURATUM. U. S., Br.

CLARIFIED HONEY Mel Depurat.
[Mel Despumatum, U. S. 1890]

"Purified Honey is honey of commerce melted and strained, the specific gravity, if necessary, being adjusted to 1.36 by the addition of Distilled Water." Br.

Purified Honey; Mellite simple, Fr. Cod.; Miel despume, Fr.; Mel depuratum, P. G.; Gereinigter Honig, G.; Miele depurate, It.; Miel depurada, Sp.

"Honey, a convenient quantity, Distilled Water, Glycerin, each, a sufficient quantity. Weigh the honey in a tared dish, mix it intimately with two per cent. of paper pulp, which has been previously reduced to shreds, thoroughly washed and soaked in water, and then strongly expressed and again shredded. Then heat on a water bath at a temperature not exceeding 70° C. (158° F.), and carefully remove the scum which rises to the surface. Add enough distilled water to make up the loss incurred by evaporation, strain, and mix the strained liquid with five per cent. of its weight of glycerine” U. S.

The U. S. method of clarifying honey was new as far as the Pharmacopoeia was concerned in 1890. Paper-pulp is very effective as a clarifying agent, and the glycerin offers some protection to the honey against change. Honey may be made brilliant by hot nitrification through paper. (See Remington's Practice of Pharmacy, "Hot Filtration."

Honey, by the heat of the water bath, becomes so fluid that the wax and other lighter impurities which it contains rise to the surface and may be skimmed off, while the heavier substances which may have
been accidentally or fraudulently added, such as sand or other earth, sink to the bottom. It is officially required that "Clarified Honey, diluted with twice its weight of water, has a specific gravity of not less than 1.095 at 25° C. (77° F.); in other respects it conforms to the tests for purity under Mel." U. S.

A neat method of separating is described in N. R., Feb., 1880. It is as follows: "Pour the honey into a perfectly clean cylindrical vessel, with straight sides, rather narrow, and having a small lip at the open margin, and heat the vessel on a water-bath. When the water is hot, pour enough honey into the vessel to fill it to within about 1 inch of the edge, and allow it to remain at rest in the water-bath, at a moderate heat, for about one hour. During this time, most of the impurities will rise to the top, while some others may sink to the bottom. Now remove the vessel very carefully from the water-bath, and pour on top of the hot honey, very gently, a sufficient amount of cold water to fill the vessel completely. This will cause all the impurities floating on the honey to rise at once to the top of the cold water, where they will often solidify to a tough skin or cake, which may be taken off without difficulty. Then pour off the water through the lip, remove the last remnants, if necessary, by means of blotting paper, and filter the honey through a piece of well-washed, wetted, and dense white flannel. The resulting product—if the honey be pure—will be very brilliant." The French Codex directs one part of honey to be diluted with one part of distilled water. The specific gravity of this solution should be not less than 1.300.

(For other processes of purifying honey, see 14th edition of this work, p. 1321, also 19th ed., p. 775, and A. J. P., 1877, p. 19; also 1879, pp. 193, 598; and 1880, p. 132.) Heugel's method is to mix two pounds each of honey and water with a half-ounce of magnesium carbonate, frequently agitate for two or three hours, filter through doubled white filtering paper, boil slowly, remove the scum carefully, and evaporate upon a steam bath to a syrupy consistence. Dieterich recommends the following process: Mix the honey with sufficient water (the amount depending on the consistence), heat for about seven hours on a water bath, and clarify it with 5 per cent. of its weight of powdered talc, neutralize, if necessary, with magnesium carbonate; allow to deposit, filter, add a few drops of acetic acid, and evaporate to the proper specific gravity. (Ph. Ztg., 93, 712.)
The British Pharm. describes it as "a syrupy, translucent, pale yellowish liquid. Aromatic odor; taste at first sweet, afterwards faintly acrid. Specific gravity 1.36. Optical rotation at 15.5° C. (60° F.) of a solution in water, containing 25 grammes in 100 millilitres, decolorised by filtration with animal charcoal, in a tube 200 millimetres long, between 0° and -5° C. (32° and 23° F.); 5 millilitres of the same solution when mixed with 15 millilitres of absolute alcohol do not become more than faintly opalescent (absence of starch sugar). When 2 grammes are dissolved in 20 millilitres of boiling water and cooled, the solution does not become blue on the addition of one drop of N/10 solution of iodine (absence of starch). Ash not more than 0.25 per cent.; solution of the ash in water is not alkaline to litmus, and when acidified with nitric acid yields not more than a very faint opalescence with solution of barium chloride, or with solution of silver nitrate (limit of sulphates and of chlorides)." Br.

Honey clarified with calcium carbonate and animal charcoal, or as in the first process described, is as clear and colorless as syrup made with sugar, but still retains a peculiar flavor. It is less disposed to ferment than crude honey, and is said not to be so liable to produce griping pain when swallowed.

Dose, one to four fluidraehms (3.75-15 mils).

**MEL ROSAE. U. S.**

**HONEY OF ROSE**

Mellitum Rosatum; Mellite de Rose rouge, Fr. Cod.; Miel Rosat, Fr.; Mel Rosatum, P. G.; Rosenhonig, G.; Miele rosato, It.; Miel de rosas, Sp.

"Fluidextract of Rose, one hundred and twenty mils [or 4 fluidounces, 28 minims]; Clarified Honey, a sufficient quantity to make one thousand grammes [or 35 ounces av., 120 grains]. Mix the fluidextract of rose in a tared vessel' with enough clarified honey to make the product weigh one thousand grammes [or 35 ounces av., 120 grains]." U. S.
Though one of the official preparations in the London and Edinburgh Pharmacopoeias, the Honey of Rose has been dropped in the British. The U. S. formula is based on that of Grahaeme. (See A. J. P., 1859, p. 443.) As is well known, honey of rose deposits honey sugar upon standing even but a short time. Touflet (Ph. Centralh., xxxvi, 307) obviates this precipitation in the following manner: Take of Powdered Rose Leaves, 25 parts; Alcohol, sp. gr. 0.875, 75 parts; Honey, 80 parts; Sugar, 34 parts. Percolate the rose leaves with the alcohol, filter and distil off the filtrate to 40 parts. To this add the honey and sugar, and bring to the boiling-point. Honey of rose forms a pleasant addition to the gargles employed in inflammation and ulceration of the mouth and throat.

Dose, one fluidrachm (3.75 mils).

**Off. Prep.**—Mel Rosae et Sodii Boratis, N. F.

**Melaleuca (Cajuputi).**—Under the names of gomenol and Niaouli oil there has been put upon the market a volatile oil obtained from the leaves of *Melaleuca Leucadendron* L. and the var. minor Smith, myrtaceous trees growing in upper India, the islands of the Indian Ocean and Australia. Its sp. gr. is 0.922, and its rotatory power plus 0.420. Its odor and taste are said to resemble those of camphor and peppermint. The chief constituent of the oil (66 per cent.) is cineole, and in addition to this is a crystallized terpineol, C\(_{10}\)H\(_{18}\)O, and the valeric ester of the same. These together make up 30 per cent. additional. (Gilde-meister and Hoffman, Aetherische Öle, p. 686.) It has been recommended in the chronic catarrhs of the pulmonary mucous membrane, and especially in whooping cough. It may be given by the mouth or exhibited in the form of intramuscular injections being diluted with from four to ten parts of a sterilized fixed oil to one part of volatile oil. The hypodermic dose of a 10 per cent. solution is two and one-half fluidrachms to one-half fluidounce (9.3-15 mils). The injections should be practised every other day. Gomenol has been used by Brimont (Press Med., 1910, p. 800) as a vermifuge in ankylostomiasis, in doses of five minims (0.3 mil).

**Melan.**—Under the name of melan, there has been introduced a dark-brown, oily fluid which is stated to be a preparation of *Melilotus coerulescens*. It is used as a local application to ulcers and bzirns.

**Melastoma. Melastoma Ackermann.**—This Colombian plant of the Fam. Melastomataceae is used in South America as an anti- neuralgic. Its abundant essential oil resembles methyl salicylate, if indeed it be not identical with it. (See N. R., Aug. and Sept., 1883.)

**Melilotus. N. F. IV. Yellow Melilot. Yellow Sweet Clover. Berba Meliloti, Yellow Sweet
Clover, G.—'The dried leaves and flowering tops of Melilotus officinalis (Linne) Lamarck (Fam. Leguminosae)." N. F. An annual or biennial plant of the Fam. Leguminosae, indigenous in Europe, and growing also in this country. The plant, when in flower, has a peculiar sweet odor, which, by drying, becomes stronger and more agreeable, somewhat like that of the tonka bean. The N. F. describes it as follows: "Stems mostly less than 3 dm. in length, slender, straight, mostly simple, often leafy below, terminating in long slender racemes, the younger portions very finely pubescent; leaves glabrous or nearly so; petiolate, trifoliate, stipulate, the stipules subulate, entire, the leaflets from 1 to 3 cm. in length, varying from narrowly oblong to oval or occasionally broader above the middle, rounded, truncate, or slightly notched at the summit, sharply serrate; racemes 1 dm. or less in length, many flowered, the flowers yellow, from 5 to 6 mm. in length; calyx bell-shaped, the fine, nearly equal lobes shorter than the tube, corolla papilionaceous, the keel shorter than the other petals, which are about equal; legumes reflexed, from 2.5 to 3.5 mm. in length, obovate, wrinkled, one-seeded. Odor aromatic, tonka-like; taste sweetish, slightly pungent and bitter. Melilot yields not more than 10 per cent of ash." N. F. This similarity is accounted for by the fact that coumarin, C₉H₆O₂, the chief constituent of tonka beans, is present in melilot, combined with melilotic acid, C₉H₁₀O₃, and coumaric acid, C₉H₈O₃, of which latter acid coumarin is the anhydride.

Melissa. U. S. 1890. Melissa. Balm.—Under this name were formerly recognized by the U. S. P. the leaves and tops of Melissa officinalis L. (Fam. Labiatae), or the ordinary balm of Southern Europe, which has become naturalized in this country. Balm contains some tannic acid, and a yellowish, highly flavored essential oil which, however, is present in such small quantities that the plant has practically no remedial value. The allied Satureja Calamintha (L.) Scheele, var. Sylvatica Brig., is said to contain sufficient aromatic volatile oil to be of possible commercial interest.

Under the name of oil of lemon balm or oil of balm the essential oil of melissa has been used as a diaphoretic in doses of from one to three minims (0.06 to 0.2 mil). This oil is a yellow liquid with a specific gravity of 0.9 to 0.925. Its most important constituent is citral.

M. canadense L.—This is a woody, climbing plant, which grows from Western Quebec and New England southward. It is specifically characterized by its peltate, three to seven-lobed leaves, its small clusters of greenish-yellow flowers, and its somewhat kidney-shaped, glaucous fruit, which is ripened in September. Menispermum was officially described as follows: "Rhizome 5 to 6 dm. long, 5 mm. thick, brown or yellowish-brown, somewhat knotty, finely wrinkled longitudinally and beset with numerous thin, rather brittle roots; fracture tough, woody; internally yellowish, the bark rather thick, the wood-rays broad, porous, and longest on the lower side; pith..."
distinct. Nearly inodorous; taste bitter." U.S. 1890. Maisch proved the presence of a white alkaloid, and of a small quantity of berberine. The former reacts with the usual alkaloidal precipitants, is not very soluble in water, but soluble in alcohol and ether. H. L. Barber (A. J. P., 1884, p. 401) obtained the white amorphous alkaloid above referred to, for which Maisch proposed the name menispine. Starch was also found in the root. (A. J. P., 1863, p. 301.) H. M. Gordin states that berberine is not present in menispernum. (Proc. A. Ph. A., 1909.) Menispermum has been used as a substitute for sarsaparilla but is probably inert. A fluidextract made with a menstruum of 2 parts of alcohol and one part of water was recognized by the U. S. P., 1890; dose one-half to one fluidrachm (1.8-3.75 mils).

Mentha Aquatica.—Under the name of poco oil, the volatile oil of this plant, which is a native of China, is used in the Island of Java as a popular remedy for headache, and also in cholera.

MENTHA PIPERITA. U. S.

PEPPERMINT Menth. Pip.

"The dried leaves and flowering tops of Mentha piperita Linne (Fam. Labiatae)." U. S.

Brandy Mint; Menthe poivr6e, Fr. Cod.; Folia Menthae Piperitae, P. G.; Pfefferminzblatter, Pfeffermunze, G.; Menta piperita, It., Sp.

The genus Mentha comprises at least fifteen species, of which there are also a great many varieties. Some of the mints have been in use for culinary and medicinal purposes since antiquity, but no well defined distinction is made as to just what plants were employed. It is stated that M. piperita L. (1753), also Smith (1800)—the most important member of this genus, was long ago cultivated by the Egyptians. It is mentioned in the Icelandic Pharmacopoeia of the thirteenth century. Peppermint is now grown in considerable amounts in Europe, North America, and Eastern Asia. It is also found growing wild in other parts of the world, as South America and Australia. The oldest existing peppermint district is in the neighborhood of Mitcham (Surrey), England. In some parts of the United States, especially in Michigan, the western part of New York, Ohio and Indiana, it is largely cultivated. On the continent of Europe other species of Mentha (particularly M. arvensis) grow with M. piperita, deteriorating the product. In America other plants (as Erigeron canadensis and Erechthites hieracifolia) cause the same trouble. Besides M. piperita other species are cultivated, as some Asiatic varieties of M. arvensis, M. spicata, M. longifolia (var. undulata), M. gentilis, M.
dalmatica, and M. Pulegium. Miss Henkel reviews the situation regarding the cultivation of peppermint in the United States and describes the three kinds of mint grown for the production of peppermint oil: Mentha piperita L.; Mentha piperita vulgaris Sole, and Mentha piperita officinalis Sole. (Bul. Bur. Plant Ind., U. S. Dept. Agric., No. 90, 1906.) A comprehensive article on the cultivation of peppermint in Japan is that by Inouye in Schim. Rep., November, 1908, p. 199. Peppermint has recently been successfully grown in Wisconsin. (Paint, Oil and Drug Rev., xliv, p. 18.) The cultivation of peppermint is a growing industry on the reclaimed lands of Louisiana. (Spatula, xvii, p. 18.) Great interest recently has been taken in the cultivation of peppermint in Germany. (See Thorns in B. P. G., xx, p. 244; Arb. Pharm. Inst. Univ. Berl., viii, p. 93.) Mitlacher reports on the cultivation of peppermint in Austria and outlines methods for its culture on a large scale. (Ph. Post, xlv, p. 215; Zeit. Oest. Apoth. Ver., 1, p. 422.) It has been repeatedly pointed out that the essential oil-bearing plants of the Labiates are very capricious and constantly changing character with change of soil and climate. For an account of the cultivation of peppermint in Russia, see Proc. A. Ph. A., 1902, 831.

Peppermint is a perennial herbaceous plant, producing creeping stolons. The steins are quadrangular, channelled, purplish, somewhat hairy and branching towards the top. The leaves are opposite, petiolate, ovate, sharply seriate, pointed, smoother on the upper than on the under surface, and of a dark green color, which is paler beneath. The flowers are small, purple, and in terminal obtuse spikes, interrupted below, and cymosely arranged. Late in the season, the growth of the lateral lower branches often gives to the inflorescence the appearance of a corymb. The calyx is tubular, often purplish, furrowed, glabrous below, and five-toothed, the teeth being hirsute. The corolla is purplish, tubular, with its border divided into four segments, of which the uppermost is broadest, and notched at its summit. The four short stamens are concealed within the tube of the corolla; the style projects beyond it, and terminates in a bifid stigma. The plant should be cut for medicinal use in dry weather, in August, about the period of the expansion of the flowers. John C. Umney points out differences between white and black peppermint, in P. J., 1896, 123. For a paper on the histology of powdered peppermint by Smith Ely Jelliffe, see D. C., 1899, 252.

Properties.—It is officially described as follows: “Leaves more or less crumpled and frequently detached from the stems; stems quadrangular,
from 1 to 2 mm. in diameter, glabrous except for a few scattered deflexed hairs; leaves when entire ovate-oblong to oblong-lanceolate, petioles from 4 to 15 mm. in length, slightly pubescent, laminae from 1 to 9 cm. in length, acute and sharply serrate, light green to purplish-brown, upper surfaces nearly glabrous, lower surfaces glandular hairy, especially on the veins; flower-whorls in oblong or oval spikes which are usually compact, or somewhat interrupted at the base, from 1 to 1.5 cm. in breadth, rounded at the summit, and in fruit attaining a length of from 3 to 7 cm.; bracts oblong-lanceolate, very acuminate, 7 mm. in length; calyx tubular, equally 5-toothed, pubescent and glandular-punctate, often dark purple in color; corolla tubular-campanulate, 4-cleft, about 3 mm. in length and often light purple; stamens 4, short and equal; nutlets ellipsoidal, about 0.5 mm. in diameter, blackish-brown; odor aromatic, characteristic; taste aromatic, pungent, followed by a cooling sensation in the mouth." U. S.

The morphology of Mentha piperita and other species of Mentha are discussed by Eriksson in B. P. G., xviii, p. 244. The herb, both in the recent and in the dried state, has a peculiar, penetrating, grateful odor. Peppermint is quite frequently contaminated with spearmint and in one instance the leaves of belladonna were found. The latter, while no doubt accidental, shows the necessity for the examination of crude drug's generally. (Pharm. Prax., iv, p. 38.) There is sometimes difficulty in distinguishing between the leaves of M. piperita and those of M. spicata. According to Joseph Schrenk, crystals can always be found in the glandular hairs of the peppermint, but are absent in those of the spearmint. The crystals are doubly refractive, and so transparent that sometimes a polariscope is necessary for their easy detection. These crystals have been thought to be menthol, but they seem not to dissolve in alcohol, and are probably hesperidin.

The medicinal properties depend on a volatile oil, of which from 1 to 1.25 per cent. can be obtained from the herb. The leaves are said to contain a little tannic acid. The virtues of the herb are imparted to water, and more readily to alcohol.

**Uses.**—Peppermint is an aromatic stimulant, much used to allay nausea, relieve spasmodic pains of the stomach and bowels, expel flatus, or cover the taste or qualify the nauseating or griping effects of other medicines. The medicine is rarely used in infusion. (See Oleum Menthae Piperitae)
Dose, one drachm (3.9 Gm.).

Off. Prep.—Spiritus Menthas Piperitse, U. S.

*Mentha Pulegium* L.—European Pennyroyal. Pouliot oommun, Fr. Polei, G. Pulegium vulgare Mill.—This European labiate yields an oil which is known in England as the oil of pennyroyal, and must not be confounded with the American oil of the same name. The oil, which is also known as the oil of poley, has been examined by Beckmann and Pleisner (Arm. Ch. Ph., 262, 1), who discovered as the most important constituent pulegone, C_{10}H_{16}O, an unsaturated ketone, which makes up 80 per cent. of the oil. It boils under a pressure of 60 mm. at from 54.5° to 55° C. (130°-131° F.), turns the plane of polarization to the right, and has a, sp. gr. 0.9323 at 0° C. (32° F.). It forms crystalline compounds with hydroxylamine and with hydrogen bromide. When reduced by sodium in ethereal solution pulegone is changed into menthol. Pulegone is most abundant in the Spanish oil, and less abundant in American and Algerian oils. (See also Wallach, Ann. Ch. Ph., 272, 122, and Semmler, Ber. d. Chem. Ges., 25, 3515.) Schimmel states that the oil is sometimes adulterated with eucalyptus oil. (Schim. Rep., 1908, 67.) It is stated (B. M. J., March, 1890) that the oil is largely used for the purpose of producing abortion, and is popularly believed to be safer and more certain than the other volatile oils. Taylor denies, however, that the oil is an abortifacient and it appears to be demonstrated that it is capable of causing fatty degeneration. (See S. Jb., cdxvii, p. 230.)

**MENTHA VIRIDIS. U. S.**

**SPEARMINT** Menth. Vir.

"The dried leave's and flowering tops of Mentha spicata Linne (Mentha viridis Linne) (Fam. Labiatae)." U.S.

Herba Menthae Acutae (vel Romanæ); Brown, Lamb, Garden, or Mackerel Mint; Menthe verte, Fr. Cod.; Menthe romaine, Baume vert, Menthe a epi, Fr.; Grune Munze, Romische Minze, G.

Spearmint, sometimes called simply mint, differs from *M. piperita* chiefly in having sessile, or nearly sessile, oblong or ovate-lanceolate, unequally serrate leaves; elongated, interrupted, panicled spikes; setaceous bracts; and stamens longer than the tube of the corolla. It is a native of Europe and Asia, and naturalized in waste places from Nova Scotia and Ontario to Minnesota and Kansas in the West and Florida in the South United States. It is also cultivated for domestic use and for the sake of its oil. Its flowering season is August. Spearmint is officially
described as "leaves more or less crumpled and mixed with a large proportion of the light brown or purplish-colored stems, occasionally with their characteristic opposite branches; stems distinctly quadrangular, from 1 to 3 mm. in width, nearly glabrous; leaves when entire ovate-lanceolate, unequally serrate', nearly sessile or with a petiole less than 5 mm. in length, of a bright green color and somewhat glandular-hairy on the under surface; flowers arranged in opposite clusters and in more or less interrupted or crowded lanceolate, nearly acute spikes; bracts linear-lanceolate, subulate, from 7 to 10 mm. in length, subtending the flowr clusters; calyx tubular, 5-toothed, glandular punctate and somewhat pubescent near the teeth; corolla nearly white or light brown; stamens extending beyond the corolla tube; odor slightly pungent, characteristic; taste aromatic, characteristic but not followed by a cooling sensation in the mouth." U. S.

Spearmint was cultivated in the Convent gardens of the ninth century. It is largely used as a domestic and popular flavor in foods, chewing gum, and confectionery. The plant is widely cultivated, and Schimmel and Co. present a review of its cultivation in Michigan, Indiana and New York in their Schim. Rep., October, 1910, p. 131. Recently experiments have been conducted in Louisiana, and Phenis states the resulting oil to be of the highest grade. (Paint, Oil, and Drug Review, xlvi, p. 27.) Successful experiments have also been conducted in Wisconsin. (Ibid., xlv, p. 18.) Miltlacher has reported that Mentha crispa can be successfully grown in Austria. (Ph. Post, xlv, p. 215.)

Spearmint is sometimes admixed with peppermint. This is probably due to carelessness. The taste and odor of spearmint are retained for some time by the dried plant. They depend on a volatile oil. (See Oleum Menthae Viridis.)

Dose, one drachm (3.9 Gm.).

**Off. Prep.**—Spiritus Menthae Viridis, U. S.

**Menyanthes** N. F. IV. Buckbean. Marsh Trefoil. Bogbean. Water Shamrock. Folia Trifolii Fibrini.—" The dried leaves of Menyanthes trifoliata Linne (Fam. Gentianaceae)." It is an ingredient in Vinum Aurantii Compositum, N. F. IV. This gentianaceous plant is a native both of Europe and North America, from Greenland to Alaska and south to Pennsylvania, Minnesota, and California. All parts of menyanthes are efficacious, but only the leaves are official.
It is described by the N. F. as "glabrous; petioles from 10 to 15 cm. in length, stout but soft and weak, the base more or less sheathed with broad, thin, and membranaceous, somewhat translucent stipules; blade ash-green, trifoliate; leaflets, sessile or very short-petioled from 5 to 8 cm. in length and usually about two-thirds as broad, obovate, blunt, entire or occasionally coarsely and unequally crenate. Odor slight but characteristic; taste decidedly bitter. Menyanthes yields not more than 10 per cent. of ash." N. F. Its virtues depend on a bitter principle denominated menyanthin, which may be obtained sufficiently pure for use by treating the spirituous extract of the plant with hydrated lead oxide, removing the lead by hydrosulphuric acid, filtering and evaporating the liquor, exhausting the residue with alcohol, and again evaporating with a gentle heat. It has a bitter taste, is soluble in alcohol and water, but not in pure ether, and is chemically neutral. Kromayer (1865) assigned to it the formula $C_{30}H_{46}O_{14}$, and stated that it breaks up on heating with diluted sulphuric acid into a fermentable sugar and menyanthol, a colorless, difficultly volatilizable oil, with an odor like that of bitter almond. K. Leuderich (A. Pharm., 1892, 38 and 48) has studied menyanthin, and gives it the formula $C_{33}H_{50}O_{14}$, and states that its decomposition products are a phenol-like body, menyanthol, $C_7H_{11}O_2$, a resinous product, and a left-rotatory sugar.

Vridevel (P. J., 1910, lxxxv, p. 465) has separated a second glucoside from menyanthes, to which he gives the name of meliatin. It is a crystalline body, with a melting point of 217° C. (422.6° P.).

With the ordinary properties of the bitter tonics, menyanthes unites a cathartic power; in large doses it may cause vomiting. The dose of the powdered leaves or root as a tonic is from twenty to thirty grains (1.3-2.0 Gm.); of an infusion, prepared with half an ounce to a pint of boiling water, from one to two fluidounces (30-60 mils); and of the extract, ten or fifteen grains (0.65-1.0 Gm.), to be repeated three or four times a day. A drachm of the powder, or four fluidounces of the strong decoction, generally purges, and often occasions vomiting.

**Mercurialis.** Mercurialis annua L. Mercury Herb. French Mercury.—An herbaceous European plant, of the Family of Euphorbiaceae which has been employed from the most ancient times as a purgative, diuretic, and emmenagogue. When boiled, it loses its acridity, and in this condition has been used as an emollient. Another species, *M. perennis* L., or dog's mercury, also a native of Europe, is poisonous. (Merat and De Lens.) Reichardt has discovered in *M. annua* a volatile alkaloid, which he named mercurialine. According to E. Schmidt (P. J., vol. x, 29), mercurialine is identical with methylamine, $CH_3NH_2$, and is associated in the mercurialis with trimethylamine. It is a liquid of an oily appearance, narcotic odor, and alkaline reaction; boils at 140° C. (284° F.); forms salts with the acids; absorbs carbon dioxide; has a strong affinity for water; on exposure to the air it is changed into a resin of a buttery consistence, and is said to be poisonous to man; but Hugo Schuiz (A. E. P. P., April, 1886, 88) found that neither the fluidextract nor the herb given as food was capable of killing either the pig or the rabbit, and that four and a half grains (0.29 Gm.) of the mercurialine hypodermically injected had no effect. The urine is increased in quantity and colored reddish.
Mesembryanthemum. Mesembryanthemum crystallinum L. Iceplant. Diamond Fig.—A biennial plant of the Fam. Aizoaceae, a native of the south of Europe, now distributed, to the Canary Islands, Southern Africa, Australia and California. The stem and under surface of the leaves are covered with crystalline drops, which give the plant the appearance of being coated with ice. H. Mangon obtained as much as 43 per cent. of salts of potassium and sodium from the dried leaves. (A. J. P., 1863, 370.) The herb is without odor, and has a saline, somewhat nauseous taste. It is considered demulcent, diuretic, and has been used in inflammations of the pulmonic and genito-urinary mucous membrane.

Mesenna. Musenna. Bisenna. Musena. Moucena. Fr. Musennarinde, G.—Under these different names has been brought into notice, as a powerful tenifuge, the bark of an Abyssinian tree, Albismia anthelmintica Brongn. (Fam. Leguminosae). The bark is in flat pieces from five to ten inches long, smooth, slightly fissured, of a rusty gray color exteriorly, and pale yellow and fibrous within. It consists of four layers, one of which contains very large cells, with thick coats, and is supposed to be the active part. E. Caventou and Legendre found in the bark no alkaloid, but a peculiar, acid, acrid, resinous substance. The musennin of Theil is probably the same, although not as yet in a pure state. The Abyssinians employ the powdered bark, in the dose of about two ounces, suspended in water or other liquid, or mixed with flour in the form of bread, or made into a confection with honey, butter, etc. It is taken in the morning, three or four hours before breakfast, and no other precautions are used. It produces no pain nor any disturbance of the functions, not even purging actively. Fragments of the worm are voided the same evening, and the greater portion of it the next day.

MEZEREUM. U.S.

MEZEREUM [Mezereon]

“The dried bark of Daphne Mezereum Linne, Daphne Gnidium Linne, or of Daphne Laureola Linne (Fam. Thymeleaceae).” U. S.

Mezerei Cortex, Br. 1898; Mezereon Bark; Cortex Mezerei, Cortex Thymeoleae (vel Coccognidii); Dwarf Bay, Wild Pepper, Spurge-flax, Spurge-olive, Magell; Mezereon ou Bois gentil, Fr. Cod.; Laureole, Thymelee, Fr.; Kellerhals, Seidelbastrinde, Kellerhalsrinde, G.; Mezereo, It.; Mezereon, Sp.

All the species of Daphne are possessed of active properties, but three only are official—D. Mesereum, D. Laureola, and D. Gnidium, all of which are recognized in the United States Pharm., and the last in the former French Codex, 1884.

1. Daphne Mezereum is a very hardy, low shrub, with a branching stem,
and a smooth, dark gray bark, very easily separable from the wood. The leaves spring from the ends of the branches, are deciduous, sessile, obovate-lan-eeolate, entire, smooth, and of a pale green color, somewhat glaucous beneath. They are preceded by the flowers, which appear very early in the spring, and sometimes bloom even amidst the snow. These are of a purple-rose color, rarely white, highly fragrant, and disposed in clusters, each consisting of two or three flowers, forming together a kind of spike at the upper part of the stem and branches. At the base of each cluster are deciduous floral leaves. The fruit is oval, shining, fleshy, of a bright red color, and contains a single round seed. Another variety produces white flowers and yellow fruit. This species of Daphne occurs throughout the forests of Europe, and extends in Western Asia from the Caucasus to the Altai. It is cultivated in Europe, and is occasionally found in our own gardens. D. Mezereum is locally naturalized from New York and Massachusetts to western Quebec and Ontario.

2. Daphne Gnidium.—In this species, called garou or sain-bois by the French, the leaves are linear-lanceolate, acute, entire, smooth, and irregularly but closely set upon the branches. The flowers are white, downy, odoriferous, and disposed in terminal panicked racemes. The fruit is globular, dry, at first green, but ultimately black. D. Gnidium grows in dry uncultivated places in the south of Europe, and flowers in June. Its bark, which in France is used indiscriminately with that of the former species, is of a deep purplish-brown color, and hairy in the younger portions. It appears to be equally as active, medicinally, as the other official species.

Besides the species above described, Daphne Laureola, or spurge laurel, is said to furnish a portion of mezereum of commerce, and is recognized by the U. S, Pharmacopoeia, but its product is inferior in acrimony, and consequently in medicinal activity.

Properties.—The bark of the root was formerly directed, but the mezereum with which our markets are supplied is evidently the bark of the stem, and the Pharmacopoeias at present very properly direct the bark, without designating the part from which it must be taken. The official description is as follows: "In flexible, tough quilled pieces or somewhat flattened strips, attaining a length of 90 cm.; from 0.3 to 1 mm. in thickness; outer surface yellowish-or olive-brown (D. Mezereum) or purplish-brown (D. Gnidium) or purplish-gray (D. Laureola), smooth, numerous lenticels giving a transversely striated appearance.
and occasionally with numerous, circular, brownish-black apothecia; outer corky layer easily separable from the middle bark which varies from light green to olive-brown and with more or less detached bast-fibers; inner surface yellowish-white, satiny lustrous, finely striate; fracture tough, fibrous, the inner bark lamellated; odor very-slight; taste at first slight, becoming gradually and increasingly pungent and acrid. Under the microscope, transverse sections of Mezereum show a rather thick cork composed of from 20 to 30 rows of cells, the outer being compressed and with yellowish-brown walls, and the inner more or less tabular with nearly colorless walls; a hypodermis of 3 to 5 rows of collenchymatous cells containing chloroplastids or a yellowish-green resinous substance; an inner bark consisting mostly of nearly colorless non-lignified bast-fibers occurring in loosely united groups, and a few starch-bearing medullary rays one cell in width. The powder is light grayish-brown; bast-fibers numerous, from 0.4 to 3 mm. in length and about 0.015 mm. in width, frequently more or less uneven or irregularly bent and considerably attenuated at the ends, the walls being from 0.001 to 0.005 mm. in thickness, colorless, non-lignified and free from pores; fragments of yellowish-brown cork cells and starch-bearing medullary rays; starch grains relatively few, mostly spherical or elliptical, occasionally 2- to 4-compound, the individual grains from 0.003 to 0.015 mm. in diameter."

British writers state that the bark of the root is the most active. The berries and leaves of the plant are also active, and the former have sometimes proved fatal to children who have eaten them. Pallas states that they are used as a purgative by the Russian peasants, and that thirty berries are required to act. French authors observe that fifteen are sufficient to kill. A tincture of them is used in Germany as a local application in neuralgia.

Vauquelin discovered a peculiar principle in the bark of Daphne alpina. This has subsequently been found in other species, and has received the name of daphnin. Gmelin and Bar found it in the bark of D. Mezereum, associated with wax, an acrid resin (mezerein), a yellow coloring matter, a reddish-brown extractive, and uncrystallizable and fermentable sugar, a gummy matter containing nitrogen, ligneous fiber, malic acid, and several malates. By J. B. Eng it has been discovered, together with a volatile oil, in the flowers of D. Mezereum. (Wittstein's Viertelj., viii, 23.) Daphnin is in prismatic crystals, grouped together, colorless, transparent, brilliant, slightly soluble in cold water, very soluble in...
boiling water and alcohol, without odor, and of a bitter, somewhat harsh taste. According to Zwenger (Ann. Ch. Ph., 1860, cxv, 1) it is a glucosidal acid, being resolvable by sulphuric or hydrochloric acid into sugar, and a peculiar crystallizable principle called daphnetin, $C_9H_6O_4 + 2H_2O$. He gives for daphnin the formula $C_{15}H_{16}O_9 + 2H_2O$, the same as that of aesculin, of which it is, therefore, an isomer. W. Will and O. Jung (A. J. P., 1885) have investigated daphnetin, which was shown in 1879 by Stunkel to be dioxy coumarin,

$$\begin{array}{c}
\text{C}_9\text{H}_6\text{O}_4 + 2\text{H}_2\text{O} \\
\text{C}_9\text{H}_6\text{O}_4 + 2\text{H}_2\text{O}
\end{array}$$

about one ounce of daphnetin from fifty pounds of extract of mezereum, and they proved that it has the same relation to pyrogallic acid that coumarin has to phenol, or umbelliferone to resorcinol. (For a method of preparing the glucoside daphnin, see U. S. D., nineteenth edition, p. 781.) Coccognin, isolated in 1870 by Casselmann from the fruits of D. Mezereum, appears to be closely allied to, if not identical with, daphnin. By the dry distillation of an alcoholic extract of mezereum bark, Zwenger obtained umbelliferone, $C_9H_6O_3$.

**Uses.**—The recent bark applied to the skin produces inflammation followed by vesication, and has been popularly used as an epispastic, from time immemorial, in some of the southern countries of Europe. The dried bark, though less active, is possessed of a similar property, and is occasionally employed in France by regular practitioners for the purpose of forming issues. A small square piece, moistened with vinegar, is applied to the skin, and renewed twice a day until a blister is formed, and occasionally afterwards to keep up the discharge. It is slow in its operation, generally requiring from twenty-four to forty-eight hours to vesicate. The ointment was formerly used for maintaining the discharge from blistered surfaces, and may be applied advantageously to obstinate, ill-conditioned indolent ulcers. It was recognized by the U. S. 1880. (See U. S. D., 19th ed., p. 781, for formula.)

An alcoholic extract has also been employed to communicate irritant properties to issue-peas. Internally administered, mezereum is a stimulant capable of being directed to the skin or kidneys, and in large doses likely to excite purging, nausea, and vomiting. In overdoses it produces the fatal effects of the acrid poisons, and a case of apparently severe narcotic effects has been recorded. (Am. J. M. S., xxii.) It had at
one time much reputation as an alterative in syphilis, chronic rheumatism, etc., but is of no value as an internal remedy and is almost never administered save as an ingredient of the compound fluidextract of sarsaparilla.

Dose, ten grains (0.65 Gm.).

**Off. Prep.**—Fluidextractum Sarsaparillae Compositum, U. S.; Decoctum Sarsaparillae Compositum, N. F.; Fluidextractum Mezerei, N. F.; Linimentum Sinapis Compositum (from Fluidextract), N. F.

**Michelia.** Michelianilagirica Zenker. (Fam. Magnoliaceae)—This tree, which is said to be abundant in the Neilgherry hills, India, yields an aromatic volatile oil, which has entered commerce. (P. J., Jan., 1888.)

**Micrampelis.** Micrampelis fabacea (Naud.) Greene. (Megarrhiza californica Torr., Echinocystis fabacea Naud.) Man Foot. Big Root. Gerba marra. (Fam. Cucurbitaceae)—J. P. Heaney has obtained a substance from this root of resinous character which he calls megarrhizin, and another which he believes to be a glucoside and calls megarrhizin. It is said to be actively cathartic. (A. J. P., 1877, 451.) A second glucoside was obtained by W. M. Young (A. J. P., 1883, 195), to which the name of megarrhin was given. It resembles saponin, and possesses the property of dilating the pupil. Young also found two resins, one soluble in alcohol and the other soluble in ether.

**Micromeria.** Micromeria Chamissonis (Benth.) Greene. Yerba Buena.—This sweet scented labiate, which is popularly known as yerba buena is a trailing perennial, indigenous to the Pacific Coast. Power and Salway have obtained besides 0.16 per cent. of a volatile oil with a mint-like odor, two new alcohols, which they named micromol, and micromeritol, and a phenol, xanthomicrol. (J. Am. C. S., 1908, 251.) The fluidextract prepared from this plant has been used popularly as an emmenagogue. Dose, one-half to two fluidrachms (1.8-7.5 mils).

**Mitchella.** Mitchella repens L. Squaw Vine. Partridge Berry. Checkerberry. Winter Clover. (Fam. Rubiaceae)—This small, indigenous evergreen has been supposed to possess remedial properties, and is said to be employed, in decoction, by the Indian squaws, to facilitate parturition. It appears to be diuretic, tonic, and astringent, resembling in these respects the pipsissewa, for which it is often substituted. E. Breneiser (A. J. P., 1887, 228) found it to contain some resin, wax, mucilage, dextrin, and what appeared to be saponin.

**Momordica.** Momordica Balsamina L. Balsam Apple. Balsamina. (Fam. Cucurbitaceae)—An annual climbing East Indian plant, cultivated in our gardens for the sake of the ornamental fruit. The latter is ovate, attenuated towards each extremity, angular, warty, not unlike a cucumber in appearance, of a lively red or
orange-yellow color, easily falling when touched, and spontaneously separating into several pieces. A liniment formed by infusing the fruit, deprived of its seeds, in olive or almond oil, is applied to chapped hands, burns, piles, prolapsus ani, etc.; and the mashed fruit is sometimes used as a poultice. According to Descourtiz, two or three drachms taken internally will kill a dog. An extract prepared from it is said to be useful in dropsy. Dose, six to fifteen grains (0.4-1.0 Gm.).

Monarda. Monarda punctata L. Horsemint. Menthe de Cheval, Fr. Pferdeminze, Gr.—This is an indigenous perennial or biennial labiate, growing in light gravelly or sandy soils from New York to Texas and west to Wisconsin. The whole herb is employed. It has an aromatic odor, and a warm, pungent, bitterish taste, and abounds in a volatile oil, which may be separated by distillation with water. Herman J. M. Schroeter (A. J. P., 1888, 120) found the oil to consist of a hydrocarbon, \( \text{C}_{10}\text{H}_{16} \) (56 per cent.), thymol, \( \text{C}_{10}\text{H}_{14}\text{O} \) (25 per cent.), and higher oxygenated compounds, \( \text{C}_{10}\text{H}_{18}\text{O} \). Kremera (Ph. Rev., 1896, 223) examined the oil from authentic specimens and found it to yield from 56 to 61 per cent. of a phenol (thymol). Horsemint is stimulant and carminative, but is seldom used in regular practice. In the state of infusion it is occasionally employed in families as a remedy for flatulent colic and sick stomach, and for other purposes to which the aromatic herbs are applied. Monarda fistulosa L., wild bergamot, Oswego tea, an active diuretic (see Proc. A. Ph. A., 1895, 256; 1896, 238), contains, according to J. W. Brandel and E. Kremers, hydrothymoquinone, thymoquinone, besides cymene, carvacrol and limonene (Ph. Rev., 19.) The oil of Monardacitriodora Cerv., or prairiebergamot, according to Brandel (P. J., 53, 547), contains 65 per cent. of a phenol and 1.2 per cent. citral. See also MidlandDruggist, 1910, 526, and a paper by Nellie Wakeman in the Proc. A. Ph. A., 1910, 979. For the composition of monarda oils see Ph. Archiv., 1899, 73.

Monesia.—A South American vegetable extract, which is believed to be derived from the bark of Lucumai glycyphloea Mart. and Eichl. (Fam. Sapotaceae), a tree of moderate size, growing in the forests near Rio Janeiro and elsewhere in Brazil (J. P. C., 3e ser., vi, 63.) The bark, which has also entered commerce, is in pieces, some of which are three or six mm. thick, is very compact and heavy, of a deep brown or chocolate color, contrasting strongly with the grayish color of the epidermis when this remains, and of smooth fracture. The extract is of a dark brown almost black color, very brittle, the fracture neither very dull nor very shining, and of a taste at first sweet, then astringent, and ultimately acid, the acridity being very persistent, and especially felt in the fauces. It is entirely soluble in water. The bark contains, according to Peckolt (A. J. P., 1884, 626), monesia-tannic acid, which gives a black coloration with iron salts, gallic acid, monesin, an acrid, amorphous body, lucumin, a body crystallizing in silky needles, a bitter substance, glycyrrhizin, tartaric and citric acids, wax, etc. Monesin, which is considered as identical with saponin, \( \text{C}_{32}\text{H}_{54}\text{O}_{18} \), was obtained by treating the bark or extract with alcohol, adding to the tincture an excess of calcium hydroxide in fine powder, filtering, evaporating the clear liquor to dryness, treating the residue with water and animal charcoal, filtering, and again evaporating to dryness. Thus procured it was in transparent, yellowish scales, which were easily pulverized, forming a white powder. It was uncrystallizable, readily soluble in alcohol and water, to the latter of which it gave the property of frothing, and
insoluble in ether. It had no power to saturate acids, was without odor, but had a
slightly bitterish taste, followed by a decided and permanent acrimony in the posterior
mouth and fauces. Monesia owes its activity prob. ably to this principle and to tannic
acid.

Monesia is stomachic and feebly astringent, and has been used with asserted
advantage in diarrhea, hemoptysis, menorrhagia, scrofula, scurvy, also as a local
remedy in leucorrhrea, ulcerations of the mouth and fauces, and ulcers. It is applied to
ulcers either by being sprinkled in powder upon the surface or in the form of ointment
made with one part of the extract and seven parts of simple ointment. The dose of the
extract is from two to half an inch to an inch in diameter, and several inches long.
This is enclosed in a covering of silk or linen sewed firmly around it; and, when used,
may be cut by a razor into transverse slices a few lines in thickness. By leaving a
hole in the center of the cylinder, the combustion will be rendered more vigorous, and a
deeper eschar produced.

Cauterization by fire has been used from time immemorial among savages, half-
civilized, and intelligent communities, and is said to have been re-introduced into
Europe by the early Portuguese navigators from the Far East. Though at one time
much employed for the purposes of révulsion, this form of cauterization has fallen
into complete desuetude. The details of its application are described in the 18th ed., U.
S. D. The first sensation experienced is not disagreeable; but the operation becomes
gradually more painful, and towards the close is for a short time very severe. The pain
could probably be prevented by the use of cocaine.

**Mongumo Bark.**—For analysis of this Madagascar bark, which is said by E. M.
Holmes to resemble the bark of Ochrosia borbonica J. F. Gmel (Fam. Apocynaceæ),
see P. J., ix, 816. It was examined by Dragendorff, who found mongumic acid, resin,
waxy substance, a glucoside soluble in water and alcohol, metarabic acid, fatty
matter, calcium oxalate and a substance insoluble in alcohol and soluble in water.

**Monsonia.**—According to John Maberly (L. L., Feb., 1897; July, 1898), certain South
African plants belonging to the family of Geraniacæ, having large fleshy roots, are
valuable remedies in the treatment of both acute and chronic dysentery; such are
especially Monsonia ovata Cav. and M. Burkeana Planch., also certain Pelargoniums.
Under the name of t'Namie, the natives of Namaqualand are said to use the root of
Pelargoniumantidysentericum Kostel. Maberly believes that the Pelargoniums are
especially valuable in ulceration of the stomach and upper portions of the intestinal
tract, and the Monsonias when the disease is low down in the intestines. The dose of
monsonia is given as half an ounce (15.5 Gm.). It is believed that the plants are not
poisonous. Dose, of the saturated tincture, from one to two fluidrachms (3.75-7.5
mils) every three or four hours.

**Morinda.**—From the wood of the Morinda tinctoria Roxb. (Fam. Rubiaceæ), or
Indian Mulberry, Anderson (P. J., 1886) claimed to have obtained a glucoside
morindin, which yielded on hydrolysis trihydroxy-methyl-anthraquinone. Oesterle (A.
Pharm., 1907, cxxiv), however, was unable to find this glucoside, but did obtain a
monomethyl-ether-tri-oxymethyl-anthra-quinone, C_{16}H_{12}O_{5}. M. umbellata L., M. citrifolia L., and the M. longiflora G. Don., all yield anthraquinone derivatives. (See Barrowcliff and Tutin, Trans. British Chem. Soc., 1907.) These plants are used by the African aborigines as remedial agents, but there is no reliable evidence of their therapeutic value.

**Moxa.** Moxa, Fr. Brenncylinder, Gr.—These are small combustible masses used to produce an eschar by being burned in contact with the skin. In Japan and China they are made from the leaves or the downy hairs on the leaves and stems of one or more species of Artemisia. A. chinensis L. and A. indica Willd. (A. vulgaris L.) were indicated by the Dublin College; but Lindley states that it is the A. moxa of De Candolle which is employed. A similar moxa has been made in France, by a similar process, from the leaves of A. vulgaris. According to Percy, the dried stem of the ordinary sunflower may be used for moxa. Artificial moxas may be made by the following processes: One pound of cotton is introduced into a vessel containing two ounces of potassium nitrate dissolved in half a gallon of water, and a moderate heat applied till all the liquid is evaporated. The cotton, when perfectly dry, is formed into thin, narrow sheets, which are rolled round a central cord of linen, so as to form a cylinder from half an inch to an inch in diameter, and several inches long. This is enclosed in a covering of silk or linen sewed firmly around it; and, when used, may be cut by a razor into transverse slices a few lines in thickness. By leaving a hole in the center of the cylinder, the combustion will be rendered more vigorous, and a deeper eschar produced.

Cauterization by fire has been used from time immemorial among savages, half-civilized, and intelligent communities, and is said to have been re-introduced into Europe by the early Portuguese navigators from the Far East. Though at one time much employed for the purposes of revulsion, this form of cauterization has fallen into complete desuetude. The details of its application are described in the 18th ed., U. S. D. The first sensation experienced is not disagreeable; but the operation becomes gradually more painful, and towards the close is for a short time very severe. The pain could probably be prevented by the use of cocaine.

**Muawin Bark.**—This is the bark of a Mozambique tree, which in Eastern Africa is used as an ordeal poison. In appearance and structure it closely resembles, the erythrophloeum bark obtained from numerous species of Erythrophloeum (Fam. Leguminosae). An alkaloid, muawine, was discovered in it by E. Merck, 1891. The hydro-bromide, a yellowish powder soluble in water and alcohol. The characteristic test is said to be that with vanadinsulphuric acid, which gives with muawine first a pale green, passing into a pale blue. (H. Jacobsohn, In. Dis., Dorpat, 1892; see also Merck’s Jahresbericht, 1891.) According to Jacobsohn, the hydrobromide when injected sub-cutaneously does not cause any irritation, but produces in frogs symptoms similar to those caused by digitalin, and in warm-blooded animals slowing of the pulse, increase of the heart action, elevation of blood pressure, and contraction of the arterioles. The action of muawine is, therefore, like that of digitalin, but is distinguished by being very temporary.
MUCILAGINES

MUCILAGES

Mucilages, Fr.; Schleime, G.; Mucilagines, It.

Mucilage, in the ordinary acceptation of the term, and in the sense in which it is employed in the U. S. Pharmacopoeia, is an aqueous solution of gum, or of substances closely allied to it. In the British Pharmacopoeia (1885) the term is applied also to the semi-liquid, jelly-like substance resulting from the cooling of a hot solution of starch.

MUCILAGO ACACIAE. U. S., Br.

MUCILAGE OF ACACIA Mucil. Acac.

Mucilage of Gum Arabic; Mucilage of Gum Acacia; Mucilage de Gomme, Fr. Cod.; Mucilage arabique, Fr.; Mucilago Gummi Arabici, P. G.; Gummischleim, G.; Mucilagine di gomma arabica, It.; Mucilago de goma arabica, Sp.

“Acacia, in small fragments, three hundred and fifty grammes [or 12 ounces av., 151 grains]; Distilled Water, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Place the acacia in a tared bottle or flask having a capacity not exceeding one thousand mils [or 33 fluidounces, 6% fluidrachms], wash the drug with cold water, allow it to drain, and then add enough warm distilled water to make the mixture weigh one thousand grammes [or 35 ounces av., 120 grains]. Securely stopper the container, and agitate it from time to time until the acacia is dissolved. Strain the Mucilage and preserve it in small, well-filled bottles in a refrigerator or in a cool place. Mucilage of Acacia should be frequently made and must not be dispensed if it has become sour or moldy." U. S.

"Gum Acacia, 100 grammes; Distilled Water, 150 millilitres. Rapidly rinse the Gum Acacia with a little water; then dissolve it in the Distilled Water in a closed vessel and strain. The Mucilage should be recently prepared. In India and the Eastern Divisions of the Empire, Mucilage of Indian Gum may be employed in making the official preparations for which Mucilage of Gum Acacia is directed to be used (see ‘Gummi Indicum ’)." Br.
The gum used for this purpose should be in small fragments or coarse powder, as it is more readily dissolved in this state than when finely pulverized. Straining is necessary to separate the foreign substances which are often mixed with gum arabic. This mucilage is semi-transparent, almost colorless, if prepared from good gum, viscid, tenacious, of a feeble, peculiar odor, and nearly tasteless. By straining a solution of gum through a layer of freshly precipitated alumina it can be almost entirely decolorized, particularly if the operation be repeated several times. By keeping, the mucilage becomes sour, and this happens even though it be enclosed in well-stoppered bottles; but, according to Guerin, the solution of pure gum undergoes no change in vacuo. Heat in its preparation is said to favor the production of acid, and hence cold has been substituted for boiling water in the present formulas. The U. S. P. VIII directed the addition of lime water in making this mucilage; this addition has proved advantageous by neutralizing the acidity generally found in acacia and it promotes stability, but the U. S. P. IX process deleted the lime water. According to R. Bother (A. J. P., xliv, 113), if glycerin be employed in the proportion of one to eight of the mass, and the mixture of water and glycerin be added to the gum in a bottle and solution secured by agitation at intervals over several hours, the resulting mucilage does not spoil; the presence of glycerin is objectionable, however, for many of the uses of mucilage of acacia. E. D. Oesch (West. Drug., 1892, 38) adds about 6 per cent. of alcohol as a preservative. Keller preserves the mucilage by the addition of acetanilid (two grains in the fluid-ounce). (C. D., 1896, 378.) Archer & Co. have found (A. J. P., xlvi, 469) that if "Tolu water" be substituted for water the mucilage will keep for months. The Tolu water is made by rubbing two drachms of the tincture with magnesium carbonate and two pints of water, and filtering. Mucilage is employed chiefly in the making of pills, and in suspending insoluble substances in water. In prescribing it for mixtures, it should be recollected that it is a solution of definite strength, containing, according to the U. S. formula, half an ounce of the gum to each fluidounce of mucilage. The British mucilage is a little stronger. The adhesiveness of the mucilage is stated to be very much increased by the addition of one part of aluminum sulphate to one hundred and twenty-five parts of the mucilage, but this would not be permissible for a mucilage intended for medicinal purposes.
MUCILAGO GUMMI INDICI. Br.

MUCILAGE OF INDIAN GUM

"Indian Gum, 50 grammes; Distilled Water, 150 millilitres. Rapidly rinse the Indian Gum with a little water; then dissolve it in the Distilled Water in a closed vessel and strain. The Mucilage should be recently prepared. In India and the Eastern Divisions of the Empire, Mucilago of Indian Gum may be employed in making the official preparations for which Mucilage of Gum Acacia is directed to be used (see 'Gummi Indicum')." Br.

This mucilage was made official in the British Pharmacopoeia (1914); it is not as adhesive as the mucilage of acacia.

MUCILAGO TRAGACANTHAE. U. S., Br.

MUCILAGE OF TRAGACANTH Mucil. Trag.

"Tragacanth, six grammes [or 93 grains]; Glycerin, eighteen grammes [or 278 grains]; Water, a sufficient quantity, to make one hundred grammes [or 3 ounces av., 231 grains]. Mix the glycerin with seventy-five mils [or 2 fluidounces, 257 minims] of water in a tared vessel, heat the mixture to boiling, remove the heat, add the tragacanth, and macerate during twenty-four hours, stirring occasionally. Then add enough water to make the mixture weigh one hundred grammes [or 3 ounces av., 231 grains], beat it until of a uniform consistence, and strain it forcibly through muslin." U. S.

"Tragacanth, in powder, 1.25 grammes; Alcohol (90 per cent.), 2.50 millilitres; Distilled Water, sufficient to produce 100.00 millilitres. Mix the Tragacanth with the Alcohol; add the Distilled Water as quickly as possible, and shake vigorously." Br.

A part only of tragacanth is soluble in water. The remainder swells up and forms a soft tenacious mass, which may be mechanically mixed with water, but does not form a proper solution. Hence trituration is
necessary to complete the incorporation of the ingredients. This mucilage is thick and very viscid, but not permanent, as the water separates from the insoluble portion of the tragacanth on standing. It is chiefly used in making pills and troches. The addition of glycerin renders it more serviceable as an excipient. From its great tenacity, it may be advantageously employed for the suspension of heavy insoluble substances, such as the metallic oxides, in water. When kept long, it is apt to undergo decomposition, and to become offensive, but it will keep well if phenol be added. (A. J. P., 1864.) Lyon (P. J., 1901, 600) recommends the use of chloroform water as a preservative in making this mucilage; this is preferred in all cases if the mucilage is not to be used internally. The alcohol in the British process facilitates the quick production of the mucilage, and in addition acts as a preservative.

**Mucuna.** Mucunapruriens De Cand. Cowhage. Cowage. SetaeSiliquaeHirsutae. Pois veins, Pois a gratter, Fr. Kratzbohnen, Kuhkratze, G.—This is a leguminous climbing plant which grows in the West Indies and tropical countries of both hemispheres. The fruit is a coriaceous pod, shaped like the Italic letter f, about four inches long, and covered with brown bristly hairs, which easily separate, and when handled stick in the fingers, producing an intense itching sensation.

The spicula are said to be very destructive to the round worm, acting mechanically by penetrating their bodies. Neither the tincture nor the decoction is effective. Cowhage is efficient, but so disagreeable that it has passed out of vogue. The usual mode of preparing it is to dip the pods into syrup or molasses, and scrape off the hairs with the liquid, which is in a proper state for administration when it has attained the consistence of thick honey. The dose of this preparation is a tablespoonful (15 mils) for an adult, a teaspoonful (3.75 mils) for a child three or four years old, to be given every morning for three days, and then followed by a brisk cathartic.

**Muira-Puama.**—The wood of a Brazilian tree, believed to be from Liriosma ovata Miers (Fam. Olacaceae), which, according to Th. Peckolt, contains an alkaloid, muira-puamine, and is used by the Brazilian aborigines as an aphrodisiac, also in the treatment of dysentery. In impotence, ten to twenty minims (0.6-1.3 mils) of the fluidextract may be taken three or four times a day. (See M. R., 1902.)

**Mulberry.**—There are in the United States three species—the indigenous Morus rubra L., with dark purple fruit; M. alba L., introduced from Europe, and at one time extensively cultivated as a source of food for the silk worm, having a white fruit; and M. nigra L., a tree of middle size, supposed to have been brought originally from Persia into Italy and widely cultivated. The fruit of the last species has a sweet, mucilaginous, acidulous taste, and abounds in a deep red juice having the sp. gr. 1.060. (Mori Sucous, Br., 1885.) For analysis of mulberries see U. S. D., 19th ed., p. 1573. In amount of grape sugar the mulberry is surpassed only by the cherry, 10.79, and the grape, from 10.6 to 19.0. Mulberries are refreshing and laxative, and serve to
prepare a grateful drink well adapted to febrile cases.

**Muscari.** Muscari comosum (L.) Mill. (Fam. Liliacee.)—In the bulbs of this plant Curd (Rept. de Pharm., March, 1889) has found comosic acid, which he believes to act physiologically like saponin.

**Musamma Abyssinica.**—A substance known as taeniol which is claimed to be derived from the rind of the Musamma abyssinica, has been recommended as a vermifuge especially for the treatment of anchylostoma. According to Liermberger (B. K. W., 1905, p. 390), it is an efficient and non-toxic anthelmintic. The only unpleasant symptom produced was slight giddiness. It is marketed only in the form of capsules of which 10 to 15 may be taken at intervals of ten minutes. After the sixth or seventh capsule there should be allowed an interval of an hour.

**Mushrooms and Toadstools.** (Edible and Poisonous Fungi.) —Notwithstanding the fact that it has been shown that edible fungi, when compared with other articles of food, do not possess a high food value, the interest in the study of the Fungi, as well as the consumption of edible forms, is constantly increasing. The study of the fungi is one of the most highly specialized, as there have been up to the present time no less than 64,000 species described. From a food standpoint the differentiation of the edible from the poisonous is one of the most difficult that the novice can undertake, as it is almost impossible to lay down any invariable rules.

The fungi are divided into a number of classes, each of which is again subdivided into sub-classes, series, and families. The family of Basidiosporae include the largest and most conspicuous of the fungi and all of the mushrooms and toadstools. It is commonly believed that mushrooms are edible and that toadstools are poisonous; in reality, however, no such distinction should be made. The plants of the Hymenomycetes are characterized in general in that they arise from a mass of colorless threads, known as "mycelium" or "spawn," produced in the ground, bark of trees, etc. Their first appearance above ground is marked by the production of small solid balls (called buttons), which gradually enlarge, and at length shoot up into a stem or stipe bearing at its summit the umbrella top or "pileus," which is at first closed around the stalk like a closed umbrella and then expands more or less widely, according to the species. The under side of the pileus is the part which bears the spores, which correspond to the seeds of higher plants. In some cases the under surface consists of a series of gills resembling knife blades, which radiate from the top of the stalk to the circumference, like the spokes of a wheel, as in Agaricaceae; in others it consists of a mass of small pores or tubes packed closely together, side by side, as in Polyporaceae; in others of teeth, as in Hydnaceae; in others only slightly wrinkled or undulated, as Thelephoraceae, etc. The Basidiosporae include about 14,000 species which are included in nine orders and subdivided into twenty-five families. A few of the important are the following:

1.—Agaricaceae (the mushrooms and toadstools proper) comprises about 4600 species, some of which are poisonous, as the Amanitas (Fly and Deadly Agarics) Lactarius (with a milky juice), whereas others are edible, as Agaricus (Psalliata)
campestris L., the common mushroom, Cantharellus cibarius, Fr., etc.

2.—Polyporaceae (pore-fungi) includes about 2000 species, many of which are parasites on trees and destructive to timber; some are edible, as Boletus edulis Bull., whereas others are poisonous, as B. satana Lenz.

3.—Hydnaceae (teeth-bearing fungi); Most of the species are too small and woody to be eaten. Hydnum repandum forms "fairy rings" in woods.

4.—Thelephoraceae: Most of the species are small, and the larger species are tough and leathery.

5.—Clavariaceae (coral-shaped fungi) includes some large fungi; none are poisonous and some, as Clavaria flava Schaeff., are palatable.

Of these, the most important group are the Agaricaceae, both from the point of view of the toxicologist and the epicure.

It is not possible in this limited space to even mention the various poisonous and edible fungi that experience has demonstrated as such. The number of species which have been eaten or experimented with, however, is small compared to the number recognized by botanists. Many students of fungi have formulated rules for distinguishing edible from poisonous fungi. "The different popular tests for distinguishing edible from poisonous fungi, such as, for instance, the blackening of a silver coin or spoon when placed in a mass of poisonous fungi while they are being cooked, are all absolutely worthless." The only safe rule is to use no mushroom which the collector is not absolutely sure from previous experience is edible.

The common mushroom (Agaricus campestris L.) is practically the only species cultivated in this country, and is the only fresh species sold in the northern markets during the winter months. It is found wild in open grassy fields and pastures in great abundance in August and September. It is not common on the mountains, never found in woods, and never grows on trees or fallen trunks. The color of the stalk and pileus varies from a whitish shade to drab, but the color of the gills, a point which should never be overlooked, is at first pinkish and then a brownish-purple. The stalk is cylindrical and solid, and has, rather more than half way up, a membranous collar called the ring; but there is no membrane or scales found at the base of the stalk, which appears to come directly out of the ground. "In specimens which are not fully expanded there is a thin membrane or veil which extends from the stalk to the margin of the pileus. When the veil is ruptured, exposing the gills behind, a part remains attached to the stalk, forming the ring already referred to. In older specimens the ring shrinks, but generally a mark remains showing where it has been attached."

Two of the most poisonous forms resembling the common mushroom, and which have been eaten in mistake for it, are the deadly agaric and fly agaric.

The fly agaric (Amanita muscaria (L.) Pers.), so called because decoctions have been used for killing flies, is in some localities much more abundant than the common
mushroom. It is seldom found in the grassy pastures preferred by the common mushroom, but more generally in poor soil, especially in groves of coniferous trees. "It grows singly and not in groups and differs from the common mushroom in having gills which are always white, never pink or purple and in having a hollow stem, which is bulbous at the base and cloathed with irregular fringy scales on all the lower part. The pileus varies in color from a brilliant yellow to orange and a deep red, the yellow arid orange being more frequent than the red. The surface ia polished, and has scattered over it a larger or smaller number of prominent, angular warty scales which can be easily scraped off. The gills and stalks are white, and there is a large membranous collar which hangs down from the upper part of the stem."

The deadly agaric (Amanita phalloides (Pers.), Fr.), so named because it probably has been more frequently the cause of death than any other fungus, prefers a damper and less sandy soil than the fly agaric and is not pre-eminently an inhabitant of grassy pastures. " The pileus is often a shining white, but may be of any shade from a dull yellow to olive, and when wet is more slimy than the common mushroom or the fly agaric. It has no distinct scales and only occasionally a few membranous patches on the pileus. The gills and stalks are white, and the latter has a large ring like the fly agaric and is hollow, or when young, is loosely filled with cottony threads, which soon disappear. The base of the stalk differs from that of the fly agaric in being more bulbous and in having the upper part of the bulb bordered by a sac-like membrane called the volva. The volva is often of considerable size but more frequently is reduced to a membranous rim."

The list of edible and poisonous fungi are relatively long, and while most belong to the Hymenomycetes, some are also yielded by the Gasteromycetes, as the puff-balls. The giant puff-ball, Lycoperdon bovista (L. giganteum Batsch), is found in the region of San Francisco Bay, not rarely forty inches in diameter.

We may conveniently consider the poisonous mushrooms in four groups following the divisions of Kobert. (Über Pilzvergiftung, 1891.)

In the first group is the genus Lactarius which owe their toxic properties to the presence of an irritant resin. Some of this genus, as L. deliciosus, are stated to be edible, but most of them produce severe or even fatal gastric enteritis.

The second group contains species belonging to the genus Helvellae, whose juice contains helvellaic acid, isolated by Boehm. It is asserted that these fungi, when thoroughly dried are not poisonous, and that hot water also extracts from them the poisonous acid, so that boiling makes them edible. The chief physiological action of the acid seems to be to destroy the red blood corpuscles, and, probably by such action, to produce vomiting, hemoglobinuria, jaundice, irritation of the kidneys, etc.

The third and most important group are the Amanitas. They are the most common source of mushroom poisoning, not only because of their resemblance to many of the edible species, but also because of the virulence of their effects. The most important of this species is the A. phalloides, or skunk mushroom. According to Ford (J. P. Ex. T., 1910,1, p. 275), they contain two poisonous substances, one being hemolytic, and the
other causing degenerative changes in the various internal organs, especially the liver, kidney, spleen and muscles. The Amanita-hemolysin, which is probably identical with the Phallin of Kobert, appears to be glucosidal, and because it is destroyed by heat, probably plays little part in human poisoning. The nature of amanita-toxin is not yet determined, but poisons of a similar nature appear to be widespread throughout the whole of the genus.

In the fourth group are included those which contain muscarine. This alkaloid was first obtained from the Amanita muscaria, but is also found in the A. pantherina, the Russula, emetica, in Boletus luridus, B. Satanus, and, according to Ford (J. P. Ex. T., 1911, ii, p. 549), occasionally also in the Clitocybe dealbata, which has by some been classed as an edible fungus. Decoctions of the Amanita muscaria are used to poison flies, whence the common name of the fly agaric. The inhabitants of the Caucasus also use this fungus as an intoxicant. The A. pantherina is used in Japan for like purposes.

Muscarine was first obtained in a state of purity by Schmiedeberg and Koppe. (Das Muscarin, Leipzig, 1869.) The alkaloid may be produced artificially by gently heating choline platino-chloride with strong nitric acid. Potassium chloride is used to decompose the muscarine platino-chloride and produce muscarine hydrochloride; treatment with moist silver oxide yields the muscarine as a hydrate (CsH_{15}O_{3}NH_{2}O). Muscarine resembles pilocarpine in its physiological action, and is antagonistic to atropine. It increases the secretions of the sweat, salivary and lachrymal glands, contracts the pupil, slows the pulse, and causes motor weakness. The reduction in the pulse rate is due to stimulation of the pneumogastric nerve, and after very large doses diastolic arrest occurs. If atropine be given so as to paralyze inhibition the cardiac movements reoccur. The vasomotor nerves are said to be paralyzed. There is a stimulation of the muscles of the intestines, bladder and spleen. Thus the intestines are transformed into hard, white cords, or afterwards, becoming somewhat relaxed, exhibit a tumultuous peristalsis. The abdominal secretions are greatly increased.

The symptoms of mushroom poisoning will vary greatly according to the special fungus which has been ingested. In the case of the deadly agaric (Amanita phalloides) which is the most common source of toadstool poisoning, the symptoms usually do not appear for several hours after the fungus has been eaten. They consist of great prostration and collapse, cold sweats, stupor, sometimes preceded by delirium, convulsions, frequently cyanosis and not rarely icterus. There is usually, also distinct fever and either hemoglobinuria or methemoglobinuria, and evidence of irritation of the kidney is shown by the presence of albumen, or partial suppression of the urine. When the poisoning is produced by fly agaric, to these symptoms will be added those of muscarine poisoning, namely, profuse salivation, contracted pupils and slowing of the pulse. In the poisoning by the lactarii the symptoms are those simply of violent inflammation of the alimentary tract, vomiting, purging and collapse. In poisoning by the Helvellae the symptoms resemble those produced by the Amanitas.

Little can be done to save the patient. Our utmost efforts should be directed to preventing absorption. A promptly acting emetic, such as apomorphine, should be
administered to produce vomiting. Secheyon (P. J., 1910, lixiv, p. 492) highly recommends animal charcoal for the purpose of absorbing the poison, and thus preventing its entrance into the system. At least a table-spoonful, stirred up in water, should be administered, and repeated libitum. It is also advisable to administer atropine hypodermically in one-sixtieth-grain doses (1 mgm.), as it is the physiological antagonistic to muscarine, and may prove a life-saving remedy in poisoning by fly agaric, and by its general stimulant effect will also exercise a feeble influence in combating the collapse even although due to other forms of poisoning. A rapidly acting cathartic should also be administered to cleanse the intestinal tract. Aside from these measures, the treatment is purely symptomatic—the use of opium if necessary to check the diarrhea and vomiting, and various stimulants to maintain the circulation and respiration.

B. W. Richardson, having noticed that the smoke of the Lycoperdon Proteus or puff-ball was used for stupefying bees, found that the inhalation of the fumes caused various animals to become insensible. He has himself inhaled the fumes clarified by passing them through water, and experienced symptoms of intoxication and drowsiness. (M. T. G., 1853, 610.) Thornton Herapath, however, maintains, as the result of his experiments, that these anesthetic effects are in reality not owing to any narcotic principle present in the fungus, but to the carbon dioxide gas generated during their combustion. (Philos. Mag., July, 1855.)

**Mutisia.** Mutisia viciaefolia Cav.—This composite, a native of Chile, is stated to be a valuable anti-spasmodic, useful in hysteria and croup; it is also a cardiac tonic.

**Myrica.** N.F. IV. Myrica cerifera L. Wax Myrtle. Bayberry. Candle Berry. Arbre a suif, F. Wachsbaum, Wachsgagel, G.—"The dried bark of the root of Myrica cerifera Linne (Fam. Myricaceae), without the presence of more than 5 per cent. of adhering wood." N. F. IV.

This is an indigenous myrtaceous shrub growing in great abundance in the sandy soil along the seashore, and even on the shores of our northern lakes. The leaves of the wax myrtle have resinous dots on both sides, and are very fragrant when rubbed. The fruit is covered with a coating of white wax, and sometimes continues on the plant for two years or more. The coating of wax upon the surface is collected, and known in commerce as myrtle wax. (See Vegetable Wax.)

For a study of the Myricaceae of the Eastern United States, see Youngken. (A. J. P., 1915, p. 391.) The bark of the stem and root is supposed to possess valuable remedial properties, and has been employed to a considerable extent. It yields its virtues to water and alcohol. George M. Ham-bright found in it volatile oil, starch, lignin, gum, albumen, extractive, a red coloring substance, tannic and gallic acids, an acrid resin soluble in alcohol and ether, an astringent resin soluble in alcohol and not in ether, and a peculiar acrid principle having acid properties. (A. J. P., 1863, 193.) Myrtle wax consists of the glycerides of stearic, palmitic, and myristic acids and a small quantity of oleic acid. (Lewkowitsch, Oils, Fats, and Waxes, p. 542.)
The National Formulary IV describes the bark as: "In quills or quilled pieces or strips, of variable length and up to 20 nun. in breadth, the bark rarely exceeding 2 mm. in thickness; outer surface varying from dark-brown to gray-brown, occasionally slightly silvery, somewhat lustrous, at least in patches, bearing occasional warts or slight transverse ridges, the periderm frequently much wrinkled; inner surface deep rusty-brown, finely short-striated and somewhat roughened; fracture short and weak, light brown in the outer layer, yellowish-brown in the inner layer. Odor characteristic, rather disagreeable; taste astringent, mildly bitter and slightly acrid." N. F. IV.

The bark appears to be moderately tonic and astringent, and in large doses emetic, it has been considerably used by the eclectics in diarrhea, jaundice, scrofula, etc. Externally the powdered bark is used as a stimulant to indolent ulcers, and the decoction as a gargle and injection in chronic inflammation of the throat, leucorrhœa, etc. Dose of the powder, twenty to thirty grains (1.3-2.0 Gm.), of a decoction (one ounce to one pint), one or two fluidounces (30-60 mils). An alcoholic extract, very inappropriately named myricin, is given in the dose of about five grains (0.32 Gm.).

From the bark of Myrica Nagi Thunb., the yellow coloring matter of which is known as myricetin, A. G. Perkin has separated a glucoside, myricetrin, closely resembling quercitrin. (See Proc. Chem. Soc., xviii, 11.) For analysis of the rhizome, Myrica asplenifolia L., see A. J. P., 1892, 303.

The leaves of the Myrica Gale L. (sweet gale) or Dutch myrtle have been used in France as an emmenagogue and abortifacient, and were formerly official in that country under the name of Herba Myrti Rabantini. They contain a poisonous volatile oil.

**MYRISTICA. U. S., Br.**

**MYRISTICA Myrist. [Nutmeg]**

"The ripe seeds of Myristica fragrans Houttuyn (Fam. Myristicaceae), deprived of the arilli and seed-coats. Preserve the kernels in tightly-closed containers, adding a few drops of carbon tetrachloride or chloroform from time to time to prevent attack by insects. Reject broken or wormy kernels." U. S. "Nutmeg is the dried kernel of the seed of Myristica fragrans, Houtt." Br.

The nutmeg tree is about thirty feet high, with numerous branches, and an aspect somewhat resembling that of the orange tree. The leaves are alternate, petiolate, oblong-oval, pointed, entire, bright green and somewhat glossy on their upper surface, whitish beneath, and of an
aromatic taste. The staminate and pistillate flowers are upon different trees. The former are disposed in axillary, peduneled, solitary clusters; the latter are single, solitary, and axillary; both are minute and of a pale yellowish color. The fruit, which appears on the tree mingled with the flowers, is round or oval, of the size of a small peach, smooth, at first pale green, but yellow when ripe, and marked with a longitudinal furrow. The external covering, which is at first thick and fleshy and abounds in an austere, astringent juice, afterwards becomes dry and coriaceous, and, separating into two valves from the summit, discloses a scarlet reticulated membrane or arillus, commonly called mace, closely investing a thin, brown, shining shell, which contains the kernel or nutmeg. The nutmeg tree is a native of the Moluccas and other neighboring islands, and abounds especially in that small cluster distinguished by the name of Banda, whence the chief supplies of nutmegs were long derived. But numerous varieties of the plant are now cultivated in Sumatra, Java, Singapore, Penang, Ceylon, and other parts of the East Indies, and have been introduced into the Isles of France and Bourbon, Cayenne, and several of the West India islands. Various species of the genus Myristica, other than those which are official, yield commercial seeds or products:

The larger part of the nutmegs of commerce is said still to come from the Dutch Banda Islands. The Penang nutmegs are distinguished by not being limed. The tree is produced from the seed. It does not flower until the eighth or ninth year, after which it bears flowers and fruit together, without intermission, and is said to continue bearing for seventy or eighty years. Little trouble is requisite in its cultivation. A branch of the staminate tree is grafted into all the young pistillate plants when about two years old, so as to insure their early fruitfulness. J. H. Hart presented an interesting report (Bull. Bot. Dept., Trinidad, 1907, p. 202) showing that 16-year-old nutmeg trees growing in Trinidad bear both staminate and pistillate flowers. Indeed, he found both kinds of flowers on the same branch of the tree, and he therefore suggests that an attempt should be made to perpetuate this variety by grafting.

In the Moluccas the tree yields three crops annually. The fruit is gathered by hand, and the outside covering rejected. The arillode, constituting the mace of commerce, is then carefully separated, so as to break it as little as possible. It is flattened, dried in the sun, and afterwards sprinkled with salt water, with the view of contributing to its preservation. The nuts are dried in the sun or by ovens, and exposed to
smoke until the kernel rattles in the shell. They are then broken open, and the kernels, having been removed and steeped for a short time in a mixture of lime and water, in order to preserve them from the attacks of worms, are now cleaned, and packed in casks or chests for exportation. Lumsdaine has found them to keep better if rubbed over with dry lime than when prepared in the moist way. (See Am. J. Sci., Nov., 1851.) Tschirch confirms the value of liming as a preservative against the attacks of insects. (Ph. Rev., 1898, 196.) This is, however, not sufficient protection, as the commercial nutmegs are sometimes "wormy." Nutmegs are brought to this country either directly from the East Indies or indirectly' from England and Holland. They are also occasionally imported in small quantities from the West Indies.

The amount of unground nutmegs imported into the United States averages about two million pounds a year.

Properties.—Myristica is officially described as "ovoid or ellipsoidal, from 20 to 30 mm. in length and about 20 mm. in thickness; externally light brown to dark brown, reticulately furrowed, the broad end with a large, circular upraised scar from which arises a furrow extending to the chalaza; easily cut, the surface having a waxy luster and mottled by reason of the light brown perisperm penetrating into the yellowish-brown endosperm; a longitudinal section through the endosperm above the large scar shows a small irregular cavity with the more or less shrunken remains of the embryo, and usually containing a growth of mold; odor and taste agreeably aromatic. The powder is dark reddish-brown; consisting of irregular, yellowish-brown or brownish-black fragments; fragments of perisperm yellowish-brown with large, circular or elliptical oil reservoirs containing a volatile oil, small, thin-walled parenchyma cells, and occasional spiral tracheae; parenchyma cells of endosperm more or less polygonal and filled with starch grain and aleurone grains; starch grains single or compound, the individual grains being spherical, plano-convex or polygonal, from 0.003 to 0.02 mm. in diameter and colored blue with iodine T.S. (distinction from starch grains in mace, which are colored yellowish-red); mounts in hydrous chloral T.S. show numerous globules of a fixed oil which later may separate in the form of rod-like crystals; mounts in fixed oil show the separation of spheroidal aggregates of crystals which polarize light strongly. The powder made from 'limed' nutmegs show under the microscope, upon the addition of water containing 25 per cent. of sulphuric acid, the immediate separation of crystals of calcium sulphate.
in the form of small needles or short rods which do not polarize light. Myristica yield's not more than 5 per cent. of ash." U. S.

" Broadly oval or rounded, rarely more than twenty-five millimetres long; greyish-brown externally, marked with reticulated furrows, and minute black points and lines; internally greyish-red with darker brownish-red veins. Transverse section marbled. Strong aromatic odor; taste aromatic, warm and somewhat bitter." Br.

The microscopical structure of nutmeg and mace have been well illustrated by Winton and Moeller in the "Microscopy of Vegetable Foods." Spaeth has recently made an interesting contribution to the pharmacognosy of nutmeg and the detection of the prevalent adulterations in Ph. Zentralh., xlii, p. 627. It has been stated that much of the ground nutmeg of commerce has been made from small, stunted and worthless nutmegs, so-called "grinding nutmegs." The powdered drug is sometimes adulterated with corn meal, powdered beans, curcuma and various nut-shells.

Under the names of long, female, or wild nutmeg, Macassar nutmeg, Papua nutmeg, New Guinea nutmeg, horse nutmeg, certain seeds have long been known in European commerce; they have finally become an important article of trade, nearly 77,000 kilos of them having been sold in Holland in the year 1894. These seeds have been variously ascribed to M. fatua Houtt. (M. tomentosa Thumb., M. macrophylla Roxb.), and other species of the genus Myristica, but by Bassermann and Warburg have in all their varieties been traced to the M. argentea Warburg, of New Guinea, from which country they are often taken to Macassar to finally enter commerce as Macassar nutmegs. (P. J., 1898, 97.) The numerous varieties of these false nutmegs are readily reducible to two, which differ chiefly in size, the larger being commonly known as the Papua nuts, the smaller as the Macassar nuts. They are distinguished from the nutmeg by their greater length, their elliptical shape, their comparatively feeble odor and disagreeable taste, and by the absence of the dark brown veins. (Holmes, P. J., Ixxxii, p. 459.) Heckel has described two new so-called wild nutmegs from Madagascar. (Rep. d. Pharm., 1909, p. 49.)

Clifford Richardson (Bulletin U. S. Dept. Agriculture, No. 13, 1887) gives as the average of three analyses of imported nutmegs: water, 5.56 per cent.; ash, 2.88; volatile oil, 3.23; fixed oil or fat, 34.22; starch, etc.,
The concrete or expressed oil of nutmeg (Oleum Myristicae Expressum, Br., 1885), often called oil of mace, or nutmeg butter, is obtained by bruising nutmegs, exposing them in a bag to steam, and then compressing them strongly between heated plates. A liquid oil flows out, which becomes solid when it cools. Nutmegs are said to yield from 10 to 12 per cent. of this oil, but Fliickiger and Hanbury obtained as much as 28 per cent. (See analyses of Richardson, quoted previously.) A process for obtaining it by means of carbon disulphide has been proposed by Lepage, of Gisors, in France, and has received the sanction of the Society of Pharmacy of Paris. It consists in treating the nutmeg, thoroughly comminuted, with three times its weight of the well-rectified liquid referred to, agitating the mixture frequently for 24 hours, expressing, repeating the process with two parts only of the menstruum, mixing the products of the two macerations, filtering in a covered vessel, and then distilling off the disulphide until the residue is entirely deprived of the solvent. (J. P. C., 3e ser., xxxi, 28.) It would seem difficult to prevent the retention of a little of the solvent. The best nutmeg butter is imported from the East Indies in stone jars, or in rectangular blocks 10 inches long by 2 inches wide, wrapped in palm leaves. It is solid, soft, unctuous to the touch, of a yellowish or orange-yellow color, more or less mottled, with the odor and taste of nutmeg. It is composed, according to Schrader, of 52.09 per cent. of a soft oily substance, yellowish or brownish, soluble in cold alcohol and ether; 43.75 of a white, pulverulent, inodorous substance, insoluble in these liquids; and 4.16 of volatile oil. The pulverulent constituent, which received from Playfair the name of myristin, has a silky luster, melts at
31° C. (88° F.), and yields on saponification glycerin and myristic acid, 
\( C_{14}H_{28}O_2 \). Myristin, \( C_3H_5(OC_{14}H_{27})_3 \), is a true fat, or glyceryl 
myristate. It is also found in spermaceti, in cocoanuts, and in the fixed 
oil of linseed and poppy oil. It may be obtained directly from nutmeg by 
exhausting it by means of benzene, filtering the liquid, and allowing it 
to crystallize by spontaneous evaporation. To purify the product, it may 
be dissolved in a mixture of two parts of absolute alcohol and three of 
benzene with the aid of heat, then filtering the liquid while hot, and 
setting it aside. On cooling, it deposits the pure myristin in crystals. (J. 
P. C., June, 1859, p. 471.) Analyzed by Koller, the expressed oil was 
found to contain, in 100 parts, 6 of a volatile oil analogous to the oil of 
mace, 70 of myristin, 20 of olein, 3 of resin, and 1 of salts, etc. (A. 
Pharm., clxxiii, 280.) Wallach found in the volatile oil pinene and 
dipentene of the class of terpenes and Semmler found myristicol, 
\( C_{10}H_{16}O \), which is liquid, and myristicin, a solid ester of the composition 
\( C_{12}H_{14}O_3 \). An inferior kind of the oil is prepared in Holland, and 
sometimes found in commerce. It is in hard, shining, square cakes, 
lighter-colored than that from the East Indies, and with less odor and 
taste. It is supposed to be derived from nutmogs previously deprived of 
most of their volatile oil by distillation. An artificial preparation is 
sometimes sold for the genuine oil. It is made by mixing various fatty 
matters, such as suet, palm oil, spermaceti, wax, etc., adding some 
coloring substance, and giving flavor to the mixture by the volatile oil.

Ucuhula nut is a round or oval seed of Myristica surinamensis. It is one-
half to two-thirds of an inch in diameter, light brown, but usually 
covered by a blackish, thin, friable testa. Internally it resembles the 
nutmeg, but is distinguished by the presence of extraordinarily large 
and handsome albuminous crystalloids. These seeds are said to contain 
over 70 per cent. of a solid yellow fat, melting at 36° C. (96.8° F.). (See A. 
J. P., 1886; also A. Pharm., July, 1888.) The kernel of the fruit of the 
Brazilian Myristica officinalis Mart. (M. Bicuhyba Schott), resembles 
the nutmeg in form and structure, but is covered with a black shell 
marked with broad furrows. It contains crystals like those above spoken 
of, but less splendid and regular, and apt to be in three forms. It yields a 
fat (bicuhyba fat, or bicuhyba balsam) very much like that of the 
ordinary nutmeg, but having a rather sour, sharp taste, melting at 47° 
C. (116.6° F.). It contains a peculiar fatty acid, bicuhybasteeric acid. The 
otoba fat is the product of the fruit of Myristica Otoba. It is almost 
colorless, when fresh has a nutmeg-like odor, melts at 38° C. (100.4° F.),
and contains myristin, olein, and otobite. The latter principle crystallizes in shiny, colorless crystals, melting at 133° C. (271.4° F.). The fruit of Virola sebifera Aubl. (s. Myristica sebifera Lam.), also yields a fatty substance which is known as ocuba wax. The so-called California nutmeg is not a nutmeg at all, but the seed of a coniferous tree, Torreya californica. It is oblong, with a smooth, brownish, thin testa, and affords a marbled cross-section. Its odor and taste are terebinthinate. Neither are the Jamaica or calabash nutmeg, from Monodora Myristica, the New Holland or plume nutmeg, from Atherosperma moschata, and the clove nutmeg, from Agathophyllum aromaticum, true nutmegs.

**Uses.**—Nutmeg owes its medicinal and toxic properties solely to the volatile oil which it contains. Powdered nutmeg is rarely used in medicine alone, although it enters into the composition of a number of galenicals. The expressed oil is occasionally used as a gentle external stimulant and was an ingredient in the Emplastrum Picis of the 1885 British Pharmacopoeia. Mace possesses properties essentially the same as those of nutmeg.

Dose, five to twenty grains (0.32-1.3 Gm.).

**MYROBALANUM. Br.**

**MYROBALANS**

"Myrobalans are the dried immature fruits of Terminalia Chebula, Retz., usually distinguished in commerce as Chebulic myrobalans." Br.

Five varieties of these East India fruits are distinguished by authors. The most important are as follows: (1) Myrobalani Chebula. This is the only variety which is official. It is produced by the Terminalia Chebula Retz (Buceras Chebula). This by some is believed to be identical with the T. Bellerica noted below. The fruit is roundish or ovate, varying in size.
from that of a hazel nut to that of a walnut. It consists of an exterior firm fleshy portion and an interior kernel which is light brown, inodorous and with a bitterish, astringent taste.

(2) Myrobalani Bellericae. This is obtained from the T. Bellerica Roxb. It closely resembles the previous variety but is of a more grayish brown color and is sometimes supplied with a short thick foot stalk which is lacking in the official form.

(3) Myrobalani citrinae vel flava. These are from a variety of the same tree which affords the chebula myrobalans, from which they differ only in being somewhat smaller, of a light brown or yellowish color, and of a taste rather more bitter. They were formerly sometimes sold in the shops of Philadelphia, under the name of white galls, to which, however, they bear no other resemblance than in taste.

(4) Myrobalani indices vel nigrae. These are thought to be the unripe fruit of T. Buceras (Bucida Buceras). They are ovate-oblong, from four to eight lines long and from two to three lines thick, of a blackish color, wrinkled longitudinally, and presenting, when broken, a thick brown mass, without kernel, but with a small cavity in the center. They are sourish and very astringent.

(5) Myrobalani emblica. This variety is wholly different from the preceding, and derived from a plant having no affinity to the Terminaliae, of the fam. Combretaceae—namely, the Phyllanthus Emblica L. (fam. Euphorbiaceae).

Myrobalans are officially described in the Br. Pharm., 1914, as "irregularly ovoid or fusiform, from ten to thirty millimetres or more long and from five to fifteen millimetres wide; strongly shrivelled longitudinally, dark brown or nearly black; in transverse section dark, with a small central cavity; hard. No odor; taste very astringent." Br.

When the fruit is entire, it is blackish, spherical depressed, of the size of a cherry, presenting six obtuse ribs with as many deep furrows, and separating into six valves, and has a strongly astringent and acidulous taste. It is often in segments, as found in commerce. These fruits contain about 40 per cent. of tannin which is identical with gallotannic acid. They have occasionally been used for the commercial manufacture of tannin. The resulting product is less pure, however, than that from nut
Uses.—Myrobalans were in high repute with the Arabians, and were long employed by European practitioners, as primarily laxative and secondarily astringent, in various complaints, particularly diarrhea and dysentery. Pierre Apery states that when roasted they are still used in Turkey with excellent results in intestinal catarrhs. (R. T., Dec., 1887.) Although the myrobalans are of various origin, they all probably depend for their physiological activity upon the presence of gallotannic acid. Procter states that they contain from 30 to 35 per cent. of gallotannic and ellagitannic acids.

The ointment is used as a local astringent.

The internal dose of myrobalans is one-half to one drachm (2.0-3.9 Gm.), given in the form of a powder.

Off. Prep.—Unguentum Myrobalani, Br.; Unguentum Myrobalani cum Opio, Br.

MYRRHA. U. S., Br.

MYRRH Myrrh. [Gum Myrrh]

"A gum-resin obtained from one or more species of Commiphora (Fam. Burseraceae)." U. S. "Myrrh is an oleo-gum-resin obtained from the stem of Commiphora Myrrha, Holmes, and probably other species." Br.

Arabian or Somali Myrrh, Herabol Myrrh; Gummi Resina Myrrha; Myrrhe, Fr. Cod.; Myrrha, P. G.; Myrrhe, G.; Mirra, It., Sp.; Murr, Ar.; Bowl, Hindost.

Though myrrh has been employed from the earliest times, it is still uncertain by what plant it is yielded. The Amyris Kataf of Forskhal, seen by that traveller in Arabia, was supposed by him to be the myrrh tree, but without sufficient proof. Afterwards Ehrenberg met on the frontiers of Arabia Felix with a plant from the bark of which he collected a gum-resin precisely similar to the myrrh of commerce. From the specimens of the plant taken by Ehrenberg to Germany, Nees von Esenbeck referred it to the genus Balsamodendron of Kunth, and
named it Balsamodendron Myrrha. It was not thought by De Candolle sufficiently distinct, but is now generally recognized under the name of Commiphora, first given it by Jacquin in 1797, and therefore preceding the name of Kunth by some 27 years. Berg found another species in Ehrenberg’s collection, to which was attached a label by the discoverer, stating that he had collected myrrh from it, and proposed to call it Balsamodendron ehrenbergianum. (A. J. P., 1873, 314.) Both Oliver and Trimen agree that this plant is not specifically distinct from B. Opobalsamum. It is probable that there are gum resins from several species of the Commiphora which furnish commercial myrrh. Hildebrand (P. J., 1878, ix, p. 893) collected the C. Myrrha on the north Somali coast in 1873, and presents evidence to show that it yields myrrh. Although this view has been disputed, E. M. Holmes (Y. P. B., 1913, p. 453) supports it and this species is recognized by the British Pharmacopoeia. Deflers and Schweinfurth (Ber. d. Pharm Ges. zu Berlin, 1893), however, believe that genuine myrrh is yielded by Commiphora abyssinica (Berg.) Engl, which is found in Southern Arabia, Erithrea, and Northern Abyssinia. C. Schimperi (Berg.) Engl, occurring in the Yemen, Abyssinia, and from Kern to Tigre, is likely also to yield some of the commercial Arabian myrrh. It appears to be established that C. Myrrha produces myrrh, but it is probable that it is also yielded by other trees belonging to the genus Commiphora, which genus includes more than 60 species, natives of Arabia and Africa.

Commiphora Myrrha (Nees) Engler (Syn. C. Myrrha Holmes) is a small tree, with a stunted trunk, covered with a whitish-gray bark, and furnished with rough abortive branches terminating in spines. The leaves are ternate, consisting of obovate, blunt, smooth, obtusely denticulate leaflets, of which the two latter are much smaller than the one at the end. The fruit is oval-lanceolate, pointed, longitudinally furrowed, of a brown color, and surrounded at its base by the persistent calyx. The tree grows in Arabia Felix, in the neighborhood of Gison, in dwarfish thickets, interspersed among the Acaciae and Euphorbiae. The juice concretes spontaneously upon the bark.

Formerly the best myrrh was brought from the shores of the Red Sea by way of Egypt and the Levant, and hence received the name of Turkey myrrh, while the inferior qualities were imported from the East Indies, and were commonly called India myrrh. These titles have ceased to be applicable, as myrrh of all qualities is now brought from the East Indies, whither it is carried from Arabia and the northeastern coast of Africa.
Aden in the former region, and Berbera in the latter, would appear, from the statements of James Vaughan, to be the chief entrepots of the trade. (P. J., xii, 226.) It is usually imported in chests containing between one and two hundred-weight. Sometimes the different qualities are brought separate, but oftener more or less mingled. Only the best kind should be selected for medicinal use.

There are several varieties of myrrh recognized in commerce. The official description corresponds to that of that known as the Arabian myrrh or Somalian myrrh.

Another variety of myrrh coming from Arabia known as the Fahdi myrrh is described in the Pharmacographia as "occurring in irregular masses, seldom exceeding 1 1/2 inches long, and having a somewhat gummy-looking exterior. The larger lumps seem formed by the cohesion of small, rounded, translucent, externally shining drops or tears. The fracture is like that of common myrrh, but less unctuous, and has not the whitish markings. The odor and taste are those of the ordinary drug." This myrrh is said to be collected on the hills about Shugraea and Sureeae, east of Aden. "Meetiya," or Arabian Myrrh of Dymock, is said to be sold in India as true myrrh. It has a dull surface, a dark reddish-brown color, a more unctuous and waxy fracture, and has white marks like Somali myrrh, which it resembles in taste, but its odor is rather less fragrant. Yemen Myrrh, which is said by Hanbury to contain a resin which differs from that of Somali myrrh and the Arabian myrrh or Fahdi in that its solution in petroleum spirit does not give a violet color on the addition of bromine. This myrrh is said to enter commerce chiefly from Makulla via Aden and Bombay. It occurs in large pieces 1 to 3 inches long, irregularly rounded and characterized by a dark reddish-brown color with a similarly colored fracture free from whites streaks. Odor and taste similar to Somali myrrh, but stronger and more rank.

Mecca balsam, according to G. Schweinfurth, ia yielded by Commiphora Opobalsamum, from which it is collected in the valleys near Mecca. It is said to be the myrrh of the Bible, the error of translation having been made on account of the similarity of the old Hebrew word "mar" with the modern Arabic word "morr," the name of the true myrrh.

Properties.—Myrrh is "in rounded or irregular tears or masses, brownish-yellow or reddish-brown, and covered with a brownish-yellow
dust; fracture waxy, somewhat splintery, translucent on the edges, sometimes marked with nearly white lines; odor balsamic; taste aromatic; bitter and acrid. The powder is yellowish-brown; 0.001 Gm. of the powder, when added to a drop of fixed oil on a slide and examined under the microscope, shows numerous angular fragments varying in color from pale yellow to yellowish-brown; when mounted in hydrated chloral T.S. the color of the yellowish fragments is intensified; the addition of iodine T.S. to the powder, previously mounted in hydrated chloral T.S., may show the presence of a few starch grains varying in shape from spherical, polygonal, and narrowly ellipsoidal to somewhat pear-shaped, from 0.01 to 0.035 mm. in diameter; when mounted in phloroglucinol T.S. and hydrochloric acid the powder may show a few fragments of lignified tissues consisting of either sclerenchymatous fibers, or of small groups of stone cells, the individual cells of the latter with very thick, porous walls and from 0.015 to 0.05 mm. in length. Not less than 35 per cent. of Myrrh is soluble in alcohol. Myrrh yields not more than 8.5 per cent. of ash." U. S.

"In rounded or irregular tears, or masses of agglutinated tears, varying much in size; reddish-brown or reddish-yellow externally, dry, and more or less covered by a fine powder; brittle, the fractured surface irregular, somewhat translucent, of a rich brown color, oily, and frequently exhibiting whitish marks. Aromatic odor; taste aromatic, bitter and acrid. Not more than 70 per cent. insoluble in alcohol (90 per cent.). The solution obtained by boiling 0.1 gramme of coarsely powdered Myrrh with 2 millilitres of alcohol (90 per cent.), evaporated in a porcelain dish so as to leave a thin film, yields a residue which assumes a violet color in contact with nitric acid diluted with an equal volume of water. Ash not more than 5 per cent." Br.

Under the teeth it is at first friable, but soon softens and becomes adhesive. It is inflammable, but does not burn vigorously, and is not fusible by heat. Its sp. gr. is stated as 1.36. The inferior kind is in pieces much darker, more opaque, less odorous, and often abounding with impurities. We have seen pieces of India myrrh enclosing large crystals of sodium chloride, as if the juice had fallen from the tree and concreted upon the ground where this mineral abounds. Pieces of bdellium, and other gummy or resinous substances of unknown origin, are often mixed with it. Among these is a product which may be called false myrrh. It is in irregular pieces, of a dirty reddish-brown color, a vitreous brownish-yellow fracture, semi-transparent, of a faint odor of myrrh,
and a bitter balsamic taste. Myrrh is best purchased in mass, as in powder it is liable to adulterations not easily detected. It is sometimes admixed with small stones which are added when the myrrh is in a moist state. Much of the commercial article is contaminated with the so-called Somali myrrh which does not meet the Pharmacopoeia requirements. It is also adulterated with Senegal gum and chestnuts.

George F. Merson (P. J., Jan., 1900, 42) proposes as a test of the quality of myrrh that it should yield not more than 5 per cent. of ash, which should be almost entirely soluble in diluted hydrochloric acid, and that when, exhausted with 90 per cent. alcohol and dried at 100° C. (212° F.) one gramme should not afford more than 0.6 Gm. of residue.

Myrrh is partially soluble in water, alcohol, and ether. Triturated with water it forms an opaque yellowish or whitish emulsion, which deposits the larger portion upon standing. Its alcoholic tincture is rendered opaque by the addition of water, but throws down no precipitate. According to Neumann, alcohol and water severally extract the whole of its odor and taste. By distillation a volatile oil rises, having the peculiar flavor of myrrh, and leaving the residue in the retort simply bitter. The gum-resin, is soluble in solutions of the alkalies, and, when triturated with them in a crystalline state, forms a tenacious liquid. Hence potassium carbonate may be used to facilitate its suspension in water. Hirschsohn recommends as a reagent for myrrh, trichlor-acetal-chloroform, which is obtained by conducting chlorine into seventy-five per cent. alcohol until turbidity ensues and two layers are formed; the lower of these is shaken with an equal volume of water and then with calcined magnesia and filtered. In one part by weight of the triehloracetel thus obtained, four parts by weight of hydrated chloral are dissolved by heating. The syrupy reagent thus made, which fumes slightly in the air, gives a violet color with the smallest quantity of pure Herabol myrrh. Hirschsohn failed to get a similar reaction with any other resin, not even with Bisabol myrrh. (Ph. Centralh., 1903, 809.) An analysis by Buickoldt gave 2.183 per cent. of volatile oil, 44.760 of resin, 40.818 of gum or arabin, 1.475 of water, and 3.650 of calcium and magnesium carbonate, with some gypsum and ferric oxide. The volatile oil has been called myrrhol or myrrhenol, and, according to Ruickoldt, has the formula C₁₀H₁₄O. Koehler (A. J. P., 1890, p. 346) confirms this formula, and states that this body, while isomeric with thymol and carvol, is distinct from them. He found 7 or 8 per cent. of essential oil, instead of 2.18 as previously given. Gladstone (J. Chem. S. [2], 2, 1)
found that the oil had a sp. gr. of 1.0189 at 7.5° C. (45.5° F.), a boiling point of 266° C. (510.8° F.), and was laevorotatory. The resin, which he calls myrrhin, C_{48}H_{32}O_{10}, is neutral, but becomes acid when kept for a short time in fusion. In the latter state Buickoldt proposes to call it myrrhic acid. (A. Pharm., 1x1, 1.) Koehler has found in the portion soluble in alcohol an indifferent soft resin, to which he gave the formula C_{26}H_{32}O_{5}, containing three replaceable OH groups, and two dibasic resin acids, of the formulas C_{26}H_{32}O_{16} and C_{26}H_{32}O_{9}. An investigation of the essential oil of Bisabol myrrh from the interior of the Somali country was made by W. Tucholka. (Schism. Rep., Oct., 1897, 36.) He obtained by distillation 7.8 per cent. of an oil of 0.8836 sp. gr., boiling at from 220° to 270° C. 428°-518° P.). From this was separated, by means of the crystalline hydrochloride, a terpene boiling at from 259° to 260.2° C. (498.2°-500.36° F.), which the author calls bisabolene, and an oxygenated portion to which he gives the rather strange formula C_{56}H_{96}O. According to Bley and Diesel, myrrh containing a little volatile oil always has an acid reaction, which they ascribe to the oxidation of the oil. They also found formic acid in the specimen examined by them. The same investigators propose as a test of myrrh the production of a transparent dirty-yellow liquid with nitric acid, while false myrrh affords a bright-yellow solution in the same fluid, and bdellium is not dissolved, but becomes whitish and opaque. (A. J. P., xviii, 228.) According to Righini, if powdered myrrh, rubbed for fifteen minutes with an equal weight of ammonium chloride, and fifteen times its weight of water gradually added dissolves quickly and entirely, it may be considered pure. Chas. E. Escott (A. J. P., 1887) extracted a sample of myrrh with petroleum benzin, and on spontaneous evaporation of the solvent obtained 18.75 per cent. of oily residue. The gum left after treatment with alcohol had a barely perceptible odor of myrrh, and a slightly mucilaginous taste, was neutral to test paper, and, though of a pale color, gave with water a dark-brown solution. The insoluble portion amounted to 15 per cent., or 8.4 per cent. of the weight of the myrrh. The diluted solution acquired a purple color by ferric chloride, changed to reddish-yellow by ammonia. Stronger solutions were precipitated by alcohol, not gelatinized by borax, and the precipitate with lead subacetate was not redissolved. The gum makes a good mucilage, and, when making tincture of myrrh, the residue insoluble in the alcoholic menstruum should be saved for that purpose.

**Uses.**—Myrrh is a stimulant tonic, with some tendency to the lungs,
and perhaps to the uterus. It is also employed as a tonic in dyspepsia, and as an expectorant and emmenagogue in debilitated states of the system, in the absence of febrile excitement or acute inflammation. The diseases in which it is usually administered are chronic catarrh, phthisis pulmonalis, other pectoral affections in which the secretion of mucus is abundant but not easily expectorated, chlorosis, amenorrhæa, and the various affections connected with this state of the uterine function. It is generally given combined with chalybeates or other tonics, and in amenorrhæa very frequently with aloes. It is used also as an application to spongy gums, the aphthous sore mouth of children, and various kinds of unhealthy ulcers.

A plaster of myrrh is made by rubbing together powdered myrrh, camphor, and balsam of Peru, of each an ounce and a half, then adding the mixture to 32 ounces of lead plaster previously melted, and stirring well until the plaster thickens on cooling. It is then to be formed into rolls. This plaster may be employed in all cases where a gentle and long-continued rubefacient effect is desired.

Myrrh may be given in the form of powder or pill, or suspended in water, as in the famous antihectic mixture of Griffith. (Mistura Ferri Composita.) The infusion is also sometimes given, and an aqueous extract has been recommended as milder than myrrh in substance. The tincture is used chiefly 'as a local application.

Dose, ten to thirty grains (0.65-2 Gm.).

Myrtus. Myrtus communis L. Myrtle. (Fam. Myrtaceae.)—From the leaves of this plant is distilled a volatile oil which, under the name of myrtol is employed in medicine. This oil contains pinene, cineol and a characteristic alcohol, myrtenol. The mixture usually known as myrtol is collected between 160° and 180° C. (320°-356° F.). Myrtol has been recommended as an antiseptic and a powerful stimulant to the pulmonic and genito-urinary mucous membranes, and useful in chronic bronchitis, cystitis, or pyelitis. Dose, from one to two minims (0.06-0.13 mil), given in capsules, from four to
eight times a day. A. de Vevey (R. T., Ixiii, 1896) has used the 10 per cent. solution in sterilized olive oil hypodermically in doses of eighty to one hundred and sixty minima (5-10 mils) once or twice in twenty-four hours.
The Dispensatory of the United States of America
Twentieth Edition (1918)
Edited by Joseph P. Remington, Horatio C. Woods and others.

[This was the last era in pharmacy when plant drugs were widely prepared, both for Regular School, Eclectic and Irregular physicians, and the Dispensatories were the major reference works used by pharmacists to prepare these products. Official plant drugs and preparations are in larger case, unofficial plant drugs and preparations are in smaller case. I have extracted all plant drugs and preparations, excluded non botanicals and those most reasonably used only by physicians...Opium, Digitalis, etc. I have deleted some of the wonkish essay tests for the 'Oleum' group - Michael Moore]

**Nabalus.** Prenanthes alba L. Rattlesnake Root. White Lettuce Cancer Weed. Gall of the Earth. Lion's Foot. (Fam. Composiae)—In certain portions of Virginia and North Carolina, where this perennial herb grows, great value is attached to it in rattlesnake bite. The milky juice is taken freely internally, and its leaves steeped in water which is locally applied and frequently changed. The plant is also used in dysentery, and N. B. Williams has found tannin in the rhizome. (A. J. P., 1887.)

**Nance Bark.**—This bark is believed to be obtained from the Malpighia glabra L. (Fam. Malpighiaceae) It is much used in Mexico for tanning, and, according to F. Holberg, contains 26.2 per cent of tannin. (A. J. P. xvi. 239.)

**Narcissus.** Narcissus Pseudonarcissus L. Daffodil. Narcisse des pres, Porillon, Fr. Gelbe Narcisse, G. (Fam. Amaryllidaceae)—Both the bulb and the bright yellow flowers of this common garden plant have been used in medicine. The flowers have a feeble peculiar odor, and both have a bitter mucilaginous taste. They are an uncertain emetic. It is probable that the flowers of the wild European plant are more powerful than those of the cultivated. A. W. Gerrard examined the bulbs of daffodil, and obtained a crystalline neutral principle and an amorphous alkaloid, which he calls pseudonarcissine. According to Ruiger, the alkaloid obtained by Gerrard from the bulb of the flowering plant dries the mouth, checks perspiration, dilates the pupil, especially when applied locally, quickens the pulse, and acts on the heart of the frog antagonistically to muscarine and pilocarpine, while the alkaloid taken from the bulb after flowering causes salivation and perspiration, internally taken contracts the pupil, and topically applied dilates it slightly. (J. P., i, 436.) In France, narcissus flowers have been used as an antispasmodic. The dose of the powder, to produce an emetic effect, varies, according to the statements of different physicians, from twenty grains to two drachms (1.3-7.7 Gm.); while the extract is said to cause vomiting in the dose of two or three grains (0.13-0.20 Gm.). The bulb is most powerful in the recent state.

**Nard.** Spikenard.—Several aromatic roots were known to the ancients under the name of nardus, distinguished, according to their origin or place of growth, by the names of Nardus indica, Nardus celtica, Nardus montana, etc. They are supposed to have been derived from different valerianaceoua plants. Thus, the Sardus indica, is
referred to Nardostachys, Jatamansi (Roxb.) DC. (Valeriana Jatamansi Roxb.), of Bengal, the Nardus Celtica to V. celtica L., inhabiting the Alps, Apennines, etc., and the Nardus montana to V. tuberosa, which grows in the mountains of the south of Europe. The Indian ward, or spikenard, sometimes also called Syrian nard, is still occasionally to be found in commerce. It is a small delicate root, from one to three inches long, beset with a tuft of soft, light brown, slender fibers, of an agreeable odor, and a bitter aromatic taste. It was formerly very highly esteemed as a medicine, but is now almost out of use. Its properties are analogous to those of valerian.

Naregamia, or Goanese Ipecacuanha.—The root of Naregamia alata Wight and Arn. (Fam. Meliaceæ), of Western India, has been much employed as an emetic, as an hepatic stimulant in dysentery, and in small doses as an expectorant in bronchitis. Drasche of Vienna, confirms the value of the drug. (06. G. T., 1890.) In it Hooker has found an alkaloid, naregamine, an oxidizable fixed oil, and a wax. (See P. J; vol. xv, 1887.) The dose of a concentrated tincture (1 to 4) is from five to ten minims (0.3-0.6 mil); as an emetic, from fifteen to thirty minims (0.9-1.8 mils).

Nasturtium. Watercress. Cresson de fontaine, Fr. Brunnenkresse, G. Radicula Nasturtium aquaticum (L.) Britten et Rendle. (Fam. Cruciferae)—In sensible and medicinal properties watercress bears some resemblance to scurvy grass, though milder, and on this account is preferred for the table. It is thought to be useful in scorbatic affections and visceral obstructions. It contains a volatile oil, which, according to A. W. Hofman, contains as its chief constituent a body boiling at 253° C. (487.4° F.), which he considers to be the nitrile of phenyl-propionic acid, C₉H₁₀O₂, and therefore has the formula C₉H₁₀N. The expressed juice is sometimes given in the dose of one or two fluidounces (30-60 mils); but the herb is more frequently used in the form of a salad.

Other species of Radicula grow in similar situations with the R. Nasturtium, and act similarly.

Nerium. Nerium Oleander L. Laurier Rose, Laurose, Fr. Oleander, Rosenlorbeer, G. (Fam. Apocynaceae)—The common ornamental shrub known as oleander is affirmed to. have been used from time immemorial in portions of Southern Europe for destroying rats, and a number of cases of poisoning by it have been reported. (For collection, see T. G., July, 1888.) The symptoms have been vomiting, abdominal pain with frequent cries, dilatation of the pupil, vertigo, convulsive movements, insensibility, small, very slow pulse, and in fatal cases epileptiform convulsions with coma ending in death. The action on the heart has in some cases in which death has not ensued, been very pronounced, the pulse for five days remaining as low as forty per minute. The infusion made from four ounces of the root is affirmed to have taken life.

Two supposed alkaloids have been discovered in oleander by Leukowsky (J. P. C. (3"), 46, 397), one named pseudocurarine, the other named oleandrine. Both neutralize acids; the former dissolves in water and alcohol, but not in ether, and is neither volatile nor poisonous; the latter is yellow, amorphous, very bitter, very slightly
soluble in water but more freely in alcohol and ether, and poisonous in its action on
the system. H. G. Greenish isolated two substances, neriodorin and neriodorein, which
are probably not pure proximate principles. (A. J. P., 1881, 350). B. C. L. Bose (P. J.,
1901, 553) obtained a resinous substance, karabin, C_{21}H_{49}O_{6}, which he states is
one of the active constituents of this plant. Haemel (Ph. Ztg., 1901, 58) obtained a
semi-concrete oil to the amount of 0.025 per cent. from the leaves of N. Oleander.
Dubigadoux and Durieu affirm that they have obtained stpophanthin from the
deleander of Algeria.

Schmiedeberg (A. E. P. P., 1883, Bd. xvi, 145) finds two active substances in the
oleander leaf—neriin and oleandin. Schmiedeberg shows that the latter, which had
been previously described by Leukowsky as an alkaloid, is a glucoside, and on boiling
with very dilute acids breaks up into sugar and a yellow resinous substance like digi-
taliresin. With concentrated acids it also decomposes, yielding an inactive resin.
Schmiedeberg also obtained from African leaves a glucoside, nerianthin, which he
surmises to be an educt from oleandrin. He found oleandrin to be a powerful cardiac
poison, but nerianthin not to have the power of arresting the frog's heart, although it
exerts some influence upon it, possibly, as Schmiedeberg surmises, through
contaminating oleandrin. Piesczek obtained from oleander bark a principle which he
named rothagin, which was very poisonous, resembling strychnine in its action. (A.
Pharm., coxxviii, 352.) (See also M. R., 1911, and J. P. C., 1912, 108.)

Leulier found in oleander bark a glucoside which seems to be identical with the Isevo-
strophathin of Thorns. (P. J., Ixxxvii, p.407.)

Pouloux (B. G. T., May 15, 1888) having confirmed the earlier conclusions of Pelikau
(C. R. A. S., 1866, 239) that oleander acts upon the heart like digitalis, used it
successfully in a few cases of valvular heart disease. In seventy-five cases under the
care of Freiherr (Acrzt. Rund., 1892) it acted promptly as a heart stimulant and tonic.
Its diuretic action is said to be very marked, and not rarely it acts as a cathartic. Any
irritation of the alimentary canal contra-indicates its use. Under its influence the
pulse rapidly becomes regular and slow, and dyspnea and edema disappear. Freiherr
asserts that it is safer than digitalis in atheromatous diseases. Freiherr used it in
infusion or tincture, representing as the daily dose from three-quarters to one and a
half grains (0.048-0.096 Gm.) of the dried oleander bark, one and a half to three grains
(0.096-0.2 Gm.) of the fresh bark, one and a quarter to three and a half grains (0.08-
0.23 Gm.) of the dried fruit. Pouloux's dose of the extract was three-quarters of a grain
(0.048 Gm.). Orfele has used the dried flowers—dose, three grains (0.2 Gm.) in
substance, or from ten to twenty minims (0.5-1.0 mil) of a 10 per cent. tincture—with
success.

**Nierenbergia Hippomanica.** Chus-chu.—This solanaceous plant is the not
infrequent source of poisoning to cattle in Argentine, where it is a native. Laveuir and
Sanchez (J. P. G., 1907, xxvi) have isolated a poisonous alkaloid to which they give
the name nierenbergine. Apparently this alkaloid resembles saponin in some of its
properties. They were not able to find the glucoside hippomamin which had previously
been reported.
**Nigella.** Nigella sativa L. Nutmeg-flower. Small Fennel-flower. Faux Cumin, Fr. Schwarz-kummel, G. (Fam. Ranunculaceae)—A small, annual plant, growing wild in Syria and the south of Europe, and cultivated in various parts of the world. The seeds, semen nigellae, are ovate, somewhat compressed, from 2.5 to 3.5 mm. in length and less than 2 mm. in thickness, usually three-cornered, with two sides flat and one convex, black or brown externally, white and oleaginous within, of a strong, agreeable, aromatic odor, like that of nutmegs, and a spicy, pungent taste. (P. J., 1882, 681.) Their chief constituents are a volatile and a fixed oil (1.5 per cent. of the former and 35 per cent. of the latter), and an amorphous glucoside, melanthin, which is decomposed by diluted hydrochloric acid into melanthigenin and sugar. The nigellin of Reinsch does not seem to have been a pure substance. Rochebrune has found a powerful paralyzing alkaloid, to which he gives the name of nigelline (Toxicol. Africaine, vol. i.) Melanthin, according to W. von Schuiz, exhibits the typical physiological action of the most poisonous saponins. In India the seeds are considered as stimulant, diaphoretic, and emmenagogue, and are believed to increase the secretion of milk. They are also used as a condiment, and as a corrigent or adjuvant of purgative and tonic medicines. In the seeds of the Nigella Damascena Schneider (Ph. Centralh., 1890, xxxi, p. 173) found an alkaloid which he called damascenine, whose construction was studied by Pommerehne and Keller. (A. Pharm., 1904, ccxiii, p. 295.) It has been made synthetically. They were unable to find any alkaloid in N. sativa. (See also A. Pharm., 1908.)

**Njimo Wood.**—The wood of Sarcocephalus aesculentus Afzel. (Fam. Rubiaceae), known as Njimo, was introduced into Germany from the Cameroons with the statement that it had digestive properties similar to those of pepsin. It is a stem wood, often with pieces of root, of a yellow color, musk-like odor, and bitter taste. Schulz (Ph. Ztg., June 12, 1886) finds that it is not a digestive, and that it yields a resinous extract not poisonous to frogs. The alcoholic extract of the rug is yellow by transmitted light, but exhibits a green fluorescence resembling uranium glass. The bark of this same plant called "Dundaki," according to Heckel and Schlagdenhauffen (Compt. Rend., 1885, 69) contains an alkaloid, Dundakine.

**NUX VOMICA. U. S., Br.**

**NUX VOMICA** Nux Vom. [Strychni semen, P. I.]

"The dried, ripe seeds of Strychnos Nux-vomica Linne (Fam. Loganiaceae), yielding not less than 2.5 per cent. of the alkaloids of Nux Vomica." U. S. "Nux Vomica consists of the dried ripe seeds of Strychnos Nux-vomica, Linn." Br.

Semen Nucis Vomicae; Poison Nut, Quaker Buttons, Dog Buttons; Noix vomique, Fr. Cod.; Semen Strychni, P. G.; Krahenaugen, Brechnuss, G.; Noce vomica, It.; Nuez vomica, Sp.
Strychnos Nux-vomica is a tree of a moderate size, with numerous strong branches, covered with a smooth, dark gray bark. The young branches are long, flexuous, smooth, and dark green, with opposite, roundish-oval, petiolate, entire, smooth, and shining leaves. The flowers are small, white, funnel-shaped and in terminal corymbs. The fruit is a round berry, about as large as an orange, with a smooth, yellow or orange-colored, hard, fragile rind, and many seeds in a juicy pulp. It has frequently been asserted that the pulp is innocuous, but Fluckiger and Hanbury, and also Dunstan and Short (P. J., 3d series, xv, 1) have demonstrated that it contains strychnine. Dunstan and Short have also proved that of the commercial varieties of nux vomica Bombay seed stands first in percentage of contained strychnine, then Cochin, and lastly Madras. (P. J., 1883, xiv, 1053.)

The tree is a native of the East Indies, growing in Bengal, Malabar, on the Coromandel Coast, in Ceylon, in many islands of the Indian Archipelago, in Cochin China, and in Northern Australia. The drug is largely shipped from Madras, where it is estimated that in 1912 nearly 400,000 pounds were marketed. Much of the nux vomica shipped to the United States is exported from Bombay, and in 1910-1911 some 45,000 pounds of nux vomica were exported to the United States from the Bombay district. The chief markets for nux vomica are China, and America, small quantities are shipped to London, and the importations to Hamburg are very irregular. Joblin states that during the fiscal year 1909 there were imported into the United States 1,666,957 pounds of nux vomica; in 1910, 2,738,662 pounds. (Cons. & Tr. Rep., 1911, p. 350.)

The wood and root are very bitter, and are employed in the East Indies for the cure of intermittents. The radices colubrinae and lignum, colubrinum of the older writers, long known in Europe as narcotic poisons, have been ascribed to this species of Strychnos., under the impression that they were identical with Strychnos colubrina, to which Linnaeus refers them. They were ascertained by Pelletier and Caventou's researches to contain a large quantity of strychnine. The bark has been mistaken for cusparia, and hence is sometimes referred to as false angustura. Gehe & Co. (Handelsbericht, 1914, p. 119) state that a new variety of nux vomica, the origin of which is unknown, is being exported from Burma. The seeds are externally light gray, internally yellow and are devoid of strychnine.
Properties.—Nux vomica is officially described as "orbicular, nearly flat, occasionally irregularly bent, from 10 to 30 mm. in diameter and from 4 to 5 mm. in thickness, very hard when dry; externally grayish or greenish-gray, covered with appressed hairs giving it a silky luster, hilum indicated by a circular sear at the center of one of the flattened sides and connected with the micropyle at the edge by a ridge; internally showing a thin, hairy seed-coat and a large grayish-white endosperm at one end of which is embedded a small embryo with two broadly ovate, 5- to 7-nerved cotyledons; inodorous; taste intensely and persistently bitter. The powder is light gray; consisting chiefly of thick-walled endosperm cells containing globules of a fixed oil and a few small aleurone grains, and fragments of strongly lignified, non-glandular hairs, the walls of the latter possessing large, circular, or long, slit-like pores. In the tissues of the adhering pulp occur a few small, nearly spherical starch grains. Nux Vomica yields not more than 3.5 per cent. of ash." U. S.

"Seeds disc-shaped, nearly flat, but sometimes irregularly bent; rounded or somewhat acute at the margin, from a small prominence on which a raised line passes to the central hilum. Ash-grey or greenish-grey. From two to two and a half centimetres in diameter, and about six millimetres thick. Surface densely covered with short, satiny, radiately arranged and closely appressed hairs. Endosperm large and horny; cotyledon small and leafy. Powdered Nux Vomica exhibits fragments of the endosperm, the cell-walls of which are very thick but not lignified, also slender rod-like fragments of the hairs and their thickened, pitted, lignified basal portions. No odor; taste extremely bitter. Yields not less than 1.25 per cent. of strychnine when tested by the following process." Br.

The seeds are destitute of odor, but have an acrid, very bitter taste, which is much stronger in the kernel than in the investing membrane. They impart their virtues to water, but more readily to diluted alcohol. For a method of distinguishing powdered nux vomica from powdered ignati'a and other powders, see Proc. A, Ph. A., 1897, 503.

Herder has proposed a detection of the alkaloids in nux vomica by various microchemical means and shows how they may be localized in the seeds and growing-plants. (A. Pharm., 1906, p. 129.) Tunmann (A. Pharm., 1910, 644) has studied the distribution of the alkaloids in the germinating seeds of Strychnos Nux vomica, and concludes that the
embryo of the seed contained only brucine and that strychnine, which was contained in the endosperm only in the cell plasma of the cell content, appears to act as a protection for the growing plant. Grutterink has also published an illustrated article on the microchemical examination of the several alkaloids of nux vomica. (Zeit. An. Chem., li, p. 187.) Rushy has reported the shipment of nux vomica which consisted of small inferior seeds which had been rolled in some mixture of clay. (Proc. A. Ph. A; 1908, lvi, p. 794.) Powdered nux vomica has been adulterated with ground olive stones and the rasplings of vegetable ivory. (See Rep. d. Pharm.,, 1909, p. 241; Ann. d. chim. Analyt., 1909, p. 261.)

The chemists Pelletier and Caurentou discovered in nux vomica two alkaline principles, strychnine and brucine, united with a peculiar acid which they named igasuric. Its other constituents are a yellow coloring matter, a fixed oil, grun, starch, a small quantity of wax, and several earthy phosphates. Charles Bullock, in preparing the alcoholic extract of nux vomica with a moderate continuous heat, so as to dry it sufficiently to be pulverized, separated from 150 pounds of the seeds 5 pints of a liquid oil. This oil has a saponification number of 124, and an iodine number of 64 to 67. The unsaponifiable portion of the oil was identified as a mixture of phytosterin. (A. Pharm., 1912, p. 398.) F. Meyer (In. Dis., St. Peters burg, 1875) investigated the fatty oil from nux vomica, and found it to consist of the glycerides of capric, caprylic, caproic, butyric, and palmitic acids. (A. J. P., 1874, 405.) Shenstone (J. Chem. S., xxxix, 453) has shown that the igasurine of Desnoix is a mixture of strychnine and brucine. A glucoside, loganin, has also been found in the nux vomica seeds, but it exists more largely in the surrounding pulp. Dunstan and Short, its discoverers (P. J . 1883, xiv, 1025), gave to it the formula C_{25}H_{34}O_{14}. Boorsma stated that he had discovered a new alkaloid in the leaves of S. Nux vomica (Bull. de l'Inst. Bot. de Buitenzorg) and he named it strychnicine; it is only slightly poisonous. (See also P. J ., 1902, 65.)

Hugo H. Schafer (J. A. P. A., 1914, p. 1077) announces a new alkaloid in nux vomica which he has named struxine. This alkaloid is stated to have the chemical formula C_{21}H_{30}C_{4}N_{2}. It is present only in the drug coming from Cochin China, and was found in an amount of 0.1 per cent.

Igasurine was said to be found in the mother waters from which strychnine and brucine have been precipitated by lime. Jorgensen
believed that it was identical with brucine (see A. J. P., June, 1872, p. 257), and W. A. Shenstone confirmed this view. (A. J. P., Dec., 1881.)

Loganin is present in the pulp to the amount of 4 or 5 per cent., and is contained in small quantity also in the seeds. It was obtained by exhausting the pulp with a mixture of chloroform and alcohol (100:25). The exhaustion was effected in an apparatus for hot repercolation. The percolate, on cooling, deposited crystals, which when recrystallized a number of times from alcohol, and finally from absolute alcohol, were obtained pure. Loganin is easily soluble in water and alcohol, less soluble in ether, chloroform, and benzene. Its aqueous solution is not precipitated by any of the alkaloidal reagents. Its most characteristic reaction is found in its behavior with concentrated sulphuric acid. A very small quantity of loganin, when gently warmed with a few drops of concentrated sulphuric acid, yields a fine red color, which, on standing, develops into a deep purple. By boiling with dilute sulphuric acid, loganin is resolved into glucose (reducing Fehling's solution) and a body for which the name loganetin is proposed. This substance, like loganin, gives the characteristic reaction with sulphuric acid, but the purple color does not develop so rapidly. Loganetin is soluble in water and alcohol, less soluble in ether, carbon disulphide and chloroform. (P. J., 1884, p. 1025.)

Strychnine \(\text{C}_{21}\text{H}_{22}\text{O}_{2}\text{N}_{2}\) was discovered by Pelletier and Caventou in 1818, in both the nux vomica and the bean of St. Ignatius, and received its name from the generic title of the plants (Strychnos) to which these two products belong. According to these chemists, it exists much more abundantly in the bean of St. Ignatius than in the nux vomica, the former, yielding 1.2 per cent., the latter only 0.4 per cent., of strychnine, but Dragendorff obtained from nux vomica from 1.9 to 2.1 per cent. of mixed alkaloids, about half of which was strychnine. (Jahresbericht, 1874, 103.) For valuable practical information about the yield of the alkaloids, extracts, etc., by E. L. Patch, see Proc. A. Ph. A., 1891, 91; also P. J., 1889, 341; Proc. Michigan Pharm. Assoc., 1889; Proc. Ohio Pharm. Assoc., 1889; P. J., 1890, 493.

Other species of Strychnos contain the poisonous alkaloids, and may some time become a commercial source of them. Bidara laut of the Indian bazaars, believed to be obtained from S. ligustrina, has been analyzed by Russow, who found the wood to contain 2.26 per cent. and the bark 7.38 per cent. of brucine without strychnine. Henry Q.
Greenish found in the wood and bark respectively of S. colubrina 0.96 per cent. and 5.54 per cent. of mixed alkaloids; the same analyst obtained from false Angustura bark (S. Nux vomica), young bark 3.10 per cent., old bark 1.68. (P. J., 3d ser., ix, 1014.) According to Bernelot-Moens, the dry seeds of the S. tieute contain 1.469 per cent. of strychnine, with a trace of brucine. (A. J. P., 1866, p. 506.) From the seeds of Strychnos Rheediii. W. R. Dunstan obtained a yield of 0.06 per cent. of brucine and no strychnine. (Imp. Inst. Rep., 1901-1902.) The Congo poison known as Cupua Apus, according to Vinci (A. I. P. T., xx), is produced from the Strychnos kipapa. The bark of the root contains 6 per cent. of strychnine and the wood 0.1 per cent.

Brucine (C_{23}H_{26}O_{4}N_{2}) was discovered by Pelletier and Caventou, first in the bark called false Angustura, in combination with gallic acid, and subsequently, associated with strychnine in the form of igasurates, in the nux vomica and the bean of St. Ignatius. It is crystallizable from alcohol, the crystals then containing 4H_{2}O. It is without odor, but of a permanent, harsh, very bitter taste; is soluble in 850 parts of cold and in 500 of boiling water; very soluble in alcohol, whether hot or cold; it dissolves in 4 parts of chloroform, 440 parts of ether, 60 parts of benzene, and 120 parts of petroleum benzin. It is permanent in the air, but melts at a temperature a little above that of boiling water, and on cooling congeals into a mass resembling wax. The hydrated crystals melt at 115° C. (239° F.), and sublime at 204° C. (399.2° F.), while the anhydrous base melts at 178° C. (352.4° F.), changing color, and depositing carbon. (P. J., 1868, 375.) It forms crystallizable salts with acids. Concentrated nitric acid produces with brucine or its salts an intense crimson color, which changes to yellow by heat, and upon the addition of stannous chloride becomes violet. A test for brucine, given by Stanislas Cotton, consists in adding to a warm solution of brucine (from 40° to 50° C. (104°-122° F.)) in nitric acid, a concentrated solution of sodium thio-sulphate. The mixture first becomes violet, and then passes to green when the alkaline salt is in excess. (J. P. C; Juillet, 1869, 18.) These effects serve to distinguish brucine from strychnine, and, if produced with the latter alkaloid, evince the presence of the former. According to Larocque and Thibierge, auric chloride produces, with solutions of the salts of brucine, precipitates at first milky, then coffee-colored, and finally chocolate-brown. (Journ. de Chim. Med., Oct., 1842.) Chlorine water produces with solution of brucine a rose color, due to the formation of dichlor-brucine. This is a reddish-brown, hygroscopic
powder. (A. Pharm., 1886, 934.) A dinitro-brucine, $C_{23}H_{24}(NO_2)_{2}N_2O_4$, has also been obtained by the action of nitrogen trioxide upon the brucine in alcoholic solution. Brucine appears to bear a definite relation to strychnine in chemical constitution, being a dimethoxy-strychnine. According to the analyses of Shenstone and Dragendorff, the bark of the nux vomica contains brucine, with a trace of strychnine, while in the leaves Hooper found only brucine. (P. J., 1890, xxi.)

Brucine may be procured from false Angustura bark, in a manner essentially the same as that in which strychnine is procured from nux vomica, with this difference, that the alcoholic extract obtained from the precipitate produced by lime or magnesia should be treated with oxalic acid, and subsequently with a mixture of rectified alcohol and ether, which takes up the coloring matter, leaving brucine oxalate. This is decomposed by magnesia, and the brucine is separated by alcohol, which by spontaneous evaporation yields it in the state of crystals. Prescott (Organic Analysis, 1887, p. 458) gives two methods for the separation of strychnine from brucine; first, by the use of alcohol of 0.97 sp. gr., which easily dissolves brucine, but has very slight solvent power upon strychnine; second, by Dunstan and Short's method with potassium ferrocyanide. This method has been reported upon by Hoist and Beckurts (Ph. Centralk., N. P., 1887, p. 119), who find that if the hydrochloric acid solution containing mixed alkaloids is not too dilute, on the addition of potassium ferrocyanide the whole of the strychnine will be precipitated as ferrocyanide, while the brucine salt will remain in solution.

The separation of brucine from strychnine is most conveniently effected by exposing the mixed alkaloids to the action of diluted nitric acid, which destroys brucine very rapidly while having no appreciable action on strychnine; this method is used in the former official assay process.

Igasuric acid has been regarded as erroneously named, and investigators have stated that it was malic acid and tannic acid, while Q. Sander (A. Pharm., 1897, 133) believes that the acid found in nux vomica, heretofore known as igasuric acid, is caffeo-tannic acid.

**Uses.**—The medicinal and toxic properties of nux vomica are those of its alkaloid. (See Strychnina.) The belief held by some physicians that it acts more favorably as a bitter upon the stomach has only this much of justification—namely, that it is more slowly absorbed, and therefore acts
locally somewhat more persistently.

BRUCINE.—On account of the difficulty of separating strychnine from brucine, it has been found by physiologists difficult to determine the exact action upon the human organism of the pure alkaloid. It was formerly taught that brucine closely resembled strychnine in its physiological action, except that it was less poisonous and that it was depressant to the peripheral sensory nerves. Dickson and Harvey (P. J., 1908, lxxxi, p. 367), however, experimenting with a chemically pure brucine, reach the conclusion that its dominant action is a paralysis of the peripheral motor nerves, and that the convulsive action which is the characteristic effect of strychnine is almost entirely absent in the case of brucine. According to the observation of Mays, brucine is an active paralyzant to the sensory nerves and a 5 or 10 per cent. solution applied to the mouth causes local anesthesia. He has used it for the relief of pruritus. Bumett also asserts that a 5 per cent. solution is a valuable local anodyne in inflammations of the external ear.

Dose, of nux vomica, one to four grains (0.065-0.26 Gm.).

Nymphea.—The seed of Nuphar luteum Smith (Nympheæa luteæ Linne), European Yellow Pond Lily (Fam. Nympheææææ), according to W. Grun-ng, contains nuphar-tannic acid, C_{56}H_{56}O_{37}, in considerable quantity. (A. J. P., 1883, 96.) Goris and Crete state that the nupharine of Gruning has the composition C_{18}H_{24}O_{2}N_{2}. They obtained it from the fresh rhizome of N. luteum. (J. Chem. 8., 1910.) The name Nympheæ has been incorrectly applied also to the American white pond lily, which belongs to the genus Castalia, Castalia odorata (Ait.) Woodv. and Wood. (Nympheæa odorata (Ait.) ), Sweet-scented Water Lily. The root of this well-known American plant is very astringent and bitter, and, according to Bigelow, contains much tannin and gallic acid. The root of Castalia alba Presl. (Nympheæa alba L.), or European white water lily, was esteemed anaphrodisiac by the ancients and the tannic acid contained in it has been named nymphae-tannic acid, and the formula C_{56}H_{68}O_{38} given it. (A. J. P., 1883, 96.)

Nyssa. Nyssa aquatica L. Tupela Gum. Sour Gum. Swamp Tupelo. (Fam. }

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - N-O Page 11
The Southwest School of Botanical Medicine http://www.swsbm.com
Cornaceae)—A large tree growing in deep swamps in the Southern United States. The root, known as Tupelo root, has been recommended for surgical tents. (A. J. P., 1883.)

Ocimum. Ocimum Basilicum L. Basil. Sweet Basil. Grand Basilic, Fr. Basilienkraut, G. (Fam. Labiatae)—An annual, aromatic plant, a native of India and Persia, and cultivated in Europe and in this country in gardens. It yields by distillation from 0.02 to 0.04 per cent. of a yellowish, volatile oil. The French and German oil have a penetrating odor resembling estragon, the Reunion has a camphor-like odor, a higher specific gravity and is dextrogyrate. Basil has the ordinary properties of the aromatic plants, and is used as a condiment. The seeds are said by Ainslie to be used in India in gonorrhea.

Œnanthe. O. crocata L. Water Hemlock. Water Dropwort. Dead Tongue.—A perennial, umbelliferous, aquatic, European plant, exceedingly poisonous both to man 'and inferior animals. The root, which has a sweetish not unpleasant taste, is sometimes eaten by mistake for other roots, often with fatal results. The symptoms produced are those of irritation of the stomach, besides failure of circulation, and great cerebral disturbance, indicated by giddiness, convulsions, and coma. (See P. J., 1874, 202.) Externally applied, the root produces redness and irritation of the skin, with an eruption. It is said to be sometimes used empirically as a local remedy in piles. Other species of Œnanthe are poisonous, and the whole genus should be suspected. We have two or three indigenous species. In cases of poisoning, the stomach should be at once evacuated, and symptoms met as they arise. A peculiar resinoid principle, denominated cenanthin, has been found by Gerding in Œnanthe fistulosa L., the common water hemlock of Europe, of which half a grain (0.032 Gm.), given to an adult, produced long-continued irritation of the fauces, and a grain (0.065 Gm.), occasional vomiting. (See A. J. P., xxii, 68.) Poehl (A. E. P. P., 1885, xxxiv, p. 258) claimed to have isolated a toxic principle, to which he gave the name of Œnanthotoxin, and assigned a formula of $C_{17}H_{22}O_5$. Tutin, however (P. J., Aug. 26, 1911), asserts that this body is not a pure principle but a mixture of neutral resins of unknown nature. He confirms the conclusions that the resin is an active poison. He also examined the tuberous roots of O. crocata and found triacontane, $C_{30}H_{62}$, and hentriacontane, $C_{31}H_{64}$. In the P. J., vol. xvi, 357, is a paper by Henry William Jones upon the recognition of O. crocata in cases of suspected cattle poisoning; he found that the starch granules possessed characters which enabled him to distinguish the tubers from all others.

Œnanthe aquatica Lam. (Œnanthe Phellandrium Lam., Phellandrium aquaticum L.) Fine-leaved Water Hemlock. Water Fennel. Fructus Phellandrii. Wasserfenchel, G. Phellandrie aquatique, Fenouil d’Eau, Fr.—A biennial or perennial, umbelliferous, European water plant, the fresh leaves of which are said to be injurious to cattle, producing a kind of paralysis when eaten. By drying, they lose their deleterious properties. The seeds are from 4 to 5 mm. in length (about 2 mm. broad), ovate-oblong, narrow above, somewhat compressed, marked with ten delicate ribs, and crowned with the remains of the calyx, and with the erect or reverted styles. Their color is yellowish-brown; their odor peculiar, strong, and disagreeable; their taste acid
and aromatic. Among their constituents is a volatile oil, upon which their aromatic flavor depends. By C. Fronefield it has been rendered probable that they contain a volatile alkaloid, analogous to coniine, if it be not coniine itself, for if the powdered seeds are rubbed with solution of potassium hydroxide, the peculiar mouse-like odor of that alkaloid is exhaled. The powder was submitted to distillation with potassium hydroxide, the alkaline liquid obtained was neutralized with sulphuric acid and evaporated to a syrupy consistence, alcohol was added to precipitate the ammonium sulphate, the liquid was then filtered, treated with potassium hydroxide, and again distilled. On the surface of the distillate a yellow oily fluid floated, which was only slightly soluble in water but readily so in ether and alcohol, evinced an alkaline reaction with turmeric paper, and neutralized the acids. (A. J. P., May, 1860, 211.)

The ethereal oil of water fennel which is present to the extent of 1 to 2.5 per cent. is a yellow liquid of strong, pleasant characteristic odor and burning taste. It has a sp. gr. of 0.85-0.89 and is dextrorotatory. It contains about 80 per cent. of the terpene phellandrene, O_{10}H_{16}. In overdoses the seeds produce vertigo, intoxication, and other narcotic effects. They have been used in chronic pectoral affections, such as bronchitis, pulmonary consumption, and asthma; also in dyspepsia, intermittent fever, obstinate ulcers, etc. The dose of the seeds, to commence with, is five or six grains (0.32-0.4 Gm.), so repeated as to amount to a drachm (3.9 Gm.) in twenty-four hours. They should be given in powder. Dose of the alcoholic extract, three grains (0.2 Gm.). (P. J., xii, 591.)

**Œnothera.** Œnothera biennis L. Tree Primrose, Evening Primrose, Onagre Fr. Nachtkerze Gr. (Fam. Onagraceae.) —The fleshy root of this plant, before the introduction of the potato, was used as a table vegetable. Many years ago R. E. Griffith commended very highly a strong decoction of the plant frequently applied to eruptive skin diseases. More recently the drug has been commended in whooping cough and spasmodic asthma, and the ointment has been used in prurigo and other cutaneous affections of infants, and as an application to ulcers. Dose, of fluidextract, from a half to one fluidrachm (1.8-3.75 mils). The ointment may be made by incorporating four ounces of the fluidextract in a pound of vaseline or lard.

**Oil of Akee.** —This is a yellow, non-drying, butter-like fat obtained from the Blighia sapida Kon. (Fam. Sapindaceae), native of Guinea, but cultivated in Jamaica. (P. J., 65, p. 691.)

**Oil of Aleurites Triloba.** —The Aleurites triloba Forst. is a small tree belonging to the Euphorbiaceae. It is widely diffused throughout the tropics. The fruit is a nut nearly as large as a walnut, consisting of a thick shell enclosing a kernel containing much protein and rich in oil, of which it is said to yield nearly one-half its weight by expression. The nuts strung together on the fibers of the palm leaf were formerly used in many Pacific islands as a substitute for candles. The oil has been long known in the various countries inhabited by the plant, being called in Jamaica Spanish walnut oil, in India Belgaum walnut oil, in Ceylon kekune oil, and in the Hawaiian Islands kukui oil. It is very fluid, of an amber color, without odor, of a nutty, pleasant taste, congealing at 0° C. (32° P.), insoluble in alcohol, readily saponifiable, "and very strongly drying." It is said to be a mild cathartic, acting like castor oil, but more
promptly and without griping effects. (J. P. C., 3e ser., xxiv, 228.) The dose is from one-half to one fluidounce (15-30 mils), the smaller quantity generally answering. The cake left after the expression of the oil, given to a dog in the dose of about half an ounce (15 Gm.), produced no vomiting, but acted strongly as a purgative.

The oil of the Tung Tree, Aleurites cordata (Thunb.) Mull.-Arg., is used to a large extent in the arts in China, under the name of Chinese wood oil or tung oil. (This must not be confounded with the Indian oil of wood.) It is prepared in China by a crude process of expression. It occurs in two forms, white oil, a moderately thick, yellowish, transparent liquid, and the black oil, which is thick, black, and opaque. Wood oil is used in China and Japan either as a direct application to wood or mixed with various substances, as lacquer varnish, or paint. Its most remarkable characteristic is its extraordinary drying property, which is said to exceed that of any known oil. When applied to wood it forms a resinous layer which is affirmed to be impermeable by water and ordinary solvents. Wood oil is also exported to Europe, where it is used in the making of varnishes. This oil is obtained from the seeds of the tung tree, which contains about 53 per cent. of fixed oil. According to R. H. Davies, its sp. gr. at 15.5° C. (60° F.) is 0.94015; it remains liquid at -13.3° C. (8° F.). 100 Gm. of the oil require 0.39 Gm. potassium hydroxide for neutralization, and 21.1 Gm. for complete saponification. (P. J., 1885, 636.) E. M. Holmes believes that the dark colored oil is made by boiling the kernels previous to expression, the cold drawn oil being colorless, inodorous, and nearly tasteless. The latter, according to Cloez (C. R. A. S., 1875, vol. Ixxx, 469), has the sp. gr. 0.9362, congeals at -18° C. (-0.4° F.) to a transparent mass, solidifies rapidly when exposed to light in a closed vessel, and is the most drying oil known. (C. D., May, 1902.) (See also Proc. A. Ph. A. 1897, 677; and Chem. News, 1912, 14.) Over 60,000 kilo-grammes are said to be sent yearly from Hankow, on the Yang-tse-kiang, to the various Chinese seaports. It has been used in ulcerations and skin diseases. The seeds of the tung tree are used in China for killing rats, and are also affirmed to have emetic properties.

Oil of Anda.—A fixed oil procured by expression from the seeds of Johannesia princeps Veil. (Fam. Euphorbiaceae) The bark of J. princeps, growing in the maritime provinces of Brazil, yields on being wounded a milky juice, which is said to be poisonous, and to be used for stupefying fish. The fruit, which is about as large as an apple, ash-colored, with two larger and two smaller ridges, encloses a two-celled nut, containing two seeds, about the size of a chestnut. Like the seeds of other euphorbiaceous plants, these are actively purgative, one seed, according to Martius, being the dose for a man. By expression these seeds yield a pale yellow, transparent oil, with little odor or taste, which is said to be used in Brazil for burning and painting. It has a sp. gr. 0.927, and in properties belongs to the class of semi-drying oils. (P. J., 1905, 910.) Mello Olliveria has found in it an alkaloid, johannesine, which Couty affirms to be inert. (N. R., 1881, 260.) Norris, who tried the oil at the Pennsylvania Hospital, found it to operate on the bowels moderately in the dose of fifty drops (2.5 mils), and copiously when more largely given. Manoel de Castro and other Brazilian physicians assert that in doses of from one to two teaspoonfuls (3.75-7.5 mils) it acts in a manner very similar to castor oil, over which it has the great advantage of not being nauseous to the taste.
Oil of Anise Bark.—There has appeared in the European markets a bark, closely resembling Massoia bark, and is supposed to be derived from a species of *Illicium*, probably *I. parviflorum* Michaux, growing in Madagascar, which yields fully three and a half per cent. of a light, yellow oil, the odor of which slightly resembles safrol. It has a spicy taste, but is only slightly sweet. Its specific gravity is 0.969 at 15° C. (59° F.). Optical rotation -0° 46' in a 100-mm. tube. Refractive index at 16° 1.52510. It contains a small quantity of ordinary anethol, but consists principally of the isomeric fluid anethol, the methyl-chavicol of Eykman, CH$_3$O.CH$_2$.CH:CH$_2$.

Oil of Ben. Behen Oil.—This is a fixed oil extracted from the seeds of *Moringa arabica* Pers. (Fam. Moringaceae), and from *M. pterygosperma* Gaertn. (M. Oleifera Lam.). It should not be confounded with oil of benne from *Sesamum indicum* L. (Fam. Pedaliaceae). These are trees of the Fam. Moringaceae, inhabiting different parts of India, Arabia, Syria, etc., and introduced into the West Indies. The leaves and other parts have an acrid property, which has probably given the name of horseradish tree to *M. pterygosperma*. According to Henry Schachan (Nouv. Rén., 1890), the tincture of the root is very actively diuretic and useful in cardiac dropsy. The oil of the seeds has long been known, though used in the arts rather than in medicine. It is prepared in Europe from the seeds brought from Egypt; and it would appear, from the statements of Macfadyen, that the idea generally prevailing that it is also extracted in the West Indies is incorrect. The oil has a sp. gr. of from 0.912 to 0.917; it solidifies at about 0° C. (32° F.); indeed at 7° C. (44.6° F.) it begins to deposit the solid fats. It is inodorous, clear, and nearly colorless, and keeps long without becoming rancid. It resembles olive oil, and is used for similar purposes. Merat and De Lens say that it is purgative; but most of the fixed oils are so in sufficient doses. According to Volcker, the oil contains palmitin, olein, and a peculiar fatty matter yielding an acid by saponification, which he names benic (or behenic) acid. (J. P. C., xvi, 77.) Heintz considered benic acid as simply a mixture of palmitic and myristic acids. (Pogg. Ann., xci, 601.) It is, however, now recognized as one of the normal fatty acid series, possessing the formula C$_{22}$H$_{44}$O$_2$.

Oil of Bergamot. N. F. IV (U. S. 1890). Oleum Bergamottae. Oleum Bergamii. U. S. 1880. —"A volatile oil obtained by expression from the rind of the fresh fruit of *Citrus Aurantium Bergamia* (Risso et Poiteau) Wight et Arnott (Fam. Rutaceae), and containing not less than 36 per cent. of ester, calculated as linalyl acetate. Preserve it in small, amber-colored, well-stoppered bottles in a cool place, protected from light." N. F.

The bergamot tree has oblong-ovate, dentate, acute, or obtuse leaves, somewhat paler on the under than on the upper surface, and with footstalks more or less winged or margined. The flowers are white, and usually small; the fruit is pyriform or roundish, about three inches in diameter, terminated by the remains of the short style, with concave receptacle of oil in the rind. The pulp of the fruit is sourish, somewhat aromatic, and not disagreeable. The rind is shining, and of a pale-yellow color, and abounds in a very grateful volatile oil. This may be obtained by expression or distillation. In the former cage it preserves the agreeable flavor of the rind, but is
somewhat turbid; in the latter it is limpid but less sweet. The mode of procuring it by
expression is exactly the same as that used for oil of lemon. (See Oleum Limonis.) It
is brought from Italy, the south of France, and Portugal.

"Oil of Bergamot is a green or greenish-yellow liquid, neutral or only faintly acid,
having a characteristic fragrant odor and an aromatic bitter taste.

"Two volumes of the Oil, when mixed with 1 volume of alcohol, give a clear solution
and this does not become turbid on the further addition of alcohol. It is soluble in 2
volumes of 80 per cent. alcohol with not more than a slight cloudiness, and no
separation of oil globules. Also soluble in all proportions in glacial acetic acid.

"Specific gravity: 0.875 to 0.880 at 25° C. (77° F.).

"It is dextrorotatory, the angle of rotation varying from + 8° to + 24°, in a 100 mm.
tube, at25°C. (77° F.).

The oil of bergamot, often called essence of bergamot, has a sweet, very agreeable odor,
a bitter, aromatic, pungent taste, a pale greenish-yellow color, and a slightly acid
reaction.

It contains limonene, dipentene, linalool, a solid greasy compound called bergaptene, or
bergamot camphor, and linalool acetate, \( \text{C}_{10}\text{H}_{17} \cdot \text{C}_{2}\text{H}_3\text{O}_2 \), which latter makes up about
40 per cent. of the expressed oil, but is decomposed in large part by the process of
steam distillation. Bergaptene has been very fully studied by Pomeranz. (M. Chem.,
1891, 379.) It melts at 188° C. (370.4° F.), and has the composition \( \text{C}_{12}\text{H}_8\text{O}_4 \), being
the lactone or inner anhydride of bergaptenic acid, \( \text{C}_{12}\text{H}_{10}\text{O}_5 \). By fusion with
potassium hydroxide, bergaptene yields phloroglucin. (See Schim. Rep., April, 1893,
and 1895, 24; also Proc. A. Ph. A., 1897, 630.) The oil is distinguished from lemon and
orange oils by readily dissolving in solution of potassium hydroxide and forming with it
a clear solution. (Zeller.) Though possessed of the stimulant properties of the volatile
oils in general, it is employed chiefly as a perfume.

According to Galewsky (Ph. Ztg., 1915, Ix, p. 55) the oil of bergamot is an
extraordinarily active insecticide and useful to protect the body against lice and other
vermin.

It is often adulterated. (See C. D., 1908, 383; also 1910, 52.)

**Oil of Birch Tar, Rectified.** Oleum Betulae Empyreumaticum Rectifactum. N. F. IV.
Rectified Oil of Birch Tar. Rectified Empyroligneous Oil of Birch. Oleum Rusci
Rectificatum.—" The pyroligneous oil obtained by the dry distillation of the bark and
wood of Betula alba Linne (Fam. Betulaceae), rectified by steam distillation." N. F.

Under this name the National Formulary IV has introduced this oil of tar from the
birch. It is, however, not certain whether the rectification has removed some of the
valuable constituents. (See Betula)
It is described as follows:

"Rectified Oil of Birch Tar is a limpid, dark brown liquid having a penetrating, empyreumatic odor resembling that of Russian leather.

"It yields clear solution with 3 volumes of dehydrated alcohol, and with ether, chloroform, glacial acetic acid, amy alcohol, oil of turpentine, benzene, or carbon disulphide. When mixed with 3 volumes of alcohol or purified petroleum benzine, the solution is not more than slightly turbid but a decided turbidity is produced when mixed with the same volume of methyl alcohol.

" Specific gravity: 0.886 to 0.950 at 25° C. (77° F.).

Oil of Callitris. —The pine trees of Australia belong to the genus Callitris, of which only one or two species are found outside of Australasia and New Zealand. The wood of these trees is of great value as building timber because of the fact that it is not attacked by white ants. According to Baker and Smith ("Research on the Pine Trees of Australia," 1910) this protection is due to the presence of a phenol-like body, to which they give the name callitrol. The constitution of this substance which they have obtained from the wood of C. glauca they have not as yet determined. Several of the Australian species yield a resin with the same properties as those of Sandarac, but at present they have not been employed commercially as sources of this resin. The term cypress pine is applied in Australia to a number of these trees.

Oil of Cardamom. N. F. IV. Oleum Cardamomi.—"A volatile oil distilled from the seeds of Elettaria Cardamomum White et Meton (Fain. Zingiberaceae). Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light." N. F.

This oil has been introduced into the National Formulary IV. It is used in the preparation of compound spirit of cardamom, which is an ingredient in compound elixir of cardamom. It is also used as a flavor in other elixirs. It is to be regretted that cardamom seeds were not used instead of this oil which is largely adulterated. In fact oil of cardamom has been found in the market made from oils which contain no oil of cardamom whatsoever. The high price of cardamom seeds and the small percentage of volatile oil found in them offers an extraordinary inducement to adulterators. Care must therefore be used to employ only the oil which complies strictly with the requirements of the National Formulary IV. It is described as follows:

" Oil of Cardamom is a colorless or very pale yellow liquid having the characteristic, aromatic, penetrating and somewhat camphoraceous odor of cardamom, and a persistent, pungent, and strongly aromatic taste.

" It is very soluble in alcohol and readily soluble in four volumes of 70 per cent. alcohol, forming a clear solution.
"Specific gravity: 0.924 to 0.947 at 25° C. (77° F.).

"It is dextrorotatory, the angle of rotation varying from, +22° to +44°, in a 100 mm. tube, at 25° C." (77° F.) N. F. (See A. J. P., 1910, 167.)

Oil of cardamom is not used medicinally but solely for pharmaceutical purposes.

**Oil of Chione.**—The bark of this West Indian tree, Chione glabra (Fam. Rubiaceae) yields on distillation 1.5 per cent. of a light yellow volatile oil, consisting chiefly of o-oxyacetophenone, \( C_6H_4.OH.CO.CH_3 \). A compound obtained synthetically from o-nitrocinnamic acid proved to be identical with that isolated from the oil. (See J. Chem. Soc., vol. lxxv, 1899.)

**Oil of Citronella.**—There are a group of closely allied grasses which yield sweet scented volatile oils. Of these volatile oils, which are sometimes spoken of collectively as Indian Grass Oils, there are at least five commercial varieties, namely. Oils of Citronella, Lemon Grass, Palmarosa, Ginger Grass, and of Vetiver. The botany of the sweet-scented grasses from which perfumery oils are obtained, has been somewhat confused. Stapf (see Schim. Rep., April, 1907, p. 20) divides them into three groups, the Cymbopogon, Andropogon and Vetiveria.

Andropogon nardus L. (Fam. Gramineae) yields citronella oil. It grows in Ceylon, the Malaccan Peninsula, India and to some extent in tropical East Africa. There are two principal varieties, the one, Lana Batu, grows widely in Ceylon and yields an oil relatively poor in geraniol and is the principal source of the oil of commerce. The second variety, known as Matia pangiri, is generally cultivated in the Straits Settlements and in Java. This latter oil has a lower specific gravity, a lighter color and is claimed to be superior in quality.

Oil of citronella is produced in Ceylon, the Straits Settlements, close to Malabar, the Malay Peninsula and Java, the last named being the most highly esteemed. The exports of citronella oil from Ceylon amounted in the year 1909 to 1,512,084 pounds. Oil of citronella is of a yellowish-green color, having a characteristic odor and pungent taste. Its sp. gr. is, according to Gilde-meister and Hoffmann, 0.886-0.900. It mixes with alcohol in all proportions, and the test for purity given by Schimmel and Co. is based upon its behavior towards alcohol of 80 per cent: " One volume of the oil must form an absolutely clear solution with two, or at least two and a half, volumes of 80 per cent. alcohol at a temperature not below 20° C. (68° F.). A cloudy mixture indicates the presence of turpentine, certain fixed oils, and other essential oils which are sometimes used to adulterate it." The most important ingredients in this oil are geraniol and citronellal which together may make up as much as 93 per cent. of the oil. It is not used in medicine, but is largely used in the arts, for perfuming cheap soaps, especially so-called honey soap. An ointment containing 25 per cent. of the oil of citronella affords an excellent protection against the bities of mosquitoes and other insects.

Oil of lemon grass is official in the British. Pharmacopoeia (1914). (See Oleum
The Palmarosa oil is produced chiefly in India, and is the product of the Cymbopogon martini (Andropogon schoenanthus Pluck. and Hanb. not L.). Its most important ingredient is geraniol, of which it may contain as high as 94 per cent. It is largely employed in the perfumery arts, and also as an adulterant to the oil of rose and the oil of geranium.

Ginger grass oil resembles palmarosa oil in its properties but contains a much smaller percentage of geraniol.

From the roots of the vetiver or cus-cus grass, Vetiveria zizanoides Stapf. (A. muraticus Retz), which grows in the island of Reunion and in the Philippine Islands, is distilled a volatile oil. The odoriferous principle of this oil is at present unsettled. It has been attributed by Genivesse and Landlois to a peculiar alcohol which they named vetivenol, but this has been denied by Bacon. (Philippine journal of Science, 1909, iv, p. 118.)

Various other allied grasses, such as the Cymbopogon polyneuros or Delft Grass, and the C. Coloratus, etc., yield sweet-scented oils which have, however, not become commercially important.

**Oil of Coconut.** Cocoanut Oil. Cocoanut Butter. Oleum Cocos, P. G. Oleum Cocois. Beurre de Coco, Fr. Kokosnussol, G.—This must not be confounded with the fixed oil of the chocolate nut, which is often called cocoa butter. (See Oleum Theobromatis) The substance here considered is the fixed oil of the coconut, which is the fruit of a species of palm, Cocos nucifera L., universally known as the coconut tree, or cocoa-nut tree. The oil is obtained either by expression or decoction, often by insolation—i.e., exposing the rasped nuts to the heat of the tropical sun. It is of a fine white color, of the consistence of lard at ordinary temperatures, becoming solid, like suet, between 4.4° C. (40° F.) and 10° C. (50° F.), and liquid at about 26.7° C. (80° F.), of a bland taste, and a peculiar, not disagreeable odor. It is readily dissolved by alcohol. It contains large quantities of the glycerides of myristic and lauric acids, with smaller quantities of the glycerides of palmitic and oleic acids. It has also been found to contain several volatile acids, as caproic, caprylic, and capric acids. (Lewkowitsch, Chemical Analyses of Oils, Fats, and Waxes, 2d ed., 1898, 538.)

The oil has been used for various purposes in medicine and pharmacy. It has been employed as a substitute for cod liver oil, especially in the form of a proprietary preparation, coco-olein. In Germany it has been used in pharmacy, to a considerable extent, as a substitute for lard, to which, according to Pettenkofer, it is preferable on account of its lesser tendency to rancidity, its more ready absorption when rubbed on the surface of the body, and its lesser liability to produce chemical changes in the substances with which it is associated. Thus, the ointment of potassium iodide, when it is made with lard, becomes yellow in a few days, while, if made with coconut oil, it remains unchanged for two months or more. Vegetable substances also keep better in ointments prepared with this oil than with lard. Besides, it takes up one-third more
water, which is a useful quality when it is desirable to apply saline solutions externally. To prepare it for use, nothing more is ordinarily necessary than to melt it at a moderate heat, and strain it through linen. If colored, it may be digested with powdered animal charcoal, and subsequently filtered through paper. (A. J. P., xxix, 331.) When chilled and pressed, a solid residue, which is coco-stearin, is obtained. This is extensively used as a substitute and adulterant of the genuine cocoa butter in the confectionery trade. Coconut oil is employed in the manufacture of soap, particularly of the transparent varieties, and the so-called "marine soaps" and filled soaps; it is also largely used for giving firmness and lathering qualities to the ordinary soap; this property also permits of the addition of a large quantity of water to the soap. Unfortunately, coconut oil soap is very apt to contain free caprylic acid; and the persistent rancid odor, resembling that of infants' vomit, left upon the skin after washing with its soap is an effectual bar to its very extended use. The exportations of coconut oil from Ceylon amount to 15,000 tons annually, from British India to 4000 to 6000 tons, and from the Dutch Indies to 1300 tons per annum. Besides the oil itself, the dried pulp of the coconut is sent to European markets in large amounts under the name of copra. The export of copra from Ceylon amounts to 5000 tons annually, from Tahiti to 4000 tons, from Samoa to 3000 tons, and from Singapore to 4000 tons.

The importations of coconut oil into the United States for 1914 amounted to 74,386,213 pounds, valued at $6,703,942, and for 1915, 63,135,428 pounds, valued at $3,430,581.

According to Parisi, the endocarp or meat of the coconut is a powerful tenicide. The patient should drink the milk and then eat the flesh of the nut. The coconut is said to be largely used in India as a vermifuge, and the matter appears to have practical importance.

Powdered coconut shells have been largely used in America as an adulterant for spices. Their debris is readily recognized by the microscope. (See A. J. P., 1901.)

E. Millian describes the following test to determine the purity of coconut oil: 4 mils of the clean, water-free fat is introduced into a test tube with 2 mils of ethereal solution of phloroglucin and 'mixed by circular agitation; 2 mils of benzene solution of resorcin is then added and the whole again mixed. The tube is then immersed for a few minutes in ice-water, to bring the temperature to 10° C. (50° F.) ; 4 mils of nitric acid, sp. gr. 1.35, free from nitrous fumes, is then added, and the tube being closed with a rubber cork previously washed with the same acid, the whole is well shaken for five seconds. Pure coconut oil remains perfectly unaltered, negligible traces of impurities may impart a scarcely perceptible rose tint to the mixture; but the presence of any seed oil, such as cotton, sesame, arachis, etc., will at once be indicated by a distinct currant-red color if 5 per cent. of the adulterant be present. The color reactions which occur later, when the temperature of the mixtures rises to 40° C. (104° F.) are disregarded. It is important that the reagents and solvents employed should be absolutely pure, and that the temperature of the reagents and the oil be between 10° C. (50° F.) and 12° C. (53.6° F.). (C. R. A. S., 1903, cxi, 1702.)
Oil of Colza.—An oil expressed from the seed of Brassica campestris L., or field cabbage, a cruciferous plant which grows wild throughout the greater part of Europe, and is largely cultivated in France and Germany for the sake of this oil. Colza oil is used in Europe as a burning oil, as a lubricating oil, and, after purification by heating with starch, as a table oil. The raw oil has a sp. gr. of 0.915, and the refined oil 0.9136. Chilled to -4° C. (24.8° F.), stearin separates out, and at -6° C. (21.2° F.), it becomes a yellowish buttery mass. The oil contains the glycerides of stearic, erucic (or brassic) acid, C_{22}H_{42}O_2, and an acid isomeric with, but differing in some respects from, ordinary oleic acid. A similar oil is derived from rape-seed (Brassica napus). The total consumption of rape and colza oil in Europe is estimated at from 280,000 to 300,000 tons per annum. For analysis of commercial samples, see C. D., 1894, 140.

Oil of Cypress.—An oil derived from Cupressus sempervirens L. (Fam. Pinaceae) has been strongly recommended by Bravo in whooping cough; it is used by sprinkling the oil upon the clothes, bed, etc., of the patient.

Winterseel (In. Dis., Bonne, 1908) has studied cypress oil physiologically and finds that its action is similar to the other essential oils, but is of relatively low toxicity. When the reflexes are excited by spinal stimulants it acts as a depressant to the spinal cord. He confirms the favorable results of its inhalation in cases of whooping cough.

Oil of Doegling. Oleum Choenoceti. Doegling Oil. Doegling Thran. Ernie de Rorqual Rostre, Fr.—The oil derived from the Norwegian whale, Balaena rostrata, is said by Gustave Guldberg to possess a lower specific gravity than any other animal oil (0.876 at 15° C. (59° F.), and also remarkable penetrative properties. It is affirmed that if mixed in equal quantities with chloroform it carries the latter agent through the skin, and enables it to act as a local anesthetic in pruritus, neuralgia, etc. Mixed with wax, it is highly recommended as a basis for ointments by the same authority.

Oil of Egg Yolk.—A fatty oil obtained by expression from the yolks of fresh eggs. It has been used in lotions and as a popular remedy on the continent in the treatment of corneal opacities.

Thorpe's Dictionary gives the following composition and properties of egg oil: Specific gravity, 0.9144; solidification point, 8°-10° C. (46.4°-50° F.); melting point, 22°-25° C. (71.6°-77° F.); acid value 1.2; saponification value 184.4-190.2; iodine value 68.5-81.6; insoluble fatty acids and unsaponifiable matter 95.16 per cent.

Benedikt states that the refractive index of egg oil is 1.4655, and that it gives the elaidin reaction. It is also stated that the oil obtained by expression differs from that extracted by solvents in that the latter contains cholesterol and lecithin.

Oil of erigeron is limpid, of a light straw color, a peculiar, aromatic, persistent odor, and a characteristic taste. By exposure it becomes darker and thicker. Its reaction is neutral. Its sp. gr. is about 0.850, increasing with age (0.855 to 0.890, Sohim. Rep.). It consists chiefly of dextrogyrate limonene, together with some terpineol. (A. J. P., 1893, 420.) It was officially described as "a pale yellow, limpid liquid, rapidly becoming darker and thicker by age and exposure to the air, having a peculiar, aromatic, persistent odor, and an aromatic, slightly pungent taste. Specific gravity, 0.845 to 0.865 at 25° C. (77° F.). Soluble in an equal volume of alcohol (distinction from oil of fireweed derived from Erechthites hieracifolia Rafinesque (fam. Compositae) and from oil of turpentine). It is dextrogyrate, the angle of rotation being not below +45° in 100 mm. tube, at a temperature of 25° C. (77° F.)." U. S. When distilled without water, it comes over colorless, and a little resinous matter is left behind, probably resulting from the oxidation of one or both of the constituent oils. It is slowly reddened by potassium hydroxide, combines with iodine without explosion, is instantly decomposed by sulphuric acid, and is acted on by strong nitric acid, slowly at ordinary temperatures, but with heat explosively. (Procter, A. J. P., xxvi, 502.) The plant yields 0.2 to 0.4 per cent. of oil. When exposed to the air, the oil darkens and rapidly resinifies. For an account of the difference in properties between this oil and that from Erechthites hieracifolia, see a paper by Albert M. Todd, A. J. P., 1887, p. 302; also one by Frank Rabak, Ph. Rev., 1905, 81, and also Ph. Rev., 1906, 326.

It was first brought into notice by the so-called eclectic physicians, who use it in diarrhea, dysentery, and the hemorrhages, and apparently it is a valuable remedy in hemoptysis when there is no fever or other marked evidence of constitutional irritation. J. W. Moorman speaks of it most highly, in diarrhea of debility, in dysentery after sufficient evacuation of the stomach and bowels, and especially in hemorrhage from the bowels during typhoid fever. (Am. J. M. S., Oct., 1865, p. 393.) It probably acts like the oil of turpentine as a hemostatic, but is much less irritant and stimulating.

Dose ten minima to half a fluidrachm (0.6-1.8 mils), repeated every hour or two.

Oil of Eulachon.—The fish known by the North Pacific Indians under the name of Eulachon or Oulachon, and by the English as Hoolakins or Candle fish, the Thaleichthys pacificus of scientists, yields a great abundance of an oil which has been proposed as a substitute for cod liver oil. According to the editor of N. R. (1881, 356), this oil first begins to congeal and become opaque at -7° C. (19.4° F.), although authorities state that at ordinary temperatures it grows solid and lard-like. Specific gravity at 15.5° C. (60° F.), 0.907; mixed with one-half its volume of nitric acid, specific gravity 1.37, it develops a beautiful pink color which fades slowly to amber, and after standing fifteen hours it is considerably thickened and its color is changed to a deep amber of a reddish cast. It contains about 20 per cent. of palmitic and stearic acids, and 60 per cent. of oleic acid and 13 per cent. of an unsaponifiable substance, which resembles the similar constituent of sperm oil. (T. (?., Sept. 15, 1884.)

Oil of Euphorbia.—A fixed oil, obtained from the seeds of Euphorbia Lathyris L.
(Fam. Euphorbiaceae), a biennial plant somewhat naturalized in this country, though believed to have been introduced from Europe. It is often found near gardens and in cultivated fields, and is generally called mole plant, under the impression that moles avoid the ground where it grows. (Pursh.) It is the caper plant of England. Like the other species of Euphorbiaceae, it contains a milky juice, which is extremely acrid, and the whole plant possesses the properties of a drastic purge; but the oil of the seeds is the only part used in medicine. This may be extracted by expression, or by the agency of alcohol or ether. In the first case, the bruised seeds are pressed in a canvas or linen bag, and the oil which escapes is purified by decanting it from the whitish flocculent matter which it deposits upon standing, and by subsequent filtration. By the other process, the bruised seeds are digested in alcohol, or macerated in ether, and the oil is obtained by filtering and evaporating the solution. According to Soubeirari, however, the oils obtained by these different processes are not identical. That procured by expression is probably the purest.

Oil of euphorbia is colorless, inodorous, and, when recent, nearly insipid; but it speedily becomes rancid, and acquires a dangerous acridity. Soubeirani has ascertained that it has a complex composition, containing, besides the pure oil, four distinct proximate principles. (J. P. C., xxi, 259.) From 40 to 44 parts are obtained by expression from 100 of the seed. It is a powerful purge, but in doses of from five to ten drops is stated by Continental physicians to act kindly upon the bowels. In this country, however, it has been found very uncertain in its effects, and very liable to cause vomiting. (A. J. P., iv, 124.)

**Oil of Jasmine.**—This oil is obtained from the flowers of the common white jasmine (Jasminum grandiflorum L.). Alternate layers of the fresh flowers, and of cotton saturated with the oil of ben or other fixed oil, are exposed in a covered vessel to the warmth of the sun, the flowers being renewed until the oil becomes impregnated, when it is separated from the cotton by pressure. This method is necessary, as the flowers do not yield their aroma by distillation. According to Gildemeister and Hoffmann, jasmine oil contains 65 per cent. of benzyl acetate, and in addition linalyl acetate, benzyl alcohol, and linalool. The oil is used only as a perfume. W. H. Hall records (M. S. Rep., Jan., 1861) the case of a child poisoned by the fruit of a jasmine, probably the common white species. The symptoms were coma, widely dilated pupil, and snoring respiration, with a cold pale surface, and slow and feeble pulse, followed by violent convulsions, with rigidity of the muscles about the head and throat.

**Oil of Kuromoji.**—Under this name there have entered commerce two fragrant Japanese oils— one, Kouro motsi, said to be obtained from the Lindera sericea Bl., and one, Kuro matsi, yielded by Lindera umbellata (Fam. Lauraceae). (See Schimmel's Bericht, 1904.)

**Oil of Linaloe.**—This volatile oil which is produced in Mexico, according to Seyffert (Schim. Rep., Oct., 1907), is obtained from the wood of two species of Bursera, one of which is known in the Spanish as Linaloe, and the other as Copal limon. The latter tree is probably the B. aloexylon Engl. Better grades of this oil have a pleasant odor resembling a mixture of lemon and jasmine, while the poorer grades have a caraway-
like odor. It is important in perfumery as the source of linalyl acetate, and is used as a substitute for oil of bergamot.

**Oil of Maize.**—Our American maize or Indian corn yields a bright golden-yellow oil, of peculiar pleasant odor and taste. It is moderately thick, and has a sp. gr. at 15° C. (59° F.) of 0.916 to 0.924. It consists of olein and palmitin, and solidifies at -10° C. (14° F.). The oil is contained in the germs of the seed alone. Reckoned on the whole weight of the seeds the oil constitutes about 5 per cent., reckoned on the weight of the germ itself, after separation from the starchy body of the seed, the oil amounts to nearly 50 per cent. It is now being extensively produced in connection with the working of starch and glucose factories. It is used as a lubricant and for soap making, and as a substitute for cotton seed oil. In 1914 the amount of corn oil exported was 18,281,576 lbs., and in 1915, 17,789,635 lbs.

**Oil of Myrcia.** N. F. IV. Oleum Myricze. Oil of Myrcia. Oil of Bay.—"A volatile oil distilled from the leaves of Pimenta acris Wight (not Myrcia acris DC.) (Fam. Myrtaceae)." This oil, formerly official in U. S., 1890, is now official in the National Formulary IV.

"A volatile oil distilled from the leaves of Pimenta acris (Swartz) Wight (Fam. Myrtaceae). Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light." N. F.

The commercial oil of bay is a mixture of both heavy and light oils, as G. M. Beringer found the specific gravity of two samples of undoubted purity to be 0.975 and 0.994. (A. J. P., 1887, 286.) Mittmann (A. Pharm., 1889, 529) reported the following constituents: 1, pinene; 2, possibly dipentene; 3, a polyterpene, probably diterpene (insoluble in alcohol); these three in small quantity only; 4, eugenol, the chief constituent; and, 5, methyl-eugenol, in smaller quantity. It has since been examined (March, 1895) by Power and Kleber, who state that it contains from 60 to 65 per cent. of phenols, of which two were identified: eugenol, $C_{10}H_{12}O_2$, and chavicol, $C_9H_{10}O$; two phenol esters, methyl-eugenol, $C_{11}H_{14}O_2$, and methyl-chavicol, $C_{10}H_{12}O$; phellandrene and a newly discovered terpene which they named myrcene, $C_{10}H_{16}$, and citral, $C_{10}H_{16}O$. (Ph. Rund., 1895, 60.) The oil is officially described as "a yellow or brownish-yellow liquid having a pleasant, aromatic odor and a pungent, spicy taste.

"With an equal volume of alcohol, glacial acetic acid, or carbon disulphide, it yields slightly turbid solutions. An alcoholic solution is slightly acid to litmus paper.

" Specific gravity: 0.962 to 0.990 at 25° C. (77° F.).

" It is laevorotatory, the angle of rotation not exceeding -3°, in a 100 mm. tube, at 25° C. (77° F.).

Oil of bay is not used internally, but solely for making bay rum. (See Spiritus Myrciae Compositus, Part III.) For a paper describing the manufacture of bay rum and oil of bay, see W. O. Fishlock, C. D., 1912, 714.
For an English formula for bay rum, see P. J., 1896, 468.

The oil of bay is an active antiseptic, 1 part in 1000, according to Peck (J. A. M. A. 1899, xxxii, p. 6) being sufficient to prevent the growth of bacteria.

Bay rum is used chiefly as a refreshing perfume in cases of nervous headache, faintness and other nervous disorders, either held to the nostrils, or applied on soft linen to the head and forehead. According to Berger (Th. M., 1907, xxi, p. 221) it is a valuable local application in various diseased conditions of the skin, especially in seborrhea of the scalp. It is also grateful to the feeble and convalescent patient, by being sprinkled on the bed covering or otherwise made to impregnate the air of the chamber. The oil of bay is often adulterated, and is frequently sold by smugglers.

Oil of Neat's-foot. Oleum Bubulum. Oleum Pedum Tauri. Axungia Pedum Tauri. Huile (Oraisse) des Pieds du gros Betail, Fr. Klauenol, Ochsen Klauenfett, G.—This formerly official oil is obtained by boiling for a long time the feet of the ox, previously deprived of hoofs. The fat and oil which rise to the surface are removed and introduced into a fresh portion of water, heated nearly to the boiling point. The impurities having subsided, the oil is drawn off, and, if required to be very pure, is again introduced into water, which is kept for twenty-four hours sufficiently warm to enable the fat which is mixed with the oil to separate from it. The liquid being then allowed to cool, the fat solidifies and the oil is removed and strained, or filtered through layft-s of small fragments of charcoal free from powder. The oil is clear and yellowish in color, of sp. gr. 0.916 at 15° C. (59° F.), and, when properly prepared, inodorous and of a bland taste. It thickens or congeals with great difficulty, and is, therefore, very useful for greasing machinery. It is also used for softening leather and in grinding metals. It has been given as a substitute for cod liver oil in scrofulous diseases. It is apt to be laxative, and in certain cases proves useful in this way. It is given in the same dose as cod liver oil. (See Am. J. M. S., N. S., xxiv, 498.) It is at present difficult to obtain pure neat's-foot oil in commerce.

This oil, official in the U. S. P., 1890, is employed for its odor and taste, and is largely used as an ingredient in cologne water, perfume, etc. The best quality of oil of neroli, as it is universally called in commerce, comes from Nice, and is derived from the flowers of the Citrus Aurantium sinensis L., or sweet orange, by distillation with water; this is called neroli petale. The next quality is obtained in the same way, but by using the blossoms of the Citrus Bigaradia Risso, or bitter orange; this is called neroli bigarade while an inferior sort, essencedepetit grain, is made by distilling the leaves and unripe fruit. This should not be classed with neroli, as it is unworthy of the name. Oil of petit grain citronnier is a fragrant oil, distilled from the leaves and twigs of the
lemon tree; it closely resembles the essence de petit grain which is made from the orange leaves and fruit. (C. D., 1897, 53.)

It is officially described as follows:

"Oil of Orange Flowers is a pale yellow, slightly fluorescent, neutral liquid, having a distinctive fragrant odor similar to that of orange blossoms and an aromatic, at first sweet then somewhat bitter, taste.

"It is soluble in an equal volume of alcohol, the solution having a violet fluorescence and a neutral reaction to litmus paper. Also soluble in two volumes of 80 per cent. alcohol, the solution becoming cloudy on the further addition of alcohol of the same percentage.

"Specific gravity: 0.868 to 0.880 at 25° C. (77° F.).

"It is dextrorotatory, the angle of rotation varying from +1° 30' to +5°, in a 100 mm. tube, at 25° C. (77° F.).

Under the name of nerolin an artificial product has been placed upon the market in the form of a white crystalline powder, soluble in alcohol and fixed oils and almost insoluble in water. It is used by soap makers as a substitute for oil of neroli, and is said to be ten times as strong. This compound is said to be the ethyl ether of ß-naphthol. (Ber. d. Chem. Ges., 1893, 2706.) It is also used in the manufacture of eau-de-Cologne with advantage instead of neroli oil. (Schim. Rep., April, 1893.) Oil of neroli of excellent quality is now produced artificially; Schimmel & Co. state that it contains pinene, camphene, dipentene, terpineol, phenyl, acetic acid, benzoic acid, decylic aldehyde, and linalool.

Oil of Palm. Palm Oil. Huile (Beurre) de Palme, Fr. Palmol, Palmbutter, G.—This highly valuable fixed oil is the product of Eloeis guineensis Jacq., a palm growing on the western coast of Africa, and cultivated in the West Indies and South America. It is among the handsomest trees of its graceful family which flourish in the tropical regions of Africa. The oil is obtained by expression from the fruit. It is brought to this country chiefly from Liberia and other places on the African coast, although prepared also in the West Indies, Cayenne, and Brazil. It is not improbable that various species of Palmaeae contribute to the supply of this article of commerce. At present the chief ports for its shipment are Cape Palmas and Lagos, prima and secunda Lagos being the choicest varieties. The annual export from the African coast is about 50,000 tons, of which the bulk goes to England. The importation into the United States amounted in 1914 to 61,753,482 lbs., valued at $4,118,077, and in 1915 to 31,482,292 lbs., valued at $2,024,827.

Palm oil has the consistence of butter, a rich, orange-yellow color, a sweetish taste, and an agreeable odor, compared by some to that of violets, by others to that of the Florentine orris. By age and exposure it becomes rancid and of a pale yellow or nearly white color. It melts with the heat of the hand, and when perfectly fluid passes readily
through blotting paper. Highly rectified alcohol dissolves it at common temperatures, and in ether it is soluble in all proportions. Its constituents are tripalmitin and triolein, \( C_3H_5(C_{16}H_{31}O_2)_3 \) and \( C_3H_5(C_{18}H_{33}O_2)_3 \). The tripalmitin is converted into palmitic acid by superheated steam, with liberation of glycerin. It appears also that a considerable proportion of this acid, together with some glycerin, exists uncombined in the oil, as ascertained by Pelouze and Boudet; so that the changes which are effected in oils, through the agency of alkalies, in the process of saponification, take place, to a certain extent, spontaneously in palm oil. (J. P. C., xxiv, 389.) Hence it is more easily saponified than any other fixed oil. Preparatory to saponification, it may be bleached rapidly, according to J. J. Pohl, by heating it quickly to 240° C. (464° F.) and keeping it for ten minutes at that temperature. It loses for a time its peculiar odor by the process, acquiring an empyreumatic one; but this after a while ceases to be perceived, and the characteristic odor returns. (See A. J. P., xxvii, 346.) Englehart bleaches it in the following manner: 1000 lbs. of the oil are heated in a boiler to 62.2° C. (144° F.) and kept at that temperature until the next day, when it is decanted into a clean vessel, and cooled to a point between 36.6° C. (98° F.) and 40° C. (104° F.). In another vessel 15 lbs. of potassium dichromate are dissolved in 45 lbs. of boiling water, and, when the solution is partially cooled, 60 lbs. of hydrochloric acid are added. This solution is then mixed with the oil, and briskly agitated. In five minutes the color changes to green, through the reduction of the chromic acid, and, with a continuation of the agitation, the chromium oxide separates, and then nothing more is necessary than washing with water to get the oil colorless. (A. J. P., 1868, 333.) Palm oil is said to be frequently imitated by a mixture of lard and euet, colored with turmeric, and scented with Florentine orris. It is much employed in the manufacture of toilet soap, which retains its pleasant odor. Palm oil is emollient, and has sometimes been employed in friction or embrocation, though not superior for this purpose to many other oleaginous substances. It is sometimes used to impart a yellow color to mixtures of fats or manufactured products, such as oleomargarine. In the latter case it is considered as an artificial coloring matter which necessitates the payment of ten cents per lb. additional tax. It is detected in the presence of other fats by a color reaction developed when sulphuric acid is added to a mixture of the suspected oil and an equal volume of acetic anhydride. This is known as Crampton-Simons test for palm oil, but it has been attacked by A. G. Gill (J. I. & E. C., 1917, p. 136) as being fallacious, due not to a specific substance present in palm oil only, but to the presence of carotin, which is present in butter and some other constituents likely to be normally present in oleomargarine, to which this test is usually applied for the purpose of detecting the palm oil as an added coloring matter. The test as carried out is as follows: Preparation of Sample: The sample should be kept in a cool dark place until tested, as exposure to light and air or the presence of water, alcohol, ether or similar reagents, interferes with the tests. Immediately before testing, the sample is filtered as quickly as possible at a temperature not exceeding 70° C. (158° F.). First Method: Dissolve 100 mils of the fat in 300 mils of petroleum ether and shake out with 50 mils of 0.5 per cent. potassium hydroxide solution. Draw off the aqueous layer, make distinctly acid with hydrochloric acid and shake out with 10 mils of pure carbon tetrachloride. Separate the carbon tetrachloride solution, transfer a portion to a porcelain crucible, add 2 mils of a mixture of one part colorless, crystallized phenol and two parts of carbon tetrachloride, then 5 drops of hydrobromic acid (sp. gr. 1.19).
and mix by gentle agitation. The almost immediate development of a bluish-green color is indicative of palm oil.

Second Method (usually preferred): Shake out 10 mils of the melted and filtered fat with an equal volume of colorless, chemically pure, acetic anhydride, add 1 drop of sulphuric acid (sp. gr. 1.53) and shake the mixture for a few seconds longer.

If palm oil is present the lower layer, on settling, will be found to be colored blue with a tint of green. The color in this as well as in the preceding test is transient. Leach, p. 541-543.

Oil of Patchouli.—The genuine oil is obtained from Pogostemon Patchouli Pellet, a plant cultivated in the Straits Settlements and in Penang. The plant has also been cultivated in the West Indies and in Paraguay. A small amount of oil is also obtained from Microtana cymosa Prain, a plant cultivated in the mountainous districts of Assam. The patchouli herb is sometimes dried and sent into commerce. It is not infrequently adulterated with a number of other plants, the latter being present to the extent of 80 per cent. It is believed by Arabs, Chinese, and Japanese to possess prophylactic powers. The oil as found in commerce is of two kinds. The best is that distilled in the East in the neighborhood of the patchouli plantations, from selected fresh leaves; the other kind is distilled in Europe from imported leaves; the latter often arrive in a more or less damaged condition, and are frequently adulterated. Oil of patchouli is a thick, brownish-yellow oil with a green tint, and was shown by Gladstone to contain coerulein, an intensely blue compound found in oils of absinthium, calamus aromaticus, matricaria, achillea, etc. The oil has the sp. gr. 0.970-0.990 at 15° C. (59° F.), and is laevorotatory. Rodie states that the odor improves by age and hence perfumers prefer the older oils. It deposits a solid, patchouli alcohol, $C_{15}H_{25}O$, which crystallizes in hexagonal prisms, melts at 56° C. (132.8° F.), and boils at 206° C. (402.8° F.), while cadinene, $C_{15}H_{24}$, remains; oil of cedar and oil of cubeb are frequently used to adulterate the oil. They may be detected by fractional distillation. Oil of patchouli is used in perfumery mainly for its valuable property of conferring upon other odors lasting qualities; its characteristic and persistent odor when un-combined is usually not popular among Caucasians.

Oil of Turtle. Turtle Oil.—In South America an oil is prepared from the eggs of turtles, and in the Seychelle Islands and in Jamaica from the fat of the turtle itself. These oils are said to be of equal value with cod liver oil for strumous persons and others in whom the nutritive processes are defective. (See P. J., vol. xv, 573.) C. E. Sage examined turtle oil as sold in London drug auctions and found the sp. gr. 0.919 at 25° C. (77° F.). The oil was yellow and semi-solid, having an odor of beef-drippings. (C. D., 1906, 691.) It is stated that 50,000 gallons are sent to Para yearly from the Orinoco, the Amazon, and the Rio Negro, and that 60,000 gallons are consumed by the tribes who prepare the oil. The Seychelles Islands are said to produce 6000 gallons of oil yearly.

Oil of Wood. Wood Oil. Gurjun Balsam.—In the P. J. for August, 1854 (p. 65), appeared an account by Charles Lowe of Manchester, of a "new variety of balsam of
copaiba," derived from the East Indies. In a subsequent communication to the same journal (1856, 321) from Daniel Hanbury, it appears that this product, though offered for sale in the London market as balsam of copaiba, is known in India under the names of wood oil and gurjun balsam. Considerable quantities had been imported from Moulmein, in Burma, specimens of a similar drug had been received from Canara and Tenasserim, and it appears to be widely diffused in the Indian markets. This must not be confounded with the Chinese wood oil, which is used as a varnish. (See Oil of Aleurites.)

This liquid is obtained from Dipterocarpusturbatinus Gaertn. f., and several other species of Dipterocarpus growing in East India (Fam. Dipterocarpaceae), a very large tree which forms forests in Pegu and other parts of Farther India. A large notch is cut in the trunk of the tree, between two and three feet from the ground, and a fire made so as to char the wound. The juice then begins to flow, and is received in suitable vessels. Every three or four weeks the charred surface is cut off and burned anew. A single tree sometimes yields forty gallons in a season. D. tuberculatus Roxb. yields a liquid known in Burma as in oil, which is sometimes sold as gurjun balsam. (Proc. A. Ph. A., 1913, 223.) It is at first turbid, but may be clarified either by filtration or deposition. After filtration, wood oil is a clear, dark brown liquid, of the sp. gr. 0.964 (Hanbury), and, in consistence, odor, and taste, bears a close resemblance to copaiba. It is soluble in two parts of alcohol of the sp. gr. 0.0796, with the exception of a very small proportion of darkish flocculent matter, which subsides on standing. According to Lowe, it contains 65 per cent. of volatile oil, 34 of resin, and 1 of acetic acid and water. A characteristic property noticed by Lowe, by which it may be distinguished from copaiba, is that, when heated in a closed vial to 266° F. (230° F., Lowe), it becomes slightly turbid and coagulates, so that the vial may be inverted without changing the position of its contents, and this consistence is retained when the liquid cools. By a gentle heat with agitation the fluidity returns; but the liquid again coagulates if heated to 266° F. According to D. Brandis, this property of coagulation is characteristic of the wood oil from D. alatus Roxb. (P. J., xxv), a wood oil which is further to be distinguished by the greenish opalescence of its surface.

Guibourt states that wood oil does not solidify, like copaiba, with one-sixteenth of magnesia, and the two separate on standing. (J. P. C., xxx, 192.) De Vrij of Rotterdam, proposes the reaction of benzene with wood oil and copaiba respectively as a test to distinguish them. With an equal volume of the wood oil, benzene forms a turbid mixture, from which, after a long time, a resinous matter is deposited in flocculi; with copaiba it forms a transparent solution. (P. J., 1857, 374.) The volatile oil from gurjun balsam is a yellow, somewhat thick liquid, of sp. gr. 0.915 to 0.930, and has at times a high optical rotation— viz., -35° to -130°. The oil boils in larger part at 255° to 256° C. (491°-492.8° F.) and consists of a sesquiterpene; C_{15}H_{24}. With hydrochloric acid it yields a deep blue color. The resin left after distilling off the volatile oil is essentially gurjunicad, C_{22}H_{34}O_{4}. This when purified dissolves readily in ether and strong alcohol, and slowly in benzene. It melts at 220° C. (428° F.) and congeals again at 180° C. (356° F.). Fluckiger has also described a neutral resin from gurjun balsam, which is insoluble in caustic potash, fuses at 126° C. (258.8° F.), and is of the composition C_{28}H_{46}O_{2}. Fluckiger (A. Pharm., 1876, 420) noticed that wood oil may be
recognized by the violet color it assumes if dissolved in twenty parts of carbon disulphide and mixed with a drop of a cold mixture of equal parts of concentrated sulphuric and nitric acids.

According to O'Shaughnessy, the oil of dipterocarpus is little inferior to copaiba in the diseases for which that medicine is employed. T. B. Henderson has found it very useful in gonorrhea, given in the dose of a teaspoonful two or three times a day, uncombined. (M. T. G., 1865, 571.) It probably has a remedial influence on diseased mucous membranes similar to the different turpentines, which it appears to resemble in composition. The juice may be given in emulsion, in doses of from fifteen to forty minims (0.9-2.5 mils); the volatile oil from ten to thirty minims (0.6-1.8 mils).

**Oil of Ylang Ylang.** Cananga Oil. Oleum Anonae. Oleum Unonae.—This is a volatile oil obtained from the flowers of Cananga odorata Hook. f. and Thorns (Fam. Anonaceae), a large tree inhabiting most parts of Southern Asia; the oil from the Philippine Islands is especially esteemed. According to Schimmel & Co. (Schim. Rep., April, 1897), it contains pinene, linalool, geraniol, esters of acetic and benzoic acids, cadinene, and para-cresol-methyl ester. It is used only as a perfume. (See N. R., April, 1881.) The so-called Macassar hair oil is said to be a solution of it in coconut oil. (See A. J. P., 1881, 123; also A. J. P., 1893, 529.)

**Ointment of Cucumber.** Cucumber Ointment.—An emollient ointment, prepared from the common cucumber (fruit of Cucumis sativus L., Fam. Cucurbitaceae), has been considerably employed in irritated states of the skin. The following is the mode of preparing it, recommended by Procter. Take of green cucumbers 7 pounds avoirdupois, pure lard 24 ounces, veal suet 15 ounces. Grate the washed cucumbers to a pulp, express, and strain the juice. Cut the suet into small pieces, heat it over a water bath till the fat is melted out from the membrane; then add the lard, and, when melted, strain through muslin into an earthen vessel capable of holding a gallon, and stir until thickening commences, when one-third of the juice is to be added, and the whole beaten with a spatula till the odor has been almost wholly extracted. The portion which separates is to be decanted, and the remaining two-thirds of the juice is to be consecutively incorporated and decanted in the same manner. The jar is then closely covered and placed in a water bath, until the fatty matter entirely separates from the juice. The green co-agulum floating on the surface is now removed, and the jar put in a cool place that the ointment may solidify. The crude ointment is then separated from the aqueous liquid on which it floats, melted and strained, and placed in glass jars, which must be kept closely sealed. A layer of rose water upon its surface will favor its preservation. A portion may be triturated with a little rose water until white and creamy, and put into a separate jar for present use. (A. J. P., xxv, 409.)

Emile Mouchon prepares the ointment by obtaining the juice mixed with a little alcohol, and incorporating this with benzoinated lard and steayn. He directs 16 parts of the cucumber to be rendered to a pulp, 1 part of alcohol of 36° B. (&7 per cent. vol.) to be added, and the mixture to be placed on the diaphragm of a percolator. Twenty-four hours afterwards 10 parts of the liquid are obtained of 19° B. Of this liquid 6 parts are to be incorporated with 37.5 parts of benzoinated lard and 12.5 of stearin;
the fatty matters having been previously melted together by means of a water bath, and beaten vigorously on cooling. The liquid is to be added before the completion of the beating, which should then be continued until the whole becomes as light and white as possible. The benzoin and alcohol enable the ointment to keep a long time. (J. P. C., Juillet, 1854, 41.) We prefer to make this ointment by incorporating one part of distilled spirit of cucumbers with seven parts of benzoinated ointment. The spirit is made by distilling a mixture of one part of grated cucumbers with three parts of diluted alcohol, retaining the first two parts or distillate which come over. This spirit is permanent, and ointment or cream made from it keeps well, and cucumber cream can be made extemporaneously.

The most frequently used preparation of cucumber at the present time is the cosmetic preparation known as cucumber jelly, which is used as a soothing application in roughness of the skin, etc. It consists of a jelly of tragacanth, quince seed, or some similar mucilaginous drug made up with cucumber juice which imparts to the preparation a characteristic odor.

**OLEA.**

**OILS**

These are liquid or solid substances, unctuous to the touch and characterized by inflammability. They are divided into two classes, the fixed and the volatile, because distinguished, as their names imply, most readily by their different behavior on the application of heat.

**OLEA FIXA. Fixed Oils.**

These are sometimes termed fatty oils, because they constitute in part the vegetable and animal fats. The distinction between liquid and solid fats is for the most part a physical one only, as they contain the same chemical compounds, although in relatively different proportions. The fatty oils, though existing in greater or less proportion in various parts of plants, are furnished for use exclusively by the fruit, and, as a rule, are most abundant in the dicotyledonous seeds. They are obtained either by submitting the bruised seeds to pressure in hempen bags, or by boiling them in water, and skimming off the oil as it rises to the surface. When pressure is employed, it is customary to prepare the seeds for the press by exposing them to a moderate heat, so as to render the oil more liquid and thus enable it to flow out more readily. Another mode of extracting certain oils is by means of liquids having the power
of dissolving them, and this method is now largely used in practice, carbon disulphide, carbon tetrachloride, and petroleum benzine being used. For the details of the process, see A. J. P., Nov., 1868, 549. Fixed oils may be clarified and decolorized by suboxide, filtration through animal charcoal, clays or earths, or porous solids, precipitation with tannin, lead acetate, plaster of Paris, albumin, gelatin, or other agents; cellulose and asbestos filters are often used, and on the large scale, for separating mechanical impurities, centrifugal machines like those employed for milk. Some oils are given a preliminary treatment with sulphuric acid which is later removed by treatment with alkali. Fixed oils containing stearin or palmitin are likely to deposit these fats in cold weather, leaving the olein in a liquid condition. The olein may be separated by filtration in the cold.

Hydrogenated Fats and Oils.—A class of solid fats has appeared upon the market which are produced by a process known as hydrogenation, which is carried out in practice by bringing liquid fats into intimate contact with metallic catalysts (finely divided nickel is usually employed), at elevated temperatures (160°-200° C. or 320°-392° F.). Under these conditions the unsaturated members of the fatty acid series which are usually liquid and are represented by oleic acid, become converted into the solid members of the series, which are saturated as stearic acid. The best known commercial product made in this way is the proprietary fat known as Crisco, largely used for culinary purposes.

CLASSIFICATION.

The following scheme of classification of the fixed oils, both liquid and solid (Allen, Com. Org. Anal., 3d ed., vol. ii, Part I, pp. 88-102), gives a general view of their essential characters, points of difference, etc.

I. Olive Oil Group. Vegetable Non-drying Oils.—The oils of this group solidify on treatment with nitrous acid or mercuric nitrate, but do not lose their power of producing a greasy stain on paper, however long they may be exposed to the air. Their density varies from 0.914 to about 0.920, and hence is less than that of Groups III, IV, and V. Their viscosity is notably greater than that of the drying oils.

This group includes almond oil (from Amygdalus communis), peach oil (from kernels of Prunus Persica), apricot oil (from kernels of Prunus armeniaca), oil of ben (from Moringa oleifera), earth nut oil (from
Arachis hypogaea), and olive oil (from Olea europaea).

II. Rape Oil Group.—The oils of this group are all derived from seeds of the family Cruciferae. They are non-drying but less distinctly so than the oils of Group I. They show higher saponification values, higher iodine absorption and less solid elaidins than Group I.

This group includes Colza oil and rape seed oil (from Brassica campestris, B. napus and other species); oil of black mustard (from seeds of Brassica nigra); oil of white mustard (from seeds of Sinapis alba).

III. Cotton Seed Oil Group.—The oils of this group occupy a position intermediate between the vegetable non-drying and the true drying oils (Groups I and IV). In density they somewhat exceed the oils of Group I, but are lighter than those of Groups IV and V. They form more or less elaidin on treatment with nitrous acid or mercuric nitrate, but do not become wholly solidified. On the other hand, they undergo more or less drying on exposure to the air, but not so markedly as the oils of Group IV.

This group includes beech nut oil (from Fagus sylvatica), cotton seed oil (from Gossypium species), hazel nut oil (from Corylus avellana, see Proc. A. Ph. A., 1893), sesame or teel oil (from Sesamum orientale), and sunflower oil (from Helianthus annuus; H. perennis), camelina oil (from Myagrum sativum), cress seed oil (from Lepidium sativum), and maize oil (Corn Oil).

IV. Linseed Oil Group. Vegetable Drying Oils.—These oils are not solidified by treatment with nitrous acid or mercuric nitrate, but become gradually converted into solid masses or varnishes, by exposure to the air. In density the oils of this group vary from about 0.923 to 0.937, and hence are distinctly heavier than the non-drying oils and than most of the oils of Group III. On the other hand, they are lighter than the oils of Group V. The fluidity of the drying oils is also much higher than that of the non-drying oils.

This group includes niger seed oil (from Guizotia oleifera), hemp seed oil (from Cannabis sativa), linseed oil (from Linum usitatissimum; L. perenne), poppy seed oil (from Papaver somniferum), Scotch fir seed oil (from Pinus sylvestris), tobacco seed oil (from Nicotiana Tabacum), walnut oil (from Juglans regia), weld seed oil (from Reseda Luteola),
and soya bean oil (from Soja hispidus).

**V. Castor Oil Group.**—The oils of this group are distinguished from those of Groups I, II, III, and IV, by their very high density and viscosity. They are also remarkable for their ready solubility in alcohol, and their marked purgative properties. In their drying characters and behavior with the elaidin test they resemble the oils of the cotton seed oil group. Both castor and croton oil are miscible in all proportions with glacial acetic acid.

This group includes castor oil (from Ricinus communis), croton oil (from Croton Tiglium), Japanese or Chinese wood oil (from seeds of Aleurites cordata or Elaeococca vernicia), boiled linseed oil, blown oils (made by oxidation of rape seed, cotton seed, linseed, lard, and other oils).

**VI. Palm Oil Group.** Solid Vegetable Fats — This group includes solid fats not containing notable quantities of glycerides of lower fatty acids. The densities for the melted fats at 98° and 99° C. (208.4°-210.2° F.) are compared with the density of water at 15.5° C. (60° F.) taken as 1.000, and vary from 0.920 to 0.995.

This group includes palm oil (from fruit of Elaeis guineensis), cacao butter (from nuts of Theobroma Cacao), nutmeg butter (from nuts of Myristica fragrans), and shea butter (from seeds of Bassia Parkii).

**VII. Cocoanut Oil Group.** Solid Vegetable Fats.—This group includes solid fats containing notable quantities of glycerides of lower fatty acids—that is, of acids distilling with more or less facility in a current of steam at 100° C. (212° P.). The group includes cocoa-nut oil (from the nuts of Cocos nucifera), palm oil (from the kernels of the nuts from Elaeis guineensis), laurel oil (from fruit of Laurus nobilis), Japan wax (berries of Khus succedanea), myrtle wax (berries of Myrica cerifera). For a description with constants of some of the rarer fixed oils belonging to the vegetable group, see papers by J. A. Wijs, Ph. Ztg., 1903, 563; by Pancoast and Graham, A. J. P., 1904, 70; and by Lewkowitsch, P. J., 1904, 492.

**VIII. Lard Oil Group.** Animal Oleins.—This group includes those oils fluid at ordinary temperatures which are obtained from terrestrial animals. They resemble the whale or fish oils in their reaction with chlorine, but are not turned red or brown by boiling with caustic soda.
On exposure to air and on treatment with nitrous acid or mercuric nitrate, they behave like the non-drying vegetable oils (Group I). This group includes bone oil, lard oil, tallow oil, and neat's-foot oil. For a paper by P. L. Simmonds on various animal oils, see Bull. Pharm., 1893, 297, 344.

IX. Tallow Oil Group. Solid Animal Fats. — This group comprises oils that are solid or semisolid at ordinary temperatures. Their melting points vary somewhat, and are capable of permanent alteration. The group includes bone fat, butter fat, hog's lard, horse fat, beef tallow and mutton tallow.

X. Whale Oil Group. Marine Animal Oils. — This group comprises the various fluid oils obtained from fish and cetaceous mammals. They are distinguished as a class by their offensive fishy odor, by the brown color they assume when subjected to the action of chlorine, and by the reddish color which is produced on boiling them with a solution of caustic alkali. With sulphuric acid they give colorations varying from light red to purple or brown. The fish oils do not dry on exposure to air, and mostly yield but little elaidin on treatment with nitrous acid. The term "train oil" includes whale, seal, shark, cod, and all similar oils. Cod oil (from Gadus morrhua and allied species), cod liver oil (from the same), menhaden oil (from Alosa menhaden), porpoise oil (from Delphinus phocaena and allied species), seal oil (from Phoca of various species), shark oil (from Squatus maximus and allied species), and whale oil (from Balaena mistecetus and allied species) are all members of this group.

XI. Sperm Oil Group. Liquid Waxes. — The members of this group differ from all the fatty oils of previous classes in not being glycerides, consisting essentially of esters of monatomic alcohols of the ethylic series, in which respect they resemble the true waxes, but are fluid at ordinary temperatures. They are less dense than glycerides, they do not dry or thicken notably on exposure to air, but they yield solid elaidins on treatment with nitrous acid. The group includes sperm oil (from cranial cavities of Physeter macrocephalus), doegling or bottle-nose oil, and dolphin oil.

XII. Spermaceti Group. Waxes Proper. — Spermaceti and the various waxes differ from the true fixed oils and fats in not forming glycerin when saponified, yielding instead certain of the higher monatomic
alcohols, the identity of which varies with the nature of the wax. These alcohols are insoluble in water, and dissolve to but a limited extent in alcohol, but they are soluble in ether, chloroform, carbon disulphide, benzene, and petroleum benzin, and are apt to be mistaken for added paraffin wax when the substance is saponified and the soap extracted with a solvent.

This group includes beeswax (from honeycomb of various species of bees), Carnauba or Brazil wax (from the leaf-coverings of Copernicus cerifera), Chinese wax or Pela wax (produced by a species of Coccus which punctures the branches of certain trees), myrtle wax (from berries of Myrica cerifera), Ocuba wax (from Myrica Ocuba), palm wax (from bark of Ceroxylon andicola, of the Cordilleras), and spermaceti (deposit from the oil found in the cranial cavities of the sperm whale, Physeter macrocephalus). "Wool fat, which consists largely of cholesterol (an alcohol), belongs to this group.

When oils are decomposed by heat they emit vapors of acrolein allyl aldehyde, CH$_2$CHCHO, a highly volatile liquid resulting from the decomposition of glycerin, upon which the fumes of oils mainly depend for their irritating effects on the eyes and nostrils. Exposed to a red heat, in closed vessels, they yield, among other products of the destructive distillation, a large quantity of combustible and illuminating gases, among which ethylene and acetylene are readily recognized. Heated in the open air, they take fire, burning with a bright flame, and producing water and carbon dioxide. When kept in air-tight vessels, they remain unchanged for a great length of time, but exposed to the atmosphere they attract oxygen and undergo change.

Effervescent Oils.—K. Dieterich recommends oils and fats which have been supersaturated with carbon dioxide and introduced by him under the name of "effervescent oils." (See Proc. A. Ph. A., 1900, 494.) Under the influence of carbon dioxide, compounds which are easily split with the fatty acids are produced, which, particularly in the case of cod liver oil, permit the more complete absorption of the oil than is the case with oil not treated with carbon dioxide. The latter, moreover, acts as a preservative of the oils and renders them more palatable, destroying the unpleasant taste of cod liver oil, and to a certain extent also that of added medicaments, very materially. The absorbability of carbon dioxide is, however, not the same in all oils. Cod liver oil is capable of absorbing the largest quantity, castor oil the smallest, while olive oil stands
Some fixed oils, in drying, lose their unctuous character, and are converted into a transparent, yellowish, flexible solid. These are called drying oils. Others, especially such as contain mucilaginous impurities, become rancid, acquiring a sharp taste and an unpleasant odor. This change is owing to the development or liberation of free fatty acids, from which the oil may be freed by boiling it for a short time with magnesium hydroxide and water.

Cloes has made investigations in relation to the influence of light in promoting oxidation, and obtained some curious results. The general influence of light is very great, as oils undergo comparatively little change in the dark for a long time; though in relation to some of them the change is at length as great as under the light. Thus, while the oil of poppies had in 30 days increased about 5 per cent. in weight under white light, and had gained only a 5000th in the dark, yet at the end of 150 days the weight in the former condition was rather lessened than augmented, and in the latter, or in the dark, had increased 6.4 per cent. The effect of the different colored rays is also very different. The change is at first most rapid under the white light, less so under the blue, and much less under the red, yellow, and green, being least of all with the green; but with the advance of time the blue overtakes and even passes the white and at the end of three or four months all are about equal in effect. Heat also accelerates the concretion of the oils, by favoring their oxidation; and the same effect is produced by introducing into the unchanged oil a little which has already been altered by exposure to the air. The oxidation of an oil may be very greatly hastened in this way without the aid of heat.

The fixed oils are insoluble in water, but are miscible with that fluid by means of mucilage, forming mixtures which are called emulsions. They are in general very sparingly soluble in alcohol, but readily dissolved by ether, which serves to separate them from other vegetable proximate principles. By the aid of heat they are enabled to dissolve sulphur and phosphorus. The stronger acids decompose them, giving rise, among other products, to oleic, palmitic, and stearic acids. Boiled with diluted nitric acid, some of them give rise to malic and oxalic acids, besides other substances usually resulting from the action of this acid upon vegetable matter. Several acids are dissolved by them without producing any sensible change. They are saponified by various alkalies. The
compounds which these acids form with potassium and sodium hydroxide are the common detergent soaps, although strictly speaking, a soap is the combination of a fatty acid with any metal or base. By the addition of one part of potassium or sodium carbonate, 160 parts of oil may be brought with distilled water into the form of an emulsion. The potassium and sodium soaps and the alkaline sulphides have a similar effect, but not the bicarbonates. The fixed oils also serve as good vehicles for various metallic bases and subsalts, which form soaps to a certain extent soluble in the oil, and thus become less irritant to the tissues. Oils thus impregnated may, like the pure oils, be brought to the state of emulsion with water, for convenient administration, by the addition of a small proportion of potassium carbonate. The fixed oils dissolve many of the alkaloids, the volatile oils, resin, and other proximate principles of plants. The alkaloids are more readily dissolved in them by being first combined with oleic acid, the oleates being more soluble than the alkaloids themselves. According to Buignet, they are, with very few exceptions, indifferent to polarized light; of all those used in medicine, the only exceptions are the liver oils of the ray and dog fish, which have a very feeble lasvo-rotatory power, and castor oil, which is decidedly dextrogyrate.

It is very likely that, with the exception of castor oil, whose rotatory power is due to the asymmetric carbon atom of the ricinoleic acid, the rotatory power is not due to the glycerides themselves but to small proportions of optically active substances such as cholesterol. (Lewkowitzh, Chem. Analysis of Oils Fats and Waxes, p. 121.)

The fixed oils, whether animal or vegetable, in their natural state consist in most cases of at least two or three distinct constituents, one liquid at ordinary temperatures, and the other two solid or semisolid. The liquid is a distinct proximate principle, called olein; the more solid principles consist of stearin and palmitin, the former being found most largely in animal and the latter in vegetable oils or fats, and the two in most cases existing together in the same oil. The substance formerly known as Margarin is now generally recognized to be a mixture of palmitin and stearin. As the most frequent of these proximate constituents of the fixed oils, and existing in many different oleaginous substances, olein, palmitin, and stearin merit a special notice. Preliminarily to their individual consideration, it will be proper to refer to their nature and composition generally.
These three substances, olein, palmitin, and stearin, together with butyrin, caprin, and other minor fat principles, are glycerides; that is, esters or salts of the triatomic alcohol glycerol, \( \text{C}_3\text{H}_5(\text{OH})_3 \), and of the several fatty acids, oleic, palmitic, stearic, etc., all of which are monobasic acids. The three mentioned glycerides have the following composition:

Olein, \( \text{C}_3\text{H}_5 \)  
(triolein) \(
\begin{align*}
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O}
\end{align*}
\)

Palmitin, \( \text{C}_3\text{H}_5 \)  
(tripalmitin) \(
\begin{align*}
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O}
\end{align*}
\)

Stearin, \( \text{C}_3\text{H}_5 \)  
(tristearin) \(
\begin{align*}
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O}
\end{align*}
\)

There are also mixed glycerides exemplified by the following formula:

\( \text{C}_3\text{H}_5 \)  
(oleopalmitostearin) \(
\begin{align*}
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O}
\end{align*}
\)

When these substances, or oils composed principally of them, are treated with alkali with the aid of heat, decomposition takes place, which may be illustrated as follows:

\(
\begin{align*}
\text{C}_3\text{H}_5 & \quad \begin{align*}
\text{OC}_1\text{C}_1\text{H}_3\text{O} \\
\text{OC}_1\text{C}_1\text{H}_3\text{O} + 3\text{NaOH} &= \\
\text{OC}_1\text{C}_1\text{H}_3\text{O}
\end{align*}
\end{align*}
\)

\(
\begin{align*}
\text{C}_3\text{H}_5 & \quad \begin{align*}
\text{OH} \\
\text{OH} + 3\text{Na.OC}_1\text{C}_1\text{H}_3\text{O} &= \\
\text{OH}
\end{align*}
\end{align*}
\)

that is, olein is decomposed by sodium hydroxide into glyceryl
hydroxide, or glycerin, and sodium oleate, or a sodium soap.

The waxes differ from the fats proper in being esters of the higher monatomic alcohols like cetyl alcohol, \( \text{C}_{15}\text{C}_{33}\text{OH} \), and myricyl alcohol, \( \text{C}_{30}\text{H}_{61}\text{OH} \), instead of being glycerides. The fatty acids present are partly palmitic and stearic, but more largely still higher ones, like cerotic acid, \( \text{C}_{27}\text{H}_{54}\text{O}_2 \).

Other fatty acids represented in fixed oils are: butyric acid, \( \text{C}_4\text{H}_8\text{O}_2 \); valeric acid, \( \text{C}_5\text{H}_{10}\text{O}_2 \); caproic acid, \( \text{C}_6\text{H}_{12}\text{O}_2 \); caprylic acid, \( \text{C}_8\text{H}_{16}\text{O}_2 \); capric acid, \( \text{C}_{10}\text{H}_{20}\text{O}_2 \); lauric acid, \( \text{C}_{12}\text{H}_{24}\text{O}_2 \); myristic acid, \( \text{C}_{14}\text{H}_{28}\text{O}_2 \); arachidic acid, \( \text{C}_{20}\text{H}_{40}\text{O}_2 \); erucic acid, \( \text{C}_{22}\text{H}_{42}\text{O}_2 \); hypogaeic acid, \( \text{C}_{16}\text{H}_{30}\text{O}_2 \). The first few members of the above list are known as the volatile fatty acids, which serve as the basis for the determination of what is known as the Reichert-Meissl number.

Olein. Elain. Liquid Principle of Oils.—It is extremely difficult to obtain olein pure. Being in most oils associated with the solids stearin and palmitin, it must be separated by pressure and other mechanical means, which separation is not always perfectly effected. As ordinarily procured, therefore, olein contains more or less of palmitin or stearin, or both. In this somewhat impure state it is obtained either by the agency of alcohol or by expression. When one of the oils, olive oil, for example, is dissolved in boiling alcohol, the solution, on cooling, deposits the concrete principles, still retaining the olein, which it yields upon evaporation. The other method consists in compressing one of the solid fats, or one of the liquid oils rendered concrete by cold, between folds of bibulous paper, which absorb the olein, and give it up afterwards by compression under water. Olein is a liquid of oily consistence, congealing at -6° C. (21.2° F.), colorless when pure, with little odor and a sweetish taste, insoluble in water, soluble in boiling alcohol and ether. Its formula, as already stated, is \( \text{C}_3\text{H}_5(\text{OC}_{18}\text{H}_{33}\text{O})_3 \), being an oleate of the triad radical glyceryl, \( \text{C}_3\text{H}_5 \). By reaction with nitric acid, or, more exactly stated, under the influence of nitrous acid fumes, olein is converted into a deep yellow butyraeous mass. If this be treated with hot alcohol, a deep orange-red oil is dissolved, and a peculiar fatty matter remains, called elaidin. This is white, crystalline, fusible at 34° C. (93.2° F.), insoluble in water, readily soluble in ether, and appears to be isomeric with olein. It is resolved by saponification with the alkalies into elaidic...
acid and glycerin.

Palmitin.—Palmitic acid occurs in the more liquid fats, such as palm oil and cocoa-nut oil, as well as in butter and human fat, as glyceride, while in spermaceti and some forms of wax it is combined with monatomic alcohol radicals. Palmitin is the palmitic acid glyceride, or glycercyl tripalmitate. It is best obtained from palm oil.

Stearin.—This exists abundantly in tallow and other animal fats. It may be obtained by treating the concrete matter of lard, free from olein, by cold ether so long as anything is dissolved. The palmitin is thus taken up, and stearin remains. A better method is to dissolve suet in heated oil of turpentine, allow the solution to cool, submit the solid matter to expression in unsized paper, repeat the treatment several times, and finally dissolve in hot ether, which deposits the stearin on cooling. This is concrete, white, opaque in mass, but of a pearly appearance as crystallized from ether, pulverizable, fusible at 66.5° C. (151.7° F.), soluble in boiling alcohol and ether, but nearly insoluble in those liquids cold, and quite insoluble in water. It consists of glycercyl and stearic acid in combination as a glyceride, \( C_3H_5(OC_{18}H_{36}O)_3 \), and has been formed synthetically by heating a mixture of these two materials to 280° to 300° C. (536°-5720 F.).

Commerically the fixed oils are frequently sold under the names summer pressed and winter pressed. These were once really seasonal designations, as an oil pressed during the warmer months would contain more dissolved stearin and would consequently congeal or cause a deposit when chilled, while an oil pressed during cold weather would remain transparent at low temperatures, and thus winter pressed oils were safer for lubricating purposes and commanded a higher price. Artificial refrigeration now makes it possible to make either grade of oil at any season of the year, although the former seasonal names are still used.

The fixed oils are liable to certain spontaneous changes, which have been investigated by Pelouze and Boudet. It appears from their researches that the oils are accompanied, in the seeds which contain them, with principles which act as a ferment and cause the oils to resolve themselves spontaneously into the several fatty acids which they afford on saponification, and into glycerin. This change takes place in the seeds as soon as the cells containing the oils are broken, so as to
permit the contact of the fermenting principle existing in the grain. The
decomposition of fats by the action of enzymes has been made a working
method capable of technical application, by Connstein, Hoyer and
Wartenburg. The enzyme contained in the castor oil bean has been
found best adapted for this. An emulsion of fats, water, 10 per cent. of
ground castor oil beans and a small amount of free acid are used, when
the decomposition proceeds rapidly. As rancidity in fats renders them
altogether useless in pharmacy, and as it is not always readily
discoverable by the senses in its earlier stages, it becomes desirable to
possess a test by which it may be detected. Such a test is to be found,
according to Thos. B. Groves, in potassium iodide, which is rapidly
decomposed by the new principles developed, and the orange-brown
discholoration produced by the liberation of the iodine indicates the
existence 'of rancidity, and the degree of that discoloration,
approximately, the extent of the change. The alteration of color is said
by Groves to be plainly perceptible when only one-twentieth of rancid
fat is present. The presence of water in a fatty oil favors the production
of rancidity.

It is also extremely important to be able to protect fats against this
change. The complete exclusion of air, light, and moisture—and, when
in relation to air this may not be entirely practicable, the destruction by
heat of the ferment-germs contained in the air, by which the
decomposition is 'often originated— will go far to effect this object; but it
would often be very inconvenient, if not impossible, to carry these
measures into complete effect, and hence the discovery of substances
which may have the effect of retarding, if not wholly preventing, these
fermenting processes, whether by the destruction of the ferment-germs
or otherwise, is extremely desirable; this preservative effect has been
known and practically used many years, and since the principle upon
which they are supposed to act has been discovered the number has
been extended. Thus, benzoin rubbed up with fats is well known to
preserve them long against rancidity, and benzoinated lard, made by
extracting ten per cent. of benzoin with melted lard, is one of the official
preparations, and the buds of the poplar (Populus nigra) are perhaps
still more effectual, as, according to Deschamps, lard impregnated with
their virtues will keep good indefinitely. In the French Codex the poplar
buds are employed in the Pommadé de Bourgeon de Peuplier, in which 8
parts of the dried buds are used to 40 parts of the ointment, consisting
of lard impregnated with the virtues of several narcotic substances, the
fresh narcotic plants being boiled with lard until all their water is
evaporated, and the buds afterwards digested in the strained liquid for twenty-four hours. Groves made experiments with many volatile oils and other analogous substances to test their preservative power. (See A. J. P., 1865, 54, 61.) Hirzel says that animal fats may be kept in a good condition for a year by the following plan. Mix 14 pounds of the recently melted fat with 5 drachms of common salt and 15 grains of alum, in fine powder, heat till a scum is formed on the surface, separate the scum, and, when the clear liquid has cooled, wash it many times with water with malaxation, so as to remove all the salt, then evaporate the water at a heat insufficient to injure the fat. (A. J. P., 1868, 334.)

The adulteration of the fixed oils may be effected in several ways—by admixture with the fatty oil of substances distinctly foreign to the fats, and by adding a cheaper or inferior oil to one of greater value. In the former case we may have the addition of paraffin wax, ceresine, mineral oils, neutral tar ‘oils, resin oils, resin, and waxes. Of these, the first three are entirely unsaponifiable, resin oils contain but small quantities of saponifiable substances, waxes are partly saponifiable, and resin almost completely saponifiable. The determination of unsaponifiable matter is therefore of great importance. The common method for this is to saponify the suspected sample with alcoholic potassium hydroxide and then to shake out the unsaponifiable matter with ether or petroleum ether. From this solution, on evaporation, will be obtained the mineral, resin, or tar oils that may have been present. For these there are appropriate tests elsewhere noted. In case a cheaper oil or fat has been added for the purpose of adulterating a more valuable one, we must be guided by the determination of certain constants, such as those mentioned below by Cowley, or by the indication of certain qualitative color tests. The constants referred to are much more to be depended upon in such a case.

R. C. Cowley (P. J., 1897, 331) regards the following as the most important determinations in examining fats and fixed oils. 1. Specific gravity. 2. Melting and solidifying points. 3. Melting and solidifying points of fatty acids. 4. Behavior with solvents. 5. The Hehner value. 6. The Reichert-Meissl value. 7. The saponification value. 8. The iodine value. To these have been added during recent years: 9. The refractive index. 10. The acetyl number. 11. The temperature rise with sulphuric acid (Maumene number).

It is sometimes desirable to deprive the fixed oils of color. The following
process for this purpose is recommended by Brunner. The oil is first brought to the state of emulsion by strongly agitating it with water rendered mu-cilaginous by gum or starch; the emulsion is treated for each part of oil with two parts of wood charcoal, previously well heated and coarsely powdered, the finer particles being sifted out; the pasty mass is then completely dried at a heat not exceeding 100° C. (212° F.), and exhausted by cold ether in a percolator; finally, the ethereal solution, having been allowed to stand, in order that any charcoal present in it may subside, is submitted to distillation, so as to separate the ether, and the oil remains colorless in the retort. (J. P. C., Sept., 1858.) Berlandt recommends the following method: Shake strongly for some minutes 900 parts of the fixed oil with 120 parts of water holding in solution 3 parts of potassium permanganate, allow the mixture to stand for some hours in a warm place, and then filter. The oil becomes colorless. (J. P. C., Oct., 1867.)

The modern method of decolorizing vegetable oils is to filter them through kaolin or Fuller's earth. Preliminary treatment with acids and alkalies is sometimes advisable.

OLEA VOLATILIA. [Olea Destillata]

Volatile Oils.

These are sometimes called distilled oils, from the mode in which they are usually procured; sometimes essential oils, from the circumstance that they possess, in a concentrated state, the organoleptic properties of taste and odor of the plants from which they are derived. The word essence is used in same countries to designate the volatile oils themselves, but in America this word has unfortunately been largely applied to the alcoholic solutions of the volatile oils, usually called the spirits, and the word soluble essence has been used to describe hydro-alcoholic solutions of volatile oils which possess the property of mixing clear with water.

The term Ætheroleæ is used in some countries to distinguish the volatile oils in general from those which are produced by destructive distillation, like oil of amber, oil of cade, oil of tar, etc., which are given the collective
name pyrolea (pyroligneous oils).

They exist in all odoriferous vegetable tissues, sometimes pervading the plant, sometimes confined to a single part; in some instances contained in distinct cells, and partially retained after desiccation, in others formed upon the surface, as in many flowers, and exhaled as soon as formed. Occasionally two or more are found in different parts of the same plant. Thus, the orange tree produces one oil in its leaves, another in its flowers, and a third in the rind of its fruit. In a few instances, when existing" in distinct cells, they may be obtained 'by pressure, as from the rind of the lemon and orange; but they are generally procured by steam distillation. (See page 738.) Some volatile oils, as those of bitter almond and mustard, are formed in the presence of moisture out of substances of a different nature pre-existing in the plant, and may be subsequently distilled.

The volatile oils are usually colorless when freshly distilled, or at most yellowish, but some are brown, red, green, or blue. There is reason, however, to believe that in all instances the color depends on foreign matter dissolved in the oils. Septimus Piesse succeeded, by the fractional distillation of certain volatile oils, in separating a blue liquid, which, by repeated rectification, he has obtained quite pure. In this state it has the sp. gr. 0.910, and a fixed boiling point of 302.3° C. (576° F.), and yields a dense blue vapor having peculiar optical properties. He named this principle azulene, and believed that upon it depends the blueness of volatile oils wherever existing. The yellowness of the oils he ascribed to the resin resulting from their oxidation, the green and brown colors to a mixture of azulene and resin in various proportions. The formula of azulene he gave as C_{16}H_{26}O. (Chem. News, Nov. 21, 1863, p. 245.) Gladstone named this blue coloring constituent caerulein, and stated that it contains nitrogen and is colored green by acids and alkalies. The volatile oils differ from the fixed oils in not yielding glycerol when treated with alkalies.

The volatile oils have a strong odor, resembling that of the plants from which they were procured, though generally less agreeable. Their taste is hot and pungent, and, when they are diluted, is often gratefully aromatic. The greater number are lighter than water, though some are heavier; their sp. gr. varies from 0.847 to 1.17. They vaporize at ordinary temperatures, diffusing their peculiar odor, and are completely volatilized by heat. When distilled alone, they nearly always undergo
partial decomposition. Heated in the open air, they take fire and burn with a bright flame attended with much smoke. Almost all of them are optically active, and advantage may sometimes be taken of this property to detect adulterations of one of these oils with another. The refractive index is another physical constant that is being studied in connection with volatile oils, but the accumulation of data is not yet sufficiently large to give the factor much value as yet. Exposed at ordinary temperatures, some of them absorb oxygen, assume a deeper color, become thicker and less odorous, and are ultimately converted into resin. This change takes place most rapidly under the influence of light. Before the alteration is complete, the remaining portion of oil may be recovered by distillation.

The volatile oils are sometimes hydrocarbons, although with these are frequently associated alcohol- or ketone-like bodies called camphors, and products of oxidation known under the general name of resins, and undoubtedly formed from the hydrocarbons. Phenols, aldehydes, esters, ethers, and sulphides are also represented. The hydrocarbons are generally known as terpenes, from oil of turpentine, which is taken as a type. Olea aetherea sine terpeno is the name proposed by Schweissinger for concentrated volatile oils made so by the removal of the non-fragrant hydrocarbon, and representing from two to thirty volumes of the ordinary essential oils. Thus, one volume of the concentrated oil represents two volumes of the oils of anise, cassia, fennel, gingergrass, mentha crispa, mentha piperita, cloves, sassafras, and star anise; two and one-half volumes of the oils of bergamot, caraway, and lavender; four volumes of cumin and rosemary; five volumes of thyme; six volumes of coriander; eight volumes of calamus; ten volumes of absinthe; twenty volumes of juniper; thirty volumes of angelica, lemon and orange. It is asserted that these concentrated oils are more permanent, more soluble in alcohol and in water, have a finer odor, and are of constant composition, thus enabling the specific gravity and boiling point to be used as tests of purity. They should be kept in the dark. (Ph. Centralh., 1888, No. 25.) Under the name of "terpeneless volatile oils," similar products can now be found in the market; they are undoubtedly superior to the ordinary volatile oils both in odor and strength.

Wallach, to whom much of our knowledge on volatile oils is due, divides the hydrocarbons into classes, as follows:
1.—True terpenes, of the formula \( C_{10}H_{16} \), of which there are two main
groups: (a) the terpane group, uniting with two molecules of haloid acid
or four atoms of bromine; this group includes limonene, dipentene,
sylvestrene, terpinolene, terpinene, thujene, and phellandrene, and its
members boil between 175° and 185° C. (347° and 365° F.); (b) the
camphane group, uniting with one molecule of haloid acid or two atoms
of bromine; this group includes pinene, bornylene, camphene, and
fenchene, and its members boil between 151° and 161° C. (303.8° and
321.8° F.).

2.—Hemiterpenes, of the formula \( C_5H_8 \), such as isoprene.

3.—Polyterpenes, such as cedrene, cubebene, etc., of the formula \( C_{15}H_{24} \)
(sesquiterpenes); colophene, of the formula \( C_{20}H_{32} \); and caoutchouc,-of
the formula \( (C_{10}H_{16})_x \).

Hydrocarbons other than those of the ter-pene class or derivable from
them, occur very sparingly in the natural oils. Thus there is of the
paraffin series of saturated hydrocarbons, heptane, \( C_7H_{16} \), occurring in
the oil from the Pinus sabiniana, or California digger pine, and solid
hydrocarbons of the same series in oil of rose, and probably in oils of
wintergreen and sweet birch. Of the benzene series there is a single
representative in cymene, \( C_{10}H_{14} \), found in the oils of the Thymus and
Monarda species.

In addition to these naturally occurring hydrocarbons, there is a class
of artificially prepared hydrocarbons known as hydroterpenes, such as
dihydridipentene from dipentene, men-thene and carvomenthene from
menthol and carvone.

The terpenes in general are practically insoluble in water, but soluble in
alcohol, ether, chloroform, benzene, petroleum benzin, and the fixed
and volatile oils.

Many of the essential oils, however, owe their essential character and
their value to other constituents than hydrocarbons. We shall briefly
notice the most important of these, either describing them or referring to
other places in the text where they are already described, and shall
then give a classification of the commonly known essential oils based
upon the character of the most important compounds present in them.

I. Alcohols.
Geraniol, Linalool, Citronellol, Terpineol, Menthol, Borneol, Nerol, Sabiol, Santalol.

II. Aldehydes.
Citral, Citronellal, Salicyl Aldehyde, Cumic Aldehyde, Benzaldehyde, Cinnamic Aldehyde, Anisic Aldehyde, Piperonal, Santalal.

III. Ketones.

IV. Esters.
Methyl Salicylate, Methyl Anthranilate, Benzyl Acetate, Linalyl Acetate, Geranyl Acetate, Bornyl Acetate, Menthyl Acetate, Bornyl Valerate, Geranyl Tiglate.

V. Phenols and Phenol Ethers.
Chavicol, Methyl-chavicol, Anethol, Thymol, Carvacrol, Eugenol, Methyl-eugenol, Iso-eugenol, Chavibetol, Safrol, Iso-safrol, Thymohydro-quinone dimethyl ether, Asarol, ApioI, Diosphenol.

VI. Neutral Bodies, Oxides, etc.
Cineol (Eucalyptol).

VII. Sulphides and Sulphur Compounds.
Diallyl Disulphide, Allyl Isothiocyanate, Dimethyl Sulphide, Butyl Isothiocyanate, Vinyl Sulphide, Acrinyl Isothiocyanate, Phenyl Ethyl Isothiocyante.

The classification of the volatile oils in any rational and practical manner is a difficult task.
Any system that is devised is either exceedingly complex and cumbersome or, if conciseness is attempted, there are too many inconsistencies and discrepancies. For instance, one of the favored methods of classification is to divide them into four groups, i.e., the terpenes, oxygenated oils, nitrogenated oils, and sulphurated oils. If this be critically studied it is seen that oil of lemon, which is usually given as a typical example of the terpene class, owes its real identity and value to citral, an aldehyde present in only a very small proportion (less than 5 per cent.), and that oil of bitter almond, which is given as the example of the nitrogenated class, owes its classification in this respect only to the incidental presence of hydrocyanic acid, which is frequently removed from the oil, especially when it is used for flavoring purposes. This leaves the sulphurated class, which contains only one important member and the oxygenated class, which is the repository of over 90 per cent. of oils of diversified character.

It is therefore more suitable to follow the foregoing outline adding such explanatory matter and examples as will serve to make it intelligible and valuable for either study or reference purposes.

NOTE.—Although the alcohols only were mentioned in the first group given above it will be found convenient to refer to the more important esters of these alcohols as they are taken up for discussion.

1. Alcohols and Their Esters.—This is an interesting group of open chain, unsaturated alcohols, which, with their esters and aldehydes, play a very important part in the composition of many essential oils. It is the geraniol, linalool and citronellol group.  

\[
\text{Geraniol, } \text{C}_{10}\text{H}_{17}\text{OH, or } \frac{\text{CH}_3}{\text{CH}_3} > C = \text{CH,} \\
\text{CH}_2\text{CH}_2\text{C}<\text{CH,CH}_2\text{OH, is a colorless liquid}
\]

of a pleasant rose geranium odor, boiling at 229° to 230° C. (444.2°-446° F.), under ordinary pressure, and at 129° C. (264.2° F.) under a pressure of 16 mm. Its specific gravity is about 0.881 and its refractive index 1.478. It is optically inactive. By careful oxidation with chromic trioxide it yields its aldehyde, citral, and by heating it in an autoclave with water to 200° C. (392° F.), it is partly converted into its isomer, linalool. It is a monatomic, primary, open chain alcohol, and is the principal constituent of true geranium (pelargonium) oil, as well as of
the so-called "Turkish geranium oil," or oil of palmarosa. It is a constituent of rose oil, of citronella oil and in very small proportions of a number of other oils. Of the esters of geraniol the most important is the geranyl acetate. This is a fragrant oil of specific gravity 0.917, boiling at from 128° to 129° C. (262.4°-264.2° F.), under a pressure of 16 mm. It occurs naturally in several essential oils, and can be made artificially by the action of acetic anhydride upon geraniol. Commercial geraniol is also known as rhodinol.

2.—Linalool, $\text{C}_{10}\text{H}_{17}\text{OH}$, or $\text{CH}_3$ $\begin{array}{c} \text{CH} \\ \text{C} \\ \text{CH}_3 \end{array}$ $\begin{array}{c} \text{CH}_3 \\ \text{C} \\ \text{CH}_3 \end{array}$, is known in both of the optically active forms as well as in the inactive. It is a liquid having a pleasant odor, and boils under normal pressure at about 198° C. (388.4° F.), and at from 86° to 87° C. (186.8°-188.6° F.) at 14 mm. pressure. Its specific gravity ranges from 0.868 to 0.877, and its refractive index is 1.463. It is a monatomic, tertiary, open chain alcohol, and is an essential constituent of oil of linaloe, and is found in the free state or as an acetic ester in oils of bergamot, coriander, lavender, neroli, etc. The most important of its esters is linalyl acetate, which occurs in many essential oils, as in oil of bergamot. It is an odoriferous liquid of the specific gravity 0.912, and boiling at from 105° to 108° C. (221°-226.4° F.) at 11 mm. pressure. It is so prepared artificially, and the artificial ester is an important commercial article.

3.—Citronellol, $\text{C}_{10}\text{H}_{19}\text{OH}$, or $\text{CH}_3$ $\begin{array}{c} \text{C} \\ \text{CH}_3 \\ \text{CH}_3 \end{array}$ $\begin{array}{c} \text{CH}_3 \\ \text{C} \\ \text{CH}_3 \end{array}$, is found in oil of rose and in Spanish geranium oil. It is an odoriferous oil, boiling at from 117° to 118° C. (242.6°-244.4° F.), under a pressure of 17 mm.; specific gravity, 0.8565 at 17.5° C. (63.5° F.); refractive index, 1.457. It is an open chain alcohol closely related to geraniol and is found in oil of rose, oil of geranium, etc. When obtained from oil of rose it is laevogyrate, while when obtained by reducing the aldehyde it is dextrogyrate; in most geranium oils both varieties exist.

A second group comprises the mono-cyclic alcohols, terpineol, which is unsaturated, and menthol, a saturated compound.

4.—Terpineol, $\text{C}_{10}\text{H}_{17}\text{OH}$, $\text{CH}_3$ $\begin{array}{c} \text{CH} \\ \text{C} \\ \text{CH}_3 \end{array}$ $\begin{array}{c} \text{CH}_3 \\ \text{C} \\ \text{CH}_3 \end{array}$, occurs in liquid
and solid modifications, inactive, as well as in the two optically active, varieties. Besides occurring naturally it is made artificially by the dehydration of terpin hydrate, and is largely used in the perfume industry because of its lilac odor. It has a sp. gr. of 0.940 at 15° C. (59.2° F.). Its most important ester is the acetate, which occurs in eajuput and cardamom oils.

5.—**Menthol, menthyl alcohol, C_{10}H_{19}OH,**

\[
\text{CH}_3\text{-CH-CH}_2\text{-CHOH.C-CH}_3
\]

is now official. Two of its esters are recognized as occurring with it in peppermint oil, menthyl acetate and menthyl iso-valerate. Of these the former is the more important. It is an oil having a penetrating odor, boiling at 224° C. (435.2° F.).

To a third group of compounds known as dicyclic, belongs:

6.—**Borneol, C_{10}H_{17}OH, or CH.CH\_2.CH\_2.CH\_3.C.CH\_3.CH\_2.CHOH.C—CH\_3.**—This compound occurs naturally in both optically active modifications. It also occurs optically inactive. It forms crystalline masses, which, when quite pure, melt at 203° C. (397.4° F.). Borneol can be prepared artificially by reducing its ketone (camphor) with metallic sodium. In this case, however, there results a mixture of borneol and iso-borneol. Borneol forms a number of esters, of which bornyl acetate is the most important. This compound melts at 29° C. (84.2° F.), and has a specific gravity of 0.991 at 15° C. (59° F.). It is the characteristic constituent of the pine needle oils.

Nerol is an alcohol discovered in oil of neroli. It is a stereo-isomer of geraniol. Santalol, so called, is found as an alcoholic constituent of oil of sandalwood. It has been given the formula C_{15}H_{25}OH, but is probably a mixture of several isomeric or closely related alcohols. Sabinol, C_{10}H_{15}OH, is a constituent of oil of savin.

Fenchyl alcohol, thujyl alcohol, and pulegol, all having the same empiric formula as geraniol, C_{10}H_{17}OH, do not occur naturally, but are produced from the respective ketones.

II. **Aldehydes.**—Of the alcohols just enumerated, only the first group are primary alcohols, and will yield aldehydes. Thus, from geraniol,
there is obtained by oxidation, citral, the corresponding aldehyde, and from its isomer, linalool, the same.

1.—Citral, C₉H₁₅COH, or (CH₃)₂C.CH.CH₂.CH₂.C(CH₂)CH₂.CO—Although at one time called geranial, this compound is now universally known as citral, which indicates its importance in the oils of the citrus family. It is obtained most abundantly from lemon grass oil by the aid of the bisulphite process. It is an oily liquid, boiling at from 228° to 230° C. (442.4°-446° F.), under ordinary pressure, and at 110° C. (230° F.), under 12 mm. Its specific gravity is about 0.89 and its refractive index 1.49. It is optically inactive. Under the influence of alkalies, citral condenses with acetone with the elimination of water to form pseudo-ionone, C₁₃H₂₀O, which is converted into its isomer ionone by means of acids. Reduction with sodium produces the alcohol geraniol.

2—Citronellal, C₉H₁₇OH, or C(CH₃)₂CH.CH₂CH₂CH(CH₃)CH₂COH, the aldehyde of citronellol, occurs in several essential oils, as in citronella oil. It is an oily liquid of characteristic odor; specific gravity 0.8768, refractive index 1.4481. It is dextrogyrate.

Of the class of aromatic aldehydes, there are found in essential oils, salicyl aldehyde, cumic aldehyde, benzaldehyde, and cinnamic aldehyde.

3.—Salicyl Aldehyde, C₆H₄(OH)COH.—This body is an oily liquid of aromatic odor, boiling at 196° C. (384.8° F.), and having a specific gravity of 1.172. It occurs in the oils of the several varieties of Spirisa. It can also be formed by the oxidation of its alcohol saligenin, or by the action of chloroform and potassium hydroxide on phenol.

4.—Cumic Aldehyde, C₆H₄(C₃H₇)COH.—This is p-isopropyl-benzaldehyde, and is found in several essential oils, as in cumin oil. It is an aromatic oil, having a specific gravity of 0.973, and boiling at 235° C. (455° F.).

5.—Benzaldehyde, C₆H₅.COH.—This is now official.

6—Cinnamic Aldehyde, C₆H₅.CH:CH.COH.—This was official in the U. S. P. VIII.
Anisic Aldehyde, $\text{C}_6\text{H}_4\text{OCH}_3\text{COH}$ (oxy-methyl-benzaldehyde), is a synthetic product used in artificial hawthorn perfume.

Piperonal or Heliotropin, $\text{C}_6\text{H}_3\text{O}_2\text{CH}_2\text{COH}$, is a synthetic product used in heliotrope perfume.

Santalol, $\text{C}_{14}\text{H}_{23}\text{COH}$, is found in sandalwood oil.

III. Ketones.—This class of chemical compounds is largely represented in essential oils. Of aliphatic saturated ketones there is only one fairly important representative.

1.—Methyl-nonyl-ketone, $\text{CH}_3\text{CO.C}_9\text{H}_{19}$, which is found in oil of rue, is a liquid of strong odor, boiling at 225° C. (437° F.), and specific gravity 0.8295 at 17° C. (62.6° F.). It solidifies when cooled, and melts at 13° C. (155.4° F.).

Of aliphatic unsaturated ketones there is also one occurring naturally.

2.—Methyl-heptenone, $\text{CH}_3\text{CO.C}_6\text{H}_{11}$, is found in lemon grass oil and other oils, and results from the oxidation of citral or the distillation of cineolic anhydride. It has a specific gravity of 0.853 at 20° C. (68° F.) and boils at 174° C. (345.2° F.).

A methyl-amyl-ketone, $\text{C}_5\text{H}_{11}\text{COCH}_3$, boiling at 151° C. (303.8° F.) and having a specific gravity of 0.837 at 50° C. (122° F.), is found as a minor constituent in oil of cloves.

The most commonly occurring ketones, however, belong to the cyclic compounds:

3.—Carvone, $\text{C}_{10}\text{H}_{14}\text{O}$, $\text{CH}_3\text{C}\text{CH}—\text{CH}_2\text{CO—CH}_2\text{CH}—\text{C}\text{CH}_3\text{CH}_2$. This compound, found in oils of caraway fennel and dill, is a colorless oil boiling at 225° C. (437° F.) and having a sp. gr. of 0.960 at 18° C. (64.4° F.). It is optically active, occurring in both forms. Its most interesting addition compound is that with hydrogen sulphide; this is obtained in crystals, decomposing with alcoholic potassium hydroxide and liberating pure carvone. When heated with glacial phosphoric acid, it is changed
into the isomeric carvacrol, a phenol compound.

4.—*Pulegone*, C$_{10}$H$_{16}$O, CH$_3$CH$\left\langle\begin{array}{c}CH_2-CO \\ CH_2-CH_2\end{array}\right\rangle$ C$\equiv$C$\left\langle\begin{array}{c}CH_3 \\ CH_3\end{array}\right\rangle$.

This characteristic ketone of pennyroyal oil is a liquid boiling at 221° C. (429.8° F.), and having a specific gravity of 0.9323 at 20° C. (68° F.). An isomerio body, iso-pulegone, has been obtained artificially.

5.—*Menthone*, C$_{10}$H$_{18}$O, CH$\left\langle\begin{array}{c}CH_3-CH_2 \\ CH_2-CO\end{array}\right\rangle$ CH$\left\langle\begin{array}{c}CH \end{array}\right\rangle$ CH$\left\langle\begin{array}{c}CH(CH_3)_2 \end{array}\right\rangle$.

This occurs along with the corresponding secondary alcohol menthol, in oil of peppermint. It is an oily liquid boiling at 206° C. (402.8° F.), with a specific gravity of 0.897 at 15° C. (59° F.). By the action of oxidizing agents it can be converted into thymol, C$_{10}$H$_{14}$O.

To the class of dicyclic ketones belong the following isomeric bodies:

6.—*Camphor*, C$_{10}$H$_{16}$O, C$_9$H$_{14}$.

— This most important compound of the ketone class is official.

7.—*Fenchone*, C$_{10}$H$_{18}$O, CH$_2$CH$\left\langle\begin{array}{c}CH \end{array}\right\rangle$ CH$\left\langle\begin{array}{c}CH(CH_3)_2 \end{array}\right\rangle$.

This ketone occurs as dextro-fenchone in oil of fennel, and as laevo-fenchone in oil of thuja. When purified, it forms an oil of camphoraceous odor, boiling at 193° C. (379.4° F.), and having a specific gravity of 0.9465 at 19° C. (66.2° F.).

8.—*Thujone*, C$_{10}$H$_{16}$O, CH$_3$CH$\left\langle\begin{array}{c}CO-CH_2 \\ CH-CH_2\end{array}\right\rangle$ C$\left\langle\begin{array}{c}CH \end{array}\right\rangle$ CH$\left\langle\begin{array}{c}CH \end{array}\right\rangle$.

This ketone is found in oils of thuja, tansy, wormwood and sage, and is identical with the bodies formerly known as tanace-tone and salvone. It is an optically active liquid, boiling at from 200° to 203° C. (392°-397.4° F.) and having a specific gravity of 0.9126 at 20° C. (68° F.). A more complex ketone yet to be noted is:

9.—*Irone*, C$_{13}$H$_{20}$O, (CH$_3$)$_2$C$\left\langle\begin{array}{c}CH(C(CH_3)_2)COCH_3 \end{array}\right\rangle$ CH$\left\langle\begin{array}{c}CH \end{array}\right\rangle$.

The characteristic constituent of orris oil, to which also the violet odor is due, is irone. It is an oil almost insoluble in water, but readily soluble in
alcohol, boiling at 144° C. (291.2° F.) at 16 mm., and having a specific 
gravity of 0.939 at 20° C. (68° F.). In the attempt to effect the synthesis 
of irone, Tie-mann and Kriiger obtained an isomeric body, ionone, from 
citral, which is now used as the artificial violet odor.

IV. Acids and Their Esters.—While esters of several of the fatty 
acids, both saturated and unsaturated, are found in the essential oils, 
the compounds are not so distinctive or characteristic, that they require 
mention here. Some of the esters have been already described under the 
appropriate alcohols, see geraniol, linalool, etc. Of esters of aromatic 
acids there are several of importance, however, comprising the most 
valuable constituents of the oil in which they occur.

1.—Methyl Salicylate is the chief constituent of the oils of wintergreen 
and sweet birch.

2.—Methyl Anthranilate (o-amidobenxoate), C₆H₄(NH₂)COOCH₃—This 
is the odoriferous constituent of neroli oil. It is an oil solidifying at low 
temperatures in crystals melting at 24.5° C. (76.1° F.), and boiling at 
127° C. (260.6° F.) at 11 mm. Its specific gravity is 1.163 at 26° C. (78.8° 
F.). It is strongly fluorescent and has a powerful neroli odor.

V. Phenols and Phenol Ethers.—This is an important class, largely 
represented in the volatile oils. Of monatomic phenols there are:

1.—Chavicol (para allyl-phenol), C₆H₄(OH)C₃H₅.—This occurs in the oil 
of Chavica Betle, and is a colorless liquid having a strong odor and a 
specific gravity of 1.035 at 20° C. (68° F.), boiling at 237° C. (458.6° F.). 
Still more abundantly formed in nature is its methyl ether, which is:

2.—Methyl-chavicol, C₆H₄(OCH₃)C₃H₅. — This occurs in the oils of 
anise, star anise, sweet-basil, bay, etc. It is a colorless liquid of an anise-
like odor, boiling at from 215° to 216° C. (419°-420.8° F.), and having a 
specific gravity of 0.979 at 12° C. (53.6° F.).

3.—Anethol, C₆H₄(OCH₃)C₃H₅, is the methyl ether of p-propenyl-
phenol, and is therefore isomeric with methyl-chavicol. It can be formed 
from the latter by heating it with alcoholic potassium hydroxide. It is the 
most abundant constituent of the oils of anise, star anise and fennel. It 
forms white scales having a specific gravity of 0.986 at 25° C. (77° F.),
melting at 21° C. (69.8° F.), and boiling at 232° C. (449.6° F.).

4.—Thymol (methyl-propyl-phenol), \( \text{C}_8\text{H}_3\text{.CH}_3\text{.(OH)}\text{C}_3\text{H}_7 \) 1:3:4.—This is one of the best known of the phenols occurring in volatile oils. As it is official its description will be found under Thymol.

5.—Carvacrol (methyl-propyl-phenol), \( \text{C}_6\text{H}_6\text{.CH}_3\text{(OH)}\text{C}_3\text{H}_7 \) 1:2:4—This important phenol, occurring in oils of marjoram and savory, is isomeric with thymol. It is a thick oil, solidifying at 0° C. (32° F.) and boiling at 236° C. (456.8° F.). It can be prepared artificially by heating carvone, an isomeric ketone, with phosphoric acid or by heating camphor with iodine.

Of diatomic phenols and their ethers, there are the following:

6.—Eugenol, \( \text{C}_6\text{H}_3\text{.OH.OCH}_3\text{.C}_3\text{H}_5 \) 4:3:1, is the methyl ether of allyl-dioxybenzene. It occurs in the oils of cloves, allspice, bay, Ceylon cinnamon and cinnamon leaves.

7.—Methyl-eugenol, \( \text{C}_6\text{H}_3\text{(OCH}_3\text{)2.C}_3\text{H}_5 \), is found together with eugenol in oil of bay. It has a specific gravity of 1.041 at 11° C. (51.8° F.) and boils at 248° C. (478.4° F.).

8.—I-iso-eugenol is the methyl ether of pro-penyl-dioxybenzene, and is produced from eugenol when the latter is heated with alcoholic potassium hydroxide. It is used in the manufacture of artificial vanillin.

9.—Chavibetol, \( \text{C}_9\text{H}_8\text{(OCH}_3\text{)OH} \), is another isomer of eugenol, and occurs with chavicol in oil of betel leaves.

10.—Safrol, \( \text{C}_6\text{H}_3\text{O} \xrightarrow[O]{\text{CH}_2\text{.C}_3\text{H}_5} \), is the methylene ether of allyl-dioxybenzene. It is found quite largely in the oils of sassafras, camphor, etc. It was official in the U. S'. P. VIII.

11.—Iso-safrol is the methylene ether of propenyl-dioxybenzene, and is produced from safrol by heating the latter with alcoholic potassium hydroxide. It is used in the manufacture of piperonal (artificial heliotropin).
12.—Thymohydroquinone dimethyl-ether, \( \text{C}_6\text{H}_2.\text{(OCH}_3\text{)}_2.\text{CH}_3.\text{C}_3\text{H}_7 \), constitutes the bulk of the oil of arnica root. It is a liquid distilling at from 248° to 250° C. (478.4 °-482 ° F.).

Of triatomic phenols and their ethers, the representative is:

13.—Asarol, \( \text{C}_6\text{H}_2(\text{C}_3\text{H}_5)(\text{OCH}_3)_3 \).—This is the trimethyl ether of propenyl-trioxybenzene. It forms the solid constituent of the oil of \( \text{Asarum europium} \), and occurs in prisms melting at 61° C. (141.8° F.), and boiling at from 295° to 296° C. (563°-564.8° F.). It has also been made synthetically.

Of tetratomic phenols and their ethers, there is also a representative, as follows:

14.—Apiol, \( \text{C}_{12}\text{H}_{14}\text{O}_4.\text{C}_9\text{H}_6(\text{OCH}_3)_2\text{O}_2.\text{CH}_2 \), is the dimethyl-methylene ether of allyl-tetroxy-benzene. It occurs in two isomers—the apiol from oil of parsley and dill apiol from some varieties of oil of dill. Of these, the former is a crystalline solid melting at 30° C. (86° F.) and boiling at 294° C. (561.2° F.) and the latter is an oily liquid boiling at 288° C. (550.4° F.).

**VI. Neutral Bodies, Oxides, etc.**—One important compound of frequent occurrence in volatile oils has not been classified under any of the preceding groups, for the reason that it is relatively inert in a chemical way and is considered as an oxide of neither distinct acid or basic character.

1.—Cineol (Eucalyptol), \( \text{C}_{10}\text{H}_{18}\text{O} \).—This is found in nature in large amounts in eucalyptus oil (hence the name "eucalyptol" sometimes given to it), in cajuput oil (hence the name of "cajuputol"), in lavender, wormseed, and other oils.

**VII. Sulphides and Sulphur Compounds.**

1.—Di-allyl-disulphide, \( \text{C}_6\text{H}_{10}\text{S}_2 \), is a constituent of oil of garlic and occurs in many oils belonging to the \( \text{Cruciferae} \). It is a liquid of very unpleasant odor, boiling at 140° C. (284° P.)

2.—Allyl-isothiocyanate, \( \text{C}_3\text{H}_5.\text{NCS} \), is the principal constituent of the
volatile oil of mustard. It is, however, a decomposition product of the glucoside potassium myronate, which breaks up under the influence of the ferment myrosin. The allyl thiocyanate can also be obtained artificially by distilling allyl iodide or bromide with alcoholic potassium thiocyanate. This artificial product is largely sold in place of the natural oil. It is a liquid having a very unpleasant odor, boiling at 151° C. (303.8° F.), and having a specific gravity of 1.017 at 10° C. (50° F.).

Vinyl sulphide, \((C_2H_3)_2S\), is found in a variety of garlic.

Butyl isothiocyanate, \(CH(CH_3)C_2H_5NCS\), is found in oil of horseradish, acrynyl isothiocyanate, \(C_7H_7ONCS\), is found in white mustard and phenylethyl isothiocyanate, \(C_4H_4(C_6H_5)NCS\), is found in oil of mignonette.

**CLASSIFICATION.**

Classification of the more commonly occurring volatile oils.—In considering the question of classifying the volatile oils, two methods of arrangement naturally suggest themselves, viz.: a classification according to the botanical natural orders to which they belong, and a chemical classification based on the most important chemical constituents of the oils themselves. While the first of these is the more readily made, it suffers from the disadvantage of being cumbrous and less readily understood except by the botanist. On the other hand, the second plan shows at a glance the sources of the valuable odoriferous and medicinally and technically important constituents for which the volatile oils are largely used. That it has not been generally adopted is no doubt due to the fact that many of the oils contain several different constituents of value, and it is therefore difficult to make an assignment of some of them to individual chemical groups. Nevertheless, it is believed that the chemical classification adopted here will be found to have practical value for reference.

**Group I.**—Oils containing mainly Terpenes and Sesquiterpenes.

- Cedarwood; cedrene and cedrol (an oxygenated constituent).
- Copaiba Balsam; caryophyllene.
- Cubeb; cadinene and cubeb camphor (an oxygenated constituent).
- Dog Fennel; phellandrene.
Fleabane; d-limonene.
Galbanum; pinene and cadinene.
Ginger; sesquiterpene and phellandrene.
Hemp; cannibene and other terpenes.
Hops; humulene and tetrahydro-cymene.
Myristica; terpenes and myristicol (an oxygenated constituent).
Orange; limonene with small amount of citral and citronellal (both oxygenated constituents).
Turpentine; pinene and sylvestrene.

**Group II.**—Oils containing mainly Alcohols and their esters.

a. Aliphatic saturated alcohols:
   Heracleum; octyl alcohol and octyl ester.

b. Aliphatic unsaturated alcohols:
   Bergamot; linalool and linalyl acetate.
   Coriander; linalool and d-pinene.
   Geranium; geraniol and geranyl esters.
   Lavender; linalyl acetate and geraniol.
   Lime; linalyl acetate and limonene.
   Linaloës; linalool and geraniol.
   Petit Grain; linalool and linalyl acetate.
   Rose; geraniol and citronellol with esters.

c. Monocyclic and dicyclic alcohols.
   Angostura; galipol, galipene, and cadinene.
   Fir Cones; bornyl acetate and terpenes.
   Golden Rod; borneol and bomyi esters.
   Juniper Berries; juniper camphor and cadinene.
   Ledum; ledum camphor.
   Lovage; terpineol.
   Mace; myristicol.
   Patchouli; patchouli camphor and cadinene.
   Peppermint; menthol and menthone.
   Pine Needles; boryl acetate and terpenes.
   Rosemary; borneol and bornyl acetate.
   Sandalwood; santalol and esters.
   Savin; sabinol and sabinyl acetate.
   Valerian; borneol and bornyl esters.

d. Aromatic Alcohols and Esters:
   Jasmine; benzyl acetate and benzyl alcohol.
Group III.—Oils containing Aldehydes as characteristic constituents.
   a. Aliphatic unsaturated aldehydes:
      Citron peel; citral and limonene.
      Citronella; citronellal and geraniol.
      Lemon; Citral and citronellal (this oil might also properly be classed in Group I, as the terpenes constitute over 90 per cent. of the oils).
      Lemon grass; citral, citronellal, and methyl-heptenone.
      Verbena; citral.
   b. Aromatic aldehydes:
      Bitter Almond; benzaldehyde.
      Cassia; cinnamic aldehyde.
      Cinnamon; cinnamic aldehyde and eugenol.
      Cumin; cumic aldehyde.
      Meadow Sweet; salicyl aldehyde.

Group IV.—Oils containing Ketones as characteristic constituents.
   a. Aliphatic saturated aldehydes:
      Rue; methyl-nonyl-ketone.
   b. Aliphatic unsaturated aldehydes:
      Lemon grass; methyl-heptenone.
   c. Monocyclic and dicyclic ketones:
      Artemisia; thujone.
      Camphor; camphor.
      Caraway; carvone and limonene.
      Dill; carvone and limonene.
      Orris; irone.
      Pennyroyal; pulegone.
      Peppermint; menthone and menthol.
      Sage; thujone with borneol and cineol.
      Spearmint; carvone.
      Tansy; thujone with borneol.
      Thuja; thujone and fenchone.
      Wormwood; thujone and thujyl alcohol.

Group V.—Oils containing Esters.
   a. Aliphatic Acids:
      Angelica; methyl-ethyl-acetic esters.
      Calamus; heptylic and palmitic acid and esters.
      Cardamom; acetic esters and cineol.
      German Chamomile; caproic acid esters.
Group VI.—Oils containing Phenols and Phenol Ethers.

a. Monatomic phenols and their ethers:
   - Ajowan; thymol and cymene.
   - Anise; anethol and methyl-chavicol.
   - Betel; chavicol and methoxy-chavicol.
   - Fennel; anethol and fenchone.
   - Marjoram; carvacrol and linalool.
   - Savory; carvacrol, pinene, and cymene.
   - Star Anise; anethol, methyl-chavicol and safrol.
   - Sweet Basil; Methyl-chavicol and d-linalool.

b. Diatomic phenols and their ethers:
   - Arnica Root; thymohydroquinone dimethyl-ether.
   - Bay; eugenol, methyl-eugenol and methyl-chavicol.
   - Camphor; safrol, eugenol and camphor.
   - Cascarilla Bark; eugenol and terpenes.
   - Cinnamon Leaf; eugenol and cinnamic aldehyde.
   - Cloves; eugenol and sesquiterpene.
   - Pimenta; eugenol and sesquiterpene.
   - Sassafras; safrol and camphor.

c. Triatomic phenols and their ethers:
   - Asarum; asarol and methyl-eugenol.
   - Matico; asarol.

d. Tetratomic phenols and their ethers:
   - Parsley; apiol.

Group VII.—Oils containing Neutral Bodies.
   - Cajuput; cineol, terpineol and terpenyl acetate.
   - Eucalyptus; cineol, pinene, and aldehydes.
   - Laurel Leaves; cineol and pinene.
   - Myrtle; cineol, d-pinene and dipentene.
   - Wormseed; cineol and dipentene.
Group VIII.—Oils containing Sulphur.
   Asafoetida; sulphides and pinene.
   Garlic; diallyl-disulphide and allylpropyl sulphone.
   Mustard; allyl-thiocyanate, allyl cyanide and carbon
disulphide.
   Onion; allyl-propyl sulphpide.

Properties.—Volatile oils are slightly soluble in water. Agitated with
this fluid they render it milky, but the major portion separates upon
standing, leaving the water impregnated with their odor and taste. This
impregnation is more complete when water is distilled with the oils, or
from the plants containing them. Trituration with insoluble powders, as
talc, magnesium carbonate, kieselguhr, etc., renders them much more
soluble, probably in consequence of their minute division. The
intervention of sugar also greatly increases their solubility, and affords
a convenient method of preparing them for internal use. The
hydrocarbon oils are scarcely soluble in diluted alcohol, and, according
to De Saussure, the solubility of volatile oils generally in this liquid is
proportionate to the oxygen which they contain. The volatile oils
dissolve sulphur and phosphorus with the aid of heat, and deposit them
on cooling. By long boiling with sulphur they form brown, unctuous,
fetid substances, formerly called balsams of sulphur. They absorb
chlorine, which converts them into resinous oxidation products and then
combines with these. Iodine produces a similar effect. They are
decomposed by the strong mineral acids, and unite with some organic
acids. When treated with a caustic alkali, some of them are saponified or
otherwise decomposed. Several of the metallic oxides, and various salts
which easily part with oxygen, convert them into resinous oxidation products. The volatile oils dissolve many of the proximate principles of
plant and animal tissues, such as the fixed oils and fats, resins,
camphor, and many of the alkaloids when in the free state. Exposed to
air and light, many of them absorb oxygen and become what are termed
ozonized oils which possess oxidizing properties.

Adulterations.—The volatile oils are often sophisticated. Among the
greater adulterations are fixed oils, resinous substances, chloroform,
hydrocarbon oils, and alcohol, but the most dangerous are those made
by mixing the pure oil with the cheaper volatile oils and terpenes and
fractions from other oils like limonene. The presence of the fixed oils
may be known by the permanent greasy stain "which they leave on
paper, while that occasioned by a pure volatile oil disappears entirely.
when exposed to heat. They may also in general be detected by their comparative insolubility in alcohol. Both the fixed oils and resins are left behind when the adulterated oil is distilled with wafer. If alcohol be present, the oil will become milky when agitated with water in a graduated tube, and after the separation of the liquids the water will occupy more space and the oil less than before. The following method of detecting alcohol was proposed by Beral. Put twelve drops of the suspected oil in a perfectly dry watch-glass, and add a piece of potassium about as large as the head of a pin. If the potassium remains for twelve or fifteen minutes in the midst of the liquid, there is either no alcohol present, or less than 4 per cent. If it disappears in five minutes, the oil contains more than 4 per cent. of alcohol; if in less than a minute, 25 per cent. or more. Borsarelli employs calcium chloride for the same purpose. This he introduces in small pieces, well dried and perfectly free from powder, into a small cylindrical tube, closed at one end, and about two-thirds filled with the oil to be examined, and heats the tube to 100° C. (212° F.), occasionally shaking it. If there is considerable proportion of alcohol, the chloride will be entirely dissolved, forming a solution which sinks to the bottom of the tube; if only a very small quantity, the pieces will lose their form, and collect at the bottom in a white adhering mass; if none at all, they will remain unchanged. (J. P. C., xxvi, 429.) J. J. Bernoulli proposes as a test dry potassium acetate, which remains unaffected in a pure oil, but will be dissolved if alcohol be present, and form a distinct liquid. (See A. J. P., xxv, 82.) Distillation, catching the first portion, and testing for alcohol by the iodoform reaction, will detect very small additions of alcohol. The most dangerous adulterant of volatile oils is a liquid sold under some "fancy name," found in the markets of London and other large cities, and recommended for "reducing" essential oils; one specimen examined by John Barclay (P. J., 1896, 463) had a delicate odor, and could be mixed with oils of lemon and bergamot without being detected by odor or taste. It was believed to be a laevo-pinene. There are good reasons for believing that similar liquids are used to an enormous extent.

Sometimes volatile oils of little value are mixed with the more costly. The taste and odor afford in this case the best means of detecting the fraud. The specific gravity of the oils may also serve as a test of purity. When two oils, of which one is lighter and the other heavier than water, are mixed, they may be separated by long agitation with this fluid, and will take a place corresponding to their respective specific gravities, but it sometimes happens that an unadulterated oil may thus be separated
into two portions. The difference of apparent effect produced by iodine with the several oils has been proposed as a test, and bromine was employed for the same purpose by John M. Maisch, who used both these tests preferably in the state of ethereal solution, which, as it is liable to spontaneous change by keeping, should be prepared when wanted for use. According to Liebig, when iodine is made to act on a volatile oil, a portion of it combines with the hydrogen of the oil, forming hydriodic acid, while another portion takes the place of the lost hydrogen. Oil of turpentine may be detected by remaining in part undissolved when the suspected oil is treated with three or four times its volume of alcohol of the sp. gr. 0.84; or, according to Mero, by causing the suspected oil, when agitated with an equal measure of poppy oil, to remain transparent, instead of becoming milky, as it would do if pure. The latter test will not apply to the oil of rosemary. (J. P. C., 3e ser., vii, 303.) G. S. Heppe suggests a very delicate test of oil of turpentine and most other non-oxygenated oils, when used to adulterate one of the oils containing oxygen. A piece of copper nitroprusside, of the size of a pin's head, is put into a little of the suspected oil in a test-tube, and heated until the liquid begins, to boil. The boiling must be continued only a few seconds. If the oil be pure and oxygenated, the copper nitroprusside will become black, brown, or gray; if oil of turpentine or other non-oxygenated oil be present, the deposit will be green or bluish-green, and the supernatant liquid colorless or yellowish.

The different relations of the volatile oils to polarized light may, to a certain extent, be made available for the detection of adulterations; especially where the action of the adulterating oil is in an opposite direction to that of the oil adulterated. Thus, the oils of juniper, lavender, and rosemary, rotate the plane of polarization to the left, while American oil of turpentine rotates it to the right; and if this should be added to one of the other oils it might in some degree neutralize their action, and thus offer one means for its detection. Unfortunately, the French oil of turpentine, from the juice of the Pinus maritima, acts strongly in the opposite direction. But the very strength of its left-rotatory power might lead to its detection by the abnormal increase of this power which it would impart to the oils in question. Synthetic or artificial volatile oils are now largely manufactured. They vary greatly at times in their resemblance to the natural products. They will be considered under their respective titles elsewhere, a number having received official recognition.
Volatile oils may be preserved without change in small, well-stoppered amber-colored bottles, entirely filled with the oil, and secluded from the light.

They may also be preserved by mixing with them about 5 per cent. of a bland fixed oil which will remain undissolved when the volatile oil is added to alcohol and for which allowance must be made, of course, in the volume of the oil used in formulas, etc. (LaWall, Proc. A. Ph. A., 1910, 1121.)

Manufacture.—Most of the volatile oils may be prepared by the general formula of the U. S. P. 1870: "Put the substance from which the Oil is to be extracted into a retort or other vessel suited for distillation, and add enough water to cover it, then distil by a regulated heat into a large refrigeratory. Separate the Distilled Oil from the water which comes over with it."

A large proportion of the volatile oils of European commerce is produced in Grasse, a town of France, twenty-five miles west of Nice. For an elaborate article on this industry and methods of preparation, see A. Pharm., xxii, 473, abstracted in the P. J., vol. xv, 468. Schimmel & Co., Miltitz, Germany, are large producers of volatile oils.

Under the general observations on the Aquae, or Waters, will be found remarks upon the use of steam in preparing the Distilled Waters, which are to a considerable extent applicable also to the volatile oils.

The substances from which the volatile oils are extracted may be employed in either the recent or the dried state. Certain flowers, however, such as orange flowers and roses, must be used fresh, or preserved with salt or by means of glycerin, as they afford little or no oil after desiccation. Most of the aromatic herbs, also, as peppermint, spearmint, pennyroyal, and marjoram, are usually distilled while fresh, although it is thought by some that when moderately dried they yield a larger and more grateful product. Dried substances, before being submitted to distillation, require to be macerated in water until they are thoroughly penetrated by this fluid, and to facilitate the action of the water it is necessary that, when of a hard or tough consistence, they should be properly comminuted by slicing, shaving, rasping, bruising or other similar mechanical operation.
The water which is introduced into the still with the substance answers the double purpose of preventing the decomposition of the vegetable matter by regulating the temperature, and of facilitating the volatilization of the oil, which, although in most instances readily rising with the vapor of boiling water, requires, when distilled alone, a considerably higher temperature, and is at the same time liable to be partially decomposed. Some oils, however, will not ascend readily with steam at 100° C. (212° F.), and in the distillation of these it is customary to use water saturated with common salt, which does not boil under 110° C. (230° F.). Recourse may also be had to a bath of strong solution of calcium chloride, or to an oil bath. Other oils, again, may be volatilized with water at a temperature below the boiling point, and, as heat exercises an injurious influence over the oils, it is desirable that the distillation should be effected at as low a temperature as possible. To prevent injury from heat, it has been recommended to suspend the substance containing the oil in a wire basket, or to place it upon a perforated shelf, in the upper part of the still, so that it may be penetrated by the steam, without being in direct contact with the water. Another mode of effecting the same object is to distill it in vacuo. Duncan stated that the most elegant volatile oils he had even seen were prepared in this manner by Barry, the inventor of the process. The employment of steam heat also prevents injury, and the best volatile oils are now prepared by manufacturers in this way. Steam can be very conveniently applied to this purpose by causing it to pass through a coil of tube, of an inch or three-quarters of an inch bore, placed in the bottom of a common still. The end at which the steam is admitted enters the still at the upper part, and the other end, at which the steam and condensed water escape, passes out laterally below, being furnished with a stop-cock, by which the pressure of the steam may be regulated and the water drawn off when necessary. In some instances it is desirable to conduct the steam immediately into the still near the bottom, by which the contents are kept in a state of brisk ebullition. This method is used in the preparation of the oil of bitter almond. The same method is applicable to the preparation of distilled waters.

The quantity of water added is not a matter of indifference. An excess above what is necessary acts injuriously by holding the oil in solution when the mixed vapors are condensed, and if the proportion be very large, it is possible that no oil whatever may be obtained separate. On the contrary, if the quantity be too small, the whole of the oil will not be distilled, and there will be danger of the substance in the still adhering.
to the sides of the vessel and thus become burnt. Enough water should always be added to cover the solid material and prevent the latter accident. Dried plants require more water than the fresh and succulent. The whole amount of material in the still should not exceed three-fourths of its capacity, as otherwise there would be danger of the liquid boiling over. The form of the still has an influence over the quantity of water distilled, which depends more upon the extent of surface than upon the amount of liquid submitted to evaporation. By employing a high and rather narrow vessel one may obviate the disadvantage of an excessive quantity of water. Sometimes the proportion of oil in the substance employed is so small that it is wholly dissolved in the water distilled, even though the proportion of the liquid in the still is not greater than is absolutely essential. In this case it is necessary to redistill the same water several times from fresh portions of the plant, until the quantity of oil exceeds the solvent power of the water. This process is called coelobation.

The more volatile of the oils pass with facility along with the steam into the neck of the common still, but some which are less volatile are apt to condense in the head and thus return into the still. For the distillation of the latter, a copper still should be employed having a very high head. As, after the distillation of any one oil, it is necessary that the apparatus should be thoroughly cleansed before being used for the preparation of another, it is better that the condensing tubes should be straight, rather than spiral as in the ordinary still. It should be recollected, moreover, that certain oils, such as those of anise and fennel, are rendered solid by a comparatively slight reduction of temperature, and that in the distillation of these the water employed for refrigeration should not be below 5.5° C. (42° F.).

The mixed vapors are condensed into a milky liquid, which is collected in a receiver, and, after standing for some time, separates into the oil and a clear solution of it, the former floating on the surface, or sinking to the bottom, according as it is lighter or heavier than water. The distillation should be continued so long as the liquid coming over has a milky appearance.

The last step in the process is to separate the oil from the water. For this purpose the Florentine receiver may be used. For illustrations of this, and other forms of receivers, for collecting and separating immiscible liquids, see Remington's Practice of Pharmacy, 6th edition, p. 250.
is a conical glass vessel, broad at the bottom and narrow towards the top, and very near its base furnished with a tubulure or opening, to which is adapted, by means of a pierced cork, a bent tube so shaped as to rise perpendicularly to seven-eighths of the height of the receiver, then to pass off from it at right angles, and near the end to bend downward. The condensed liquid being admitted through the opening at the top of the receiver, the oil separates, and, rising to the top, occupies the upper narrow part of the vessel, while the water remains at the bottom, and enters the tube affixed to the receiver. When the surface of the liquid attains in the receiver a higher level than the top of the tube, the water will necessarily begin to flow out through the latter, and may be received in bottles. The oil thus accumulates as long as the process continues, but it is evident that the plan is applicable only to the oils lighter than water. For the heavier oils, cylindrical vessels may be employed, to be renewed as fast as they are filled; but, as all the water cannot be removed by these plans, it is necessary to resort to some other method of effecting a complete separation. An instrument called a separator is usually employed for this purpose. It consists of a glass funnel, or a globular vessel, furnished with a stopper, and prolonged at the bottom into a very narrow tube. The lower opening being closed, the mixed liquids are introduced and allowed to stand until they separate. The orifice at the bottom is then opened, and, the stopper at the top being a little loosened, so as to admit the air, the heavier liquid slowly flows out, and may be separated to the last drop from the lighter, which floats above it. If the oil is heavier than the water, it passes out of the separator; if lighter, it remains within. According to George Leuchs, all oils obtained by distillation with water, even when perfectly clear, contain some water.

The water saturated with oil should be preserved for use in future distillations, as it can dissolve no more of the oil. One or more volatile acids are frequently found in the distilled water, as acetic, butyric, or valerianic, and Wunder has detected all three of these acids in the water distilled from chamomile flowers. (J. Pr. Chem., lxiv, 499.) For an illustration of a cheap apparatus for distilling volatile oils by steam under slight pressure, see Proc. A. Ph. A., 1894, 680.

According to Overbeck, all the volatile oils may be decolorized by distilling them from an equal weight of poppy seed oil and a saturated solution of common salt. (A. Pharm., lxxxiv, 149.)
When first procured, some volatile oils have a disagreeable somewhat empyreumatic odor, from which they may be freed by allowing them to stand for some days in vessels loosely covered with paper. They should then be filtered and introduced into small opaque bottles, which should be well stoppered so as to exclude the air. When altered by exposure to air, they may sometimes be restored to their original appearance and quality by agitation with a little recently heated animal charcoal, and the same method may be employed for freeing them from adhering water.

They may be administered upon a lump of sugar; or triturated with at least ten times their weight of sugar, forming oleosaccharates, which are then dissolved in water; or made into emulsions with water, sugar, and gum arabic. In making emulsions with volatile oils, it has been recommended first to dissolve them in one of the fixed oils, the oil of almond for example, and then to emulsionize the oleaginous solution with syrup and gum arabic. For 100 parts of water, 15 of the almond oil in which the volatile oil is to be dissolved, 10 of powdered gum arabic, and 25 of syrup may be taken. The volatile oils are often kept dissolved in alcohol under the name of essences.

Enfleurage.—This term is applied by the French to the impregnation of fixed oil and fatty matters with the odors of certain sweet scented plants, such as jasmine, tuberose, and mignonette, the oils of which are so delicate and fugitive that they cannot well be separated by distillation. The process consists in exposing the fatty matter, placed in layers, in suitable frames, to the exhalations from the flowers, which are absorbed, and give their characteristic odor to the fat. Another plan is to expose alternate layers of the flowers, and of cotton impregnated with bland fixed oil, to the sun, and afterwards to express the oil from the cotton. (A. J. P., xxix, 551.) The French sometimes give to the spirituous solutions made by extracting the odors from fats and oils with alcohol the name of Essences.

The following suggestions on preparing emulsions of the volatile oils may be useful. Oil of turpentine and other volatile oils, to be emulsionized in quantity, are most successfully treated by rubbing them with one-half their weight of powdered gum arabic, and, when intimately mixed, adding at once, with rapid trituration, water in the proportion of one and a half times the weight of the gum used. Such an emulsion is more permanent when a little fixed oil is used.
Uses.—While substances differing so widely in their source and in their chemical composition must manifestly exercise dissimilar effects upon the body, but there are certain properties common to so many of the volatile oils that a word concerning the therapeutic effects of this group of principles may be in place. Practically all of the official volatile oils are more or less irritant; some of them only feebly so and some very actively so. By virtue of this action when taken into the intestinal tract they excite peristalsis and are therefore used for the expulsion of flatus in colic as well as to enhance the effect of cathartic drugs. It is probably also to this local irritant effect that their uses as expectorants, diaphoretics, and diuretics is to be attributed. A large number of them are powerful germicides and nearly all of them more or less antiseptic. The antibacterial property of the volatile oils has been investigated especially by Martindale (Perfume and Essential Oil Record, 1910, i, p. 266) by Gilmore (P. J., 1910, p. 844) and by Peck (J. A. M. A., 1899, xxxii, p. 6). According to Martindale the oil of origanum is twenty-five times as actively germicidal as phenol and the oil of cloves about 9 times; while Peck finds that the oil of cloves prevents the multiplication of bacteria when present in about 1 part to 1100. The following volatile oils are powerfully germicidal: origanum, thyme, cinnamon, cassia, cloves, bay, and sassafras. Of considerable disinfectant power but weaker than the preceding are: peppermint, eucalyptus, cajuput, bitter almond, sandal wood, spearmint and lavender. The following are feeble in their anti-bacterial properties: anise, bergamot, juniper, cade, and turpentine. Concerning most of the other oils figures are lacking. While the cost of the volatile oils precludes their use for many disinfectant purposes yet for others they are very valuable agents, especially are they employed for their antibacterial properties in the mouth and nose.

Some of the essential oils possess marked local anesthetic powers, among which may be mentioned especially cloves, peppermint, thyme, and cajuput. For this influence they are used in toothache and pruritus.

OLEATA.

OLEATES

Oleates, Fr.; Oleate, G.

The oleates are a class of preparations which were introduced to the
medical profession by John Marshall, F.E.S., in 1872. They are usually solutions of certain bases in oleic acid, and are made by triturating the solid substance with the oleic acid until it is dissolved. Whenever it is possible, the application of heat should be avoided, and it has been observed that the freshly precipitated oxides of the metals dissolve more readily than those which are old. The title oleate is probably the best that could be devised, although it must be understood that, as found in the Pharmacopoeias, they are not pure chemical compounds, but merely compounds of the oxides or the alkaloids, as the case may be, with oleic acid dissolved in a great excess of the latter.

Oleates may be made either by direct combination of the ingredients or by double decomposition. When made by the latter method, a good quality of oleic acid should be treated with the proper quantity of solution of sodium hydroxide, to saponify it, any excess of the alkali being neutralized with a little tartario acid. This soap solution is preferably used diluted.

J. M. Good, in making the oleates of the alkaloids, proposes the use of sufficient oleic acid to dissolve the alkaloid and then diluting the solution with a bland fixed oil, such as almond oil. (Proc. Missouri Pharm. Association, 1891, p. 65.)

The medicinal properties of the oleates are, of course, dependent upon the base, so that these preparations may be considered the equivalents of the corresponding ointments, over which, however, they have certain advantages. They are much cleaner and more elegant in appearance. They seem to be more irritating than the ointments, and, unless diluted with an equal bulk of cottonseed, olive, or other bland oil, are, when applied with friction, likely to provoke a cutaneous eruption or even pustulation. Marshall recommends that they be applied with a brush, or gently spread over the part with the finger.

**OLEORESINA ASPIDII. U. S. (Br.)**

**OLEORESIN OF ASPIDIUM Oleores. Aspid.**

[Oleoresin of Male Fern]

:Liquid Extract of Male Fern contains in 100 grammes not less than 20 grammes of filicin." Br.

"Aspidium, recently reduced to No. 40 powder, five hundred grammes [or 17 ounces av., 279 grains]; Ether, a sufficient quantity. Place the aspidium in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered bottle. Note: Oleoresin of Aspidium, on standing, usually deposits a granular, crystalline substance. This should be thoroughly mixed with the liquid portion before use." U. 8.

"Male Fern, in No. 20 powder, 1000 grammes; Ether, a sufficient quantity. Exhaust the Male Fern, by percolation with the Ether; from the clear percolate recover the ether by distillation and finally evaporate on a water-bath until an oily extract remains. Specific gravity not less than 1.000. Refractive index at 40° C. (104° F.) not less than 1.490. Contains in 100 grammes not less than 20 grammes of filicin as determined by the following process:—Dissolve 5 grammes of the Liquid Extract in 40 milli-litres of ether, transfer to a separator, add 100 grammes of solution of barium hydroxide and shake vigorously and continuously for five minutes. Allow the liquids to separate and filter off 86 grammes of the aqueous liquid. Acidify this with hydrochloric acid and extract with three successive portions of 30, 20, and 15 millilitres of ether. Filter the mixed ethereal solutions, wash the filter paper with ether, evaporate, dry the residue at 100° C. (212° F.) and weigh. It weighs not less than 0.8 gramme, equivalent to not less than 20 grammes of filicin in 100 grammes of the Liquid Extract. This Liquid Extract contains not less than 20 per cent. of filicin." Br.

This is the only preparation of male fem which should be used; in its making aspidium which is green in color and recently collected should be employed. It is a thick, dark green liquid, usually containing a granular deposit of crystalline filicic anhydride, often erroneously called filicin or filicic acid, which is regarded as the active ingredient and should not be separated. For a method of determining the
percentage of filicic acid by Daccomo and Scoc-cianti, see Ph. Centralh., 1896, 208. Wm. G. Greenawalt found both the liquid and the sediment effective tenicides, the sediment somewhat the more active. It has the odor of fern, and a nauseous, bitterish, somewhat acrid taste. According to Hayes, when an absolutely dry root and an anhydrous ether (containing but little alcohol) of a specific gravity below 0.728 are used, the oleoresin remains clear. Kramer states that a very active extract of male fern may be prepared by exhausting with ether the fresh juicy rhizomes collected in May or October freed from scales and cut into small pieces. The ethereal tincture should be kept in a cool place until wanted, when the necessary quantity should be converted into extract. One dose, two to four drachms, of such an extract is said to have always produced satisfactory results. (Ph. Cb., xxv, 578.) Oleoresin of male fern is sometimes found in the market containing noticeable proportions of copper, and in many cases it is colored green artificially.

For therapeutic properties of this oleoresin, see Aspidium.

Dose, from one-half to one fluidrachm (1.8-3.75 mils), administered in emulsion.

**OLEORESINA CAPSICI. U. S.**

**OLEORESIN OF CAPSICUM Oleores. Capsic.**

Oleoresine (Extrait ethere) de Capsique, Fr.; Spanisch-pfeffer-Oelharz, Aetherisches Spaniachpleflier-extrakt, G.

"Capsicum, in No. 40 powder, five hundred grammes [or 17 ounces av., 279 grains]; Ether, a sufficient quantity. Place the capsicum in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the percolate measures eight hundred mils [or 27 fluidounces, 24 minims]. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place. Then pour off the liquid portion, transfer the remainder to a glass funnel provided with a pledget of cotton, and, when the separated fatty matter (which is to be rejected) has been completely drained, mix the liquid portions together. Keep the Oleoresin...
in a well-stoppered bottle." U. S.

One of the active principles of capsicum, called capsaicin, C9H14O2, is very soluble in ether, and is wholly extracted in the process. Its precise nature has not been determined. Another principle, even still more pungent than capsaicin, is capsacutin which is also extracted by the official solvent in making this oleoresin. (See Capsicum.) After the concentration of the acetone solution, a solid fatty matter separates on standing, but a portion of fixed oil probably still remains. The preparation is a very thick liquid, capable, however, of being dropped, of a dark reddish-brown color, and, though opaque in mass, yet transparent in thin layers. It has not very decidedly the odor of capsicum, but to the taste is intensely pungent. W. C. Alpers found a capsicum which yielded 16 per cent. of oleoresin; the statement has been frequently made that 5 per cent. is the usual yield. (M. R., 1896, 593.) It may be usefully employed to give locally stimulant properties to substances administered internally in a pilular form, in cases of gastric insensibility and excessive flatulence. One drop given three times a day has produced cystic irritation and strangury. It may be used also as a powerful rubefacient, in strengths of from one to two per cent., diluted with olive oil or soap liniment.

Dose, from one-fourth to one grain (0.015-0.065 Gm.).

Off. Prep.—Emplastrum Capsici, U. S.

OLEORESINA CUBEBAE. U.S.

OLEORESIN OF CUBEBA Oleores. Cubeb.

"Cubeb, in No. 30 powder, five hundred grammes [or 17 ounces av., 279 grains]; Alcohol, a sufficient quantity. Place the Cubeb in a cylindrical glass percolator, pack the powder firmly, and percolate slowly with alcohol, added in successive portions, until the drug is exhausted. Recover the greater part of the alcohol from the percolate by distillation on a water-bath, and, having transferred the residue to a dish, allow the remaining alcohol to evaporate in a warm place, stirring frequently. Keep the Oleoresin in a well-stoppered bottle.
"NOTE: Oleoresin of Cubeb, after standing for some time, deposits a waxy and crystalline precipitate, which should be rejected, the liquid portion only being used." U. S.

A change was made in the menstruum for this oleoresin in the U. S. P. (8th Rev.) alcohol now being used instead of ether or acetone. The use of alcohol was suggested by E. R. Squibb. This oleoresin consists mainly of the volatile oil and resin, with a portion of the cubebin and waxy matter of the cubeb. The consistence differs according to the character of the cubeb employed, its degree of fluidity being proportionate to the amount of volatile oil contained in the medicine. The color is usually blackish brown, with more or less of a greenish hue, according to the quantity of chlorophyll present, which varies with the character of the cubeb and with that of the menstruum, pure ether extracting more of the green coloring matter, while alcohol extracts the brown; unripe fruit or berries yield more chlorophyll than do the ripe fruit. Cubeb yields from one-eighth to one-fifth of its weight of the oleoresin. The preparation deposits waxy matter and crystals of cubebin on standing, which should be separated and discarded; its efficacy is not impaired on this account. It was first introduced into use by Procter. (A. J. P., xviii, 168.)

From carefully conducted experiments by P. V. Heydenreich, it would appear that, of the various constituents of cubeb contained in the official oleoresin, the cubebin has no perceptible effect in the dose of the medicine ordinarily given, that the volatile oil is simply stimulant and carminative, and, finally, that the soft resin has all the diuretic properties of the cubeb. Of the last-mentioned ingredient, twenty grains (1.3 Gm.) given every two hours until five doses were taken considerably increased the secretion of urine, producing at the same time a slight burning sensation in the passage, which ceased with the diuretic action. Pushed beyond this amount, it occasioned severe irritation of the urinary passages, with some fever.

This oleoresin, as it occurs in the market, often has a thin consistence. In one specimen three-eighths of its weight were lost in a short time by the spontaneous evaporation of the ether improperly left in the product.

Dose, from five to ten minims (0.3-0.6 mil), given suspended in water, or mixed with powdered sugar.
OLEORESINA PETROSELINI. U. S.

OLEORESIN OF PARSLEY FRUIT Oleores. Petrosel.  
[Liquid Apiol]

Apiol, Oil of Parsley Seed.

"Parsley Fruit, in No. 60 powder, five hundred grammes [or 17 ounces av., 279 grains]; Ether, a sufficient quantity. Place the parsley fruit in a cylindrical glass percolator provided with a stop-cock and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly and percolate slowly with ether, added in successive portions until the drug is exhausted. Recover the greater portion of the ether by distillation on a water bath, and, having transferred the residue to a dish, remove the remaining ether by spontaneous evaporation in a warm place, stirring frequently. Allow the Oleoresin to stand without agitation for four or five days, decant the clear liquid portion from any solid residue, and preserve" it in well-stoppered bottles." U. S.

This oleoresin is commonly called "liquid apiol." The official process should be strictly followed as cases are on record where commercial gasoline or benzin has been used as the menstruum and the percolate evaporated spontaneously, whereupon a yield of as much as 50 per cent. of a non-volatile, oily liquid was obtained which consisted chiefly of the non-volatile portions from the gasoline. Such a procedure cannot be too severely condemned.

According to L. Wolff (A. J. P., 1877, 2), commercial apiol is merely the oleoresin; he proposes a very simple process for true apiol. Powdered parsley seed is exhausted with petroleum benzin, and the liquid is spontaneously evaporated; the residue is a mixture of fixed oil, wax, and apiol; the apiol alone being soluble in alcohol can easily be separated by repeated washings with strong alcohol; the washings evaporated over a water bath at a gentle heat leave as a residue "true apiol." L. Ough (C. D., 1894, 17) obtains apiol by percolating freshly powdered parsley seeds with alcohol, recovering the alcohol from the percolate by distillation, and separating the oily residue from the deposited waxy solid.
Ciamician and Silber (Ph. Post, 1888, 391) have investigated apiol, and state that the pure substance occurs in white crystals having the composition C$_{12}$H$_{14}$O$_4$, melting at 30° C. (86° F.), and boiling at 294° C. (561° F.). Isapiol, apiolic acid, apiolaldenyde, and apion are decomposition products. They state that isapiol has physiological properties resembling those of pure apiol.

H. C. Whitney (N. R, January, 1880) proposed to change the name of commercial apiol, and call it oil of parsley seed. He believed that the volatile oil of parsley seed is the active and emmenagogue principle, and obtained it by distilling the freshly powdered seed with salt water. The yield is 4.27 per cent. of an oil which corresponded closely with Joret and Homolle's apiol. Von Gerichten (Ber. d. Chem. Ges., 16, 17) obtained besides the peculiar terpene, parsley camphor, which he thinks is alone entitled to the name of apiol. He gives its melting point as 30° C. (86° F.), boiling point 300° C. (572° F.), and sp. gr. 1.015.

Parsley camphor has been given the formula CH$_2$:CH.CH$_2$:C$_2$H(OCH$_3$)$_2$:O$_2$:CH$_2$:CH.-It may be prepared by extracting the oleoresin of parsley seed with ether and subsequent purification. It crystallizes in long needles of a slight parsley odor—insoluble in water, but readily soluble in alcohol. With strong sulphuric acid it gives a blood-red color.

**Uses.**—The oleoresin of parsley contains a number of bodies of considerable physiological power. The most important of these are crystalline apiol, white apioline, and myristicin. According to the experiments of Lutz (Bull. Sci. Pharm., 1910, xvii, p. 1) the actions of these substances are similar in kind. They produce marked slowing of the pulse with fall of the blood pressure, tremors,, and weakness of the extremities, followed by paralysis with epileptiform convulsions and gasping respirations. After death there was found marked congestion in the lungs and in the pelvic organs. Rimini and Dilitala (Archiv. di. Farmacologia e. Terap., 1908, xiv) have shown that apiol produces in the cat fatty degeneration of the liver of the same type as is caused by myristicin. They also noted that it had a direct weakening action on the voluntary muscles.

Oleoresin of parsley and other principles derived from this plant have been used in various uterine disorders, especially in dysmenorrhea. Our
knowledge of its physiological action, however, furnishes no ground for attributing to it valuable properties in this or any other disease. The congestion in the pelvic organs found after death from this drug, may easily be attributed to the asphyxial nature of the poisoning. There is no evidence that in quantities approaching those used in medicine it has any influence of any kind upon the uterus. Glatard (Journ. de Mod. et Chir. Prat., 1910, p. 674) reports a case of apiol poisoning in a pregnant woman who took six grammes in a period of forty-eight hours. There was vertigo, nausea and vomiting, urticaria, liver swollen and painful, mild icterus, urine scanty and high colored, but free from albumen; pregnancy was not interrupted. Sardou (A. G. M., 1906) recommends apiolin as an antispasmodic in intestinal colic.

Dose, five to fifteen minims (0.3-0.9 mil).

**OLEORESINA PIPERIS. U. S.**

**OLEORESIN OF PEPPER Oleores. Piper.**

Extractum Piperis Fluidum, U. S. 1850; Fluid Extract of Black Pepper; Oleoresine de Pêvre noir, Fr.; Aethenachae Pfefferextrakt, G.

"Pepper, in No. 40 powder, five Hundred grammes [or 17 ounces av., 279 grains]; Ether, a sufficient quantity. Place the pepper in a, cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, set this aside in a warm place until the remaining ether has evaporated, and the deposition of piperine has ceased. Lastly, separate the Oleoresin from the piperine by straining through purified cotton. Keep the Oleoresin in a well-stoppered bottle." U. S.

A substance has long been in use under the name of oil of black pepper, consisting mainly of the volatile oil, fixed oil, and resin of the pepper, and belonging, therefore, to the oleoresins. As usually found, it is almost black and of a thick consistence, and is a residue of the process for preparing piperine. The official oleoresin made with ether has the same general character, but is more fluid and of more uniform strength, and should, therefore, be preferred. It contains almost all the volatile oil and
acrid resin of black pepper, with little of the piperine, and, as the last-mentioned principle, when quite pure, is of doubtful efficacy, the oleoresin may be considered as representing the virtues of the fruit. The color is greener than that of the common oil of black pepper, and not so dark, owing to the fact that the solvent dissolves the green more readily than the brown coloring matter. A pound of black pepper yields about six drachms of the oleoresin.

Dose, from one-fourth to one minim (0.015-0.06 mil), in emulsion or pill.

OLEORESINA ZINGIBERIS. U. S.

OLEORESIN OF GINGER Oleores. Zingib.

Extractum Zingiberis Æthereum; Oleoresine (Piperoide) deGingembre, Fr; Zingiberin, Aetherisches Ingwerextrakt, G.

"Ginger, in No. 60 powder, five "hundred grammes [or 17 ounces av., 279 grains]; Ether, a sufficient quantity. Place the ginger in a cylindrical glass percolator, provided with a stop-cock, and arranged with a cover and a receptacle suitable for volatile liquids. Pack the powder firmly, and percolate slowly with ether, added in successive portions, until the drug is exhausted. Recover the greater part of the ether from the percolate by distillation on a water bath, and, having transferred the residue to a dish, allow the remaining ether to evaporate spontaneously in a warm place. Keep the Oleoresin in a well-stoppered bottle." U. S.

In the U. S. formula of 1870 for this preparation alcohol was used in connection with ether, on the score of economy: it was added in order to displace the ether and thus save an unnecessary expenditure of the more costly fluid. A little of the alcohol mixed with the ether at their surface of contact. In the present process both ether and alcohol have been replaced by the solvent, ether. The whole of the virtues of the root are extracted in this preparation, as the residuary ginger is nearly or quite tasteless. The oleoresin constitutes about 5 per cent. of the dried root. It is the piperoid of ginger of Beral. (Soubeiran's Traite de Pharm., i, 371.) It is a clear, dark-brown liquid, of a thick consistence (though capable of being dropped), with the flavor of ginger, and very pungent.

The oleoresin of ginger is a useful stimulant in alcoholic gastritis,
chronic serous diarrheas and other atonic conditions of the alimentary canal.

Dose, one-half to one minim (0.03-0.06 mil), well diluted.

OLEORESINÆ

OLEORESINS

Oleo-resines, Extraits etheres, Fr.; Oelharze, Aetherische Extrakte, G.

The oleoresins, as a class of preparations, were introduced into the U. S. Pharmacopoeia at the revision of 1860, having been previously classed with the Fluidextracts. Their peculiarity is that they consist of principles which, when extracted by means of ether, alcohol, or acetone, retain a liquid or semi-liquid state upon the evaporation of the menstruum, and at the same time have the property of self-preservation, differing from the fluidextracts in not having a definite relation of strength to the drug. They consist chiefly, as their name implies, of oil, either fixed or volatile, holding resin and sometimes other active matter in solution. Their preparation is very simple, consisting in the exhaustion of the drug with acetone, alcohol or ether by means of percolation, and the subsequent evaporation of the menstruum. In consequence of the great volatility of the solvent, it may in great measure be recovered by distillation, thus very materially diminishing the costliness of the process. It is proper not to continue the heat necessary for the recovery of the solvent by distillation until the whole of the solvent is driven over, lest, towards the close, a portion of the volatile matters also should pass, and the strength of the oleoresin be impaired. Hence in every instance the last portions of the menstruum are allowed to separate by spontaneous evaporation. Petroleum benzin has been proposed as a substitute for other solvents in these preparations, but should not be permitted to supersede them until officially sanctioned. It is difficult, if not impossible, to remove the last traces of this solvent without loss of volatile oil. Acetone replaced ether in most of the formulas of the U. S. P. VIII on account of economy, but as ether is again the cheaper solvent because of the use of denatured alcohol in its manufacture, it is again officially directed in the U. S. P. IX. Oleoresin of cubeb is made with alcohol,
OLEUM ABIETIS. Br.

OIL OF SIBERIAN FIR [Oil of Pine]

"Oil of Siberian Fir is the oil distilled from the fresh leaves of Abies sibirica, Ledeh." Br.

"Colorless or nearly so. Aromatic odor; taste pungent. Specific gravity 0.900 to 0.920; optical rotation —32° to —4-2°; refractive index at 25° C. (77° F.) about 1.474. Contains from 30 to 40 per cent. of esters, calculated as bornyl acetate, C_{10}H_{17}C_{2}H_{3}O_{2}" Br.

This is practically the same in its properties and uses as pine needle oil. (See Oleum Pini Pumilionis.)

OLEUM AJ OWAN. Br.

AJ OWAN OIL [Ptychotis Oil]

"Ajowan Oil is the oil distilled from the fruit of Carum Copticum, Benth. and Hook. f." Br.

Under the name of ayowan, ajwain, ajwan, and other vernacular appellations, the fruit, of the Carum Ajowan Bentley (C. Copticum Benth. and Hook. f.) are largely used in India as an aromatic. They resemble in size the fruits of the ordinary parsley and are of a grayish-brown color and have a tubercular surface with five prominent ridges to each mericarp. The odor and taste resemble that of thyme. These fruits yield from 4 to 6 per cent. of an agreeably aromatic volatile oil. Ajowan oil is "colorless, with an odor and taste resembling thyme. Specific gravity 0.910 to 0.930. Optical rotation +10 to +2°. When 10 millilitres with 100 milli-litres of solution of sodium hydroxide in a flask with a narrow graduated neck are heated on a water-bath, well shaken, and allowed to stand, the uncombined oil, cooled to 15.5° C. (60° F.), measures not more than 6 millilitres (presence of not less than 40 per cent. of thymol)." Br.

This oil, besides containing thymol, contains a terpene and also the cyclic hydrocarbon cymene.

The oil of ajowan is one of the most important commercial sources of
thymol. Its medicinal virtues are due entirely to this ingredient.

Dose, one-half to five minims (0.03-0.3 mil).

OLEUM AMYGDALÆ AMARÆ. U. S.

OIL OF BITTER ALMOND
Ol. Amygd. Amar. [Bitter Almond Oil]

"A volatile oil obtained by maceration and distillation from the ripe kernels of Prunus Amygdalus amara DeCandolle (Fam. Rosacææ), and from other kernels containing amygdalin. It yields not less than 85 per cent. of benzalde-hyde \( \text{C}_7\text{H}_6\text{O} \) and not less than 2 per cent. nor more than 4 per cent. of hydrocyanic acid \( \text{HCN} \). The botanical source from which it is derived must be stated on the label. Preserve it in small, well-stoppered, completely filled, amber-colored bottles protected from light and air. Oil showing crystals of benzoic acid must not be dispensed.

"NOTE: This Oil is intended for medicinal use; it must not be used for flavoring foods." U. S.

Oleum Amygdalarum (Amararum) Æthereum; Oleum Amygdalæ Volatile; Volatile Oil of Almond, Huile volatile d’Amande amere, Fr. Cod.; Essence d’Amandea ameres, Fr.; Bittermandelol, G.; Esencia de almendras amargas, Sp.

When bitter almonds are expressed, they yield a bland fixed oil, and the residuary cake, reduced to powder by grinding, and submitted to distillation with water, yields oil of bitter almond. This does not pre-exist in the almond, but is produced by the action of water upon the amygdalin contained in it, through the intervention of an enzyme called emulsin (see Amygdala Amara), according to the reaction:

\[
\text{C}_{20}\text{H}_{27}\text{NO}_{11} + 2\text{H}_2\text{O} = \text{C}_7\text{H}_6\text{O} + 2\text{C}_6\text{H}_{12}\text{O}_6 + \text{HCN}
\]

It is obtained also by the distillation of the leaves of the cherry-laurel, by the bark of the wild cherry, and of various products of the genera Amygdalus, Cerasus, Prunus, etc. Whipple obtained, upon an average, from the ground bitter almond cake, 1.35 per cent. of the oil. (P. J., x, 297.) Pettenkofer has ascertained that the yield is greater if the cake be macerated in water for forty-eight hours before being submitted to
distillation. (J. P. C., May, 1862, p. 432.) It is sometimes produced from peach kernels. SchimmePs Report for April, 1914, refers to the fact that the sole source of the oil at that time was apricot kernels.

Oil of bitter almond has a yellowish color, a bitter, acrid, burning taste, and the odor of the kernels in a high degree. It is heavier than water, soluble in alcohol and ether, according to Fluckiger soluble in 300 parts of hot or cold water, and deposits, upon standing, a white crystalline substance consisting chiefly of benzoic acid. It is officially described as "a clear, colorless or yellow, strongly refractive liquid, having the characteristic odor and taste of benzaldehyde. It is slightly soluble in water and soluble in all proportions in alcohol or ether. It dissolves, forming a clear solution, in 2 volumes of 70 per cent. alcohol. Specific gravity: 1.038 to 1.060 at 25° C. (77° F.). Refractive index: 1.5428 to 1.5439 at 20° C. (68° F.) (see Part III, Test No. 22). It is optically inactive or dextrorotatory, not exceeding +0° 10' in a 100 mm. tube at 25° C. (77° F.). When first prepared, the Oil is neutral to litmus paper, but afterwards develops an acid reaction due to the formation of benzoic acid. It does not respond to the Test for heavy metals in volatile oils. Hold the looped end of a piece of clean copper wire in a non-luminous flame until it glows without coloring the flame green, cool the wire, dip the loop into Oil of Bitter Almond, ignite the latter and hold it so that the liquid burns outside of the non-luminous flame. On slowly bringing the flame from the burning Oil of Bitter Almond on the loop in contact with the lower outer edge of the non-luminous flame, no green tinge is discernible (chlorinated products). Add 10 drops of the Oil to a little alcohol, then add a small amount of zinc dust and 2 mils of acetic acid and boil the mixture for a short time; no odor of phenylisocyanide develops after rendering it strongly alkaline with potassium hydroxide T.S., adding a few drops of chloroform and heating (nitrobenzene)."

Besides the peculiar volatile oil, it contains also hydrocyanic acid, with usually a small proportion of benzoic acid produced by oxidation of the aldehyde. It may be obtained pure by agitating it strongly with calcium hydroxide and a solution of ferrous chloride, submitting the mixture to distillation, and drying the oil which comes over by digestion with calcium chloride. George Whipple states that if crude oil be redistilled into a solution of silver nitrate, and again distilled from a fresh solution of the same salt, it is obtained entirely free from hydrocyanic acid, which reacts with the silver and remains behind as silver cyanide. (See
A. J. P., xxvi, 348.) Thus purified, it is colorless, but still retains its peculiar odor, with a burning, aromatic taste, and is destitute of those poisonous properties of the crude oil which are dependent on hydrocyanic acid. The odor of the oil of bitter almond has been erroneously ascribed to that acid, which, on examination, will be found to have a different and more feeble odor. Like most other volatile oils, this may produce deleterious effects if taken very largely. Hippuric acid is found in the urine of animals to which the oil has been given freely. The sp. gr. of the crude oil varies from 1.052 to 1.082, and is said to be greater when the oil is distilled from salt water than when distilled by the ordinary mode. That of the purified oil is 1.060, and its boiling point 180° C. (356° V.). It is benzoic aldehyde, C₆H₅.CO.H, which may also be produced by the action of oxidizing agents upon benzyl alcohol, C₆H₅.CH₂.OH, and yields itself, when oxidized, benzoic acid, C₆H₅.CO.OH. The benzoic acid which the oil of bitter almond deposits on standing does not pre-exist in it, but results from the absorption of oxygen, as just stated.

If sulphuric acid produce with the oil a bright-red instead of a brownish-red color, the oil has probably been distilled with salt water, in which case it is prone, according to Ferris, to deposit a blood-red substance, occasionally complained of by druggists.

Uses.—The unpurified volatile oil of bitter almond, which is the product directed by the Pharmacopoeia, acts physiologically like hydrocyanic acid. Death is said to have occurred in a man ten minutes after taking two fluidrachms (7.5 mils) of the oil. It might be substituted with advantage for medicinal hydrocyanic acid, if it always contained a uniform percentage of the acid, as the acid contained in the oil is much less liable to decomposition, remaining for several years unaltered, provided the oil be preserved in well-stoppered bottles. According to Schrader, 100 parts of the oil contain sufficient acid for the production of 22.5 parts of Prussian blue, but the proportion is not constant, varying, according to Groves, from 8 to 12.5 per cent. the U. S. official standard is, however, not less than 2 per cent. and not more than 4 per cent. It has been employed externally, dissolved in water in the proportion of one minim (0.06 mil) to a fluidounce (30 mils), in prurigo senilis and other cases of troublesome itching. To facilitate the solution in water, the oil may be previously dissolved in spirit. Oil of bitter almond is sometimes used to conceal the taste of cod liver oil and of
castor oil.

Dose, one-fourth to one minim (0.015-0.06 mil.).

**OLEUM AMYGDALÆ EXPRESSUM. U. S. (Br.)**

**EXPRESSED OIL OF ALMOND**

*Ol. Amygd. Exp. [Oil of Sweet Almond]*

"A fixed oil obtained from the kernels of varieties of Prunus Amygdalus Stokes (Fam. Rosaceae). Preserve it in well-closed containers, in a cool place." U. S. "Almond Oil is the oil expressed from the Bitter or Sweet Almond." Br.

**Oleum Amygdalae** Br.; Almond Oil; Oleum Amygdalae Dulcis, U. S. 1860; Oil of Sweet Almond; Huile d'Amande douce, Fr. Cod.; Huile d'Amandes, Fr.; Oleum Amygdalarum, P. G.; Mandel ol, G.; Olio di mandorle dolci, It.; Aceite de almendras dulces, Sp.

This oil is obtained equally pure from sweet and from bitter almonds. In its preparation, the almonds, having been deprived of a reddish-brown powder adhering to their surface, by being rubbed together in a piece of coarse linen, are ground in a mill resembling a coffee-mill, or bruised in a stone mortar, and then pressed in canvas sacks between plates of iron slightly heated. The oil, which is at first turbid, is clarified by rest and filtration. Sometimes the almonds are steeped in very hot water, deprived of their cuticle, and dried in a stove, previous to expression. The oil is thus obtained free from color, but in no other respect better, while it is more likely to become rancid on keeping. Bitter almonds treated in this way impart an odor of hydrocyanic acid to the oil. Boullay obtained 54 per cent. of oil from sweet almonds. Munch gives 55.4 per cent. as the yield of the former, and 52 per cent. as that of the latter. (J. P. C; 4e ser., iii, 400.) These figures are not realized, however, in the ordinary expression methods. Šchaedler (Technologie der Fette und Oele, 2te Auf., 532) gives 45 per cent. as the average obtained from the sweet almonds, and 38 per cent. from bitter almonds. Though sometimes expressed in this country from imported almonds, the oil is generally brought from Europe.
Properties.—It is "a clear, pale straw-colored or colorless, oily liquid, almost odorless, and having a bland taste. It is slightly soluble in alcohol, miscible with ether, chloroform, benzene, or petroleum benzin. Specific gravity: 0.910 to 0.915 at 25° C. (77° F.). The oil remains clear at -10° C. (14° F.), and does not congeal until cooled to nearly -20° C. (-4° F.) (olive or lard oil). Shake vigorously 2 mils of the Oil with a mixture of 1 mil of fuming nitric acid and 1 mil of water; a whitish mixture is formed, which, after standing for several hours at about 10° C. (50° F.), separates into a solid white or nearly white mass and a slightly colored liquid (oil of peach or apricot kernels, yielding a red color, and sesame or cottonseed oil, yielding a brown color). Heat 10 mils of the Oil with 15 mils of an aqueous solution of sodium hydroxide (1 in 6) and 30 mils of alcohol on a water bath in a flask having a small funnel inserted in the neck, occasionally agitating the mixture until it becomes clear, then transfer the solution to a shallow dish and evaporate the alcohol on a water bath. The residue, when mixed with 100 mils of distilled water, produces a clear solution (paraffin oil). Add an excess of hydrochloric acid to this solution; a layer of oleic acid rises to the surface, which, when separated, washed with warm water and clarified by heating on a water bath, remains clear if cooled to 15° C. (59° F.) (various foreign oils). One volume of the oleic acid obtained in the last test, when mixed with 1 volume of alcohol, yields a clear solution, which at 15° C. (59° F.) does not deposit any fatty acids, nor become turbid upon the further addition of 1 volume of alcohol (distinction from olive, arachis, cottonseed, sesame, or other fixed oils). Saponification value: not less than 191 nor more than 200. Iodine value: not less than 93 nor more than 100." U. S.

From the statement of Braconnoit, it appears to contain 76 per cent. of olein and 24 per cent. of a mixture of palmitin and stearin.

According to H. Hager, the oils expressed from the large sweet and the smaller bitter almonds differ considerably, as shown by the elaidin test,—the former oil congealing rapidly, and almost completely, the latter about twelve hours later, and the smaller the bitter almond has been the more imperfectly the oil congeals. Only about one-third of the bulk congeals when the oil is from the small Oporto almonds.

Oil of almond may be used for the same purposes as is olive oil, and, when suspended in water by means of mucilage or the yolk of egg and
loaf sugar, forms a pleasant emulsion, useful in pulmonary affections attended with cough.

Dose, one fluidrachm to one fluidounce (3.75-30 mils).

**OLEUM ANETHI. Br.**

**OIL OF DILL**

"Oil of Dill is the oil distilled from Dill Fruit." Br.

Huile volatile d'Aneth, Essence d'Aneth, Fr.; Dill, Dillol, G.

Oil of dill is of a pale yellow color, with the odor of the fruit, and a hot, sweetish, acrid taste. Its sp. gr. varies between 0.895 and 0.915. The fruit yields about 3.5 per cent. of it. The oil is a mixture of a paraffin hydrocarbon, and 40 to 60 per cent. of d-carvone, C_{10}H_{14}O, with d-limonene, C_{10}H_{16}. (See Oleum Cari.) Phellandrene is present in the English and Spanish oils, but not to any appreciable extent in the German oil. "Colorless or pale yellow, darkening on keeping. Odor that of Dill Fruit; taste at first sweet and aromatic, but subsequently pungent. Specific gravity 0.900 to 0.915; optical rotation +70° to +80°; refractive index at 25° C. (77° F.) 1.483 to 1.488. Soluble in 3 parts of alcohol (90 per cent.)." Br. R. Nietski obtained from dill, the fruit of Anethum graveolens, a volatile oil, which commenced to boil at 155° C. (311° F.), the boiling point rising gradually to 260° C. (500° F.). About 10 per cent. of the oil consists of a hydrocarbon, C_{10}H_{16}, having the boiling point from 155° to 160° C. (311°-320° F.), 60 per cent. boiling at from 170° to 175° C. (338°-347° F.), of the same composition, and 30 per cent. with the boiling point from 225° to 230° C. (437°-446° F.), composition C_{10}H_{14}O, and identical with carvol. The odor of the first portion of hydrocarbon is similar to that of turpentine; that of the second portion resembles oil of mace, but when mixed with a little carvol the characteristic dill odor is at once produced. (A. J. P., 1874.) The oil is sometimes used for the preparation of dill water.

Dose, from. one to three minims (0.065-0.2 mil).
OLEUM ANISI. U. S., Br.

OIL OF ANISE
Ol. Anisi [Anise Oil]

"A volatile oil distilled from the ripe fruit of Pimpinella Anisum Linne (Fam. Umbelliferae) or from the ripe fruit of Illicium verum Hooker filius (Fam. Magnoliaceae). The botanical source from which it is derived must be stated on the label. If solid material has separated, carefully warm the Oil until liquefied, and thoroughly mix it before dispensing. Preserve it in well-stoppered, amber-colored bottles, protected from light." U. S. "Oil of Anise is the oil distilled from Anise Fruit; or from the fruit of the star-anise, Illicium verum, Hook. f." Br.

Huile volatile d'Anis vert (Badaine), Fr. Cod.; Essence d'Anis, Fr.; Oleum Anisi, P. G.; Anethol, Anisol, G.; Essenza di anise, It.; Esenda de anis, Sp.

The product of oil from anise is variously stated at from 1.56 to 3.12 per cent. The oil employed in this country is imported. It is colorless or yellowish, with the peculiar odor and taste of the seed. At 10° C. (50° F.) it crystallizes in flat tables, and it does not melt under 16.6° C. (62° F.). Its sp. gr. increases with age, and is variously given at from 0.9768 to 0.9903. It is soluble in all proportions in alcohol of 0.806; but alcohol of 0.840 dissolves at 25° C. (77° F.) only 42 per cent. Ether dissolves oil of anise in all proportions.

It consists of a small quantity of terpene, C$_{10}$H$_{16}$, but mainly of anethol, parapropenyl-anisol, C$_{6}$H$_{4}$C$_{3}$H$_{5}$OCH$_{3}$ (about 85 per cent.), which is present, however, in two isomeric modifications, one solid at ordinary temperatures and heavier than water (solid anethol), the other liquid and more volatile (estragal or methyl chavicol). Anethol, both in the liquid and in the solid form, is present, and is the chief constituent of the oils of anise, star ansie, and fennel.

Star anise oil contains besides anethol, pinene and phellandrene and some samples have been reported as containing safrol which is present to an appreciable extent in the so-called Japanese star anise oil which is from the leaves instead of the fruit. This latter oil contains eugenol as well as much less anethol than the oil from the fruit.

In consequence of its high price, it is frequently adulterated with
spermaceti, wax, or camphor. The first two may be detected by their insolubility in cold alcohol, the last by its odor. In one instance as much as 35 per cent. of spermaceti was found. Schimmel & Co. have found fennel stearoptene in commercial oil of anise. (Ph. Rev., 1897, 94.) Procter met with a parcel, of which not less than five-sixths was alcohol. (A. J. P., xxvii, 513.) Its comparative mildness adapts it to infantile cases. Most of the oil of anise of commerce is the oil of star aniseed (Oleum Badiani, or Oleum Illicii). Oil of anise has also been distilled from the sweet cicely, Osmorrhisa longistylis, of the United States and Canada. (Ph. Rund., July, 1887.) For description and analysis of Russian oil of anise, see P. J., 1896, 164, also 243. Anisic acid is said to be antiseptic, resembling salicylic acid in its action.

Anethol which was official in the U. S. P. VIII is now recognized by the N. F. The description and tests are as follows: "The methyl ether of para-propenyl phenol \([C_6H_4C_3H_5OCH_3 = 148.1]\). It is the main constituent in the oils of anise, star anise, and fennel, and is usually obtained from these by fractioning, chilling and crystallizing. Preserve it in well-stoppered, amber-colored bottles protected from light and air. Anethol is a colorless or faintly yellow, highly refractive liquid at a temperature of 23° C. (73.4° F.) or above, having a sweet taste and the aromatic odor of anise. At from 20° to 21° C. (68°-69.8° F.) it solidifies to a white, glistening, crystalline mass which remeltts from 22° to 23° C. (71.6°-73.4° F.). Anethol is almost insoluble in water, readily soluble in ether or chloroform, and forms a clear solution with two volumes of alcohol. Specific gravity: 0.984 to 0.986 at 25° C. (77° F.). Boiling point: 232° to 234° C. (449.6°-453.2° F.). Refractive index: 1.5 at 20° C. (68° F.). It is optically inactive or shows a deviation of not more than 0.08° in a 100 mm. tube at 25° C. (77° F.), due to slight traces of the oil from which the Anethol has been prepared (if prepared from oil of anise, this deviation will be laevorotatory, if from oil of fennel, dextrorotatory). Shake 10 mils of Anethol with 50 mils of a saturated aqueous solution of sodium bisulphite in a graduated cylinder and allow the mixture to stand for six hours. No appreciable diminution in the volume of Anethol will be observed nor does a crystalline deposit separate (aldehydes)." N. F.

Uses.—As a flavoring agent the oil of anise rivals any of the aromatic oils in the extent of its applicability. It is especially enjoyed by young children. Therapeutically it is useful to stimulate peristalsis in colic and, according to Kobert, also as an expectorant. It has also been
recommended as a means of destroying body vermin.

Dose, from three to five minims (0.2-0.3 mil).

**OLEUM ANTHEMIDIS. Br.**

**OIL OF CHAMOMILE**

"Oil of Chamomile is the oil distilled from Chamomile Flowers." Br.

Oleum Chamomillae Romanae; Essence de Camomille romaine, Fr.; Rondschen-Kamillenol, G.

This oil was introduced into the British Pharmacopoeia 1885 with the direction that it should be distilled in Britain. No such restriction is found in the Pharmacopoeia of 1898 or 1914. It is seldom prepared in this country. Baume obtained thirteen drachms of the oil from eighty-two pounds of the flowers; according to Brande, the average product of 100 pounds is two pounds twelve ounces. It has the peculiar odor of chamomile, with a pungent somewhat aromatic taste.

It is "blue when freshly distilled, but gradually becoming greenish or brownish-yellow under the influence of air and light. Odor that of Chamomile Flowers; taste aromatic, characteristic. Specific gravity 0.905 to 0.915. Optical rotation —1° to +3°; refractive index at 25° C. (77° F.) about 1.445. Soluble in less than 1 part of alcohol (90 per cent.)." Br.

The oil was thoroughly investigated in Fittig's laboratory during the years 1878-1879. It was found to consist of a mixture of angelic, butyric, methacrylic, and tiglinic esters of isobutyl, iso-amyl, hexyl, and probably a higher alcohol. Angelic acid and tiglinic acid are isomeric, and have the formula $C_5H_8O_2$. The relative proportions of these two acids varied in different oils. An ester of a lower homologue of angelic acid having the formula $C_4H_6O_2$ was also obtained. Naudin obtained a small amount of a solid paraffin, $C_{18}H_{36}$, melting at 63° C. to 64° C. (145.4°-147.2° F.), to which the name of "anthemen" was given. (Gildemeister and Hoffmann, Aetherische Öele, p. 881.) An isomer of camphor has also been reported. It has sometimes been employed in spasm of the stomach,
and as an adjunct to purgative medicines. Its chief use, however, appears to be as an ingredient of the extract of chamomile of the British Pharmacopoeia, to which it is added in order to supply the place of the oil driven off by the heat used in its preparation. This oil must not be confounded with that of Matricaria Chamomilla, employed on the continent of Europe under the name of oil of chamomile. (See Matricaria.)

Dose, one to three minims (0.06-0.2 mil).

**OLEUM ARACHIS. Br.**

**ARACHIS OIL**

Arachis Oil is the oil expressed from the seeds of Arachis hypogaea. Linn.

Earthnut Oil, Groundnut Oil, Peanut Oil.

The oil consists of the glycerides of four different fatty acids. The chief of these is oleic acid, \( \text{C}_{18}\text{H}_{34}\text{O}_2 \), with which are associated linoleic acid, \( \text{C}_{18}\text{H}_{32}\text{O}_2 \), hypogaeic acid, \( \text{C}_{16}\text{H}_{30}\text{O}_2 \), arachidic acid, \( \text{C}_{20}\text{H}_{40}\text{O}_2 \), and lignoceric acid, \( \text{C}_{24}\text{H}_{48}\text{O}_2 \). It should be obtained by expression without heat. It is usually of a pale yellowish or green color with a faint odor, and a more distinct taste of the nuts, although on rectification a nearly colorless and tasteless oil may be obtained. Upon exposure to the air the oil slowly thickens and becomes rancid. It is soluble in all proportions in ether, chloroform, and petroleum benzin, but insoluble in alcohol.

At 3.3° C. (38°F.) it thickens, solidifies at about -5° C. (23°F.), and at 326.6° C. (620°F.) is decomposed, giving out spontaneously inflammable vapors. Winter made experiments to ascertain how far it might be employed with advantage in pharmacy, and found that it answered well in the preparation of cerates and ointments, but would not serve as a substitute for olive oil in the preparation of lead plaster. (See Proc. A. Ph. A., 1897, 179.) Its use is permitted, by the British Pharmacopoeia, in India, and in the Eastern, African, and Australasian Divisions of the Empire, for making the official Liniments, Ointments, Plasters, and Soaps for which Olive Oil is directed to be used. It is a non-drying oil, and therefore will not answer for painting; but it is enormously used for adulteration (particularly of French olive oils) and for various purposes.
in the arts, as for lubricating machinery, and in the manufacture of woollen cloths; in lamps it burns with a bright light. It saponifies slowly, but yields an excellent firm, white, and odorless soap.

**OLEUM AURANTII. U. S.**

**OIL OF ORANGE**

*Ol. Aurant.* [Oleum Aurantii Corticis, U. S. VIII Orange Oil, Oil of Sweet Orange]*

"A volatile oil obtained by expression from the fresh peel of sweet orange, Citrus Aurantium sinensis Gallesio (Fam. Rutaceae), and its varieties. Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light. Oil of Orange having a terebinthininate odor is not to be dispensed." U. S.

Oleum Aurantiorum; Essential Oil of Orange Peel, Essence of Orange; Huile volatile d'Orange, Fr. Cod.; Apfelsinencharenol, Pomeranzenschalenol, G.; Essenza di arancio amara, Ensenza delta corteccia. It.

This oil is used only for flavoring purposes, and has been introduced principally because of its employment in elixirs and in Spiritus Aurantii Compositus.

Oil of orange is prepared in Calabria and Sicily in three ways: 1, by scraping off the exterior part of the rind and submitting it to expression; 2, by putting the scrapings into hot water, depressing the pulp beneath, and skimming off the oil as it rises; 3, by distillation. The best Sicily orange oil is procured by dexterous compression, within a cask, of the fresh rind by the hand, the oil being driven out in jets. It is sometimes absorbed by a sponge. (A. J. P., 1868.) It is largely made at Messina, and in the south of France. It is also extracted by the ecuelle process, and partly from the Bigarade and partly from the sweet or Portugal orange, the scarcely ripe fruit being in either case employed. The oil made from the former is much more valuable than that obtained from the latter, and the two are distinguished in price-currents as Essence de Bigarade and Essence de Portugal.

Under the name of Oleum Aurantii Amari (Oil of Bitter Orange), the National Formulary IV has introduced the oil of bitter orange, which it defines as "a volatile oil obtained by expression from the fresh peel of the bitter orange, Citrus Aurantium amara Linne (Fam. Rutaceae)."
Preserve it in small, well-stoppered, amber-colored bottles, in a cool place, protected from light. "Oil of Bitter Orange having a terebinthinate odor is not to be dispensed." N. F. IV.

The description is as follows: "Oil of Bitter Orange is a pale yellow liquid, having the characteristic, aromatic odor of the Seville orange, and an aromatic somewhat bitter taste. Soluble in 4 volumes of alcohol, the solution being neutral to litmus paper." N. F. IV.

This oil is supposed to have a more delicate odor than the oil from the sweet orange.

Properties.—Oil of orange peel consists, as has been shown by Wallach, of d-limonene to the extent of at least 90 per cent.; of the remainder, about 5 per cent. are the odorous constituents, among which are citral, traces of citronellal, and the methyl ester of anthranilic acid. The inner thick part of the rind contains also a bitter principle, called hesperidin, discovered by Lebreton in 1828, but more fully studied by Hoffmann (Ber. d. Chem. Ges., 1876, pp. 26, 685). It is best prepared from the unripe bitter orange. Its formula is C_{22}H_{25}O_{12}, and it is a glucoside, as is shown by the reaction with diluted sulphuric acid, whereby it is decomposed into hesperetin, C_{16}H_{14}O_{6}, and glucose, C_{6}H_{12}O_{6}.

A waxy non-volatile substance is present in oil of orange, which interferes with the transparency of solution made with 90 per cent. alcohol. This oil is one of the most difficult to preserve. A method for its preservation, which we have used for years, is to shake the oil briskly with one-eighth of its volume of distilled water, and allow it to separate, then remove the essential oil, filter rapidly if necessary, and mix the filtered oil with 95 per cent. alcohol in the proportion of one volume of the oil to seven volumes of alcohol.

It may be preserved indefinitely by adding 10 per cent. of its volume of olive oil.

The oil of orange is used chiefly as a flavoring agent but Zickgraf (M. M. W., 1910, lvii, p. 1070) speaks very highly of its effect in chronic bronchitis for the same class of cases in which oil of turpentine is used. It has the advantages over the latter of being much more pleasant to
take and non-irritant to the kidneys.

Dose, three to five minims (0.2-0.3 mil).

**OLEUM CADINUM. U. S., Br.**

**OIL OF CADE**

*Cadinum*

[Cade Oil Oil of Juniper Tar, Oleum Juniperi Empyreumaticum]

"An empyreumatic oil obtained by the dry distillation of the wood of *Juniperus Oxycedrus* Linne (Fam. Pinaceae); U. S. "Oil of Cade is an empyreumatic oily liquid obtained by the destructive distillation of the woody portions of *Juniperus Oxycedrus* Linn." Br.

*Juniper Tar Oil; Huile de Cade, Fr.; Kadeol, Kadil, G.*

The *Juniperus Oxycedrus*, Linne, prickly cedar, or large brown-fruited juniper, is a common tree in the "waste places and stony hill-sides of the Mediterranean districts of Northern Africa, Spain, Portugal, and France, reaching up in its distribution as high as 3000 feet in the Apennines. It commonly attains a height of from ten to twelve feet, sometimes much more, with long spreading branches and slender drooping branchlets, covered with light-green scattered and spreading leaves of medium size, lanceolate or awl-shaped, sharply pointed, having two furrows on their upper edge. The fruits are numerous, large (half an inch in diameter), globular, shining, reddish or chestnut-brown, and marked on the apex with two white scars indicating the separation of the carpels.

From the heart-wood of this tree the oil of cade is prepared by a process of distillation in ovens per descensum, similar to that practised in the making of ordinary tar. It is a brownish or dark brown liquid, much more mobile and less thick than tar, having a tar-like but distinct odor, and a smoky, acrid, bitterish, disagreeable taste. In mass it is dark and
opaque, but in very thin layers clear; the oil contains phenols and a sesquiterpene termed cadinene, C_{14}H_{24}, the latter boiling at from 274° to 275° C. (525.2°-527° F.), and having a sp. gr. of 0.918 at 20° C. (68° F.).

"Oil of Cade is a dark brown, clear, thick liquid, having a tarry, empyreumatic odor and a warm, faintly aromatic, and bitter taste. It is almost insoluble in water, but imparts to it an acid reaction. It is only partially soluble in alcohol or petroleum benzin, completely soluble in 3 volumes of ether, soluble in amyi alcohol, chloroform, glacial acetic acid, or oil of turpentine. Specific gravity: 0.980 to 1.055 at 25° C. (77° F.). Shake 1 part of Oil of Cade with 20 parts of warm distilled water and filter; separate portions of this filtrate give a red coloration with a few drops of ferric chloride solution (1 in 1000) and reduce silver ammonium nitrate T.S. in the cold and alkaline cupric tartrate T.S. on heating. Agitate 1 mil of Oil of Cade with 15 mils of purified petroleum benzin, filter the benzin solution, add an equal volume of copper acetate solution (1 in 100), shake the mixture and then allow it to separate. On adding an equal volume of ether to the separated benzin solution, it produces no intensely green coloration and does not become colored more than light yellow to brown (rosin and rosin oil)." U. S.

"A dark reddish-brown or nearly black, oily liquid. Empyreumatic odor; taste aromatic, bitter and acrid. Specific gravity about 0.990. Soluble in ether, and in chloroform; partially soluble in cold, almost wholly soluble in hot alcohol (90 per cent.); very slightly soluble in water, the filtered aqueous solution being almost colorless and acid to litmus. Yields no reaction for pine tar when tested as follows: Shake 1 millilitre of the Oil vigorously with 15 milli-litres of petroleum spirit, and filter; to 10 millilitres of the filtrate add 10 millilitres of solution of copper acetate, shake vigorously, and set aside until separation into two layers is complete; 5 millilitres of the upper layer, when mixed with 10 millilitres of ether, become pale brownish-yellow, but not green (absence of pine tar)." Br.

Yaucher recommends acetone for disguising the odor of oil of cade, and proposes an oil of cade collodion in which acetone is used to dissolve the pyroxylin instead of the usual solvents. (C. D., 1897, 16.)

Uses.—Oil of cade has been used locally, by the peasantry, in the treatment of the cutaneous diseases of domestic animals almost from time immemorial. More recently it has been largely employed in the
treatment of chronic eczema, psoriasis, and other skin diseases of man, and has also been found to be an efficient parasiticide in psora and favus. It is applied, sometimes of full strength, sometimes diluted with a bland oil, well rubbed into the affected parts with the fingers, or with a cloth, and is also made into ointments, and especially into soaps. A glycerite is also prepared. It is very rarely, if ever, used internally, but probably resembles oil of tar in its physiological action.

Dose, one to three minims (0.06-0.2 mil).

**OLEUM CAJUPUTI. U. S., Br.**

**OIL OF CAJUPUT**

*Ol. Cajup. [Cajuput Oil Oil of Cajeput]*

"A volatile oil distilled from the fresh leaves and twigs of several varieties of Melaleuca Leucadendron Linne, especially the var. Cajeputi Roxburgh and the var. minor Smith (Fam. Myrtaceae). Preserve it in well-stoppered, amber-colored bottles, in a cool place." U. S. "Oil of Cajuput is the oil distilled from the leaves of Melaleuca Leucadendron, Linn., and other species of Melaleuca." Br.

Oleum Cajeputi; Essence de Cajeput, Huile volatile de Cajeput, Fr.; Cajeputol, G.; Essenza di Cajeput, It.; Esencia de Cayeput, Sp.; Kayuputieh, Mal.

It was long supposed that the oil of cajuput was derived only from Melaleuca Leucadendron, but it is now well established that it is derived chiefly from one or more varieties of this species. They are trees indigenous to upper India, the Islands of the Indian Ocean, Northern Australia, Queensland and New South Wales. (See The Volatile Oils, Gildemeister and Hoffmann.) It is possible, however, that the oil may also be obtained from different species of Melaleuca, as Stickel of Jena, succeeded in procuring from the leaves of M. hypericifolia, cultivated in the botanical garden of that place, a specimen of oil not distinguishable from the cajuput oil of commerce, except by a pale-green color. (Ann. Pharm., xix, 224.) M. viridifolia and M. latifolia, large trees growing
abundantly in the Island of New Caledonia, yield a volatile oil very analogous to the oil of cajuput.

*Melaleuca Leucadendron* Linne (*M. Cajuputi Bumphius*) grows with an erect but crooked stem, and scattered branches, the slender twigs of which droop like those of the weeping willow. The bark is of a whitish ash color, very thick, soft, spongy, and lamellated, throwing off its exterior layer from time to time in flakes. The leaves have short footstalks, are alternate, lanceolate, when young sericeous, when full-grown smooth, deep green, three- and five-nerved, slightly falcate, entire, from three to five inches long, from one-half to three-quarters of an inch broad, and when bruised exhale a strong aromatic odor. The flowers are small, white, inodorous, sessile, and disposed in terminal and axillary downy spikes, with solitary, lanceolate, three-flowered bracts. The filaments are three or four times longer than the petals, and both are inserted in the rim of the calyx. The oil is obtained from the leaves by distillation. It is prepared chiefly in Amboyna and Bouro, and is exported from the East Indies in glass bottles. The small proportion yielded by the leaves and the extensive use made of it in India render it somewhat costly.

Properties.—Cajuput oil is very fluid, transparent, of a fine green color, a lively and penetrating odor analogous to that of camphor and cardamom, and a warm, pungent taste. Upon rectification the green color disappears. It is very volatile and inflammable, burning without any residue. The sp. gr. varies from 0.914 to 0.9274. Its chief constituent has the formula C$_{10}$H$_{18}$O, and by repeated distillation over phosphoric oxide the hydrocarbon, C$_{10}$H$_{16}$, called cajuputene, can be obtained. The oil is, therefore, said to contain cajuputene hydrate, or cajuputol. The identity of cajuputol with cineol and eucalyptol from *Eucalyptus Globulus* in both chemical and physical properties was established by Wallach. in 1884 and by C. Jahns (A. J. P., 1885, 237.) It boils at 175° C. (347° F.). A second constituent of the formula C$_{10}$H$_{18}$O is the solid terpineol, which is present both in the free state and as acetic ester. A small amount of 1-pinene and traces of aldehydes have been found, including valeraldehyde and benzaldehyde. (Schimmel & Co's Report, April, 1897.) Oil of cajuput is "a colorless or yellowish liquid having a peculiar, agreeable, distinctly camphoraceous odor, and an aromatic, slightly bitter taste. It is soluble in 1 volume of 80 per cent. alcohol. Specific gravity: 0.912 to 0.925 at 25° C. (77° F.). Its optical rotation does
not exceed -4° in a 100 mm. tube at 25° C. (77° F.)." U. S.

"Green or bluish-green. Agreeable, camphoraceous odor; taste aromatic, bitter and camphoraceous. Specific gravity 0.919 to 0.930; optical rotation not more than -4°; refractive index at 25° C. (77° F.) 1.460 to 1.467. When 10 millilitres of the Oil are mixed with 4 to 5 millilitres of syrupy phosphoric acid in a vessel surrounded by a freezing mixture, and then pressed strongly in a piece of fine calico between folds of blotting-paper, the pressed cake, decomposed by warm water in a graduated vessel, yields an oily layer, which, on cooling to 15.5° C. (60° F.), measures not less than 4.5 millilitres (presence of not less than 45 per cent. of cineol)." Br.

The U. S. requires the oil to be colorless or yellow, but according to the Br. it has a greenish tint. When it is distilled, a light, colorless liquid first comes over, and afterwards a green and denser one. The green color has been ascribed to a salt of copper derived from the vessels in which the distillation is performed, and Guibourt obtained two grains and a half of copper oxide from a pound of the commercial oil. But neither Brande nor Goertner could detect copper in specimens examined by them, and Lesson, who witnessed the process for preparing the oil at Bouro, attributes its color to chlorophyll or some analogous principle, and states that it is rendered colorless by rectification. Guibourt, moreover, obtained a green oil by distilling the leaves of a Melaleuca cultivated at Paris. A fair inference is that the oil of cajuput is naturally green, but that as found in commerce it sometimes contains copper, either accidentally present or added with a view of imitating or maintaining the fine color of the oil. The proportion of copper, however, is not so great as to forbid the internal use of the oil, and the metal may be separated by distillation with water, or by agitation with a solution of potassium ferrocyanide. This statement as to the frequent occurrence of copper in the cajuput oil of commerce, though at the same time its presence is not desirable, has been confirmed by experiments by Edward Histed, who found copper in all of six specimens of the commercial oil, obtained from different sources. When redistilled, the oil became perfectly colorless, but after a few days' exposure to copper filings reassumed its green color. (P. J., 1872, p. 804.)

Oil of cajuput is said to be often adulterated with oils derived from other than the official species of Melaleuca, Oil of rosemary, and oil of turpentine, impregnated with camphor and colored with the resin of
milfoil, are also said to be employed as adulterants. The best test, according to Zeiler, is iodine, which, after a moderately energetic reaction, with little increase of temperature and but a slight development of orange vapors, occasions immediate inspissation into a loose coagulum, which soon becomes dry, greenish-brown, brittle mass.

**Uses.**—This oil is highly stimulant, producing when swallowed, a sense of heat, with an increased fulness and frequency of pulse, and exciting in some instances profuse perspiration. It is much esteemed by the Malays and other people of the East, who consider it a panacea. Formerly the oil of cajuput was used internally in chronic rheumatism, low fevers, and various other complaints, but is rarely employed at present for its alterative effects. It is useful internally as a stimulating expectorant in chronic laryngitis and bronchitis, as a urinary antiseptic in cystitis, and as an anthelmintic especially against the round worm. Its most frequent uses, however, are externally in the treatment of various skin diseases. For this latter group of affections it is used for its anti-parasitic effect in such diseases as scabies, tinea versicolor, etc., and for its stimulating action in acnes rosacea, psoriasis, and other chronic conditions. It is also used externally as a counter-irritant in chronic rheumatism and other painful conditions. Like many other essential oils it relieves toothache if introduced into the hollow carious tooth.

Dose, from three to ten minims (0.2-0.6 mil).

**OLEUM CARI. U. S. (Br.)**

**OIL OF CARAWAY**

Ol. Cari [Caraway Oil]

"A volatile oil distilled from the fruit of Carum Carvi Linne (Fam. Umbelliferae), and yielding not less than 50 per cent., by volume, of carvone \([C_{10}H_{14}O = 150.11]\). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Caraway is the oil distilled from Caraway Fruit, and rectified." Br.

**Oleum Carul**, Br.; Huile volatile de Carvi, Fr. Cod.; Essence de Carvi, Fr.; Oleum
Carvi, P. G.; Kummelol, Carvon, G.

This oil is prepared to a considerable extent by our distillers. The fresh fruit is cultivated in Holland yields nearly 6 per cent. of oil, while the German fruit yields about 4 per cent. The oil of caraway is somewhat viscid, of a pale yellow color, becoming brownish by age, with the odor of the fruit, and an aromatic acrid taste. Its sp. gr. is differently given at 0.946 (Baume), 0.931 (Brande), 0.916 (Buignet), and 0.900 to 0.910 at 25° C. (77° F.). (U. S. P.) It is dextrogyrate in its relation to polarized light. (Buignet, J. P. C., Oct., 1861, p. 261.) It consists of two liquid oils, of different boiling points, and separable by distillation:—one a hydrocarbon called carvene, $C_{10}H_{16}$, of the specific gravity 0.849 and boiling point 176° C. (349° F.), now recognized as identical with d-limonene, the other, the valuable constituent, d-carvone, $C_{10}H_{14}O$, of the sp. gr. 0.9638 and boiling point 224° C. (435° F.). This latter constituent is often extracted from the oil and prepared in a pure state by taking advantage of the formation of a crystalline compound of carvone and hydrogen sulphide, which can then be decomposed by treatment with alcoholic potassium hydroxide.

Sulphides are found in the aqueous distillate which comes over with the oil, as are also several constituents which are ordinarily considered only to accompany destructive distillation products as methyl alcohol, acetaldehyde, etc.

Oil of caraway is used to impart flavor to medicines, and to correct their nauseating and griping effects.

Gmeiner (B. Thier. W., 1909, p. 695) recommends the use of oil of caraway in the treatment of scabies. He employs a solution in castor oil containing five parts of alcohol and oil of caraway in seventy-five parts of castor oil.

Dose, from one to five minims (0.06-0.3 mil).

**Off. Prep.**—Pilula Aloes, Br.; Spiritus Juniperi Compositus, U. S.; Elixir Cardamomi Compositum (from Compound Spirit), N. F.; Mistura Carminativa, N. F.; Spiritus Cardamomi Compositus, N. F.
OLEUM CARYOPHYLLI. U. S., Br.

OIL OF CLOVE
Ol.Caryoph. [Clove Oil Oil of Cloves]

"A volatile oil distilled from the flower-buds of Eugenia Aromatica (Linne) O. Kuntze [Jambosa Caryophylus. (Sprengel) Niedenzu] (Fam. Myrtaceae), and yielding not less than 82 per cent., by volume, of eugenol \[C_{10}H_{12}O_2 = 164.10\]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Cloves is the oil distilled from Cloves." Br.

This oil is obtained by distilling cloves with water, to which it is customary to add common salt, in order to raise the temperature of ebulli-tion and the water should be repeatedly distilled from the same cloves, in order completely to exhaust them, Scharling has found advantage from the application of superheated steam to the distillation of this oil. (P. J., xi, 469.) It is essential also to use the same water over and over again, in order to avoid loss by the solution of the oil in the water. The product of good cloves is said to be about one-fifth or one-sixth of their weight. The oil was formerly brought from Holland or the East Indies, but since the introduction of the Cayenne cloves into our markets the reduced price and superior freshness of the drug have rendered the distillation of oil of clove profitable in this country, and the best now sold is of domestic extraction. The exportation of clove from Zanzibar in 1909 was over 20,000,000 pounds. We have been informed that from seven to nine pounds of clove yield to our distillers about one pound of the oil.

Properties.—Oil of cloves, when recently distilled, is very fluid, clear, and colorless (but becomes yellowish by exposure, and ultimately reddish-brown). It has the odor of cloves, a hot, acrid, aromatic taste, and a slightly acid reaction. Its sp. gr. is variously stated at from 1.034 to 1.061, the latter being given by Bonastre as the sp. gr. of the rectified oil.

"Oil of Clove is a colorless or pale yellow liquid, becoming darker and thicker by age and exposure to the air, having the characteristic odor..."
and taste of clove. It is soluble in 2 volumes of 70 per cent. alcohol. Specific gravity: 1.038 to 1.060 at 25° C. (77° F.). Its optical rotation does not exceed -1° 10' in a 100 mm. tube at 25° C. (77° F.)

Oil of clove is one of the least volatile of the essential oils and requires for congelation a temperature from -17.8° to -20° C. (0° to -4° F.). It is completely soluble in alcohol, ether, and strong acetic acid. Nitric acid changes its color to a deep red, and converts it by the aid of heat into oxalic acid. The same change to red is produced by nitric acid on morphine, but in this case the red is followed by yellow, which does not happen with the oil of clove. Besides, if to a solution of morphine with nitric acid a solution of chlorinated lime be added, and the mixture be exposed for some hours to the light, the solution of morphine will retain a straw color, while if oil of clove be treated in the same manner the color disappears. (Has-elden, B. F. M. H., July, 1867, 265.) It is frequent adulterated with fixed oils, and sometimes with oil of pimenta and with copaiba. When pure, it sinks in distilled water. According to E. Scherer, these adulterations may sometimes be detected by attention to the specific gravity and the boiling point, pure oil of clove varying in specific gravity from 1.03 to 1.06, and boiling at from 240° C. (464° F.) to 255° C. (491° F.). According to Zeiler, its character of congealing entirely into a crystalline mass with the alcoholic solution of potassium hydroxide, losing at the same time its peculiar odor, affords a sufficient criterion of its purity. This, however, while included among the official tests, is not sufficient, the percentage of eugenol as determined by the official assay being now a requirement.

Oil of clove contains small amounts of vanillin, methyl alcohol and furfurol, but is mainly composed of an unsaturated phenol termed eugenol which is now an official product (see Eugenol) and its acetic derivative and a sesquiterpene caryophyllene. Eugenol acetyl salicylate has also been reported. The U. S. Pharm. IX introduced an assay process for the eugenol content.

Eugenol, \(C_{10}H_{12}O_2\) (see p. 432), has been shown to be the methyl ether

\[
\begin{align*}
   C_6H_3 & \quad \begin{cases}
   C_3H_5 \quad \text{One of its most important} \\
   OCH_3 \\
   OH
   \end{cases} \\
   \text{of allyl-dioxyben zene,}
\end{align*}
\]

reactions is its conversion into vanillin. For this purpose it is boiled with
acetic anhydride, whereby ace\textit{t}eugenol is formed, which, oxidized in weak acid solution by potassium permanganate, yields ace\textit{t}vanillic acid, and this with weak potassium hydroxide solution is changed into vanillin, which is then extracted by acidifying and shaking up with ether. (See also Ph. Era, 1887, 444.) For the estimation of eugenol in the form of its crystalline benzoyl compound, see A. J. P., 1892, 26 and 508; also Schim. Rep., April, 1892, 28. The characteristic aromatic odor of oil of clove is due to methyl-amylketone, \( \text{CH}_3\text{CO.C}_3\text{H}_{11} \), which has been isolated by the chemists of Schimmel & Co., and found to be present only in minute, quantity. (Ph. Bev., 1897, 115.)

**Uses.**—By virtue of its local irritant effect oil of clove stimulates peristalsis and is frequently a useful remedy in the treatment of flatulent colic. It is also an active local anesthetic and is a favorite remedy for toothache; for this purpose a small pledget of cotton is saturated with oil and inserted into the carious cavity. It is a powerful germicide, far exceeding phenol in activity, but is not frequently used for this purpose. Eugenol has been used internally in doses of forty-five grains (3 Gm.) per diem as an antiseptic antipyretic. Little, however, is known of its physiological action. According to Leubuscher (W. M. Bl., 1889) it is a feeble local anesthetic. Landis (T. G., 1909, xxxiii, 386) has used oil of clove as a stimulant expectorant in tuberculosis and bronchiectasis with good results.

Dose, from two to six minims (0.12-0.4 mil).

Off. Prep.—Elixir Cardamomi Compositum (from Compound Spirit), N. F.; Elixir Glycyrrhizae Aromaticum, N. F.; Nebula Aromatica, N. F.; Spiritus Cardamomi Compositus, N. F.

**OLEUM CASSIÆ. U. S. (Br.)**

**OIL OF CINNAMON**

\( \text{Ol. Cass. [Oleum Cinnamonum U. S. VIII Cassia Oil]} \)

"A volatile oil distilled from Cinnamomum Cassia (Nees) Blume (Fam. Lauraceae), rectified by steam distillation and yielding not less than 80 per cent., by volume, of cinnamic aldehyde \([\text{C}_9\text{H}_8\text{O} = 132.06]\). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Cinnamon is the oil distilled from Cinnamon Bark." Br.

There are two oils of cinnamon in commerce, one procured from the Ceylon cinnamon, the other from the Chinese cinnamon, and often distinguished by the name of oil of cassia. There is no essential difference in the two oils, and that of the Chinese cinnamon, as much the cheaper and more abundant of the two, will probably continue to be generally employed, notwithstanding that the Ceylon product has the finer flavor. The U. S. P. IX and the German Pharmacopoeia recognize as oil of cinnamon only that obtained from cassia. The British Pharmacopoeia and French Codex make Oil of Ceylon Cinnamon official.

Preparation.—Oil of cinnamon of Ceylon is distilled from inferior kinds of cinnamon, of insufficient value to pay the export duty. The following account of the method of extraction is given by Marshall. The bark, having been coarsely powdered, is macerated for two days in sea water, and then submitted to distillation. A light and a heavy oil come over with the water, the former of which separates in a few hours and floats upon the surface, the latter falls to the bottom of the receiver, and continues to be deposited for ten or twelve days. In future distillations, the saturated cinnamon water is employed with sea water to macerate the cinnamon. Eighty pounds of the freshly prepared bark yield about 2.5 ounces of the lighter oil, and 5.5 of the heavier. From the same quantity kept for several years in store, about half an ounce less of each oil is obtained. The two kinds are probably united in the oil of commerce. The oil is also distilled in Ceylon from the leaves, but the product is said to be too small to yield a fair profit. (C. D., 1888.) The exportation of cinnamon chips from Ceylon has assumed large proportions, amounting in 1904 to 2,135,220 pounds. (Schim. Rep., May,

Properties.—Oil of Ceylon cinnamon is of a light-yellow color, becoming deeper by age, and ultimately red. Pereira stated that the London druggists redistilled the red oil, and thus obtained two pale-yellow oils, one lighter and the other heavier than water, with a loss of about 10 per cent. in the process. The oil has the flavor of cinnamon, and when undiluted is excessively hot and pungent. It is said sometimes to have a peppery taste, ascribable to an admixture of the leaves with
the bark in the preparation of the oil. Oil of Ceylon cinnamon has "a slightly acid reaction. Sp. gr. about 1.040. It is readily soluble in alcohol. When cooled to -10° C. (14° F.), it remains clear, but at a lower temperature a solid portion separates from it." U. S. 1880. To ascertain whether, in the distillation of oil of cinnamon from the bark, some of the oil is oxidized to cinnamic aldehyde in part and thus the yield lowered, H. A. Phillips (Tr. Br. Ph. Conf., 1914, 371) made a thorough investigation of the subject and concludes that under the ordinary conditions of steam distillation, cinnamic aldehyde is not appreciably oxidized. The British Pharmacopoeia 1914 recognizes oil of Ceylon cinnamon only, and gives the following description and tests: "Yellow when freshly distilled, gradually becoming reddish. Odor and taste those of Cinnamon Bark. Specific gravity 1.000 to 1.030; optical rotation -0.5° to -1°; refractive index at 25° C. (77° F.) 1.565 to 1.580. Soluble in from 3 to 4 parts of alcohol (70 per cent.). 1 drop dissolved in 5 millilitres of alcohol (90 per cent.) assumes a pale green, but not a blue or brown coloration, on the addition of 1 drop of I. Sol. of ferric chloride (absence of cinnamon leaf oil and cassia oil). Contains from 55 to 65 per cent. of cinnamic aldehyde as determined by the following test: To 10 millilitres of the Oil add 70 millilitres of an aqueous solution (1 in 5) of sodium sulphite and sufficient solution of phenolphthalein to give a well marked pink coloration. Heat the mixture on a water-bath, shake well, and neutralise with acetic acid diluted with twice its volume of water; repeat the heating and neutralisation until no further pink coloration is developed, the time occupied being from thirty to forty-five minutes. The oily layer which separates on standing, cooled to 35.5° C. (60° F.), measures not more than 4.5 or less than 3.5 millilitres (presence of 55 to 65 per cent. of cinnamic aldehyde)." Br.

Chinese oil of cinnamon is imported from Canton and Singapore. It is pale yellow, becoming red with age. Its flavor is similar to that of the Ceylon oil, though inferior, and it commands a much lower price. It is officially described as follows: "Oil of Cinnamon (Cassia) is a yellowish or brownish liquid, becoming darker and thicker by age and exposure to the air and having the characteristic odor and taste of cinnamon. Specific gravity: 1.045 to 1.063 at 25° C. (77° F.). The optical rotation varies from +1° to -1° in a 100 mm. tube at 25° C. (77° F.) It does not respond to the Test for heavy metals in volatile oils. Shake 2 mils of the Oil in a test tube with from 5 to 10 mils of purified petroleum benzin, and decant the latter; this liquid is colorless and does not assume a green color upon shaking it with an equal volume of (1 in 1000) copper
The cinnamon leaf oil, as formerly imported into Great Britain, was of two kinds, one containing a considerable quantity of a fatty fixed oil, perhaps cinnamon-suet from the fruit, the other a pure volatile oil. The oil was said to be obtained by distilling the leaves after maceration in sea water. It resembled the oil of clove and pimento in sensible properties, having a brownish color, a penetrating, fragrant odor, and a very pungent taste. According to Stenhouse, it was of the sp. gr. 1.053, had an acid reaction, and consisted of eugenol, a neutral substance with the formula $C_{10}H_{16}O$, and a minute proportion of benzoic acid. (P. J., xiv, 319.) Schimmel & Co. found it to have a sp. gr. 1.056 to 1.060, and contained 87 per cent. of eugenol, and about 0.1 per cent. of cinnamic aldehyde. When exposed to the air, the oil absorbs oxygen, and is slowly converted into cinnamic acid, two distinct resins, and water. Of the two resins, one is soluble both in hot and in cold alcohol; the other readily in the former, but sparingly in the latter. Cinnamic acid, $C_9H_8O_2$, is colorless, crystalline, sourish, volatilizable, slightly soluble in water, readily dissolved by alcohol, and convertible by nitric acid with heat into benzoic acid. It is sometimes seen in crystals in oil of cinnamon which has been long kept. Like benzoic acid, it is said when swallowed to cause the elimination of hippuric acid by the urine. (J. P. C., 3e ser., iii, 64.) It may be obtained by distilling the balsam of Tolu. Oil of cinnamon is almost wholly converted by nitric acid, slowly added, into a crystalline mass, producing a compound of the oil and the acid. These several facts are explained when it is found that oil of cinnamon contains from 75 to 90 per cent. of cinnamic aldehyde, $C_9H_8O$, which by moderate oxidation yields the corresponding cinnamic acid, $C_9H_8O_2$, but by more energetic oxidation yields benzoic acid, $C_7H_6O_2$. The oil has been produced artificially by Strecker from styrene, a derivative from styrax (see Styrax), and more recently from benzaldehyde and acetaldehyde, a mixture of which is saturated with hydrochloric acid gas, when a condensation takes place, as follows:

$$C_6H_5COH + CH_3COH = C_6H_5.CH:CH.CO + H_2O$$
Ordinary sodium hydroxide will also bring about the reaction between the two aldehydes, and is to be preferred to hydrochloric acid for this purpose.

Oil of cinnamon is said to be frequently adulterated with oil of cloves, which, according to Ulex, cannot be detected by the odor or taste. Thus sophisticated, it is stated, on the same authority, to evolve a very acrid vapor when a drop is heated on a watch glass, to swell up and evolve red vapors if treated with fuming nitric acid, to remain liquid with concentrated potassium hydroxide, and to assume an indigo-blue color when ferrous chloride is added to its alcoholic solution, none of which reactions occur with pure oil.

**Uses.**—Although a very powerful germicide the oil of cinnamon, because of its irritant properties, is rarely used in medicine as an antibacterial. It has the cordial and carminative properties of cinnamon, without its astringency, and is much employed as an adjuvant to other medicines, the taste of which it corrects or conceals, while it conciliates the stomach. As a powerful local stimulant, it is sometimes prescribed in gastrodynia, flatulent colic, and gastric debility. Mitscherlich found six drachms to kill a moderate-sized dog in five hours, and two drachms one in forty hours. Inflammation and corrosion of the gastro-intestinal mucous membrane were observed after death.

Dose. one to three minims (0.06-0.2 mil).

**OLEUM CHAULMOOGRÆ. Br.**

CHAULMOOGRA OIL

"Chaulanoogra Oil is the fatty oil expressed from the seeds of Taraktogenos Kurzii, King." Br.
Oleum Gynocardia, Gynocardia oil, Chaulmugra oil.

Under the name of chaulmoogra oil there has long been used in Southeastern portions of Asia a semi-solid fat. This was at one time believed to be derived from the Gynocardia odorata and was therefore been erroneously called gynocardia oil, but the investigations of Power (A. J. P., 1915, p. 493) have shown that the oil from the gynocardia seed is very different both in chemical composition and physical properties. The true chaulmoogra oil is derived from the Taraktogenos Kurzii King (Fam. Bixaceae). It is possible that some of the commercial oil may also be derived from the species of the allied genus Hydnocarpus. The chaulmoogra seeds are from one to one and a quarter inches long, more or less angular or flattened, and yield upon expression, from 25 to 30 per cent., to ether, about 50 per cent. of oil. The commercial oil is obtained by expression, or sometimes by boiling the crushed seeds with water. It is a brownish-yellow oil or soft fat. Characteristic odor; taste somewhat acrid. Melting point about 22° to 30° C. (71.6°-86° F.). Specific gravity at 45° C. (113° F.) about 0.940; saponification value 198 to 213; iodine value 96 to 104; acid value 21 to 27. Soluble in ether, in chloroform, and in carbon disulphide; partially soluble in cold alcohol (90 per cent.); almost entirely soluble in hot alcohol (90 per cent.).

The genuine chaulmoogra oil is dextrorotatory, having a specific rotation of about +52°. It consists of the glycerides of cyclic organic acids of which the most important is chaulmoogric acid, C_{18}H_{32}O_{2}, melting at 68° C. (154.4° F.), while a homologue, hydnocarpic acid, C_{18}H_{28}O_{2}, melts at 60° C. (140° F.). Palmitic acid and a phytosterol are also present.

The so-called chaulmoogra oil, from gynocardia, is optically inactive and contains none of the acids peculiar to the genuine chaulmoogra oil. It consists of glycerides of linolic, palmitic, linolenic, isolinolenic and oleic acids and a phytosterol, as well as a glucoside, gynocardin, C_{13}H_{19}O_{9}N, which resembles amygdalin and which is associated in the seeds with an. enzyme, gynocardase.

Uses.—Chaulmoogra oil was originally employed in its native countries both internally and externally in the treatment of scrofula, skin diseases, and rheumatism. In England it is very widely used as a counter-irritant application in bruises, sprains, and similar local inflammations both of man and beast as well as in open sores and
wounds. Its most important use, however, is in the treatment of leprosy. There seems to be little doubt that it is the most useful remedy known for this intractable infection, indeed many authorities have claimed that it will often produce complete and permanent cures. For review of the literature see Engel (Monatsh. f. prakt. Dermat., 1909, xlix, p. 290.) It should be used freely both internally and externally. Donato (Leprosy in the Philippines and Its Treatment, Manila, 1915) believes that its action is due to the stimulation of leucocytosis. He recommends the following solution for intramuscular injection: Camphorated oil (10 per cent. camphor), chaulmoogra oil (sterilized), of each, 60 mils; resorcinol, 4 Gm.; ether, 2.5 Gm. Of this solution 1 mil (15 minims) is injected intramuscularly every alternate day, gradually increasing the dose up to 8 or 10 mils or until reaction becomes severe.

Unna has proposed, for oral administration, the use of a soap made from the oil as affecting the stomach and intestines less unpleasantly than the oil itself. (See P. J., lxiv, 615.)

Dose, five to ten minims (0.3-0.6 mil) gradually increased to one fluidrachm (3.75 mils).

**Off. Prep.**—Unguentum Chaulmoograe, Br.

**OLEUM CHENOPODII. U. S.**

**OIL OF CHENOPODIUM**  
Ol. Chenopod. [Oil of American Wormseed]

"A. volatile oil distilled from Chenopodium ambrosioides anthelminticum Linne (Fam. Chenopodiaceae). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Huile volatile d'Anserine vermifuge, Fr. Cod.; Essence de Chenopode anthelmintique, Fr.; Amerikanisches Wurmsamenol, Chenopodiumol, G.

For description of the plant from which this oil is derived see Chenopodium. The oil is largely distilled in Maryland. It is of a light-yellow color when recently distilled, but becomes deeper yellow and even brownish by age. Its reaction is neutral. It has in a high degree the peculiar odor of the plant. It is officially described in the United States
Pharmacopoeia as "a colorless or pale yellowish liquid, having a characteristic, disagreeable odor and taste. It is soluble in 8 volumes of 70 per cent. alcohol. Specific gravity: 0.955 to 0.980 at 25° C. (77° F.). Its optical rotation varies between -4° and -10° in a 100 mm. tube at 25° C. (77° F.) (see Part III, Test No. 21)."

When freshly prepared, it has the sp. gr. 0.908, which, according to S. S. Garrigues, is increased by time to 0.960. A portion examined by him, which was of a brownish-yellow color, had the sp. gr. 0.959 at 16.1° C. (61° F.), boiled at 190° C. (374° F.), and was freely soluble in alcohol and ether. He found it to be composed of two distinct oils, separable by distillation; one of these has the formula C\textsubscript{10}H\textsubscript{16}, and is probably limonene; the other is heavier, and possesses the formula C\textsubscript{10}H\textsubscript{16}O\textsubscript{2}. This constitutes over 50 per cent. of the commercial oil and has been given the name ascaridol, which is an unstable organic dioxide, decomposing with explosive violence with inorganic acids. (A. J. P., xxvi, 405.)

**Uses.**—The oil of chenopodium is used in medicine almost exclusively as an anthelmintic. Although it has been official in the Pharmacopoeia for many years, it owes its modern popularity to the investigations of Brunning. (Z. E. P. T., 1905, i, and 1906, iii, p. 564.) This author showed that one part in five thousand paralyzed although it did not kill the round worm of dogs, and that one part in two hundred had a distinct antiseptic action. In mammals, if given in sufficient dose, it depresses the spinal cord and finally kills by arrest of respiration. According to Salant and Livingstone (A. J. Phys., 1915, xxxviii) the oil of chenopodium in doses of 0.02 mil per kilo, or more, produces a lowering of the blood pressure through a cardiac action and diminution in the amplitude and rate of respiration. Because of its efficiency, ease of administration, and low toxicity, it is perhaps the most valuable of all the vermifuge remedies. Although originally recommended against the ascarides it has been shown to be also of great service against both the tapeworm and the hookworm. In the comparative studies of Schuffner and Verwoort (M. M. W., 1913, lx, p. 129) it gave better results in uncinariasis than either eucalyptus, betanaphthol, or thymol.

Levy (J. A. M. A., 1914, lxiii, p. 1946) has collected from the literature twelve cases of poisoning by oil of chenopodium of which nine ended fatally. The smallest dose in this series was four drops three times a day for two days, which caused death in a baby one year old. In another
case a child of two recovered from a dose of two teaspoonfuls given in the course of one afternoon. The symptoms of poisoning by oil of chenopodium—which may not appear for several hours after taking the oil—are nausea, vomiting, headache followed by drowsiness, ringing in the ears, and sometimes deafness. In the fatal cases there develop coma and convulsions. The usual method of administration is to give from ten to fifteen drops either in sugar or as an emulsion twice a day for two days and followed on the second day by an ounce of castor oil. For children between the ages of six and twelve the dose should be one drop for each year of age.

Dose, five to fifteen minims (0.3-0.9 mil).

**OLEUM COPAIBÆ. Br.**

**OIL OF COPAIBA**

Oil of Copaiva; Oleum Balsami Copaivae; Essence de Copahu, Fr.; Copaivaol, G.

Oil of copaiba was not admitted to the U.S.P. IX. The oil constitutes from one-third to one-half or more of the copaiba. From one specimen of recent copaiba as much as 80 per cent. has been obtained. (A. J. P., xxii, 289.) It is prepared largely by the application of steam heat. As it first comes over it is colorless, but the later product is of a fine greenish hue. By redistillation it may be rendered wholly colorless. It has the odor and taste of copaiba, a neutral reaction, boils at 252° to 256° C. (485.6°-492.80 P.), solidifies, partly crystalline, at -26.1° C. (-15° F.) (Gmelin), is soluble in ether and in an equal weight of absolute alcohol. The oil consists chiefly of caryophyllene, a sesquiterpene, C_{15}H_{24}. It was officially described as “a colorless or pale yellow liquid, having the characteristic odor of copaiba, and an aromatic, slightly bitter, and pungent taste. Specific gravity: 0.895 to 0.905 at 25° C. (77° F.), increasing with age. It is laevogyrate.” U.S. VIII.

“(Colorless or pale yellow. Odor and taste those of Copaiba. Specific gravity 0.896 to 0.910; optical rotation -7° to -35°; refractive index at 25° C. (77° F.) 1.494 to 1.500. Distils between 250° and 275° C. (482° and 527° F.). A solution of 1 millilitre of the Oil in 5 millilitres of glacial acetic acid does not develop more than a faint violet coloration on the addition of 4 drops of nitric acid (absence of gurjun oil). When distilled in a vacuum the first 10 per cent. of the distillate has an optical rotation
lower than that of the original Oil (absence of oil of African copaiba.). BR.

From its want of oxygen, it answers even better than naphtha for preserving potassium, a fact first observed by Durand, of Philadelphia. It dissolves sulphur and phosphorus.

Its effects on the system are those of copaiba. From the experiments of C. Mitscherlich, it is one of the least injurious of the volatile oils to the animal system, six drachms of it having been introduced into the stomach of a rabbit without causing death. Externally it produces much less irritation than does oil of turpentine. It may be used for the same purposes as copaiba.

Dose, five to fifteen minims (0.3-0.9 ml).

**OLEUM CORIANDRI. U. S. BR.**

**OIL OF CORIANDER**

*Ol. Coriand. [Coriander Oil]*

"A volatile oil distilled from the ripe fruit of Coriandrum sativum Linne (Fam. Umbelliferae). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Coriander is the oil distilled from Coriander Fruit." BR.

Essence de Coriandre, Fr.; Korianderol, G.

This oil may be obtained by distillation with water from the bruised fruit in the manner directed in the U. S. Pharm. 1870, for volatile oils. The average yield of oil from coriander grown in different countries is from 0.2 to 1 per cent. It is pale yellow and colorless, and has the characteristic odor and taste of coriander, and a neutral reaction. Its sp. gr. is from 0.863 to 0.878 at 25° C. (77° F.), U. S., and its boiling point 150° C. (302° F.). It is an oxygenated oil, consisting chiefly of a compound, coriandrol, C₁₀H₁₈O. According to Semmler (Ber. d. Chem. Ges., 24, 206), coriandrol boils between 194° and 198° C. (381.2° and 388.4° F.), is optically dextrogyrate, and has a sp. gr. of 0.8679 at 20° C. (68° F.). Coriandrol is now known as dextrogyrate linalool. Schimmel & Co. (Schim. Eep., April, 1892) have also found in coriander oil about 5 per cent. of dextropinene. The characteristic odorous principle or
principles are unknown. It is officially described as "a colorless or pale yellow liquid, having the characteristic odor and taste of coriander. It is soluble in 3 volumes of 70 per cent. alcohol. Specific gravity: 0.863 to 0.875 at 25° C. (77° F.). The optical rotation varies from +8° to +13° in a 100 mm. tube at 25° C. (77° F.)." U.S.

"Colorless or pale yellow. Odor and taste those of Coriander Fruit. Specific gravity 0.870 to 0.885; optical rotation +8° to +14°; refractive index at 25° C. (77° F.) 1.463 to 1.467. Soluble in 3 parts of alcohol (70 per cent.)." Br.

Oil of coriander is extensively adulterated with colorless rectified oil of orange, which can be detected by its insolubility in 90 per cent. alcohol, in which pure coriander oil dissolves in every proportion; equal parts of oil of orange and 90 per cent. alcohol make a turbid mixture. (A. J. P., Sept., 1878.) The oil has the medicinal properties of the fruit, and, like the aromatic oils generally, may be used to cover the taste or correct the nauseating or griping properties of other medicines. It has the great advantage of being more stable and retaining its agreeable odor longer than any other oil of its class.

Dose, one to three minims (0.06-0.2 mil).

Off. Prep.—Spiritus Aurantii Compositus, U. S.; Elixir Aromaticum (from Spirit), U. S.

**OLEUM CUBEBÆ. U. S., Br.**

**OIL OF CUBEB Ol. Cubeb. [Cubeb Oil]**

"A volatile oil distilled from the unripe fruit of *Piper Cubeba* Linne filius (Fam. Piperaceae). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Cubebs is the oil distilled from Cubeks." Br.

Oleum Cubebarum; Oil of Cubebs; Huile volatile (Essence) de Cubebe, Fr.; Kubebenol, G.

The oil is obtained from cubeb by grinding the berries, and then distilling with water. From ten pounds Sebonwald procured eleven ounces of oil, and this result very nearly coincides with the experiments
of Christison, who obtained 7 per cent.; but by better methods of distillation 10 to 18 per cent. have been obtained. When recently distilled from the fruit, the oil is somewhat greenish, becoming yellowish by age, but when carefully redistilled it is colorless. It has the odor of cubeb, a warm, aromatic, camphoraceous taste, and a neutral reaction, is of a consistence approaching that of almond oil, is lighter than water, having the sp. gr. 0.920 (0.910 to 0.930, Br.), and when exposed to the air is said to thicken without losing its odor. It is soluble in an equal weight of alcohol. It is described in the U. S. P. IX as follows: "Oil of Cubeb is a colorless or a pale green to yellowish-green liquid, having the characteristic odor and taste of cubeb. Specific gravity: 0.905 to 0.925 at 25° C. (77° F.). Its optical rotation varies from -20° to -40° in a 100 mm. tube at 25° C. (77° F.). Its alcoholic solution is neutral to litmus." U. S.

"Colorless, pale green, or greenish-yellow. Odor and taste those of Cubebs. Specific gravity 0.910 to 0.930; optical rotation -25° to 40°; refractive index at 25° C. (77° F.) 1.486 to 1.500. Not less than 60 per cent. distils between 250° and 280° C. (482°-536° F.)." Br.

The oil consists chiefly of sesquiterpenes which distil over between 250° and 280° C. (482° and 536° F.), one of which is cadinene, C_{15}H_{24}, with some dipentene, and probably pinene or camphene. Upon standing, it sometimes deposits rhomboidal prismatic crystals of a stearopten. The camphor of cubeb has the formula C_{15}H_{26}O, is fusible at from 66° to 68° C. (150.8 °-154.4° F.), and volatilizes without change at from 148° to 150° C. (298.4°-302° F.). According to Schmidt, it does not pre-exist in the cubeb, but is formed by the prolonged action of the air and therefore does not occur in oil distilled from new berries. (J. P. C., June, 1875.) The oil has the aromatic properties of cubeb, but it is probably not the sole active ingredient, as it is much less pungent than the fluidextract or the oleoresin. It may, however, often be advantageously substituted for the powder, the dose to be gradually increased until its effects are obtained, or until it proves offensive to the stomach. It may be given suspended in water by means of sugar, in the form of emulsion, or enclosed in capsules of gelatin.

Dose, five to fifteen minims (0.3-0.9 mil).
OLEUM EUCALYPTI. U. S., Br.

OIL OF EUCALYPTUS Oil. Eucalypt. [Eucalyptus Oil]

"A volatile oil distilled from the fresh leaves of Eucalyptus Globulus Labillariere (Fam. Myrtaceae) or from some other species of Eucalyptus, and yielding not less than 70 per cent., by volume, of eucalyptol (cineol) \[C_{10}H_{18}O = 154.14\]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Eucalyptus is the oil distilled from the fresh leaves of Eucalyptus Globulus, Labill., Eucalyptus dumosa, A. Cunn., and other species of Eucalyptus, and rectified." Br.

Oil of Eucalyptus Globulus; Huile volatile (Essence) de Eucalyptus, Fr. Cod.; Eucalyptusol, G.; Esencia de eucalipto, Sp.

Various species of the genus Eucalyptus, grown in Australia and Algeria, yield volatile oils in sufficient quantity to be commercial products. Probably the most important of these plants is E. Globulus, on account of its high cineol (eucalyptol) content. Large quantities of oil are also distilled from other species, viz., E. odorata, E. oleosa, E. cunfolia and E. dumosa.

Oil of eucalyptus is officially described as "a colorless or pale yellow liquid, having a characteristic, aromatic, somewhat camphoraceous odor, and a pungent, spicy, and cooling taste. It is soluble in 4 volumes of 70 per cent. alcohol. Specific gravity: 0.905 to 0.925 at 25° C. (77° F.). Mix 2 mils of the Oil with 4 mils of glacial acetic acid and gradually add 3 mils of a saturated solution of sodium nitrite. When gently stirred, the mixture does not form crystals of phellandrene nitrite (other eucalyptus oils containing large amounts of phellandrene)." U. S.

"Colorless or pale yellow. Aromatic, camphoraceous odor; taste pungent, leaving a sensation of cold. Specific gravity 0.910 to 0.930; optical rotation -10° to +10°. Soluble in 5 parts of alcohol (70 per cent.). Contains not less than 55 per cent. by volume of cineol as determined by the process described under ‘Oleum Cajuputi’ When 1 millilitre is mixed with 2 millilitres of glacial acetic acid and 5 millilitres of petroleum spirit, 2 millilitres of a saturated aqueous solution of sodium nitrite being added, and the mixture gently shaken, no crystalline precipitate forms in the upper layer (absence of oils containing much phellandrene)." Br.
The valuation of eucalyptus oil being based upon its cineol (eucalyptol) content the commercial oils from other species of eucalyptus are regarded with much less favor for medicinal purposes, because of their variable quality in this respect, and the fact that the other oils contain such constituents as phellandrene, cymene, citronellal, citral and other less known constituents. Cineol being optically inactive and high in its specific gravity communicates specific properties to such oils as contain it in large amounts by which their approximate value or their genuineness may be determined irrespective of the assay for cineol, which, of course, must be the ultimate deciding factor. There is much variation in the physical constants found in the literature of the eucalyptus oils as determined by different observers, and much work yet remains to be done upon the subject.

Eudesmol, \( C_{10}H_{16}O \) (possibly a ketone), is the name given to a crystalline camphor obtained from the oil from \( E. \) piperita; H. G. Smith and R. T. Baker isolated this product, and later H. G. Smith read a paper upon it before the Royal Society of New South Wales. It proved to be isomeric with camphor, but chemically it is shown to have its oxygen atom combined in a different way.

**Uses.**—In the belief that the medicinal properties of oil of eucalyptus depend upon cineol, the Pharmacopoeia rejects those oils which contain chiefly phellandrene, but as a matter of fact, we have no definite knowledge concerning the physiological action of phellandrene. Whether or not the medicinal virtues of the official oil are due entirely to its cineol is uncertain, but many prefer to use the pure eucalyptol to the oil itself.

Oil of eucalyptus is an active germicide, although surpassed in power by many of the other volatile oils. Cineol is probably a less efficient antibacterial agent than oil of eucalyptus. When taken in overdose it causes rapidity of the pulse with general excitement and restlessness, nausea, vomiting, frequently dilatation of the pupils, and symptoms of collapse. In the lower animals it reduces the arterial pressure and the bodily temperature, causes muscular weakness, irregular respiration and death from respiratory failure. It is absorbed from the intestinal tract, eliminated partially through the breath to which it imparts its odor, and also, as an oxidation product, through the urine to which it gives an odor resembling that of violets.
The oil of eucalyptus is used locally as an antiseptic, especially in the treatment of infections of the upper respiratory tract and in certain forms of skin disease. Internally it is used as a stimulating expectorant in chronic bronchitis and tuberculosis. In these conditions it is also frequently given by inhalation; a few drops of the oil may be added to boiling water and the mixed vapors and steam inhaled. It has been specially praised in asthma, given internally or preferably by inhalation by means of cigarettes, which may be made by rolling up the dried leaves, or the vapor from boiling water containing the oil may be inhaled. It is also used as a remedy against the hookworm, but is probably of inferior value. It possesses also some antiperiodic power and may be used in malarial fever when for any reason quinine or methylthionine are not available.

Dose, three to ten minims (0.2-0.6 mil), best administered in emulsion.

**Off. Prep.**—Unguentum Eucalypti, Br.

**OLEUM FOENICULI. U.S.**

**OIL OF FENNEL**

Oil. Foenic. [Fennel Oil]

“A volatile oil distilled from the ripe fruit collected from cultivated varieties of Foeniculum vulgare Miller (Fam. Umbelliferae). If wholly or partly solidified, carefully warm the Oil until liquefied and thoroughly mix it before dispensing. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U.S.

Huile volatile de Fenoutt, Fr. Cod.; Essence de Fenouil, Fr.; Oleum Foeniculi, P. G.; Fenchalol, G.

Fennel seeds yield about 2.5 per cent., or, according to Zeiler, from 3.4 to 3.8 per cent., of oil. That used in this country is imported. "A colorless or pale yellow liquid, having the characteristic odor and taste of fennel. It is soluble in 8 volumes of 80 per cent. alcohol and in 1 volume of 90 per cent. alcohol, forming a solution neutral to litmus. Specific gravity: 0.953 to 0.973 at 25° C. (77° F.). The optical rotation varies from +12° to 4-24° in a 100 mm. tube at 25° C. (77° F.). When tested by the method under Oleum Anisi, with the following modifications, the congealing
point of the Oil does not fall below 3° C. (37.4° F.). Cool the test tube containing the 10 mils of Oil of Fennel in a freezing mixture until the temperature has fallen to 0° C. (32° F.), and induce crystallization as directed." U. S.

It congeals below 10° C. (50° F.) into a crystalline mass, separable by pressure into a solid and a liquid portion, the former heavier than water, and less volatile than the latter, which rises first when the oil is distilled. It contains anethol, $C_{10}H_{12}O$ (a phenol-ether forming a white solid melting at 21° C. (69.8° F.)) (see Oleum Anisi), the latter usually in amounts of about 60 per cent., d-pinene, phellandrene, dipentene, fenchone, $C_{10}H_{16}O$ (a liquid ketone), chavicol, anisic aldehyde, and anisic acid. Fenchone is the constituent which when present gives the disagreeable bitter taste to many of the commercial oils. Schimmel's Report for April, 1897, mentions limonene as also at times present as a constituent. Umney finds that Japanese oil contains about 75 per cent. of anethol and 10 per cent. of fenchone, besides terpenes. (Proc. A. Ph. A., 1897, 516.) There is reason to believe that much of the commercial oil is adulterated with oil from which the anethol or crystalline constituent has been separated; the official solidifying point not below 5° C. (41° F.) should be required. Fluckiger states (Pharm. Chem., 2d ed., 1888, 422) that it contains more hydrocarbon than oil of anise, and notably that from Nimes, in Southern France, contains much less anethol, and hence has a milder and sweeter taste which is also probably due to the absence of the bitter fenchone. As found in commerce, therefore, the oil of fennel is not uniform, and a specimen examined by Montgomery did not congeal at -5.5° C. (22° F.).

Dose, three to five minims (0.2-0.3 mil).

**Off. Prep.**—Aqua Foeniculi; U. S.

**OLEUM GAULTHERIA. Br.**

**OIL OF GAULTHERIA [Oil of Wintergreen]**

"Oil of Gaultheria is the oil distilled from the leaves of Gaultheria procumbens, Linn., or from the bark of Betula lenta, Linn." Br.

Oil of Teaberry, Oil of Partridge-berry; Huile volatile (Essence) de Winter-green, Fr. Cod.; Essence de Gaultherie, Fr.; Wintergrunol, Bergtheeol, G.
Oil of gaultheria is no longer official in the U. S. P. IX. Under Methylis Salicylas the Pharmacopoeia directs that oil of gaultheria and oil of betula or sweet birch may be used.

The volatile oil of gaultheria is largely obtained in the United States by distillation of the plant. It probably does not exist in the plant, but is formed by a reaction between water and a neutral principle analogous to amygdalin, to which Procter has given the name of gaultherin. (A. J. P., xv.) This substance, which was called by Schneegans betulase, probably exists in all the numerous plants which yield methyl salicylate on distillation. The oil occurs in various of our native plants, and has been detected in Polygala paucifolia, Spirea Ulmaria, Spirea lobata, and Gaultheria chiogenes. T. E. de Vrij found it in considerable proportion in the Gaultheria leucocarpa and G. punctata, plants which are abundant in the volcanic regions of Java (A. J. P., 1879); while Bourquelot (C. R. S. B., iii, 1896) detected it in Monotropa Hypopitys, in Polygala Senega, and in other species of Polygala. (See also A. J. P., 1898, 412.) Much of the so-called oil of wintergreen is obtained from Betula lenta, which yields a product physically indistinguishable and difficult to differentiate chemically from methyl salicylate.

The still in which oil of wintergreen is distilled is generally a wooden box, about eight feet long, four feet wide, four feet high, with a copper bottom and stayed with bolts. The head of the still is copper, and connecting with this is a circular worm of the same material or of tin, placed in a barrel. The still being filled with wintergreen to within about twelve inches of the top, a sufficient quantity of water is added, and this is allowed to macerate from ten to twelve hours. The fire being started, the distillation commences, and continues for about eight hours; but during the first two or three hours ninety per cent. of the oil has passed over. For collecting the distillate, most of the distillers use a wide-mouthed bottle, fitted with a large cork having two holes. A small funnel is put into one of the holes, so that the beak is below the shoulder of the receiving vessel, and connected with the other hole is a suitable pipe forming an outlet. The oil and the water separate, the oil going to the bottom, and the water passes into a larger receptacle, where it is reserved for a subsequent operation (cohobation).

Occasionally the oil is very highly colored, and the wholesale dealers have three ways of "cleanin" it—redistillation, filtration, and de-
colorization. In the last method the oil to be decolorized is put into a bottle, crystals of citric acid are added, and the whole is allowed to stand, agitating occasionally, until the oil is colorless, or nearly so.

Oil of gaultheria when freshly redistilled is nearly colorless, but as found in commerce has a brownish-yellow or reddish color. The U. S. P. VIII described it as "a colorless or almost colorless liquid, having a characteristic, strongly aromatic odor, and a sweetish, warm, and aromatic taste. Specific gravity: 1.172 to 1.180 at 25° C. (77° F.). Boiling point: 218° to 221° C. (424.4°-429.8° F.). It is slightly laevogyrate, up to -1° in a 100 Mm. tube, at 25° C. (77° F.). In other respects it has the same properties as, and conforms to the reactions and tests given under, Methylis Salicylas."

"Colorless or nearly colorless. Strong, characteristic odor; taste pungent. Specific gravity 1.180 to 1.187; optical rotation ait 25° C. (77° F.) 0° to -1°; refractive index 1.537 to 1.539. Soluble in 6 parts of alcohol (70 per cent.) at 25° C. (77° F.). Contains not less than 99 per cent. of esters, calculated as methyl salicylate, CH₃C₇H₅O₃." Br.

It is stated to have been largely adulterated with chloroform. This and other impurities are to be detected by a comparison of the specific gravities and boiling points, or by fractional distillation. It is readily soluble in alcohol. When heated to about 80° C. (176° F.), the oil should not yield a colorless distillate having the characteristics of chloroform or of alcohol. (A. J. P., 1873, p. 521.) Another distinguishing property is that in aqueous solution it gives a purple color with ferric salts. Oil of sassafras may be detected by the separation of a deep-red resinous mass on treatment with nitric acid in the cold. Japanese oil of camphor and other light volatile oils used as adulterants can be detected by simply dropping the suspected oil in water; if pure, it sinks in a few seconds; if adulterated, some minutes are required. Cahours states that one-tenth of the oil consists of a peculiar hydrocarbon, which he called gaultherilene, and the remaining nine-tenths of methyl salicylate. (A. J. P., xiv, 211, xv, 241.) Trimble and Schroeter (A. J. P., 1889, 398) found that the amount of the hydrocarbon gaultherilene was much less than that stated by Cahours—in fact, only 0.3 per cent. By analysis and vapor density, determination they fixed its formula as C₁₅H₂₄, but they state that it may consist of a solid and a liquid portion. Power and Kleber (Fritzsche Bros. Circ., No. 7) assert that this hydrocarbon belongs
to the paraffin series, and state that it is probably triacontane, \( \text{C}_{30}\text{H}_{62} \). They also find in the oil an aldehyde or ketone, with an odor like oenanthic aldehyde, an apparently secondary alcohol, \( \text{C}_6\text{H}_{16}\text{O} \), and an ester, \( \text{C}_{14}\text{H}_{24}\text{O}_2 \). To the alcohol and the ester are attributed the characteristic odor of the oil. True oil of gaultheria contains about 99 per cent. of methyl salicylate. Synthetic oil of wintergreen is now extensively manufactured and used instead of the natural oil. For a process by H. T. Thayer, see A. J. P., 1895, 244.

**Uses.**—The therapeutic properties of this oil are precisely the same as those of Methyl Salicylate.

Dose, ten to twenty minims (0.6-1.3 mils).

**OLEUM GOSSYPII SEMINIS. U.S.**

**COTTONSEED OIL**

*Oli. Gossyp. Sem.* [Cotton Seed Oil]

"A fixed oil obtained from seeds of cultivated varieties of *Gossypium herbaceum* Linne, or of other species of *Gossypium* (Fam. Malvaceae). Preserve it in well-closed containers." U. S.

Oleum Gossypii; Cotton Oil; Huile de Semences de cotonnier, Fr.; Baumwollsamenöl, Baumol, G.

This fixed oil has no other medicinal properties than those of a bland neutral oil, and has been introduced especially on account of its use in official liniments. The amount of cottonseed produced in 1914 was 7,186,000 tons, of which 5,779,665 was worked up into its various products. The oil obtained was 229,260,000 gallons. The oil cake is largely exported to England, where it is used as food for cattle, and the oil to France, Italy, and other olive growing countries of Europe, whence much of it returns to us mixed with olive oil. The exportation of cottonseed oil for 1915 amounted to 318,366,525 lbs., valued at $21,872,948. For a description of the process of extraction, see A. J. P., 1896, 42; also 1898, 497. Among the recent improvements in the purification of cottonseed oil are the processes of Chisholm using silicate of soda for clarifying and of Baskerville using a paper pulp or cellulose fiber.
This oil is obtained by expression from the seeds previously deprived of their shells. In this state they yield two gallons of oil to the bushel. As first obtained, it is thick and turbid, but it deposits a portion of its impurities on standing.

The oil is clarified by first boiling it with water, to separate the mucilage, and then heating it with a weak solution of sodium hydroxide, which combines with the coloring matter and saponifies a part of the oil. The mixture becomes filled with black flocks, which deposit on standing and leave the oil but slightly colored. The loss in refining is usually from 4 to 7.5 per cent., but occasionally amounts to 12 or 15.

Besides this crude oil, there are three varieties in commerce, more or less purified, recognized as the clarified, the refined, and the winter bleached. The last mentioned is of a pale straw-color, a mild peculiar odor, and a bland sweetish taste, not unlike that of almond oil. The oil is used in the preparations of woollen cloth and morocco leather, and for oiling machinery. It has been found to be an excellent substitute for almond and olive oils in most pharmaceutical preparations in which they are employed, but it does not answer so well in the formation of lead plaster. Citrine ointment carefully prepared with it, too great heat being avoided, retains a rich orange color and proper unctuous consistence.

As this oil is much used for adulterating olive oil, tests to distinguish it are very desirable. The test most depended upon is that known as Balphen's testy a mixed solution of amyl alcohol and carbon disulphide containing 1 per cent. of dissolved sulphur. This is given in the official test. It is stated that cotton seed oil, which has been heated to 250° C. (482° F.) no longer gives many of the characteristic reactions for detecting the oil.

Dose, two to six fluidrachms (7.5—22.5 mils).

**Off. Prep.**—Linimentum Camphorae, U. S.; Linimentum Ammonias, U. S.
OLEUM GRAMINIS CITRATI. Br.

OIL OF LEMON GRASS

"Oil of Lemon Grass is the oil distilled from Cymbopogon citratus, Stapf, and Cymbopogon flexuosus, Stapf." Br.

Lemon-grass Oil.

The East Indian Lemon Grass Oil comes from Malabar, Cochin, India and the Malay Peninsula. A product of the C. citratus comes from Ceylon, Burma and adjacent countries, as well as from Mexico and the West Indies.

It is officially described in the British Pharmacopoeia, 1914, as "Dark yellow. Odor resembling that of verbena. Specific gravity 0.880 to 0.905; optical rotation -3° to +3°. Contains not less than 70 per cent. of aldehydes as determined by the process described under 'Oleum Cinnamomi.'" Br.

The chief aldehyde present is citral, of which it contains 70 to 85 per cent. Linalool, geraniol and methyl peptenone are also reported present in small amounts. The principal use of the oil is in perfuming cheap soaps, (See also Oil of Citronella.)

Oil of lemon grass is sometimes used in Eastern countries as a carminative and stimulant in doses of one-half to three minims (0.03-0.2 mil). Its chief use is in perfumery.

OLEUM JUNIPERI. U. S., Br.

OIL OF JUNIPER

Ol. J unip. [J uniper Oil, Oil of J uniper Berries]

"A volatile oil distilled from the ripe fruit of J uniperus communis, Linne (Fam. Pinaceae). Preserve it in well-stoppered, amber-colored bottles in, a cool place, protected from light." U. S. "Oil of J uniper is the oil distilled from the ripe fruit of J uniperus communis, Linn., and rectified." Br.

The proportion of oil which juniper berries afford is stated very differently by different authors. Trommsdorff obtained 1 per cent. The highest quantity given in the table of Re-cluz is 2.34\(^{\text{a}}\) the lowest 0.31 per cent. Zeiler gives as the product of the fresh ripe fruit 1.3 per cent., of that a year old 0.86 per cent. The berries are most productive when bruised. The oil of juniper consumed in this country is brought from Europe, and is believed to be procured chiefly from the tops of the plant, being sold for a price which is altogether incompatible with the idea that it is prepared from the fruit alone. "A colorless or faintly green or yellow liquid, having the characteristic odor and taste of juniper fruit. It is soluble in 4 volumes of alcohol with not more than a slight cloudiness. Specific gravity: 0.854 to 0.879 at 25° C. (77° F.). The optical rotation varies from 0° to -15°, in a 100 mm. tube at 25° C. (77° F.)." U.S.

"Colorless or pale yellowish-green. Odor that of the fruit; taste warm, aromatic and bitter. Specific gravity 0.862 to 0.890, increasing with age; optical rotation -3° to -15°; refractive index at 25° C. (77° F.) 1.472 to 1.488. Soluble, when freshly distilled, in 4 parts of a mixture of equal volumes of alcohol (90 per cent.) and absolute alcohol/ becoming less soluble with age." Br.

According to Fluckiger (Pharm. Chem., 2d ed., 1888, 402), it is composed essentially of two hydrocarbons, the more abundant of which, boiling at 160° C. (320° F.), has been shown by Wallach to be pinene, C\(_{10}\)H\(_{16}\). Above 175° C. (347° F.) another oil is obtained, which seems to be cadinene, C\(_{15}\)H\(_{24}\). It also contains a small amount of an ester to which the peculiar juniper-like odor and taste was supposed to be due, but this cannot be the case, as the odor persists after the complete saponification of the small amount of ester. Juniper camphor is also present, its melting point is 165° to 166° C. (329°-330.8° F.). Oil of turpentine is often fraudulently added, but may be detected by the specific gravity of the mixture being less than that of the unadulterated oil of juniper.

**Uses.**—Oil of juniper is occasionally used as a carminative in intestinal flatulence, but is more popularly employed for its diuretic effect. Because of its local irritant action it should never be used when there is an active inflammatory process in the kidney or urinary tract. It is frequently combined with potassium bitartrate. To it gin owes its peculiar flavor as well as its diuretic effects.

Dose, two to ten minims (0.12-0.6 mil).

OLEUM LAVANDULA. U. S., Br.

OIL OF LAVENDER
Ole Lavand. [Oleum Lavandulae Florum, U.S. P. VIII]

"A volatile oil distilled from the fresh flowering tops of Lavandula vera De Candolle (Lavandula officinalis Chaix, Lavandula spica Linne) (Fam. Labiatae). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "The oil distilled from the flowers of Lavandula vera, DC." Br.

This oil is usually distilled from the flowers and flower stems conjointly, though of finer quality when obtained from the former exclusively. Dried lavender flowers are said to yield from 1 to 1.5 per cent. of oil. According to Zeller, the fresh flowers yield 1.03, the dried 4.3, the whole fresh herb in flower 0.76 per cent. It is stated that the lavender produced by an acre of ground under cultivation will yield from 10 to 12 pounds of the oil. (P. J., 1864, p. 257.) The oil is very fluid, of a lemon-yellow color, with the fragrance of the flowers and an aromatic, burning taste. That met with in commerce has the sp. gr. 0.898 at 20° C. (68° F.), which is reduced to 0.877 by rectification (Berzelius), or 0.886 (Buignet). It is laevogyrate. According to Brande, the sp. gr. of the oil obtained from the whole herb is 0.9206. Alcohol of 0.830 dissolves oil of lavender in all proportions, that of 0.877 only 42 per cent. (Berzelius.) Proust states that when allowed to stand in imperfectly stoppered bottles it lets fall a crystalline deposit, which often amounts to one-fourth of its weight. This has been found by Dumas to have the same point of volatilization and the same composition as true camphor, but to differ in the total want of rotatory power. It is said that the portion of oil first distilled is most fragrant, and is often kept separate, and sold at a, higher price. "Oil of Lavender is a colorless or yellow liquid, having the characteristic odor and taste of lavender flowers. It is soluble in 3 volumes of 70 per cent. alcohol. Specific gravity: 0.875 to 0.888 at 25° C. (77° F.). The optical rotation varies from -1° to -10° in a 100 mm. tube at
25° C. (77° F.). When shaken in a narrow glass cylinder with an equal volume of distilled water, its volume does not diminish (alcohol). Shake 20 mils of the Oil with 40 mils of 5 per cent. alcohol and, when the mixture has cleared, withdraw 30 mils of the alcoholic solution. Neutralize this with (half-normal potassium hydroxide V.S., using phenolphthalein T.S. as indicator, then add 5 mils of half-normal potassium hydroxide V.S. and heat the mixture on a water-bath, under a reflux condenser, during one hour. Not less than 4.7 mils of half-normal hydrochloric acid V.S. is required for neutralization (foreign esters)." U. S.

"Pale yellow or yellowish-green. Odor that of the flowers; taste pungent, slightly bitter. Specific gravity 0.883 to 0.900; optical rotation -3° to -10°. Soluble in 4 parts of alcohol (70 per cent.). Contains from 7 to 11 per cent. of esters (English oil), or not less than 30 per cent. of esters (foreign oil), calculated as linalyl acetate, \( \text{C}_{10}\text{H}_{17}\text{C}_{2}\text{H}_{3}\text{O}_{2} \)."

The principal constituent is an alcohol, \( \text{C}_{10}\text{H}_{18}\text{O} \), identical with the linalool. Besides linalool, lavender oil contains linalyl acetate (from 30 to 45 per cent. in the oil from French flowers, and from 7 to 10 per cent. in the oil from English flowers), the butyric ester of the same alcohol, geraniol, a very small amount of cineol (more in the English than in the French oil), and sometimes traces of pinene, limonene, and a sesquiterpene.

Oil of Spike is procured from the broad leaved variety of lavender which grows wild in Europe, the Lavandula Spica of De Cavanilles. Its odor is less fragrant than that of common oil of lavender, and is somewhat analogous to that of oil of turpentine, with which it is said to be often adulterated. It is used by artists in the preparation of varnishes. The oil of spike contains about 30 per cent. of cineol and but small quantities of esters. Oil of lavender is used chiefly as a perfume, though possessed of carminative and stimulant properties, and sometimes useful in cases of nervous languor and headache.

Dose, from one to five minims (0.06-0.3 mil).

OLEUM LIMONIS. U. S., Br.

OIL OF LEMON
Ol. Limon. [Lemon Oil]

"A volatile oil obtained by expression from the fresh peel of the ripe fruit of Citrus medica Limonum (Risso) Hooker filius (Fam. Rutaceae), and yielding not less than 4 per cent. of the aldehydes from Oil of Lemon, calculated as citral \([C_{10}H_{16}O =152.13]\). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light. Oil of Lemon having a terebinthinate odor is not to be dispensed." U. S. "Oil of Lemon is the oil obtained from Lemon Peel by various methods of expression." Br.

The exterior rind of the lemon abounds in a volatile oil, which, being contained in distinct cells, may be separated iby simple expression. The rind is first grated from the fruit, and then submitted to pressure in a bag of fine cloth. The oil thus obtained is allowed to stand till it becomes clear, when it is decanted, and kept in stoppered bottles. By a similar process, the oil called by the French huile de cedrat is procured from the citron. (See Oil of Bergamot and Succus Limonis.) These oils may also be obtained by distillation, but thus procured, though clearer, and, in consequence of the absence of mucilage, less liable to change on keeping, they have less of the peculiar flavor of the fruit, and the mode by expression is generally preferred. A third method of separating the oil, used in Calabria and Sicily, is to put the grated rind into hot water and skim off the oil as it rises to the surface. (A. J. P., 1868, p. 27.) The method employed to obtain the finest oil is, however, that known as the ecuelle process. The ecuelle is an instrument usually made of tinned copper, bowl-shaped, and armed with concentric rows of short spikes. Attached to the bottom of the bowl is a hollow handle, closed at the bottom. This acts as a reservoir for the oil as the fruit is rubbed by the workmen over the sharp teeth. The oils are brought from Italy, Portugal, or Southern France.

The oils of lemons and oranges, as well as those of the other Aurantiaceae, will keep indefinitely upon admixture with a small proportion of alcohol (one ounce to a pound of the oil). When wanted for
use, a quantity of water equal to that of alcohol, added to the mixture, will unite with the alcohol, and subside, leaving the oil free of the alcohol for all practical purposes. (Carl Fruh, A. J. P., 1871, 201.) E. J. Parry (Ch. & Dr., 1913, p. 378) discusses at some length the relative advantages of terpene-less and sesquiterpeneless oils and normal oils. The ordinary terpeneless oils contain from 42 to 45 per cent. of citral, while those that are sold as sesquiterpeneless contain from 65 to 72 per cent. citral. He states that the latter products lack the sweetness and softness of odor of those containing less citral, the overpowering odor of the latter constituent destroying the balance of harmony in the odor of the oil. He states that users of these products claim to get the best results from oils containing slightly less than 40 per cent. of citral and from which the whole of the terpenes have not been removed. The characters of the commercial terpeneless oil are as follows: sp. gr. at 15° C. (59° F.), 0.8935 to 0.899; optical rotation, -5° to -8° 30'; refractive index, 1.4810; citral, 42 to 48 per cent. The sesquiterpeneless oils are slightly higher in specific gravity, lower in optical rotation and always run above 65 per cent. of citral.

The great extent of the production and export of Sicilian and Calabrian essential oils (lemon, orange, bergamot, etc.) may be seen from the Italian official statistics, according to which the number of trees producing in 1896 was 17,084,-569, yielding 3,337,000,000 fruits. Of these 1,897,000,000 were exported, leaving 1,439,555,000 fruits for home consumption inclusive of those used in the manufacture of essences. (Schim. Rep., Oct., 1897, 23.)

Parry (Schim. Rep., Apr., 1912, p. 78) reports several shipments of lemon oil which upon investigation were found to be adulterated with Greek turpentine oil. They were noted by their low optical rotation, +50° to +54°, and their low citral content, 3.3 to 4.1 per cent.

Oil of lemon contains a small amount of pinene, with dextrogyrate limonene, about 7 to .8 per cent. of citral, C_{10}H_{16}O, an aldehyde yielding geraniol upon reduction, and a small amount of citronellal, C_{10}H_{18}O, also an aldehyde. Pinene, phellandrene, higher aldehydes, as octyl and nonyl, terpineol and geranyl acetate have also been reported in small amounts. Of these the citral is the constituent to which the oil chiefly owes its aroma and value. Umney and Swinton (P. J., 1898, 196) state that citral, citronellal, and an ester of geraniol are all necessary to form the true odor of oil of lemon. Citral boils under normal atmospheric
pressure, at from 228° to 229° C. (442.4°-444.2° F.) without decomposition if pure, and, like aldehydes, forms stable compounds with alkaline bisulphites. Schimmel & Co. now prepare the citral in a pure state, and recommend its use for enriching the ordinary oil of lemon.

Oil of lemon is often adulterated by the fixed oils and by alcohol, and sometimes with purified oil of turpentine, which is difficult of detection from its similar composition and specific gravity except with the polariscope. One of the tests for the presence of this oil is the terebinthinate odor produced when the adulterated oil is evaporated from heated paper; the official quantitative test defining the percentage of citral will be of service in detecting these adulterations. The most dangerous adulteration of oil of lemon is the use of citrene, the terpene left after the extraction of citral from oil of lemon which has been used in making terpene-less oil. Oil of lemon procured 'by expression is apt to precipitate and to undergo chemical change. J. S. Cobb has found no method so effectual to obviate this result, and at the same time to retain unimpaired the flavor of the oil, as to shake it with a little boiling water and allow the mixture to stand. A mucilaginous matter separates, and floats on the surface of the water, from which the purified oil may be decanted. (Ann. Pharm., ii, 86.) The best method of preservation is to add 10 per cent. of a bland fixed oil such as olive or cottonseed, which must subsequently be allowed for in measuring the oil for use.

Adulteration of Lemon Oil with Pinene.—In consequence of some seizures of lemon oil alleged to be adulterated with turpentine, in 1906, a number of importers stated their belief that pinene was normally present in appreciable amounts in some lemon oils. In consequence of this the U. S. Dept. of Agriculture undertook a special investigation of the subject, sending a trained observer and analyst to the producing countries, and published the results of the investigation in a special bulletin called "Circular 46, by E. M. Chace." The investigation showed conclusively that lemon oil shows no appreciable amount of pinene.

Spirit of Lemon (Spiritus Limonis, U. S. 1890) is no longer official. It was made by dissolving 50 mils of oil of lemon in 900 mils of deodorized alcohol, to which 50 Gm. of freshly grated lemon peel were added, the whole macerated for twenty-four hours, filtered, and enough deodorized alcohol added through the filter to make the whole measure 1000 mils.

Uses.—The oil of lemon is much less active than most of the other
official volatile oils, and is used almost exclusively for its flavoring properties.

Dose, two to five minims (0.12-0.3 mil).

**OLEUM LINI. U. S., Br.**

**LINSEED OIL**

**Ol. Lini. [Oil of Flaxseed Raw Linseed Oil]**

"A fixed oil obtained from Linseed. Preserve it in well-stoppered containers. Linseed Oil which has been ‘boiled’ must not be used nor dispensed." U. S. "Linseed Oil is the oil expressed from Linseed." Br.

This oil is obtained by expression from the seeds of Linum, usitatissimum, or common flax, which, according to Berjot, contain 34 per cent. (J. P. C., April, 1863. p. 277.) In its preparation on a large scale, the seeds are usually roasted before being pressed, in order to destroy the gummy matter contained in their coating. The oil is thus obtained more free from mucilage, but more highly colored and acrid than when procured by cold expression. For medicinal use, therefore, it should be prepared without heat, and, as it is apt to become rancid quickly on exposure, it should be used as soon after expression as possible. It may, however, be rendered sweet again by agitation with warm water, rest, and decantation. It is said to be obtained purer and in larger proportion by treating the crushed seeds with carbon disulphide than by expression. (A. J. P., xxvi, 265.)

Oil of flaxseed is a yellowish, oily liquid, having a peculiar odor and a bland taste. When exposed to the air, it gradually thickens, darkens in color, and acquires a strong odor and taste. It is slightly soluble in alcohol, miscible with ether, chloroform, petroleum benzin, carbon disulphide, or oil of turpentine. Specific gravity: 0.925 to 0.935 at 25° C. (77° F.). It is not more than slightly acid to litmus paper which has previously been moistened with alcohol (free acid). Linseed Oil when
spread in a thin layer on a glass plate and allowed to stand in a warm place is gradually converted into a hard, transparent resin (non-drying oils). To 10 mils of the Oil add 3 Gm. of potassium hydroxide, 10 mils of alcohol and 10 mils of distilled water, and heat the mixture on a water bath with frequent agitation, until a clear solution results. The addition of 100 mils of distilled water to this solution yields a clear liquid free from oily drops (mineral or rosin oils). Warm 2 mils of the Oil with frequent agitation in a test tube with an equal volume of glacial acetic acid, and, after cooling, add to the mixture 1 drop of sulphuric acid. A greenish color is produced (a violet color under these circumstances indicates the presence of rosin or rosin oils). Saponification value: not less than 187 nor more than 195. Iodine value: not less than 170."

"Yellowish-brown. Characteristic odor; taste bland. Specific gravity 0.930 to 0.940; saponification value 187 to 195; iodine value not less than 170; acid value not more than 3.0; unsapomifiable matter not more than 1.0 per cent.; refractive index at 40° C. (104° F.) 1.4725 to 1.4748. Does not congeal at temperatures higher than -20° C. (-4° F.). Gradually thickens on exposure to the air, forming, when spread in thin layers, a hard transparent varnish. A mixture of 2 millilitres of the Oil with an equal volume of acetic anhydride, warmed and shaken, and then cooled to 15.5° C. (60° F.), is not colored violet by the addition of 2 drops of a cooled mixture of 2 parts by weight of sulphuric acid and 1 part by weight of water (absence of reain and resin oils)." Br.

It has the property of drying or becoming solid on exposure to the air, acquiring during the process a strong odor and taste, and increasing as much as 12 per cent. of its weight, owing to the formation of linoxyn by atmospheric oxidation. The drying property resides in a constituent which, to distinguish it from the olein of the non-drying oils, is named linolein, and is the glyceride of linoleic acid. Linseed oil contains about 10 to 15 per cent. of glycerides of solid fatty acids, palmitic, myristic, and stearic, and 85 to 90 per cent. of liquid glycerides. Hazura (J. Soc. Chem. Ind., 1888, 506) states that the liquid fatty acids consist of about 5 per cent. of oleic acid, C\textsubscript{18}H\textsubscript{34}O\textsubscript{2}, 15 per cent. of linoleic acid, C\textsubscript{18}H\textsubscript{32}O\textsubscript{2}, 65 per cent. of isolinolenic acid, C\textsubscript{18}H\textsubscript{30}O\textsubscript{2}, and 15 per cent. of linolenic acid, C\textsubscript{18}H\textsubscript{30}O\textsubscript{2}. Boiled with litharge, red lead, manganese dioxide, and other so-called "driers," it absorbs oxygen still more rapidly, 'and gains 14 per cent. in weight. Its acridity is owing to the presence of a small proportion of an acrid oleoresin. From its drying property, it is
useful in painting and in making printers' ink and in linoleum and oil cloth manufacture. The chief adulteration of linseed oil is with mineral oils and rosin oil. For their detection, see official tests already given.

It is said that crude cod liver oil has been used for the adulteration of the oil of flaxseed, especially where the latter is intended for preparing printers' ink. Aug. Morell detects tile adulteration iby the following method. Take 10 parts by weight of the suspected oil, mix it in a small cylindrical glass tube with 3 parts of crude nitric acid, agitate the mixture well, and allow it to rest. If cod liver oil be present, the oily layer at top will assume a dark-brown to blackish-brown color, while the acid at bottom will vary from bright orange to orange or dark yellow. So little as 3 per cent. of cod liver oil may thus be detected. If the flaxseed oil be pure, it will become, during the agitation, first sea green, and afterwards dirty greenish-yellow, the acid being bright yellow. The prohibition of the use of boiled linseed oil for medicinal purposes has its origin in the fact that much of the boiled linseed oil of commerce contains a compound of lead or manganese as a drying agent. Instances are on record where lead-containing boiled linseed oils caused the death of cattle to which the oil had been administered;

Uses.—The oil is laxative in the dose of a fluidounce (30 mils), but, on account of its disagreeable taste, is seldom given internally. It has, however, been highly recommended as a cure for piles, in the dose of two fluidounces (60 mils) of the fresh oil, morning and evening. It is sometimes added to purgative enemata. Particular care must be observed not to use boiled linseed oil for any medicinal purposes, as the latter frequently contains compounds of lead which give it poisonous properties.

Dose, one to two fluidounces (30-60 mils).

Off. Prep.—Linimentum Calcis, U. S.; Ceratum Resinae Compositum, N. F.

OLEUM MENTHÆ PIPERITA. U. S., Br.

OIL OF PEPPERMINT
Ol. Menth. Pip. [Peppermint Oil]

“A. volatile oil distilled from the flowering plant of Mentha piperita
Linne (Fam. Labiatae), rectified by steam distillation, and yielding not less than 5 per cent. of esters, calculated as menthyl acetate \([C_{10}H_{19}C_2H_3O_2 = 198.18]\), and not less than 50 per cent. of total menthol \([C_{10}H_{19}OH = 156.16]\), free and as esters. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light. U. S. "Oil of Peppermint is the oil distilled from fresh flowering peppermint, Mentha piperita, Sm., and rectified, if necessary." Br.

Peppermint varies exceedingly in the quantity of oil which it affords. Four pounds of the fresh herb yield, according to Baume, from a drachm and a half to three drachms of the oil. Zeiler gives as the product of the fresh herb, from 0.37 to 0.68 per cent., of the dried 1.14 per cent. The yield is generally less than 1 per cent. This oil is largely distilled in the States of Michigan, Indiana, and New York. For a valuable account of its method of production in Michigan, by A. M. Todd, see A. J. P., 1888, 328. The oil is also largely produced in Japan. (See illustrated paper, C. D., 1896, 601.) Gildemeister and Hoffmann (Aetherische Oele, p. 836) estimate the world's production of peppermint oil at 175,000 kilos, of which the United States furnishes 90,000 kilos, and Japan 70,000 kilos. It is officially described as "a colorless liquid, having a strong odor of peppermint, and a pungent taste, followed by a sensation of cold when air is drawn into the mouth. It is soluble in 4 volumes of 70 per cent. alcohol, showing not more than slight opalescence and no separation of oil globules. Specific gravity: 0.896 to 0.908 at 25° C. (77° F.). The optical rotation varies between -23° and -33° in a 100 mm. tube at 25° C. (77° F.). Distil about 1 mil from 25 mils of the Oil and pour the distillate on 5 mils of mercuric chloride T.S.; a white film does not form at the zone of contact within one minute (dimethyl sulphide found in non-rectified oils)." U. S.

Upon cooling or long standing it deposits a stearopten. Berzelius stated that at -13.3° C. (--8° F.) the oil deposits small capillary crystals. These are called peppermint camphor or menthol, \(C_{10}H_{19}OH\). A complete summary of the composition of American peppermint oil, on the authority of Power and Kleber, given in Schimmel & Co.'s Report for April, 1897, shows the following constituents: acetaldehyde, isovaleraldehyde, dimethyl sulphide, amyli alcohol, isovalerie acid,
pinene, phellandrene, cineol, limonene, menthone, \( \text{C}_{10}\text{H}_{18}\text{O} \), menthol, the acetate and iso-valerate of menthyl, \( \alpha \)-lactone, \( \text{C}_{10}\text{H}_{16}\text{O}_2 \), and cadinene. Menthol, its oxidation product menthone, and the acetic and isovaleric esters of menthyl have been identified as present in English and French peppermint oils, which probably also contain most of the other constituents mentioned above. Menthol and its esters are regarded as the main constituents of oil of peppermint and an official assay for determining the percentage of menthol will be found above. The dimethyl sulphide and some of the other constituents are objectionable from the flavoring standpoint, and are largely removed by the steam distillation which is required for rectification. The polariscope has been shown to be an uncertain guide in determining the quality of oil of peppermint. (A. B. Stevens, Proc. A. Ph. A., 1888, p. 97.)

Fluckiger discovered that from 50 to 70 drops of peppermint oil, shaken with one drop of nitric acid, sp. gr. 1.2, turn faintly yellowish brown, and after an hour or two a most beautiful blue-violet or greenish-blue by transmitted light, or copper color by reflected light. Either a greater amount of acid or heating hastens the reaction. The color is very persistent. The presence of 5 per cent. of turpentine does not interfere with the reaction. (P. J., Feb., 1871.)

Since menthol has been prepared largely from American peppermint oil, much of the latter has been put upon the market deprived of its menthol. To detect this fraud, Fritzsche Brothers recommend that a test tube partially filled with the oil and corked should be placed in a freezing mixture of ice and salt for ten or fifteen minutes. At the end of that time, if the oil has not been tampered with, it will have become cloudy, thick, or of a jelly-like consistence. If then four or five small crystals of menthol be added, and the tube be replaced in the freezing mixture, the oil will in a very short time form a solid mass of crystals. For another method of testing dementholized oil, see a paper by E. C. Federer, Ph. Era, 1887, 36; also 1887, 97.

Power and Kleber first proposed (Ph. Rund., 1894, 157) to estimate the menthol in oil of peppermint by acetylizing a sample and saponifying an exactly weighed portion of the acetyl-ized oil after washing, drying, and filtering the same. Kleber (A. J. P., 1897, 192) proposed to take instead a weighed quantity of the oil, acetylize it, and then saponify the product after washing and neutralizing it. In Schimmel & Co.'s Report for October, 1897, Kleber criticizes Keber's modification, and claims greater
accuracy for the original method. Of course, this determination gives the total menthol; a determination of the combined menthol is had by titrating with alcoholic alkali.

Peppermint oil has been variously mixed and adulterated with the following substances: alcohol, oil of turpentine, oil of copaiba, oil of erigeron (from the erigeron plant growing with the peppermint plant, and being collected with it for distillation), oil of eucalyptus, oil of pennyroyal, and others. Most of these are detectable by the official tests, or when present lower the assay strength, or are readily recognized by the odor or taste, which they communicate to the oil. For further details concerning some of these adulterants and their detection, see U. S. D., 19th ed., p. 854, 855.

Chinese Oil of Peppermint has not found its way to any extent into commerce, yet it has at times attracted much attention. According to John Mackey, some of it has reached London in cylindrical tin canisters, and it is to be obtained in San Francisco. Some specimens resemble the ordinary oil, but become solid in cold weather; others remain liquid and show no tendency to deposit a camphor, while others are solid crystalline masses at all temperatures. It seems probable that the original Chinese oil contains a great excess of menthol, and constitutes the variety first spoken of, and that the solid and liquid oils are prepared by separating it into its two constituents. The solid oil Fluckiger states not to differ from American menthol. (See P. J., v, 366, 825.)

Uses.—Oil of peppermint possesses the physiological properties and therapeutic virtues of menthol, and may be used for practically all those conditions in which menthol is of service. It is generally preferred for internal use because of its more pleasant taste. It is an excellent carminative and gastric stimulant, and is widely employed in flatulence, nausea, and gastralgia. It adds to a stimulating effect upon the alimentary canal an antiseptic and local anesthetic influence. As a local application for coryza it may be used in strengths of from five to ten minims to an ounce of liquid petrolatum or olive oil. Incorporated into a lozenge it offers a pleasant and efficient antiseptic and anesthetic in pharyngitis. Internally it may be given either rubbed up with sugar and then dissolved in water, or more commonly in the form of the spirit. It is extremely popular as a flavoring agent.
Dose, one to five minims (0.06-0.3 mil).

**OLEUM MENTHAE VIRIDIS. U. S., Br.**

**OIL OF SPEARMINT**

**Ol. Menth. Vir. [Spearmint Oil]**

"A volatile oil distilled from the flowering plant of Mentha spicata Linne (Mentha viridis Linne) (Fam. Labiatae), and yielding not less than 43 per cent., by volume, of carvone \([C_{10}H_{14}O = 150.11]\). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Spearmint is the oil distilled from fresh flowering spearmint, Mentha viridis, Linn., or mentha crispa, Roth." Br.

Hulle volatile (Essence) de Menthe verte, Fr.; Romisch-minzol, Krauseminzol, G.

According to Lewis, ten pounds of spearmint yield an ounce of oil; by others the product is stated not to exceed one part from five hundred. The oil is largely distilled in this country, the whole plant being used. It is pale yellow or greenish when recently prepared, but becomes red with age, and ultimately almost of a mahogany color. It is officially described as "a colorless yellow or greenish-yellow liquid, having the characteristic odor and taste of spearmint. It is soluble in 1 volume of 80 per cent. alcohol, forming a clear solution; on further dilution, it usually becomes cloudy. Specific gravity: 0.917 to 0.934 at 25° C. (77° F.). The optical rotation varies between -38° and -55° in a 100 mm. tube at 25° C. (77° F.).

The peculiar odor of spearmint oil has not yet been definitely associated with any of its constituents. It was for a time thought to be due to an acetic derivative of dihydrocuminyl, but this has recently been denied so far as the oil of American origin is concerned.

Dose, one to six minims (0.06-0.4 mil).

OLEUM MORRHUA. U. S., Br.

COD LIVER OIL
Ol. Morrh. [Oleum Jecoris Aselli]

“A fixed oil obtained from the fresh livers of Gadus morrhua Linne and of other species of Gadus (Fam. Gadidae). Preserve it in a cool place, in well-closed containers, which have been thoroughly dried before filling." U. S. " Cod-liver Oil is the oil expressed from the fresh liver of the cod, Gadus morrhua, Linn., at a temperature not exceeding 85° C. (185° F.), and from which solid fat has been separated by filtration at about -5° C. (23° F.)." Br.

Oleum Hepatis Morrhuae; Cod Oil; Huile da Foie de Morue, Fr. Cod.; Huile de Morue, Fr.; Oleum Jecoris Aselli, P. G.; Leberthran, Stockfischleberthran, Dorschleberthran, Kablianleberthran, G.; Olio di fegato di merluzzo, It.; Aceite de higado de bacalao, Sp.

Gadus morrhua, Linn.; Morrhua vulgaris Storer.—The common cod is between two and three feet long, with brown or yellowish spots on the back. The body is moderately elongated and somewhat compressed, and covered with soft, rather small scales, being quite conspicuous also on the head. Of the fins, which are soft, there are three on the back (dorsal), two anal, and a distinct caudal, and the fin (ventral) under the throat is narrow and pointed. The jaws are furnished with pointed irregular teeth, in several ranks. The gilla are large, with seven rays. This species of cod inhabits the cold waters of the Northern Atlantic, and is especially abundant on the Banks of Newfoundland, where it finds food adapted to its wants.

Besides the common cod, several other species of Gadus, frequenting the seas of Northern Europe and America, contribute to furnish the cod liver oil of commerce. Among these De Jongh mentions Gadus callarias, or dorsch (Morrhua americana of Storer), G. molva, or ling, G. carbonarius, or coal fish, and G. pollachius, or pollack, as affording the oil on the coast of Norway, where from 17,000,000 to 35,000,000. of codfish are annually taken. For an account of the mode of fishing for cod and of preparing the oil practised in Norway and Denmark, see P. J., April, 1877, p. 810; N. R., March, 1878; Ph. Ztg., 1900, 261; Ph. Era, 1904, 111; C. D., 1904, 21.

On the American coast, in addition to the pollack above mentioned, it is obtained also from the hake (G. merluccius) and the haddock (G.
The oil is also largely produced in Newfoundland, Great Britain, Norway, and to some extent in Iceland.

**Preparation.**—Fishermen were for a long time in the habit of collecting this oil, which was largely consumed in the arts, particularly in the preparation of leather. Upon the coasts of Newfoundland, Nova Scotia, and New England, the boats which fish near the shore, being small, soon obtain a load, and, running in to land, deliver their cargoes to persons whose business it is to cleanse and salt the fish. The oil was formerly prepared in the huts of the fishermen, but is now prepared more largely at establishments to which the livers are conveyed in quantities. These are put into a boiler with water, and heated until they are broken up into a pultaceous mass, which is thrown upon a strainer covering the top of a cask or tub. The liquid portion passes, and upon standing separates into two parts, the oil rising to the surface of the water. The oil is then drawn off, and, having been again strained, is prepared for the market. Another and improved method, which has come into use since the extensive employment of the oil as a medicine, is to heat the livers in a wooden butt by means of low pressure steam. The pultaceous mass resulting is drained as before mentioned—the livers themselves containing, besides oil, a considerable portion of aqueous fluid, which passes off with it in the form of emulsion and separates on standing. In the case of the finest American varieties, the oil, which is made only in the winter months, is drawn off by taps from the bottom of the cooking butt, and then put into a cooling house to freeze. The solid frozen mass is put into canvas bags, and submitted, while at a low temperature, to severe pressure, whereby the pure liquid oil is forced out, leaving a whitish, tallow-like mass, composed of stearin and liver debris. This residue is sold to the soap makers, and the oil bottled without further process. The oil thus variously procured was called shore oil, and is the purest kind. The manufacture of refined oil by improved processes is developing rapidly in Newfoundland. (See West. Drug., 1897, 13.)

Formerly the crews of the larger boats, which fish upon banks far from land, cleansed the fish on board, and, throwing the offal into the sea, put the livers into barrels or other receptacles, where they underwent a gradual decomposition, the oil rising to the surface as it escaped from the disintegrating tissue. From this was obtained the so-called "Straits oil" and "banks oil." The method is, however, no longer in vogue and
these form's of the oil are unknown in commerce. For further details see U. S. D., 19th edition, p. 857, and A. J. P., xxiii, 97; xxvi, 1. Large quantities of Norwegian cod liver oil are sold in the United States; the method of extraction depending on the action of steam does not differ greatly from that used in America. Another oil is made by the cold process and B. Rauitz, Ph. Ztg., 1900, 261, furnishes the following account: The fresh livers, separated from the gall-bladder, are placed in a wooden tub, 5 feet in height by 7 feet in diameter, until the tub is nearly full, which is then left exposed to the action of the sun, shining day and night in these high latitudes. After about three weeks the extraction is completed, and, owing to the favorable atmospheric conditions and the evident absence of germs in this far polar region, not the slightest evidence of decomposition manifests itself during this process. The oil runs off pure and simply has the odor characteristic of cod liver oil, and while the "steam cod liver oil" requires refining, that obtained by the "cold process" described is ready for the market as run off from the tubs. This explains why in more southerly latitudes it is impossible to prepare a satisfactory cod liver oil; the cold process is not available, while the steam process does not yield a desirable oil.

The oil is sometimes procured by expression. Donovan recommends the following plan, which affords a very fine oil. The livers, perfectly sound and fresh, are to be placed in a clean iron pot over a slow fire, and stirred until they assume the condition of a pulp, care being taken that the mass be not heated beyond 88.9° C. (192° F.). When this temperature is attained, the pot is to be removed from the fire, and its contents introduced into a canvas bag, through which water and oil will flow into a vessel beneath. After twenty-four hours, the oil is to be decanted and filtered through paper. In this state it is pale yellow, with little odor, and a bland not disagreeable taste.

The chemical composition of the glycerides in cod liver oil is very complicated. Palmitic and stearic acids are present. But the so-called "stearin" separating from cod liver oil on cooling contains some unknown unsaturated compounds, as the cod liver stearin has a very high iodine value (113.4, Heyerdahl; 94, Lewkowitsch). The glycerides of the lower fatty acids, such as acetic, butyric, valeric, and capric acids, stated by various authors to occur in cod liver oil, are according to Salkowski and Steenbich, secondary products due to the putrefaction of the livers. The researches of Heyerdahl (Cod Liver Oil and Chemistry, P. Moller, London, 1895) give as present in the mixed fatty acids about 4 per cent.
of palmitic acid, 20 per cent. of jecoleic acid, \( C_{19}H_{36}O_2 \), and 20 per cent. of therapic acid, \( C_{17}H_{26}O_2 \), morrhuic acid, \( C_9H_{13}O_3N \), and asellic acid, \( C_{17}H_{32}O_2 \), have also been reported. The former is a nitrogenous compound and is supposed to be identical with a basic substance named gaduine which had been reported. Heyerdahl states that in the fresh state cod liver oil contains no hydroxy-acids.

A characteristic constituent of cod liver oil is cholesterol, which can be isolated by saponifying the oil and exhausting the soap with ether. The quantity of cholesterol, according to Alien and Thomson, is from 0.46 to 1.32 per cent. By reaction with ammonia in distillation the oil yields a volatile alkaloid, trimethylamine, \( C_3H_9N \), which has a strong pungent odor, recalling that of herring pickle, of which the same alkaloid is an ingredient. No other official fatty oil yields a similar product. (See A. J. P., xxiv, 343.) Gautier has obtained from cod liver oil the leucamines butylamine, iso-amylamine, hexylamine, and dihydrolutidine, and two fixed bases, aselline, \( C_{25}H_{32}N_4 \), and morrhuine, \( C_{19}H_{27}N_3 \). Aselline was found by its discoverer to be relatively feeble physiologically; morrhuine, of which about 2 milligrammes are believed to exist in a tablespoonful of ordinary cod liver oil, is affirmed to have the properties of exciting the appetite and acting as a powerful diuretic and diaphoretic. Besides these bases, an acid containing nitrogen has been found. This acid, morrhuic acid, \( C_9H_{13}NO_2 \), is probably identical with De Jongh's gaduine. Some have been disposed to ascribe the virtues of cod liver oil to its iodine and bromine, but these are in too small proportion for any effect, and the oil has produced results which have never been obtained from iodine and bromine themselves. The presence of iodine cannot be detected by the usual tests. It is necessary to convert the oil into a soap, and to carbonize this, before it will give evidence of iodine. The proportion never exceeds 0.05 per cent., or 1 part in 2000, and it is by no means certain that iodine is always, if ever, present in pure oil. The proportion of iodine present has been investigated by E. C. Stanford (P. J. [3], xiv, 353), who found it to be extremely minute, ranging from 0.00138 to 0.00433 per cent., with an average of 0.00322 per cent. The oil is capable of dissolving a larger proportion of iodine, and, if any specimen contain more than 0.05 per cent., there is reason to suspect that iodine has been added. Cod liver oil becomes rancid so easily that it contains varying amounts of free fatty acids, frequently showing their presence, even when freshly rendered. Medicinal oils, however, should not show more than from 0.3 to 0.7 per cent. of free acid, calculated as oleic acid.
The so-called active principles of cod liver oil which are found in the market under various names indicative of their origin are usually made by alcoholic extraction of the oil or of the livers themselves. They consist almost entirely of crude fatty acids, no iodine, bromine or phosphorus is detectable, the bases which are sometimes present are in very minute amount, and are probably of the ptomaine type, derived from partly decomposed products. These so-called alcoholic extracts or active principles are themselves scarcely soluble in diluted alcoholic menstrua, such as are used in preparing the so-called "tasteless" preparations of cod liver oil, so that such preparations can possess little or no activity due to cod liver products.

Uses.—Dr. Owen T. Williams (P. J., 1912, p. 806), in discussing the subject of cod liver oil from the pharmacological and biochemic standpoint, states that the idea that the value of cod liver oil is due to the presence of infinitesimal amounts of constituents, such as sulphur, iodine, phosphorus, etc., is not true, but that its peculiar effectiveness in tuberculosis is intimately associated with its food value and is due to the fat itself, which being free from phosphates and consisting almost entirely of unsaturated fatty compounds is a different type of fat from those usually administered or found in foods of the oils on the market. He states that those have the greatest value which have been prepared under the most favorable conditions to prevent oxidation.

The questions of the way in which cod liver oil exercises its beneficent influence in morbid conditions, and to which of its numerous ingredients it owes its therapeutic value, are still matters of difference of opinion. Formerly many attributed its actions to the traces of iodine, phosphorus, or organic bases it contained. This view has, however, been generally abandoned; the extracts containing these principles separated from the oil have not yielded the same results. The therapeutic virtues, therefore, apparently reside in some of the constituents of the oil itself. Whether or not it acts simply as a foodstuff or whether it has some direct influence on the bodily metabolism, is open to dispute. It seems pretty well established that not only is cod liver oil absorbed from the intestinal tract better than any other fats, but that it actually increases the utilization of other forms of fatty foods. An interesting observation has been made by Osborne and Mendel that young rats who have been fed on a diet containing no form of fat but lard until their growth has ceased, will immediately recommence growing when cod liver oil is
substituted for the lard. Williams (B. M. J., 1912, ii, p. 700) believes that
the unsaturated fatty acids have -a direct inhibiting effect on the
growth of the tubercle bacilli which may in part explain its action in
tuberculosis.

Cod liver oil is used in all forms of malnutrition, especially, however, in
various forms of tuberculosis. The old idea that it had a specific
influence in this infection is probably incorrect, but in the reaction
against its use the pendulum has swung too far and it is oftentimes
neglected or even condemned in cases in which it might be well
employed. It is often of service in those types of chronic rheumatism or
gout which are associated with malnutrition, and has been highly
lauded in rickets and other diseases of the bones. It is unique among the
oils in that it is absorbable through the skin, at least by young infants,
in sufficient quantity to have a perceptible influence upon nutrition.

Various measures have been recommended for overcoming the
objectionable taste which is a great obstacle to the wider use of this
remedy. None of these, however, are entirely successful. It is most
frequently exhibited in the form of one of the numerous emulsions upon
the market, of which that with malt extract is one of the best. It is
sometimes given in flexible capsules, but these have the objection that
they can only hold comparatively small doses. Dufourmantel (J. P. C.,
June, 1864) prepared a jelly by dissolving half a drachm of ichthyo-colla
in as little hot water as possible, and then gradually mixing with it a
fluidounce of the oil with four drops of the oil of anise, taking care that
the temperature should not rise above 24° C. (75.2° F.).

Phosphorized cod liver oil may be made by-dissolving one grain of
phosphorus in four fluid-ounces of ood liver oil.

Glyconin Emulsion of Cod Liver Oil.—The formula proposed by Close,
and at one time largely used 'by Andrews, Beard, and others, is as
follows: Cod liver oil, 4 fluidounces; glyconin, 9 fluidrachms; aromatic
spirit of ammonia, 1 fluidrachm; sherry wine, 2 fluidounces, diluted
phosphoric acid, 4 fluidrachms, essence of bitter almond (made by
dissolving 1 fluidrachm of the volatile oil in half a pint of alcohol) 2
fluidrachms. The cod liver oil is to be added very slowly to the glyconin
with brisk stirring, and the other ingredients added in the order named.
Glyconin or Glyceritum Vitelli is made by mixing 45 Gm. of fresh yolk
of egg with 55 Gm. of glycerin.
The following is Carlo Pavesi’s formula for deodorized cod liver oil. Cod liver oil, 1000 parts; ground roasted coffee, 50 parts; animal charcoal, 25 parts. Place the ingredients in a flask, which is to be well closed, and digest on a water bath during the space of one hour; then set it aside for three days, occasionally shaking the contents, and filter. This preparation has; a peculiar coffee flavor, and is quite pleasant to take, 'the only objection being the liability to cultivate in the patient a distaste for using coffee as a beverage. (N. R., Jan., 1876.)

The olein of cod liver oil has been recommended by Arthur Leared, when the oil itself disagrees with the stomach. He has found it to produce the same remedial effects, and to be borne much better. It may be given in the same dose. A solution of quinine in the oil may be made by heating the freshly precipitated alkaloid with the oil, in the proportion of two grains to a fluidounce, by means of a water bath, until the mixture becomes quite clear.

Dose, one to four fluidraehms (3.75-15 mils).

**OLEUM MYRISTICÆ. U. S., Br.**

**OIL OF MYRISTICA**

*Oleum Myristicae [Myristica Oil, Oil of Nutmeg]*

"A volatile oil distilled from the kernel of the ripe seed of Myristica fragrans Houttuyn (Fam. Myristicaceae). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Nutmeg is the oil distilled from Nutmeg, and rectified." Br.

Volatile oil of Nutmeg; Oleum Myristicae Æthereum, Oleum. Nucis Moschati, Oleum Nucistae Æthereum; Huile volatile (Essence) de Muscade, Fr.; Oleum Macidis, P. G.; Aetherisches Muskatol, Aetherisches Muskatnussol, G.

This oil is obtained from nutmegs after powdering them by distillation with water. A better method, according to J. Cloez, is to exhaust the
powder with carbon disulphide or ether, distil off the solvent by means of a water bath, and expose the butter-like residue to a current of steam, the vapor being conveyed into a refrigerated receiver, where it condenses. (J. P. C., Fev., 1864.) Schimmel & Co. (1899) state that oil of nutmeg is made from the light, worm-eaten nuts, of which large quantities are rejected in sorting the different qualities in Holland. The worm most strangely robs the nutmeg of its fat oil, while the essential oil remains in the nut in full. Oil of myristica is colorless or of a pale straw color, limpid, lighter than water, soluble in an equal volume of glacial acetic acid, in alcohol and ether, with a neutral reaction, a pungent spicy taste, and a strong odor of nutmeg. It is officially described in the United States Pharmacopoeia (Ninth Revision) as a colorless or pale yellow liquid, having the characteristic odor and taste of nutmeg. It is soluble in an equal volume of alcohol; also soluble in 3 volumes of 90 per cent. alcohol. Specific gravity: 0.859 to 0.924 at 25° C. (77° F.).

The mixture of volatile and fixed oils obtained by powerfully expressing nutmegs between heated plates may be separated by agitation with water. Upon standing, the latter deposits a crystalline solid, which was called by Playfair myristin. From its solution, in alcohol he obtained it in extremely light crystalline scales, which, after repeated crystallization, had still the odor of nutmeg, were fusible at 31° C. (87.8° F.), soluble in the ordinary menstrua of substances of the same class, and, as just said, insoluble in water. By glacial acetic acid it was first colored red. (P. J., March, 1874, 714.) It was identified as the glyceride of myristic acid, \( C_{14}H_{28}O_2 \), and had, therefore, the formula \( C_3H_5(C_{14}H_{27}O_2)_3 \). Besides the myristin or solid fat, there is present about an equal amount of a liquid fat containing free acid. The essential oil consists chiefly of pinene with probably some dipen-tene, also myristicol, \( C_{10}H_{16}O \), and myristicin, \( C_{11}H_{12}O_3 \), linalool, borneol, terpineol, geraniol, eugenol, and a number of organic acids. Semmler (Ber. d. Chem. Ges., 1890, 1803) examined an oil of myristica of sp. gr. 0.8611 which contained only terpenes; these boiled at about 50° C. (122° F.) under a pressure of 8 mm.

**Uses.**—The oil of nutmeg unites to the common properties of the aromatics considerable narcotic power. It causes in the lower animals dilatation of the pupils, unsteadiness of the gait followed by sleepiness, with slow respiration, and, if the dose be large enough, loss of reflexes. According to Dale (Proc. Royal Soc. Med., Feb., 1909) doses large enough
to produce narcosis in the cats are invariably fatal through fatty degeneration of the liver. A number of fatal cases of nutmeg poisoning have been reported in human beings. The symptoms have been the same as those which are observed in the lower animals. The toxic ingredient is myristicin.

The oil of nutmeg is used to correct the taste of various drugs and as a local stimulant to the gastro-intestinal tract.

Dose, one to five minims (0.06-0.3 mil).

Off. Prep.—Spiritus Myristicae, Br.; Elixir Glycyrrhizae Aromaticum, N. F.; Elixir Pepsini et Rennini Compositum, N. F.; Mistura Oleo-Balsamica, N. F.

OLEUM OLIVÆ. U. S., Br.

OLIVE OIL
Ol. Oliv.

"A fixed oil obtained from the ripe fruit of Olea europaea Linne (Fam. Oleaceae). Preserve it in well-closed containers, in a cool place." U. S. "Olive Oil is the oil expressed from the ripe fruit of Olea europaea, Linn., and refined." Br.

Sweet Oil; Huile d'Olive, Fr. Cod.; Oleum Olivarium, P. G.; Olivenol, G.; Olio di olive, It.; Aceite de olivas, Sp.

Olea europaea L. is one of the leading fruit trees of the world. It is usually from fifteen to twenty-five feet in height, though sometimes much larger, especially in Greece and the Levant. It has a solid, erect, unequal stem, with numerous straight branches, covered with a grayish bark. The leaves, which stand opposite to each other on short footstalks, are evergreen, firm, lanceolate, entire, two or three inches in length, with the edges somewhat reverted, smooth and of a dark green color on their upper surface, whitish and almost silvery beneath. The flowers are small, yellowish-white, and disposed in opposite axillary clusters, about half as long as the leaves, and accompanied with small, obtuse, hoary bracts. The fruit, or olive, is a smooth, oblong or oval drupe, greenish at first, but of a deep violet color when ripe, with a fleshy pericarp, and a very hard nut of a similar shape. Clusters of not less than thirty flowers
yield only two or three ripe olives.

The olive tree, though believed by some to have been originally from the Levant, flourishes at present in all the countries bordering on the Mediterranean, and has been cultivated from time immemorial in Spain, the south of France, and Italy. It begins to bear fruit after the second year, is in full bearing at six years, and continues to flourish for a century. There are forty varieties, distinguished by the form of the leaves and the shape, color, and size of the fruit. The variety longifolia of Willdenow is said to be chiefly cultivated in Italy and the south of France, and the latifolia in Spain. The latter bears much larger fruit than the former, but the oil is less esteemed. The olive is largely cultivated in the north of Africa, especially in the vicinity of Tunis, and considerable quantities of the oil are exported from that city. (P. J., Sept., 1873, 204.) The tree has been introduced into South Australia, and the oil will probably become of commercial importance there.

Olives are cultivated especially in Spain in the district of Cadiz. Two classes are produced, the one known as the "Queen olive," a large olive, which is mostly exported to the United States; the other the Manzanillo, or small olive, which is chiefly consumed in Spain, South America and Cuba. The Spanish production for 1916 amounted to 1,146,599 metric tons of olives and the oil to 207,115 tons. The olive is largely cultivated in California, where it grows luxuriantly. The production of olive oil in the United States in 1916 was 1,336,674 lbs. produced in 22 establishments. The importation of edible olive oil amounted to 7,382,353 gallons.

There are many varieties of the olive grown in California. J. L. Howland, of Pomona, reports the following percentage of oil yielded by each variety as cultivated in California as the result of two years’ test; Pendulina, 21; Rubra, 18.5; Oblonga, 18; Mission, 17.9; Uvaria, 17.5; Nevadillo Blanco, 16.5; Columella, 16.5; Precox, 14; Picholine, 10; Manzanillo, 8.5. For further information concerning the subject the reader is referred to the various Proceedings of the California State Convention of Olive Growers.

Pickled olives, made by soaking green olives first in dilute solution of sodium hydroxide and then in salt water, are largely used as an article of food; the ordjinairy green olive of commerce has been picked before ripening. The ripe olive, which, in the United States, is chiefly obtained
from California, is dark-purple, often almost black, very different in
taste from the ordinary unripe pickled fruit, and is said to contain about
50 per cent. of olive oil, so that it affords an excellent method of
administering fat.

The leaves and bark of the olive tree have an acrid and bitterish taste,
and have been employed as substitutes for cinchona, though with no
great success. Attention has been called, in France, to a hydro-alcoholic
extract of the leaves, as having considerable febrifuge powers. In the
quantity of from ten to twenty grains daily, in divided doses, it has been
found useful in preventing the hectic paroxysms. In hot countries, a
substance resembling the gum-resins exudes spontaneously from the
bark. It was thought by the ancients to possess useful medicinal
properties, but is not now employed. Analyzed by Pelletier, it was found
to contain resin, a little benzoic acid, and a peculiar principle analogous
to gum, which has been named olivile. But the fruit is by far the most
useful product. In the unripe state it is hard and insupportably acrid,
but when macerated in water or an alkaline solution, and afterwards
introduced into a solution of common salt it loses these properties, and
becomes a pleasant and highly esteemed article of diet. Mannite has
been found in all parts of the tree while in vital activity, as in the green
leaves and unripe fruit, but cannot be detected in the yellow fallen
leaves or in the perfectly ripe fruit. (A. J. P., 1866, p. 179.) The pericarp,
or fleshy part of the ripe olive, abounds in a fixed oil, which constitutes
its greatest value, and for which the tree is chiefly cultivated in
Southern Europe. In the unripe olive a peculiar green substance,
together with mannite, has been found by S. de Lutz, both of which
disappear as the fruit ripens, being probably converted into oil, which
now takes their place. (J. P. C., June and Dec., 1862.) The olives ripen
from November to March, and the oil is obtained by first bruising them
in a mill and then submitting them to pressure. The product varies
much, according to the state of the fruit and the circumstances of the
process. The best, called virgin oil, is obtained from the fruit picked
before perfect maturity, and immediately pressed. It is distinguished by
its greenish hue. The common oil used for culinary purposes and in the
manufacture of the finest soaps is procured from very ripe olives, or
from the pulp of those which have yielded the virgin oil. In the latter
case the pulp is thrown into boiling water, and the oil removed as it
rises. An inferior kind, employed in the arts, especially in the
preparation of the coarser soaps, plasters, unguents, etc., is afforded by
fruit which has been thrown into heaps, and allowed to ferment for
several days, or by the marc left after the expression of the finer kinds of oil, broken up, allowed to ferment, and again introduced into the press. The remarks made under the head of Oleum Myristicae in relation to the extraction of the fixed oils by means of solvents are applicable also to olive oil.

The greenish color is owing to the presence of a trace of chlorophyll, and a trace of choles-terin is also extracted by repeated agitation with glacial acetic acid.

Olive oil, when exposed to the air, is prone to become rancid, acquiring a disagreeable odor, a sharp taste, and a thicker consistence; it also loses its color, and the change is promoted by heating it.

It is frequently adulterated with the cheaper fixed oils, especially with cottonseed oil, arachis oil, sesame oil and poppy seed oil; the adulteration may sometimes be detected by reducing the temperature to the freezing point. As other oils are less readily congealed than is the olive oil, the degree of its purity will be indicated by the degree of concretion. Another mode has been indicated by Poutet, founded on the property possessed by mercuric nitrate of solidifying the oil of olives, without a similar influence upon other oils. Six parts of mercury are dissolved at a low temperature in seven and a half parts of nitric acid of the sp. gr. 1.35, and this solution is mixed with the suspected oil in the proportion of one part to twelve, the mixture being occasionally shaken. If the oil is pure, it will be converted after some hours into a yellow solid mass; if it contains a minute proportion, even so small as a twentieth, of poppy or cottonseed oil, the resulting mass will be much less firm, and a tenth will prevent a greater degree of consistence than oils usually acquire when they concret by cold. Lewkowitsch (Chemical Analysis of Oils, Fats, and Waxes, 2d ed., 1898, 462) says that the color reactions proposed by various authors are altogether unreliable and yield no definite results, with the exception of the color test (Baudoin's test, see Oleum Sesami) for sesame oil and perhaps Bechi's and Milliau's or Halphen's for cottonseed oil. For a method of detecting the oil of arachis (ground nut oil) in olive oil, see J. P. C., Jan., 1872, 48. Bulletin 77 (1905), of the Bureau of Chemistry, United States Department of Agriculture, showed that most of the spurious and adulterated olive oil in the United States was of domestic origin and that the oil as imported in original packages was mostly genuine. This has been verified by numerous other investigators during recent years. Since the passage of
the Food and Drugs Act in 1906 it is rare to find a labeled container of olive oil adulterated, although much that is sold in bulk is still found to be spurious. In several states it has been judicially decided that the synonyms "sweet oil" and "salad oil" when unqualified mean olive oil. A low grade of olive oil used for soap making and other technical purposes is imported at a less rate duty than is collected on edible olive oil. The frequent use of such low grade oil for table purposes by those who are not particular about quality and flavor led to the requirement on the Part of the U. S. Treasury Department that such "technical oil" must be denatured for admission. There are three alternative and optional methods of denaturing. They consist in adding to the oil a small portion of oleoresin of capsicum, of oil of rosemary or of kerosene. Arachis oil, which is produced in large quantities in Marseilles, has been found in numerous samples of imported olive oil. According to Tambon, the present-day adulterations do not consist in the addition of a single cheaper oil, but of ingeniously prepared mixtures of different oils in such proportions to each other that on analysis it becomes difficult or impossible to distinguish the adulterated from the genuine oil by the chemical and physical constants accepted for the latter. The chief adulterants are benne, peanut and cottonseed oils. Of these, benne is easily recognized, for peanut oil there is as yet no reliable color reaction, and while Bechi’s reaction may, under certain conditions, answer well for the detection of cottonseed oil, this, under others, has also proven unreliable. (Ph. Ztg., 1904, 104.) According to Kreis and Grob (S. W. P., 1901, 88) Billier’s test is very sensitive. It is carried out by shaking the suspected oil with a solution of resorcinol in benzene and afterwards with nitric acid. Olive oil under these circumstances remains unchanged in color, cottonseed and nut oil become red violet and maw seed oil is turned brown red. Bechi’s test for ascertaining the admixture of cottonseed oil with olive oil has received the approval of the Commission of Florence after most exhaustive experiments, and is as follows: One grain (0.065 Gm.) of silver nitrate is dissolved in fifteen minims (0.9 mil) of water, and six and a half fluidounces (195 mils) of alcohol are added. Two fluidounces (or 60 mils) of ether may be added to render the solution more easily miscible with the oil, but it is not absolutely necessary. A solution of eighty-five parts of amyl alcohol and fifteen parts of rape seed oil is prepared. These reagents should not be kept on hand any length of time. To ten mils of the oil to be examined one mil of the solution of silver nitrate is added, and then from eight to ten mils of the amyl alcohol reagent; the mixture is agitated strongly, and heated on a water bath for five or ten minutes. In the case of pure oils the color...
is unaltered by the addition of the reagents; if cottonseed oil be present, a brownish color or turbidity, varying from a light brown to a deep maroon or black (according to the extent of the adulteration), will be produced. (A. J. P., 1887.) See also the official silver nitrate test. Milliau's test is a modification of the foregoing. If the fatty acids instead of the oil itself are treated with the same reagents, the same reduction of the silver salts occurs and the same brown color as in the Bechi test. Halphen's test with a mixture of amyl alcohol and carbon disulphide containing about 1 per cent. of sulphur in solution is now regarded as the most distinctive for cottonseed oil. For details see the official test.

**Uses.**—Olive oil is nutritious and mildly laxative and is often used in milder cases of chronic constipation, especially when associated with malnutrition. In the form of enema it is often a useful remedy in fecal impaction. It has also been recommended as a remedy for worms, but is of doubtful value. It was formerly largely used in the treatment of gall stones with the idea that it stimulated the secretion of bile. The concretions which were passed by these patients, however, were shown to be masses of hardened soap and it is extremely questionable whether the oil has any real value in this disease. Externally it is useful to soften and relax the skin and to protect it against the action of the air. The most extensive use of olive oil is in pharmacy as a constituent of liniments, ointments, cerates, and plasters.

Dose, as a laxative, from one to two fluid-ounces (30-60 mils).

**OLEUM PIMENTÆ. U. S.**

**OIL OF PIMENTA**

*O. Piment. [Oil of Allspice Pimento Oil]*

"A volatile oil distilled from the fruit of Pimenta officinalis Lindley (Fam. Myrtaceæ), yielding not less than 65 per cent., by volume, of eugenol \([C_{10}H_{12}O_2 = 164.10]\). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Oleum Amomi; Oil of Pimento; Huile volatile (Essence) de Piment de la Jamaïque, Fr.;
Oil of pimenta was deleted from the British Pharmacopoeia 1914.

The berries yield from 1 to more than 4 per cent. of the volatile oil, which as found in commerce is brownish-red, and has the odor and taste of pimenta, though warmer and more pungent. It has a slightly acid reaction.

"Oil of Pimenta is a colorless, yellow or reddish liquid, becoming darker with age and having the characteristic odor and taste of allspice. It is soluble in an equal volume of 90 per cent. alcohol; also soluble in 2 volumes of 70 per cent. alcohol. Specific gravity: 1.018 to 1.048 at 25° C. (77° F.). The optical rotation varies from 0° to -4° in a 100 mm. tube at 25° C. (77° F.).

It consists, like oil of clove, of two distinct portions, one a sesquiterpene, $C_{15}H_{24}$, and the other a phenol, eugenol, capable of extraction by shaking out with alkaline hydroxide solution. They may be separated by distilling the oil from potassium hydroxide solution. After the hydrocarbon is distilled off the phenol may be obtained by liberation from its combination with sulphuric acid and distilling. It is readily recognized as eugenol, so that oil of pimenta is analogous in its constitution to oil of clove (see Oleum Caryophylli). Nothing is known of the constituents which give oil of pimenita its characteristic odor.

Oil of pimenta is given for the same purposes as are the other stimulant aromatic oils.

Dose, from three to six minims (0.2-0.4 mil).

Off. Prep.—Liquor Pepsini Aromaticus, N. F.; Spiritus Myrciae Compositus, N. F.

OLEUM PINI PUMILIONIS. U. S.

OIL OF DWARF PINE NEEDLES
Ol. Pin. Pumil. [Dwarf Pine Oil]

"A volatile oil distilled from the fresh leaves of Pinus montana Miller (Pinus Pumilio Haenke) (Fam. Pinaceae). Preserve it in well-stoppered,
amber-colored bottles, in a cool place, protected from light." U. S.

**Oleum Pini**, Br., 1898; Oil of Pine; Pine Needle Oil; Latchenkieferol, Krummholzol, G.; Oleum templinum, Pumiline.

The British Pharmacopoeia 1898 replaced fir wood oil by making oil of pine official. This was largely due to the investigations of J. C. Umney (P. 3., 1895, 161, 173, 542), who found that the *Pinus Pumilio* (now recognized as *P. montana* Miller) (Mountain Pine) furnished an oil of fairly constant character and superior to that from the *Pinus sylvestris* (Scotch Fir) of the British Pharmacopoeia 1885. It was not included in the Br. 1914 but is recognized by the U. S. IX. It "is a colorless or faintly yellowish oil having a pleasant, aromatic odor, and a bitter and pungent taste. Specific gravity: 0.853 to 0.869 at 25° C. (77° F.). No portion of the Oil distils below 170° C. (338° F.)." It resinifies on exposure, and in medicinal qualities resembles oil of turpentine, but is milder. Pine oil contains laevopinene, leevo-phellandrene, sylvestrene, bornyl acetate, and in the last portions of the distillate, cadinene. (Gildemeister and Hoffmann, *Aetherische Oele*, p. 338.) It is supposed that the pine oil owes its odor to the presence of the acetic ester of borneol, which is ordinarily present to the amount of about 3.5 per cent., and Schimmel & Co. (Schim. Rep. for Oct., 1897) found in a sample of American fir oil as much as 12.1 per cent.

**Uses.**—In medicine it may be employed for many of the purposes for which oil of turpentine has been used. As an expectorant in chronic bronchitis it may be administered by the mouth but is especially prized as an inhalant because of its pleasant odor. For this purpose a few drops may be placed in boiling water and the vapors inhaled. It has also been employed internally in the treatment of chronic rheumatism.

The leaves of the *Pinus sylvestris*, with those of other European firs and pines, by pounding are converted into a fibrous substance, known as fir wool (Fichtenwolle), which is much used in Germany as a local application in chronic rheumatism, the affected part being enveloped in a thick batting of the fir wool, which is also sometimes made into clothing for rheumatic persons. An extract of the leaves is also sold under the name of fir wool extract, for use in rheumatism.

Dose of oil of pine needles five to ten minims (0.3-0.6 mil).
OLEUM RICINI. U. S., Br.

CASTOR OIL Ol. Ricin.

"A fixed oil obtained from the seeds of Ricinus communis Linne (Fam. Euphorbiaceae). Preserve it in well-closed containers." U. S. "Castor Oil is the oil expressed from the seeds of Ricinus communis, Linn." Br.

Huile de Ricin, Fr. Cod.; Oleum esemine Ricini, Fr.; Oleum Ricini, P. G.; Ricinusol, G.; Olio di ricino, It.; Aceite de ricino; Oleum Palmae Christi, Sp.

The castor oil plant, or palma Christi, is a native of India and is now extensively cultivated in the warmer regions throughout the world. In India there are about seventeen different varieties grown which are grouped into two types. (1) The one consisting of tall shrubs or small trees, being usually planted as a shade for other crops and yielding large seeds which contain an abundance of inferior oil. (2) The second type includes the herbaceous annuals, which, while they produce small yields, yield a much better grade of fixed oil.

The following description applies to the plant as cultivated in cool latitudes. The stem is of vigorous growth, erect, round, hollow, smooth, glaucous, somewhat purplish towards the top, branching, and from three to eight feet or more in height. The leaves are alternate, peltate, palmately six to eleven lobed, the lobes acute or acuminate and serrate, smooth on both sides, and of a bluish-green color. The flowers are monoecious, stand upon jointed peduncles, and form a pyramidal terminal raceme, of which the lower portion is occupied by the male flowers, the upper by the female. Both are destitute of corolla. In the staminate flowers the calyx is divided into five oval, concave, pointed, reflected, purplish segments, and encloses numerous stamens, united into fasciculi at their base. In the pistillate the calyx has three or five narrow lanceolate segments, and the ovary, which is roundish and three-sided, supports three linear, reddish stigmas, forked at their apex. The fruit is a roundish, glaucous capsule, with three projecting sides, covered with tough spines, and divided into three loculi, each containing one seed, which is expelled by the bursting of the capsule. This species of Ricinus is a native of the East Indies and Northern Africa, naturalized in the West Indies, and cultivated in various parts of the world, in few countries more largely than in the Middle and Western United States. The flowers appear in July, and the seeds ripen
successively in August and September. A decoction or poultice of the leaves is sometimes used as a local galactagogue, and an infusion has been given internally for a similar purpose. (L. L., Dec., 1859.)

1. THE SEEDS.—These are from 8 to 18 mm. long and 4 to 12 mm. broad, oval, compressed, obtuse at the extremities, very smooth and shining, and of a grayish or ash color, marbled with reddish-brown spots and veins. At one end of the seed is a small yellowish caruncle, from which an obscure longitudinal ridge proceeds to the opposite extremity, known as the raphe. In its general appearance the seed is thought to resemble the insect called the tick, the Latin name of which has been adopted as the generic title of the plant. Its variegated color depends upon a very thin pellicle closely investing a hard, brittle, blackish, tasteless, easily separated shell, within which is the kernel, highly oleaginous, of a white color, and of a sweetish taste succeeded by a slight degree of acrimony. The seeds easily become rancid, and are then unfit for the extraction of the oil, which is acrid and irritating. In 100 parts Geiger found, exclusive of moisture, 23.82 parts of envelope, and 69.09 of kernel. These 69.09 parts contained 46.19 of fixed oil, 2.40 of gum, 20.00 of starch and lignin, and 0.50 of albumen. Henry Bower could find no starch, but separated from the seeds an albuminoid principle, which acted with amygdalin and water like emulsin, producing the odor of oil of bitter almond, though in a less degree. (A. J. P., xxvi, 208.) It is highly probable that it is this principle which, acting as an enzyme on the oily matter of the seeds, gives rise to changes in its nature which render them rancid. (See Olea Fixa, p. 810.) G. J. Scattergood found the odor of castor oil to be developed in the beans when bruised with water, and much more powerfully in those long kept than in the fresh. The water distilled from the seeds has a peculiar nauseous odor, quite distinct from that of the oil. (A. J. P., xxvii, 207.)

Taken internally the seeds are powerfully cathartic, and often emetic. Two are sufficient to purge with great violence, and three have produced fatal gastro-enteritis in the adult. After expression of the oil, and treatment with pure alcohol, Calloud found the residue to be powerfully emetic in the quantity of 30 grains, taken in two doses. (J. P. C., 3e ser., xiv, 190.) According to Guibourt, the toxic property pervades the whole kernel, the integuments being inert. The experiments of Scattergood, who found that the water distilled from the seeds is emetic and cathartic, would seem to show that the active principle is volatile, but the researches of Stillmark indicate that it is an enzyme, new,
which is a so-called phytalbumose and has been obtained as a white 
amorphous powder, and is best dissolved in a 10 per cent. salt solution. 
The aqueous solution of the pure ricin has a neutral reaction. It is a 
violent poison. E. L. Boerner (A. J. P., 1876, p. 481) obtained butyric acid 
by macerating the exhausted marc of the seeds with water until 
decomposed.

2. THE OIL.—This may be extracted from the seeds in three ways: 1, by 
decoction; 2, by expression; 3, by the agency of alcohol or other solvent.

The process by decoction, which has been practised in the East and 
West Indies, consists in bruising the seeds, previously deprived of their 
husk, and then boiling them in water. The oil, rising to the surface, is 
skinned or strained off, and afterwards again boiled with a small 
quantity of water to dissipate the acrid principle. The seeds, it is said, 
are sometimes roasted, to increase the yield. But by a temperature much 
above 100° C. (212° F.) the oil is rendered brownish and acrid, and the 
same result takes place in the second boiling, if care is not taken to 
suspend the process soon after the water has been evaporated; hence it 
happens that the West India oil has generally a brownish color, an acrid 
taste, and irritating properties.

The oil is obtained in this country by expression. The following, we have 
been informed, are the outlines of the process usually employed by those 
who prepare it on a large scale. The seeds, having been thoroughly 
cleansed from the dust and fragments of the capsules with which they 
are mixed, are conveyed into a shallow iron reservoir, where they are 
submitted to a gentle heat insufficient to scorch or decompose them, and 
not greater than can be readily borne by the hand. The object of this 
step is to render the oil sufficiently liquid for easy expression. The seeds 
are then introduced into a powerful hydraulic press. A whitish oily 
liquid is thus obtained, which is transferred to clean iron boilers 
supplied with a considerable quantity of water. The mixture is boiled for 
some time, and, the impurities being skimmed off as they rise to the 
surface, a clear oil is at length left upon the top of the water, the 
mucilage and starch having been dissolved by this liquid, and the 
albumen coagulated by the heat. The latter ingredient forms a whitish 
layer between the oil and the water. The clear oil is now carefully 
removed, and the process is completed by boiling with a minute 
proportion of water, and continuing the application of heat until 
aqueous vapor ceases to rise, and until a small portion of the liquid,
taken out in a vial, continues perfectly transparent when it cools. The
effect of this last operation is to clarify the oil, and to render it less
irritating by driving off the acrid volatile matter. But much care is
requisite not to push the heat too far, as the oil then acquires a
brownish hue and an acrid peppery taste. After the completion of the
process, the oil is put into barrels and sent into the market. See article
on the preparation of castor oil. (A. J. P., 1879, p. 481.) There is reason,
however, to believe that much of the American oil is prepared by merely
allowing it to stand for some time after expression, and then drawing off
the supernatant liquid. One bushel of good seeds yields five or six
quarts, or about 25 per cent. of the best oil. If not carefully prepared, it
is prone to deposit a sediment upon standing, and the apothecary may
find it necessary to filter it through coarse paper before dispensing it.
Perhaps this may be owing to the plan just alluded to of purifying the
oil by rest and decantation. We have been told that the oil in barrels
usually deposits in cold weather a copious whitish sediment, which is
redissolved when the temperature rises. A large proportion of the oil
consumed in the eastern section of the Union has been derived, by the
way of New Orleans, from Illinois and the neighboring States, where it
has been at times so abundant that it has been used for burning in
lamps and for lubricating machinery.

The process for obtaining castor oil by means of alcohol has been
practised in France, but the product is said to become rancid more
speedily than that procured in the ordinary mode. Such a preparation
has been employed in Italy, and is asserted to be less disagreeable to the
taste, and more effective, than the common oil obtained by expression.
According to Parola, an ethero-alcoholic extract and an ethereal or
alcoholic tincture of the seeds operate in much smaller doses than the
oil, and with less disposition to irritate the bowels or to cause vomiting.
(See Am. J. M. S., N. S., xiii, 143.)

Owing to the presence of ricin, “castor pomace” or the oil cake obtained
by the extraction of castor oil, is unfit for animal food. For the process of
removing the poisonous principle see P. J., lxviii, 213.

Italian Castor Oil.—The castor oil plant is cultivated throughout Italy,
but especially in the neighborhood of Verona, where the oil is prepared
with great care and is remarkably free from the peculiar odor and taste
which render this medicine so repulsive to many palates. As it is highly
desirable, for certain purposes, that the oil should be as free from these
properties as possible, it is a point worthy of investigation, why it is that
the Italian oil is superior to most commercial varieties of the oil in these
respects. The following facts in relation to the mode of preparing the oil
practised at Verona, published by H. Groves, of Florence, acquire on this
account a special value. One point of importance is that the seeds are
used fresh, as ‘the oil rapidly becomes rancid in them when kept.
Another fact is that the seeds are entirely deprived of their coating
before being submitted to pressure. This is effected by passing them
between two revolving wooden rollers, with a winnowing machine
beneath, and, to secure the complete absence of integument, they are
afterwards assorted by the hand, all being rejected which are not
perfectly decorticated. They are then put into hempen bags, which are
arranged in layers with a sheet of iron heated to 32.2° C. (90° F.)
between them, so as to enable the oil to flow. Lastly, they are submitted
to pressure by hydraulic presses. The oil which now flows is of the finest
quality. An inferior kind is obtained by pressing the marc at a somewhat
higher heat. An interesting and valuable article on the cultivation of the
209, by Joseph L. Lemberger.

Properties.—Pure castor oil is a thick, viscid, colorless liquid, with little
odor, and a mild though somewhat nauseous taste, followed by a slight
sense of acrimony. As found in commerce it is often tinged with yellow
and has an unpleasant odor, and parcels are sometimes, though rarely,
met with of a brownish color and hot acrid taste. It does not readily
congeal by cold. When exposed to the air it slowly thickens, without
becoming opaque. When exposed to the air in a thin layer, it slowly
dries to a varnish-like film. It is heavier than most of the other fixed oils.
It differs also from most other fixed oils in being soluble in all
proportions in cold absolute alcohol. "Castor Oil is a pale yellowish or
almost colorless, transparent, viscid liquid, having a faint, mild odor,
and a bland, afterwards slightly acrid and generally nauseating taste. It
is miscible with dehydrated alcohol or glacial acetic acid. Specific
gravity: 0.945 to 0.965 at 25° C. (77° F.). Castor Oil is only partly soluble
in petroleum benzin (distinction from most other fixed oils). Castor Oil
produces a clear liquid with an equal volume of alcohol (foreign oils).
Saponification value: not less than 179 nor more than 185 (see Part III,
Test No. 9). Iodine value: not less than 83 nor more than 88." U. S.

Weaker alcohol, of the sp. gr. 0.8425, takes up about three-fifths of its
weight. It has been supposed that adulterations with other fixed oils
might thus be detected, as the latter are much less soluble in that fluid, but Pereira has shown that castor oil has the property of rendering a portion of other fixed oils soluble in alcohol, so that the test cannot be relied on. (P. J.) ix, 498.) Such adulterations, however, are seldom practised in this country. Castor oil is soluble also in ether, and in its weight of glacial acetic acid. Its proximate composition has been repeatedly investigated. The bulk of it is ricinolein, \(C_3H_5(C_{18}H_{33}O_3)_3\), which is the ricinoleic acid \((C_{18}H_{34}O_3)\) glyceride. At the same time it also contains a small quantity of tristearin and of the glyceride of dihydroxy-stearic acid, together with from 0.30 to 0.37 per cent. of unsaponifiable matter. Ricinoleic acid, as obtained from the decomposition of the glyceride, is a viscid oil, which solidifies below 0° C. (32° F.), does not solidify in contact with the air by absorption of oxygen, and is not homologous with oleic or linoleic acid, neither of which is found in castor oil. On warming with 1 part of starch and 5 parts of nitric acid (sp. gr. 1.25) castor oil thickens, owing to the formation of ricinelaidin. From this ricinelaidic acid may be obtained in brilliant crystals. Ricinoleic acid is converted by potassium hydroxide into caprylic alcohol and sebacic acid, with disengagement of hydrogen, and the same products are obtained by the reaction of potassium hydroxide with the oil itself. (See J. P. C., Aout, 1885, 113.) Its purgative property is supposed by Bussy and Lecanu to belong essentially to the oil, and not to any distinct principle which it may hold in solution. According to O. Popp, castor oil differs from most other fixed oils in turning the plane of polarized light to the right. (A. J. P., Aug., 1871, 354; from A. Pharm., 1871.) Various substances containing coloring principles, which they yield to castor oil, produce beautiful fluorescence in that fluid when heated with it, such as logwood, turmeric, camwood, etc. (Charles Horner, P. J., Oct., 1874, p. 282.)

Ricinine is a basic substance, \(C_8H_8O_2N_2\), which is soluble in all of the ordinary solvents and which occurs as colorless crystals optically inactive and neutral in reaction. It is precipitated from aqueous solutions by Mayor's reagent and Wagner's reagent, showing alkaloidal properties thereby. It is not especially toxic.

Buchheim believes the active principle of castor oil to be ricinoleic acid; this has been confirmed by the experiments of Hans Meyer (A. E. P. P., xxviii, 1890), who finds that both pure ricinoleic acid and the ricinoleate of glyc-eryl are active purgatives. Ricinelaidic acid, which Buchheim
believed to be inactive, Meyer finds when given in fine emulsion to act as powerfully as does castor oil.

By the action of concentrated sulphuric acid upon castor oil is formed a valuable product known as "Turkey-red oil," much used in dyeing and printing with madder and alizarine. The water-soluble portion of this Turkey-red oil is ricinoleo-sulphuric acid, $\text{C}_{13}\text{H}_{33}\text{O.O.HSO}_3$. Turkey-red oil acts as a fixing agent, imparting a superior luster to the fiber dyed with its aid.

Castor oil which is acrid to the taste may sometimes be rendered mild by boiling it with a small proportion of water. If turbid, it should be clarified by filtration through coarse paper. On exposure to the air it is apt to become rancid, and is then unfit for use.

Twombly finds that the best method for removing the odor and taste of castor oil is by washing a cold pressed oil several times with boiling water. After separating, the oil is filtered cold very slowly through a thick layer of powdered animal charcoal. Any effort to quicken the method gives poor results.

Commercially ricin has been employed for the detection of pepsin. For details of the method see Solms. (Z. K. M., 1907.)

Uses.—The cathartic effects of castor oil are due to its ricinoleic acid which is split off in the intestinal tract. This, by gentle irritation of the mucous membrane, excites active peristalsis in the upper bowel and probably also somewhat increases the intestinal secretions, although the main action appears to be due to the increased peristalsis. Because of the thoroughness with which it empties the enteric canal there is on the following day an insufficient accumulation of intestinal contents and hence constipation is liable to follow. Because it cleans out the whole alimentary system and that with relatively small degree of irritation, it is especially valuable in conditions of irritation or inflammation of the bowels, as colic, enteritis, or dysentery; on account of the tendency to subsequent constipation it is not to be recommended as a habitual laxative. It is habitually resorted to in cases of pregnant and puerperal women, and is decidedly, as a rule, the best and safest cathartic for children. Infants usually require a larger relative dose than adults.

Externally it is useful for its emollient effects in seborrhœa and other
skin diseases, having the advantage over other oils of being soluble in alcohol.

The dose for an infant is from one to three or four fluidrachms (3.75-11.25-15 mils). It is difficult of administration, from its peculiarly disagreeable taste and from its clamminess and adhesiveness to the mouth. In a few cases, the disgust which it excites is utterly unconquerable by any effort of resolution. A common method of disguising the taste is to give it floating in mint or cinnamon water, but that which we have found, upon the whole, the least offensive is to give it floating on the froth of sarsaparilla syrup mixed with carbonic acid water. Some take it in wine, or spirituous liquors, or the froth of porter, but these are often contra-indicated by their stimulant property. When the stomach is unusually delicate, the oil may be made into an emulsion with mucilage or the yolk of an egg, loaf sugar, and an aromatic water. Tragacanth has been recommended as producing a better emulsion than gum arabic. Tincture of opium may be added in cases of intestinal irritation. A castor oil jelly containing over 90 per cent. of the oil may be made by adding a little stearic acid to the melted oil and then saponifying with a very small amount of an alcoholic solution of sodium hydroxide. This form a jelly-like preparation which may be sweetened with saccharin and flavored with any desired volatile oil. Castor oil may also be beneficially used as an enema, in the quantity of two or three fluidounces (60 or 90 mils), mixed with some mucilaginous liquid. It has been recommended as a local application to the breasts of nursing women, to promote the secretion of milk.

Though prone to become rancid by itself, it loses much of its susceptibility when mixed with lard, and some druggists are said to use it as a substitute for olive oil in ointments and cerates.

Dose, half a fluidounce to two fluidounces (15-60 mils).

**OLEUM ROSÆ. Br.**

**OIL OF ROSE**

"Oil of Rose is the oil distilled from the fresh flowers of Rosa damascena,
Oil of Rose was not admitted to the U. S. P. IX. Fats and oils saturated with the rose perfume have been used since the earliest times. Of the seven thousand or more cultivated varieties of rose only a few are used for the production of oil. The chief of these is *Rosa damascena*, which is supposed to be a hybrid between *B. gallica* and *R. canina*. The volatile oil from this species is commonly called *attar*, *otto*, or *essence of roses*. It is prepared on a large scale in Turkey in Europe, especially in the Balkan Mountains, in Egypt, Persia, Cashmere, India, and other countries of the East, but European and American commerce is at present supplied chiefly from the region constituting the southern slope of the Balkans, and to some extent, from flowers cultivated in Germany. Synthetic Oil of Rose has entered commerce. The Bulgarian production of rose oil for 1913 amounted to 3600 kilos. (Schim. Rep., Oct., 1913.) The roses are gathered in May, and are distilled with the green leaves of the calyx. From thirty to sixty pounds are put into a tinned copper boiler, of the capacity of about 150 pounds, nearly filled with water. The heat is applied over an open fire, and a boiling temperature is continued for two hours, when the first part of the distilled fluid is returned to the boiler, and the process is continued to completion. The oil collects on the top of the water in the receiver, when it is removed from time to time as it accumulates. (P. J., June, 1872, p. 1051.) In the south of France a small quantity of oil of rose is prepared by distilling the petals with water and separating the oil which floats to the surface. The annual output of the oil is small, most of it being marketed in the form of rose water of which over 3,600,000 liters are produced annually. (Schim. Rep., Oct., 1907.)

Oil of rose is furnished in very minute proportion, not more than three drachms having been obtained by Polier in Hindostan, from 100 pounds of the petals. It is usually imported in small bottles, and is very costly. Oil of rose was at one time prepared in Macedonia by crushing the petals in mills, expressing the fluid part, filtering it, and then exposing it to the sun in small glass vessels. The oil gradually collects on the surface of the liquid, and is removed. (Ph. Cb., 1847, p. 783.) Landerer states that at Damascus and in other parts of Asia Minor the oil is prepared by dry distillation. The buds, being collected before sunrise,
are placed in a glass retort, and the distillation is effected by a salt water bath, care being taken so to regulate the heat as not to scorch the petals. The water of the fresh roses and their oil come over together, and the latter, floating on the top, is readily separated.

For an account by R. Bauer of Constantinople, of oil of rose, its production, properties, adulteration, etc., see P. J., Dec., 1867, 286; also A. J. P., 1881, 367.

The experiments of Schimmel are said to indicate that the oil of rose can be prepared from German-grown flowers with commercial success. It is affirmed that the product is superior to the Turkish oil in fineness and strength of aroma, and also that it differs in having a higher congealing point, German oil solidifying at 32° C. (89.6° F.), Turkish oil at 20° C. (68° F.). For an account of its production, see P. J., Aug., 1886; also P. J., 1893, 262.

Oil of rose is nearly colorless, or presents some shade of green, yellow, or red, but, according to Polier, the color is no criterion of its value. Its odor is very powerful and diffusive. At 32.2° C. (90° F.) its sp. gr. is 0.832. Alcohol dissolves it, though not freely when cold. It was officially described in U. S. P. VIII as if a pale yellowish, transparent liquid, having the strong, fragrant odor of rose, and a mild, slightly sweetish taste. Specific gravity: 0.855 to 0.865 at 25° C. (77° F.). The addition of 70 per cent. alcohol precipitates the paraffin hydrocarbons of the Oil, but forms a clear solution with its other constituents, the solution being slightly acid to litmus T.G. The congealing point, when determined according to the following method, should be between 18° and 22° C. (64.4° and 71.6° F.). Introduce about 10 mils of Oil into a test-tube of about 15 Mm. diameter; insert a thermometer in such a manner that it touches neither the bottom nor the sides of the tube. Raise the temperature of the Oil in the tube from 4° to 5° above the saturation point by grasping it in the hand, and shake the tube gently. Allow the Oil to cool, and when the first crystals appear, note the temperature. This is regarded as the congealing point; a second test should be made for confirmation." U. S. VIII.

"A pale yellow or yellowish-green crystalline mass, semi-solid at ordinary temperatures. Strong, fragrant, rose-like odor; taste sweetish. Specific gravity at 30° C. (86° F.) (compared with water at 15.5° C. (60° F.)) 0.854 to 0.862; optical rotation —2° to -4°; refractive index at 25° C.
Oil of rose consists of two portions, one liquid, the other solid at ordinary temperatures. These may be separated by freezing the oil and compressing it between folds of blotting paper, which absorbs the liquid oil and leaves the concrete stearopten. The liquid portion is oxygenated, while the solid portion, which is odorless when pure, consists of a mixture of several hydrocarbons, one of which melts at from 35.5° to 36.5° C. (96°-97.7° F.), and is a paraffin of the formula C$_{16}$H$_{34}$. A sample of oil of rose distilled in Leipsic in 1884 yielded 28 per cent. of this stearopten, an inferior oil distilled in London gave 68 per cent., and a very good oil from the Balkans gave 9.20 per cent. The oxygenated portion consists of the two alcohols, C$_{10}$H$_{18}$O geraniol, and C$_{10}$H$_{20}$O citronellol, the former constituting 75 per cent. of the oil. The rhodinol of Eckart was a mixture of these two alcohols. (Schim. Rep., April, 1898, 40.) While these two alcohols are mainly found in rose oil in the free state, esters of the same are also present in amounts varying from 2.5 to 3.5 per cent. (Gildemeister and Hoffmann, Aetherische Oele, p. 565.) Linalool, citral and phenyl ethyl alcohol are also present in small amounts.

Oil of santal, other volatile oils, fixed oils, spermaceti, etc., are said to be added almost universally as adulterations. The volatile additions may be detected by their not being concrete; the fixed, by the greasy stain they leave on paper when heated. Guibourt has offered certain tests by which he thinks the purity of the oil may be determined. (See A. J. P., xxi, 318.) A. Ganswindt recommends the following tests. Agitate 1 drop of the oil with 45 Gm. of warm water, and sprinkle the solution in a moderately warm room, which will soon be filled with a rose odor, in which foreign odors may be detected without difficulty. An adulteration with a fixed oil produces a permanent grease stain upon paper, and spermaceti is left behind on the evaporation of a few drops of the oil from a watch crystal in a water bath. On mixing a few drops of pure oil of rose with an equal bulk of sulphuric acid, the rose odor is not changed, but oils used for adulteration change their odor, which becomes apparent in the rose odor. Or 5 drops of the oil are mixed in a dry test tube with 20 drops of pure concentrated sulphuric acid; when the mixture is cool it is agitated with 20 Gm. of absolute alcohol, when a nearly clear solution should be obtained, which, heated to boiling, remains clear yellowish-brown on cooling. In the presence of the oil of rose geranium, palmarosa, etc., the alcoholic mixture is turbid, and on
standing separates a deposit without becoming clear. (Seifens. Ztg., 1881, p. 32; A. J. P., May, 1881.) The oil of one of the sweet scented Pelargoniums, perhaps the rose geranium, is much employed in Turkey for the purpose of adulteration. According to Hanbury, who appears to have thoroughly investigated the subject, two substances especially are used in Constantinople for adulterating the oil— one spermaceti, the other a volatile oil produced by certain grasses in the East Indies belonging to the genus Andropogon, large quantities of which are exported from Bombay, partly directly to Europe, partly through the Arabian Gulf, whence it reaches Constantinople. The same oil is imported into London under the name of Turkish essence of geranium, or geranium oil.

Tedermann (Zeit. An. Chem; 1895, 5) reached the conclusion, after much experimenting, that there is no reliable chemical or physical test for the adulteration of oil of rose with geranium oil. The sense of smell, according to Conroy, furnishes the best means of determining the quality; he recommends the dissolving of one drop of oil of rose in twenty drops of alcohol, pouring the solution in one fluidounce of warm water, shaking, and comparing the odor with that of a standard sample treated in the same way. (P. J., 1896, 474; see also C. D., 1897, 53.) O. Helm (A. Pharm., 1885) states that the test with a mixture of five parts of chloroform and twenty parts of alcohol cannot be relied upon, as no separation of crystalline scales took place in four different rose oils which were doubtless genuine. But Fliiekerger, on the other hand, stated that in an experience of many years it had never failed. According to Bauer, the best tests of the purity of the oil are found in its congealing, in five minutes, at a temperature of 12.5° C. (54.5° F.), and its crystallizing, as a solid mass, in light, shiny plates, present everywhere throughout the liquid. These crystals are truncated semi-sided prisms, the angles of which are unequal, and which must be classed in the rhombic system. This stearoptene melted and allowed to cool, crystallizes in a manner so complete that the microscope can readily reveal the presence of foreign substances, such as spermaceti, fatty bodies, wax, and other analogous amorphous substances.

Oil of rhodium (Oleum ligni Rhodii, Aspalathum). This oil was attributed by Lewis to the Convolvulus Scoparius, but according to Holvaes (Perfume and Essential Oil Record, 1911, ii, p. 29) is the product of a species of Genista, either G. canariensis or virgata. It is used to adulterate oil of rose. Guaiac wood oil is also occasionally used for the
same purpose. A factitious oil of rhodium is sometimes sold as a lure for rats and other animals. It is made from oil of copaiba flavored with a trace of oil of rose. The synthetic oil of rose has largely replaced that obtained by distillation.

Oil of rose may be added, as a grateful perfume, to various spirituous preparations for internal use, and to cerates and ointments.

**Off. Prep.**—Unguentum Aquae Rosas, Br.

**OLEUM ROSMARINI. U. S., Br.**

**OIL OF ROSEMARY**

**Ol. Rosmar. [Rosemary Oil]**

"A volatile oil distilled from the fresh flowering tops of Rosmarinus officinalis Linné (Fam. Labiatae), yielding not less than 2.5 per cent. of ester, calculated as bornyl acetate \[C_{10}H_{17}C_2H_3O_2 = 196.16\], and not less than 10 per cent. of total borneol \[C_{10}H_{17}OH = 154.14\]. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Rosemary is the oil distilled from the flowering tops of Rosmarinus officinalis, Linn." Br.

Oleum Rorsimarini, Oleum Anthos; Huile volatile de Romarin, Fr. Cod.; Essence de Romarin, Fr.; Oleum Rosmarini, P. G.; Rosmarinol, G.; Essenza di rosmarino, It.; Esencia de romero, Sp.

The fresh leaves of rosemary yield, according to Baume, 0.26 per cent. of volatile oil, but the percentage is rated much higher by others. Schiimmel & Co. obtained by distillation from, dry French rosemary flowers 1.4 per cent. of oil.

This oil is colorless, with an odor similar to that of the plant, though less agreeable. Its sp. gr. is said to be 0.911, but reduced to 0.8886 by rectification (0.894 to 0.912, U. S.). Buig-net gives the sp. gr. of the rectified oil at 0.896, and states that it is moderately dextrogyrate. Its reaction is neutral. It is soluble in all proportions in alcohol of 0.830, but requires for solution at 17.7° C. (64° F.) forty parte of alcohol of 0.887. (Berzelius.) It is officially described as "a colorless or pale yellow liquid, having the characteristic odor of rosemary, and a camphoraceous taste."
It is soluble in 10 volumes of 80 per cent. alcohol. Specific gravity: 0.894 to 0.912 at 25° C. (77° F.)." U.S.

"Colorless or pale yellow. Odor that of rosemary; taste warm, camphoraceous. Specific gravity 0.895 to 0.920; optical rotation -2° to 4-15°; refractive index at 25° C. (77° F.) 1.463 to 1.473. Soluble in 1 part of alcohol (90 per cent.), and in 5 to 10 parts of a mixture of equal volumes of alcohol (90 per cent.) and alcohol (70 per cent.). Contains not less than 10 per cent. of total alcohols, calculated as borneol, C₁₀H₁₈O, and not less than 1.8 per cent. of esters, calculated as bornyl acetate, C₁₀H₁₇C₂H₃O₂." Br.

Kane gives its sp. gr. at 0.897, its boiling point at 185° C. (365° F.). Kept in bottles imperfectly stoppered, it deposits a stearopten, sometimes amounting, according to Proust, to one-tenth of the oil. Both Gladstone and Fluckiger find that most of the oil consists of a hydrocarbon of the composition C₁₀H₁₆, boiling at 165° C. (329° F.), and Schimmel & Co. (Schim. Rep; Oct., 1889) identified this hydrocarbon as pinene, but there is a smaller fraction boiling at from 200° to 210° C. (392°-410° F.), which at low temperatures deposits a camphor, C₁₀H₁₈O, identified as borneol. Weber examined oil of rosemary in Wallaces laboratory (Ann. Ch. Ph., ccxxxviii, 89), and found that the fraction boiling between 176° and 182° C. (348.8°-359.6° F.) contains cineol, C₁₀H₁₈O. The oil is therefore recognized at present as containing d-pinene, camphene, cineol, borneol (10-15 per cent.), and camphor. According to Fluckiger (A. J. P., 1885, 132), from 20,000 to 25,000 kilogrammes of oil of rosemary were produced in Grasse every year. It is said to be sometimes adulterated with oil of turpentine, which may be detected by mixing the suspected liquid with an equal volume of pure alcohol, the oil of rosemary is dissolved, and that of turpentine left. This oil is stimulant, but is employed chiefly as an ingredient in rubefacient liniments. For a case of fatal poisoning, see A. J. P., xxiii, 286.

Dose, three to six minims (0.2-0.4 mil).

OLEUM SANTALI. U. S., Br.

OIL OF SANTAL
Ol. Santal. [Oil of Sandalwood Santalwood Oil]

"A. volatile oil distilled from the wood of Santalum album Linne (Fam. Santalaceae), yielding not less than 90 per cent. of alcohols, calculated as santalol \( [C_{15}H_{26}O = 222.21] \). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Oil of Sandal Wood is the oil distilled from the wood of Santalum album, Linn." Br.

Oleum Ligni Santali; Oleum Santali Flavi; Oil of Sandal Wood; Huile volatile (Essence) de Santal, Fr.; Oleum Santali, P. G.; Ostindisches Sandelholzol, Santelol, G; Esencia de sandalo, Sp.

Under the name of sandalwood various drugs of diverse origin and character find their way into commerce. Of these, the wood of the Pterocarpus santalinus is described in this book under its official name of Santalum Rubrum, or Red Saunders. Sandal wood bark, which is believed by H. Stieren to be obtained from some species of Myroxylon or Myrospermum, is described as occurring in irregular, more or less smooth or unevenly corrugated pieces, of a light, whitish-cinnamon color, with dark, hard epidermis, and of an agreeable, custard-like odor, and an aromatic, slightly acrid, balsamic, bitterish taste. From it Stieren obtained over fifteen per cent. of a clear substance resembling Peruvian balsam. This bark is used for burning in churches as a substitute for frankincense, and bears no relation to sandalwood proper. (P. J., xv, 680.) A sandal wood is yielded by the Fusanus spicatus (S. Cygnorum) and F. acuminatus (S. acuminatum) of Australia, whence it is shipped in large quantities to China. An oil distilled from this wood, now coming into the European market, is said to be less odorous than the official product.

Other varieties of sandal wood are collected in the Hawaiian Islands from Santalum Freycinetianum Gaud., and S. pyrularium A. Gray; in the Fiji Islands from S. Tasi Seem.; in New Caledonia from S. austrocaledonicum Vieill.; and in Queensland from Eremophila Mitchelli Benth. (Fam. Myoporaceae). For an account of the sandal wood oil industry of Western Australia, see C. D., 1898, 708. For elaborate microscopic descriptions of the sandal-woods, method of obtaining the oily etc., see various papers in the P. J., vol. xvi; also Bull. Pharm.,,
1895, 55. West Australian sandalwood is derived, according to Parry (C. D., 1898, 11), from four species of Santalum, S. Cygnorum Miq. (Fusanus spicatus R. Br.), S. lanceolatum Schlecht (F. spicatus R. Br.), S. acuminatum A.DC. (F. acuminatus R. Br.), and S. persicarum F. Muell. (F. persicarius F. Muell.), Venezuelan sandal wood) the source of the so-called West Indian sandal wood of commerce, is, according to E. M. Holmes (P. J., lxii), obtained from the Schimmelia oleifera Holmes, now recognized as Amyris Balsamifera L. (Fam. Rubaceae). A tree-like shrub, Osyris tenuifolia EngL, belonging to the Santalaceae, and a native of East Africa, is said to yield a wood which is very similar to that of the genuine Indian sandal wood. (P. J., 60.)

The Santalum album, which yields the official oil, is a small tree twenty or thirty feet high, a native of the mountainous portions of India and of, various islands of the Eastern Archipelago, but cultivated in India for the sake of its oil. J. L. Pigot furnished an interesting account of sandalwood cultivation accompanied by a map. (Schimmel's Report, 1900.)

Oil of santal is distilled in the United States, Germany, England, and India, the ordinary method of steam distillation being applied after the wood has been reduced to small particles by chipping or grinding. According to the Indian Pharmacopoeia the yield of oil is about 2.5 per cent. Oil of santal is habitually adulterated, castor oil and other fixed oils being added, and on the continent of Europe by the volatile oil of cedar, which is obtained by distilling the chips left in the making of lead pencils. Chapoteaut (Bull. Soc. Chim., 37, p. 353) found two constituents, one of which he calls santalol, C_{15}H_{26}O, boiling at 310° C. (590° F.), and the other santalal, C_{15}H_{24}O, boiling at 300° C. (572° F.). Both of these are decomposed by distilling over phosphoric anhydride, the one yielding C_{15}H_{24}, boiling point 260° C. (500° F.), and the other C_{15}H_{22}, boiling point 245° C. (473° F.). Sesquiterpenes are also believed to be present in oil of santal. A specimen of oil of santal from South Australia, examined by Schimmel & Co. (Schim. Rep., Oct., 1891), afforded a white crystalline principle, melting at 104° to 105° C. (219.2°-221° F.), which crystallized out in the oil. Parry (P. J., lv, p. 118) found that a portion of the oil was eaponifiable, so he assumed the presence of esters of santalol.

In a number of specimens examined by Holmes (P. J., xvi, 821) the sp.
gr. varied from 0.96 to 0.99. The sp. gr. of the oil of cedar wood, according to Ince, is 0.948. A large percentage of it may be added to the oil of santal without affecting its density sufficiently to be detected. Holmes states that the presence of more than 10 per cent. of the cedar oil can be recognized through the different solubilities of the oils in alcohol. (See P. J., xvi, 820.) R. A. Cripps, after a thorough examination of the oils in the London market (see P. J., 1892, 461), gives this test: "Two drops of the oil added to six drops of nitric acid, sp. gr. 1.5, on a white tile, should give a yellow to bright reddish-brown coloration, without any green, indigo, or violet tint at the edges during five minutes. For complete saponification in alcoholic solution, it requires not more than 1 per cent. of potassium hydrate." (See also A. J. P., 1893, 20; Schim. Rep., Oct., 1893; P. J., 1895, 118; West. Drug., 1897, 262.)

West India oil can be distinguished from the genuine oil by its deviating the plane of polarization to the right instead of to the left. (Pharmacographia.) In two specimens of oil of santal, sp. gr. 0.9649 and 0.9573, F. H. Alcock found strong fluorescence. (P. J., 1886, 923.)

Oil of amyris is the name commercially applied to the "so-called" West Indian sandal-wood oil. This adulterant and substitute (which may be added in amounts up to 5 per cent. without fear of detection) has a sp. gr. of 0.955 to 0.965, an optical rotation of +25° to +30° and contains from 30 to 40 per cent. of alcohols capable of being estimated and calculated as santalol by the official method of assay. One of its principal characteristics in a state of purity is its insolubility in 70 per cent. alcohol. Van-soden (Ph. Ztg., 1900, 45, 878) reports the presence of a sesquiterpene alcohol named by him amyrol, and having the composition C15H26O.

**Uses**—The oil of sandalwood is used largely as a perfume. In medicine its chief use is in gonorrheal urethritis, although it is sometimes employed in chronic bronchitis and cystitis. Its general antibacterial power is comparatively weak, but it has special relations towards certain micro-organisms; thus in the experiments of Jordan (B. M. J., Sept. 13, 1913) twenty minims of oil of sandal wood three times a day had practically no effect on the growth of B. coli in the urine, but markedly retarded the multiplication of staphylococci. It was first recommended in medicine by Thomas B. Henderson who, however, is said to have used the oil of S. myrtifolium.

Dose, five to twenty minims (0.6-1.3 mils), in emulsion, or in capsule,
three or four times a day.

OLEUM SASSAFRAS. U. S.

OIL OF SASSAFRAS
Ol. Sassaf. [Sassafras Oil]

"A volatile oil distilled from the root of Sassafras variifolium (Salisbury) O. Kuntze (Fam. Lauraceae). Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

Huile volatile (Essence) de Sassafras, Fr.; Sassafrasol, G; Esencia de sasafras, Sp.

The proportion of oil yielded by the root of sassafras is variously stated at from less than 1 to somewhat more than 2 per cent. The bark of the root, directed by the U. S. Pharmacopoeia, would afford a larger amount. The usual yield is said by Sharp to be one pound from three bushels of the root. From fifteen to twenty thousand pounds were sent annually, before 1861, to the Baltimore market. (A. J. P., Jan., 1863, p. 53.) The root, chopped fine by machinery, has steam forced through it in a closed tub, and the oil is then distilled in the ordinary way. 800 pounds of unrectified oil are said to be obtained from 40,000 pounds of root. (M. S. Rep., Aug. 26, 1871.) The oil is of a yellow color or colorless, becoming reddish by age. It has the fragrant odor of sassafras, with a warm, pungent, aromatic taste, and a neutral reaction. It is among the heaviest of the volatile oils, having the sp. gr. of 1.094, or 1.087 at 15° C. (59° F.) on the authority of Buignet, who states also that it is very slightly dextrogyrate. Oil of sassafras is officially described in the United States Pharmacopoeia IX as "a yellow or reddish-yellow liquid, having the characteristic odor and taste of sassafras. It is soluble in 2 volumes of 90 per cent. alcohol, forming a solution neutral to litmus. Specific gravity: 1.065 to 1.077 at 25° C. (77° F.). The optical rotation varies from -(-3° to +4° in a 100 mm. tube at 25° C. (77° F.)" U. S.

The most complete investigation of sassafras oil is that made by Power and Kleber in 1896. (Schim. Rep., April, 1896.) They find it to have the following composition: safrol, $C_{10}H_{10}O_2$, about 80 per cent; pinene and phellandrene, $C_{10}H_{16}$, about 10 per cent.; dextrogyrate camphor, $C_{10}H_{16}O$, about 6.8 per cent.; eugenol, $C_{10}H_{12}O_2$, about 0.5 per cent.; a
high boiling portion consisting of cadinene and residue, 3 per cent. They say that the hydrocarbon constituent of sassafras oil, to which Grimaux and Kuotte gave the name of safrene, is, as just stated, a mixture of pinene and phellandrene. Safrol crystallizes well in hard four- or six-sided prisms, with the odor of sassafras. It liquefies at 11° C. (51.8° F.), boils at 232° C. (449.6° F.), has a sp. gr. of 1.106, and is destitute of rotatory power. Variation in the sp. gr. of oil of sassafras may often arise through the congelation and separation of safrol, or through stratification. (LaWall and Pursel, A. J. P., 1898, 340.) Fluckiger ascertained that safrol was one of those remarkable bodies which are capable of existing either in a solid or in a fluid condition long after they have passed their freezing or their melting point. Chemically, it has been found to be the methylene ether of allyl-dioxybenzene. Safrol appears to be widely distributed in the vegetable kingdom, probably existing in the bark of the Mespidodaphne Sassafras, also in the Puchury or Sassafras nuts (see Pichurim Beans), both of Brazil, as well as in the barks of Atherosperma moschatum and of Beilschmiedia obtusifolia of Australia, and in the bark of Doryphora Sassafras of New Caledonia. The bark described by Dymock as that of Beilschmiedia fagifolia, according to the researches of E. S. Hooper, contains saponin and probably is not derived from Beilschmiedia or any other genus of the Lauracceae (P. J., lxxii.) Safrol is now commercially extracted from oil of camphor, and it probably could be obtained from the oil of various species of the genus Cinnamomum. (See P. J., June, 1887.)

**Uses**.—Oil of sassafras is chiefly used for flavoring purposes, but has physiological properties similar to those of the oil of clove and other allied volatile oils, and may be used for similar purposes. It is a powerful antiseptic and has been highly praised by Peck (J. A. M. A., 1899, xxxii, 6) as a dental disinfectant.

A teaspoonful of it produced in a young man vomiting, collapse, somewhat dilated pupils, and pronounced stupor. (Cincinnati Lancet-Clinic, Dec., 3888.) According to the experiments of A. Heffter (Atti Dell' XI. Congres. Med. Internaz., iii, 1894), safrol is slowly absorbed from the alimentary canal, and escapes through the lungs unaltered and through the kidneys oxidized into piperonalic acid. When taken in sufficient dose, it quickly kills by a centric paralysis of respiration, preceded by great depression of the circulation, and when taken in smaller yet toxic amount, it causes death by widespread fatty degeneration of the heart, liver, kidneys, etc. Its isomer, isosafrol, is in
warm-blooded animals much less active as a poison than is safrol, and is chiefly eliminated as piperonalic acid.

Dose, of oil of sassafras, two to six minims (0.12-0.4 mil).

OLEUM SESAMI. U. S., Br.

SESAME OIL
Ol. Sesam. [Teel Oil, Benne Oil]

"A fixed oil obtained from the seeds of one or more cultivated varieties of Sesamum indicum Linne (Fam. Pedaliaceae). Preserve it in well-closed containers." U. S. "Sesame Oil is the oil expressed from the seeds of Sesamum indicum, Linn." Br.

Sesame oil, which was official in the U. S. P. 1890, was restored to an official position by the U. S. P. IX. It is reputed by many pharmacists to resist rancidity better than other fixed oils of its class. It is especially recommended by Prof. Otto Raubenheimer, of Brooklyn. It is officially described in the U. S. Pharmacopoeia as "a pale yellow, oily liquid, almost odorless, and having a bland taste. It is slightly soluble in alcohol, miscible with ether, chloroform, petroleum benzin, or carbon disulphide. Specific gravity: 0.916 to 0.921 at 25° C. (77° F.).

In India, and in the Eastern, African, and North American Divisions of the Empire, Sesame Oil may be employed in making the official Liniments, Ointments, Plasters, and Soaps for which Olive Oil is directed to be used." Br.

Benne Oil, or Teel Oil, is inodorous, of a bland, sweetish taste and a neutral reaction, and will keep long without becoming rancid. Fluckiger found that 76 per cent. of the oil consists of olein, and that the solid portions yield on saponification palmitic, stearic, and myristic acids. Linoleic acid was afterward discovered in the oil. The oil also contains a small quantity of what is probably a resinoid substance, which may be removed by glacial acetic acid or alcohol. It bears some resemblance to olive oil in its properties, and may be used for similar purposes. It is not
a drying oil. Villavecehia and Fabris (Zeit. fur Ang. Chem., 1893, 505) have investigated sesame oil, and find, in addition to the main constituents before mentioned, a higher alcohol of the formula C$_{25}$H$_{44}$O, fusing at 137° C. (278.6° F.), a finely crystallizing substance of the formula C$_{11}$H$_{12}$O$_3$, fusing at 123° C. (253.4° F.), which substance they name sesamin, and a thick uncrystallizable oil, non-nitrogenous, which is the cause of the cherry-red coloration which sesame oil shows with hydrochloric acid and sugar. Tocher (P. J., 1893, 700), after analyzing sesamin and determining its molecular weight by Raoult's method in benzene and glacial acetic acid, maintains that its formula should be C$_{18}$H$_{18}$O$_5$. Tocher, as quoted by Lewkowitsch (Chem. Anal. of Oils, Fats, and Waxes, 2d ed., 389), also believes that the higher alcohol mentioned is cholesterol. When cooled to -3° C. (26.6° F.) it becomes thick, and at -5° C. (23° F.) it congeals to a yellowish-white mass. Concentrated sulphuric acid converts it into a brownish-red jelly. If 5 mils of the Oil be shaken with an equal volume of concentrated hydrochloric acid, the latter will usually assume a bright emerald-green color, especially if the Oil has been exposed for some time to the action of air and light."

Soltzien recommends stannous chloride solution for testing benne oil. (Proc. A. Ph. A., 1897, 195.) According to Schaedler, if one mil of pure benne oil is shaken with one mil of pure hydrochloric acid, sp. gr. 1.125, and one gramme of cane sugar, a rose-red color is developed in fifteen minutes, changing to violet in twenty-five minutes, and increasing in intensity until, after five hours, the acid has assumed a violet color corresponding in intensity to that of a solution of iodine in carbon disulphide or in chloroform. In the case of all other fixed oils, this color reaction does not begin until after three-quarters of an hour. Olive and almond oils containing as little as one-fourth per cent. of benne oil exhibit the reaction in from twenty to twenty-five minutes. The failure of some experimenters to find the reactions available rests upon the fact that they searched for the color in the oil, and not, as they should have done, in the acid. (A. Pharm., 1887, p. 185.) Benne oil was known to the ancient Persians and Egyptians, and is esteemed by the modern Arabs and other people of the East both as food and as an external application to promote softness of the skin. It is laxative in large doses.

The name sesame oil is also sometimes applied to the oil from the cruciferous seed of Camelina sativa.
OLEUM SINAPIS VOLATILE. U. S., Br.

VOLATILE OIL OF MUSTARD
Ol. Sinap. Vol. [Mustard Oil]

"A volatile oil produced synthetically or obtained from the seed of Brassica nigra (Linne) Koch (Fam. Cruciferae) (freed from fatty oil) by maceration with water and subsequent distillation. It yields not less than 92 per cent. of allyl isothiocyanate \([C_3H_5SCN = 99.12]\). The label must indicate whether the Oil has been made synthetically or obtained from black mustard. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S. "Volatile Oil of Mustard is the oil obtained by distillation from black mustard seeds, deprived of most of their fixed oil and macerated in water for several hours." Br.

Oleum Sinapis, Br. 1885; Oleum Sinapis Æthereum; Oil of Mustard; Huile volatile (Essence) de Moutarde, Fr.; Oleum Sinapis, P. G.; Senfol, Aetherisches Senfol, G; Essenza di senape, It.; Esencia de mostaza negra, Sp.

The volatile oil of mustard is usually obtained from seeds which have been deprived of their fixed oil by pressure. It is "a colorless or pale yellow, strongly refractive liquid, having a very pungent and irritating odor and an acrid taste. Great caution should be exercised in smelling this Oil. It should not be tasted except when highly diluted. Specific gravity: 1.013 to 1.020 at 25° C. (77° F.). It is optically inactive. The Oil distills completely between 148° and 154° C. (298.4°-309.2° F.), and both the first and last portions of the distillate have nearly the same specific gravity as the original Oil." U. S.

Will considers volatile oil of mustard to be allyl isosulphocyanate, \(CSNC_3H_5\) (allyl isothiocyanate), it being related to oil of garlic, which is sulphide of allyl. It sometimes contains allyl cyanide and traces of carbon disulphide. (Chem. Gaz., Nos. 62 and 64.) It is the principle upon which black mustard seeds depend for their activity. Volatile oil of mustard was first produced artificially by Berthelot and S. de Luca, by treating allyl iodide, \(C_3H_5I\), with an alcoholic solution of potassium sulphocyanate. It is now extensively manufactured artificially by this method. What first forms is allyl sulphocyanate, which is not identical with, but only an isomer of, mustard oil (allyl isosulphocyanate). But if
the sulphocyanate be heated to its boiling point 161° C. (321.8° F.) the
thermometer sinks rapidly to 150° C. (302° F.), because of the change
into the isosulphocyanate, or mustard oil. This change also takes place
spontaneously at summer temperature. A small quantity of carbon
disulphide seems always to be produced at the same time. Allyl iodide is
procured by treating glycerin with phosphorus iodide. According to
Zeiler, the seeds yield from 0.33 to 0.63 per cent. of the oil. Will and
Koemer in 1863 explained the occurrence of this allyl isosulphocyanate
in mustard oil. It does not occur ready formed in the seeds, but is
produced by the decomposition of a compound, sinigrin (potassium
myronate), occurring there. This sinigrin, \( \text{C}_{10}\text{H}_{18}\text{KNS}_{2}\text{O}_{10} \), is
decomposed under the influence of myrosin, an albuminous ferment
which is present, and yields as products of decomposition \( \text{C}_{3}\text{H}_{5}\text{CNS} \)
(allyl isosulphocyanate), \( \text{HKSO}_{4} \) (acid potassium sulphate), and
\( \text{C}_{6}\text{H}_{12}\text{O}_{6} \) (glucose). "The aqueous solution of myrosin coagulates at 60°
C. (140° F.), and then becomes inactive; hence mustard seed which has
been heated to 100° C. (212° F.), or has been roasted, yields no volatile
oil, nor does it yield any if powdered and introduced at once into boiling

White mustard seeds yield different products. When deprived of fatty oil
they yield to boiling alcohol colorless crystals of sinalbin, an indifferent
substance readily soluble in cold water, but sparingly so in cold alcohol.
According to Will, it breaks up under the action of myrosin into acrinyl
sulphocyanate, \( \text{C}_{7}\text{H}_{7}\text{O.CNS} \), sinapine sulphate, \( \text{C}_{16}\text{H}_{25}\text{NSO}_{9} \), and
\( \text{C}_{6}\text{H}_{12}\text{O}_{6} \). This acrinyl sulphocyanate is a nearly colorless, non-
volatile oil, and the rubefacient and vesicating principle of white
mustard. Sinapine has not yet been isolated, but it is an unstable
alkaloid.

**Uses.**—Oil of mustard is a powerful rubefacient, although liable to
blister unless used with much caution. Diluted, either with alcohol or
lard, it is used as a counter-irritant application in sprains, rheumatism
and like conditions. It may employed in strengths of from two to four per
cent.

The volatile oil of mustard has been employed as a substitute for the
mustard plaster. For this purpose one part may be mixed with sixty
parts of alcohol, and the mixture sprinkled, not too thickly, on pilin or
muslin, covered with waxed paper. It acts speedily and efficiently.
The oil is too pungent and irritating to be given internally.

**Off. Prep.—**Linimentum Sinapis, Br.; Linimentum Sinapis Compositum, N. F.; Spiritus Sinapis, N. F.

**OLEUM TEREBINTHINÆ. U. S.**

**OIL OF TURPENTINE**

*Ol. Tereb. [Turpentine Oil "Spirits of Turpentine"]*

"The volatile oil distilled with water from the concrete oleoresin obtained from *Pinus palustris* Miller or from other species of *Pinus* (Fam. *Pinaceae*). Preserve it in well-closed containers." U. S.

Essence de Terebenthine, Fr. Cod.; Huile volatile de Terebenthine, Fr.; Oleum Terebinthinse, P. G.; Terpentinol, G;

Essenza di trementina, It.; Esencia de trementina, Aceite volatil de trementina, Sp.

This oil is commonly called spirits (or spirit) of turpentine. It is prepared by distillation from our common turpentine, though equally afforded by other varieties. It may be distilled either with or without water, but in the latter case a much higher temperature is required, and the product is liable to be empyreumatic. To obtain it quite pure it should be redistilled from a solution of potassium hydroxide. The turpentine of *Pinus palustris* is said to yield about 17 per cent. of oil, while that from *Pinus Pinaster* affords 25 per cent., and that from *Pinus sylvestris* 32 per cent. Large quantities are distilled in North Carolina. The exportations of turpentine oil from the United States in 1913 amounted to 21,039,597 gallons, valued at $8,794,656; and in 1914, 18,900,704 gallons, valued at $8,095,958.

Pure oil of turpentine is " a colorless liquid having a characteristic odor and taste, both of which become stronger and less pleasant on aging or exposure to the air. Soluble in 5 volumes of alcohol. Specific gravity: 0.860 to 0.870 at 25° C. (77° F.). Optical rotation variable. Distil 200 mils of the Oil, at the rate of two drops per second, from a 300 mil globe flask, having the side tube 8 cm. above the bulb. Ninety per cent. of the Oil distils between 154° and 170° C. (309.2° and 338° F.), the
temperature being read with the mercury column of the thermometer immersed in the vapor. Five mils of the Oil, shaken with an equal volume of potassium hydroxide T.S., does not become darker than a light straw yellow after standing twenty-four hours. Five mils of the Oil, evaporated in a small dish on a water bath, leaves not more than 0.1 Grm. of residue. Three drops of the Oil, placed on unsized, white paper, and exposed to the air, evaporates entirely without leaving a permanent stain (fixed oils). Five mils of the Oil shaken vigorously with an equal volume of hydrochloric acid in a test tube, and allowed to stand for a few minutes, does not produce a brownish or greenish color. Into a flask of from 35 to 50 mils capacity, having a long graduated neck (cassia flask), and containing 25 mils of fuming sulphuric acid, introduce very slowly, drop by drop, with constant shaking 5 mils of Oil of Turpentine, keeping the temperature just below 65° C. (149° F.) by immersion in cold water during the addition of the oil, and for five minutes thereafter, in the meantime frequently agitating the mixture cautiously but vigorously. Then cool, and add sulphuric acid until the flask is filled to the upper graduation on the neck. The clear, reddish, viscous layer, which forms after the dark mass has settled for two hours, does not exceed 1 per cent. of the volume of Oil taken. A large layer of colorless liquid with a refractive index of less than 1.5 at 20° C. (68° F.) shows the presence of mineral oil.

"Caution.—The addition of the Oil of Turpentine to the fuming sulphuric acid, drop by drop, is necessary because of the violence of the reaction." U. S.

As found in commerce, it is always somewhat ozonized, but when perfectly pure it consists exclusively of carbon and hydrogen, and is composed of one or more terpenes, among which are pinene, which constitutes the major portion of the oil, and small amounts of camphene and fenchene with derivatives of pinene. The English or American oil (prepared from *Pinus australis*) is composed of dextro-pinene, while the French oil (prepared from *Pinus Pinaster*) is composed of laevo-pinene. On the other hand, the Russian turpentine contains, in addition to pinene, dipentene (or cinene) and sylvestrene, and the Swedish turpentine contains pinene and sylvestrene. Both the American and the French oil of turpentine boil at about 156° C. (312.8° F.). On heating oil of turpentine to about 300° C. (572° F.) in a sealed tube for several hours it is converted into a polymer called iso-terebenthene, C\textsubscript{20}H\textsubscript{32}, which is so oxidizable that it is converted into a viscid mass on exposure...
to the air for a few hours. It has, moreover, a marked odor, resembling oil of lemon, and boils at 176° to 177° C. (348.8°-350.6° F.). On treatment with a small portion of sulphuric acid, oil of turpentine yields an optically inactive liquid, which boils at 160° C. (320° F.). This is a mixture resolvable by repeated fractional distillation into terebene, C_{10}H_{16}, boiling at 150° C. (302° F.); cymene, C_{10}H_{14}, boiling at 175° C. (347° F.); a small quantity of a camphor-like body, boiling at 200° C. (392° F.); colophene, C_{20}H_{32}, boiling at 318° C. (604.4° F.), and a mixture of semisolid products of higher boiling point. Oil of turpentine absorbs hydrochloric acid gas, forming with it two compounds, one a red dense liquid, the other a white crystalline substance resembling camphor, and hence called artificial camphor. Both are mono-hydrochlorides, C_{10}H_{16}.HCl, but the latter is much more stable, and can be purified by crystallization from alcohol or ether. When turpentine oil is left in contact with concentrated hydrochloric acid a dihydrochloride is formed, C_{10}H_{16}.2HCl. This forms rhombic plates, insoluble in water, and decomposed by boiling with alcoholic potash, with formation of terpinol (C_{10}H_{16})_2.H_2O. (Allen, Corn. Org. Anal., vol. ii, p. 51.) Nitric acid converts oil of turpentine into resin, and by long boiling into terebic acid, C_7H_{10}O_4. Mixed with water and chlorinated lime, and then distilled, the oil yields a liquid which Chautard found to be identical with chloroform (J. P. C., 3e ser., xxi, 88). Turpentine oil and other terpenes unite with water to form crystals of terpin hydrate, C_{10}H_{18}(OH)_2.H_2O, which sublimes often from turpentine oil which has long stood in contact with water and has then been heated to water bath temperature. These crystals are sometimes found in the natural oil also. The presence of alcohol with the water and turpentine oil facilitates their formation. Thus, a mixture of 1 part of nitric acid, 1 part of alcohol, and 4 parts of turpentine oil, spread out in flat dishes, will yield within a few days crystals amounting to 20 per cent. of the oil taken. If these crystals be fused at 116° C. (240.8° F.) they will lose water, and terpin, C_{10}H_{18}(OH)_2, will remain in crystalline needles, fusing at 104° C. (219.2° F.), and boiling at 258° C. (496.4° F.). If either of the hydrates just mentioned be boiled with sulphuric, phosphoric, or glacial acetic acid, terpineol, C_{10}H_{17}OH, will be formed along with hydrocarbons of the formula C_{10}H_{16}, such as terpinene, terpinolene, and dipentene. Terpineol is a thick, colorless, optically inactive liquid, with a pleasant hyacinthine odor and a bitter, feebly pungent taste. It is used extensively in perfumery. Baeyer (Ber. d. Chem. Ges., xxvi, p. 826) has
also prepared the methyl ether of terpineol. Oil of turpentine may be made to yield cymene identical with that existing in the oil of cumin and with that obtained by dehydrating camphor. (See Cumin Seed; also see under Olea Volatilia.) Exposed to the air the oil absorbs oxygen, becomes thicker and yellowish, and loses much of its activity, owing to the formation of resin. A small proportion of formic acid is said also to be generated. Hence the older pharmacopoeias directed the oil to be rectified by distilling it with about four measures of water. But the process is difficult, in consequence of the great inflammability of the vapor, and its rapid formation, which causes the liquid to boil over. In this country it is scarcely necessary, as the recent oil can be obtained at an expense less than that which would be incurred by redistillation on a small scale. Another mode of purifying the oil is to agitate it with one-eighth of alcohol, which dissolves the resinous portion. About one-fifth of the alcohol is retained by the oil, but is readily separated by agitation with water. (See Oleum Terebinthinae Rectificatum.) For tests, see Proc. A. Ph. A., 1893, 156.

C. T. Kingzett has shown that the atmospheric oxidation of turpentine is accompanied by the formation of a body having the formula $C_{10}H_{14}O_4$, which he regards as camphoric peroxide. This substance, by the action of water, is converted into hydrogen peroxide and camphoric acid. The disinfectant known as "sanitas" is produced by passing air through Russian oil of turpentine in contact with warm water. Berthe-lot has shown that oil of turpentine has, under certain conditions, the power, while undergoing oxidation itself, of causing the oxidation of other bodies, to which it imparts a portion of the oxygen absorbed from the air. All that is necessary to give this power to the oil is that soon after distillation it should be exposed to the air, as in a bottle half filled. Sunlight assists, but is not essential to, the change, which goes on even in the dark. The oil retains indefinitely the property thus acquired, but may be deprived of it by exposure to a boiling heat, or by agitation with reducing substances. No other chemical or physical change can be detected in the oil. (J. P. C., May, 1860, 351.)

In this country the oil of turpentine is frequently adulterated with petroleum distillates. The adulteration is best detected by the treatment with sulphuric acid followed by steam distillation of the oil layer remaining above the sludge acid; this treatment with acid and after-distillation to be repeated if necessary. The sulphuric acid will thus completely polymerize the essential oil, leaving the paraffin
hydrocarbons unaffected in the residual oily layer. A shorter and more readily executed test with sulphuric acid, though not so complete, is now given in the official test of the U. S. P. IX.

Considerable quantities of a turpentine obtained by steam distillation of the so-called "lightwood," or resin saturated stumps and pieces of pine wood, have been offered in recent years. For an experimental study of this process and an account of the product see an article by Walker, Wiggins and Smith. (Chemical Engineer, Dec., 1905, p. 78.)

The several species of pine indigenous to California and the slopes of the Sierra Nevada appear to yield quite different products. Wenzel (A. J. P., March, 1872) described, under the name of abietene, an oil distilled from the exudation of the Pinus sabiniana (Nut Pine or Digger Pine). He found it to have a sp. gr. of 0.694, and to boil at 101° C. (213.8° P.). Sadler (A. J. P., April, 1879, p. 176) examined an oil of turpentine from California said to have been obtained from the Pinus ponderosa (Heavy Pine), and found it to agree substantially with Wenzell's abietene. It had a sp. gr. at 16.5° C. (62° F.) of 0.6974, boiled at 101° C. (213.8° F.), and was slightly laevogyrate. It gave negative results when treated with hydrochloric acid for the formation of a hydrochloride, did not form a hydrate, and was not acted upon by sulphuric acid or by nitrosyl chloride. These anomalous results were at once explained by the publication of a study of the abietene which had been made by Thorpe, who showed (A. J. P., 1879, p. 293) that this exudation of the California pine is almost pure heptane, C\textsubscript{7}H\textsubscript{16}, one of the chief constituents of American petroleum. His results were also confirmed by Schorlemmer, who established the identity of the pine heptane with that from petroleum naphtha.

**Uses.**—The oil of turpentine is locally irritant and feebly antiseptic. It is absorbed through the mucous membrane of the alimentary canal and apparently also of the respiratory tract, and is eliminated partly with the breath to which it imparts its own odor, and through the urine to which it gives an odor resembling that of violets. After the ingestion of large doses it produces a sense of warmth in the stomach, accelerates the circulation, and causes a feeling of exhilaration associated with more or less vertigo and a sense of fullness in the head. These symptoms are attended frequently with nausea and frequently, although not always, succeeded by brisk catharsis. When given in small doses frequently repeated it at first stimulates the kidneys, augmenting the
secretion of urine, but if the administration is continued too long it produces painful irritation of the urinary vessels amounting at times to violent strangury and may cause inflammation of the kidney with scanty, albuminous, or even bloody urine. In some constitutions it produces, even when taken internally, an erythematous eruption of the skin. Apparently enough may be absorbed after the inhalation of its vapor to irritate the urinary organs and it is stated that seamer of vessels loaded with turpentine sometimes develop strangury and hematuria.

Most of the therapeutic uses of the oil of turpentine may be attributed to its local irritant influence; thus during its elimination through the mucous membrane of the lungs it acts as a stimulant expectorant and is a useful remedy in chronic bronchitis. In the same way it acts as a stimulant to the kidney and is occasionally used as a diuretic, although this employment has largely passed out of vogue. As a carminative in flatulent colic it is one of the most valuable remedies we possess. It is sometimes of service for its local stimulant action for chronic diarrheas or dysentery. In typhoid fever it is useful not merely in tympanitic states for its carminative effects, but appears to have a direct influence upon the disease itself. According to the observations of Omelchenko (B. G. T., 1891), while it is very feeble in its general antibacterial properties it has a special toxicity for the typhoid bacillus and this organism will not grow in an atmosphere saturated with turpentine vapor.

Oil of turpentine has been used for many years in the treatment of hemoptysis. Of its mode of action we have no knowledge, but there is considerable clinical evidence as to its power to check bleeding; Smith (B. M. J., 1908, i, p. 1218) has even recommended it in purpura hemorrhagica. Among other conditions in which it has been from time to time recommended with more or less reasonableness, are helminthiasis, leucorrhea, chronic rheumatism, amenorrhea, and puerperal fever.

For ordinary purposes the dose is from 5 to 10 minims (0.3-0.6 mil) repeated every two to six hours as may be necessary. As a remedy against the tapeworm, the dose is from one-half to one fluidounce (15-30 mils), followed in half an hour by castor oil; the safety of these large doses is dependent upon the catharsis sweeping out the bowel before the turpentine can be absorbed. It is best administered in the form of an emulsion, although it is frequently given by dropping into a teaspoonful
of sugar. The use of gelatin-icoated capsules is not to be recommended because as soon as the gelatin dissolves in the stomach the undiluted oil comes in contact with the gastric mucosa and is liable to produce an undue degree of irritation. La-cambre gives the following process for making a pill of the oil. Take of oil of turpentine 8 grammes, white wax 20 grammes, powdered sugar 9 grammes, oil of lemon, 2 drops. Melt the wax in the oil of turpentine, pour into a mortar, allow to cool, then add the sugar and oil of lemon, and form a mass to be divided into pills of 0.2 or 0.25 Gm. (3 or 4 gr.) each. Roll them in powdered starch, and keep in a well-stoppered bottle. (J. P. C., Sept., 1873, p. 223.)

In the form of an enema the oil of turpentine is highly useful in obstinate constipation, tympanitis, and seat-worms. From one-half to two fluidounces (15-60 mils) may be added to a pint of warm soapsuds.

Externally it is an excellent rubifacient and is widely employed in the form of liniments in various rheumatic affections as lumbago, arthritis, neuralgias, and the like. For this purpose it should be diluted with from one to three parts of cottonseed or other bland oil. In the form of turpentine stupe it is advantageously employed as a counter-irritant in various deep-seated inflammations, especially of the abdomen. The turpentine stupe is made as follows: a piece of flannel is wrung out in hot water and then dipped in previously warmed turpentine, quickly wrung out and applied to the part. It was also formerly employed as a local application to burns in which it was supposed to allay the pain and promote healing. For this purpose it was usually mixed with the rosin cerate so as to form a liniment capable of being spread upon linen (see Linimentum Terebinthinae).

The following is the formula adopted many years ago by the Philadelphia College of Pharmacy for the rubefacient liniment known as British Oil, which is still in use in some parts of the country as a popular remedy. Oil of Turpentine, Linseed Oil, of each, 8 fl. oz., Oil of Amber, Oil of Juniper, of each, 4 fl. oz., Barbados Petroleum 3 fl. oz., Crude American Petroleum 1 fl. oz.

It has likewise been recommended as a local application in parasitic skin diseases, especially pediculus capitis. The inhalation of its vapors has been employed in chronic bronchitis and has been especially recommended by Skoda in gangrene of the lungs.
For internal use the rectified oil should be used. (See Oleum Terebinthinae Rectificatum.)

Dose, five to ten minims (0.3-0.6 mil).

**OLEUM TEREBINTHINÆ RECTIFICATUM. U. S., Br.**

**RECTIFIED OIL OF TURPENTINE**

*Ol. Tereb. Rect.* [Rectified Turpentine Oil]*

"Rectified Oil of Turpentine is the oil distilled from the oleo-resin (turpentine) obtained from various species of Pinus, and rectified." Br.

Essence de Terebenthine purifiee, Fr.; Oleum Terebinthinae Rectificatum, P. G.; Gereinigtes Terpentinol, G.

"Oil of Turpentine, a convenient quantity; Solution of Sodium Hydroxide, a sufficient quantity. Shake the oil of turpentine thoroughly with an equal volume of solution of sodium hydroxide, and introduce the mixture into a still connected with a well-cooled condenser. Recover about three-fourths of the oil by distillation, separate the clear oil from the water, dry it by shaking with anhydrous calcium chloride, filter and preserve. Keep the product in well-stoppered, amber-colored bottles, in a cool place. Rectified Oil of Turpentine is to be dispensed when oil of turpentine is required for internal use." U. S.

When oil of turpentine is distilled in contact with sodium hydroxide solution, the distillate comes over purified and freed from the decomposition products which give the commercial oil the disagreeable odor and taste which are inseparable by ordinary distillation without alkali; hence this rectified oil is much preferable for internal administration. In the U. S. P. VIII and IX solution of sodium hydroxide was preferred to lime water, which was used in the U. S. P. 1890 to furnish an alkali to combine with resinous substances in commercial oil of turpentine. It has in other respects the same properties as Oleum Terebinthinae. "Rectified Oil of Turpentine is a colorless liquid which
conforms to the properties and tests under Oleum Terebinthinae, specific gravity excepted. Specific gravity: 0.856 to 0.865 at 25° C. (77° F.). Evaporate 5 mils of the Oil rapidly in a tared dish on a water bath; not more than 0.015 Gm. of residue remains. U. S.

"A colorless, limpid liquid. Characteristic odor; taste pungent, somewhat bitter. Specific gravity 0.860 to 0.870; refractive index at 25° C. (77° F.) 1.465 to 1.480. Distils almost entirely between 156° and 180° C. (312.8 and 356° F.), leaving no appreciable residue." Br.

Dose, five to ten minims (0.3-0.6 mil).

**OLEUM THEOBROMATIS. U. S., Br.**

**OIL OF THEOBROMA**

Ol. Theobrom. [Butter of Cacao, Cacao Butter]

"A. concrete fixed oil obtained from the roasted seeds of Theobroma Cacao Linne (Fam. Sterculiaceae)." U. S. "Oil of Theobroma is a solid fat expressed from the seeds of Theobroma Cacao, Linn." Br.

Oleum Theobroma, U. S. 1880; Cocoa butter (improperly); Beurre de Cacao, Fr. Cod.; Oleum concretum e semine Theobromae Cacao, Fr.; Oleum Cacao, P. G.; Kakaobutter, G.; Manteca de coco, Aceite de coco, Sp.

Theobroma Cacao Linn. is a handsome tree, from twelve to twenty feet in height, growing in Mexico, the West Indies, and South America. It is largely cultivated in all tropical countries, particularly in Guayaquil, Venezuela, Mexico, Trinidad, and the Philippines. The fruit is an oblong-ovate capsule or berry, six or eight inches in length, with a thick, coriaceous, somewhat ligneous rind, enclosing a whitish pulp, in which numerous seeds are embedded. These are ovate, somewhat compressed, about as large as an almond, and consist of an exterior thin shell and a brown oily kernel. Separated from the matter in which they are enveloped, they constitute the cacao, or chocolate nuts, of commerce. The cacao tree is usually cultivated in large estates, where it is grown in the shade of the banana or other large plant, and develops its pods from the stem continually, so that the harvest goes on all the time, although the product is greater in the spring and in the autumn. The pods are cut
off, opened, and the beans contained in the glutinous sweet acid pulp are allowed to ferment, during which process the outer integument comes off easily. The beans are finally carefully dried, commonly in the sun, sometimes by means of a steam drying shed. If the sweating process is carried too far, or the beans during drying are wetted by rain, they blacken and are much lowered in value. These blackened beans are sometimes artificially whitened. Cacao beans have a slightly aromatic, bitterish, oily taste, and, when bruised or heated, an agreeable odor. (See Am. Drug., 1897, 311; also Ph. Ztg., 1900, 756.)

The average of a number of analyses of raw nuts gave H. Weigmann (Konig's Nahrungs-und Genussmittel, 3d ed., vol. i, 1019) water, 7.93 per cent.; nitrogenous matter, 14.19 per cent.; theobromine, 1.49 per cent.; fatty matter (cacao butter), 45.57 per cent.; starch and other carbohydrates, 22.92 per cent.; crude fiber, 4.78 per cent.; pure ash, 3.99 per cent.; sand, 0.62 per cent. The coloring matter is probably the result of chemical change, as the fresh seeds are white. Theobromine has been found also in the shells in the proportion of about 1 per cent. (A. J. P., 1862, 509.) The latter impart to boiling water a taste analogous to that of chocolate, but weaker, and are used for making a table beverage.

Theobromine was discovered by Woskresensky, who obtained it by the following method. The kernels are exhausted with water by means of the water bath; the solution is strained through linen, precipitated by lead acetate, and filtered; the filtered liquor is freed from lead by hydrogen sulhide, and evaporated; the brown residue is treated with boiling alcohol, and the liquor filtered while hot. Upon cooling, the theobromine is deposited in the form of a reddish-white powder, which is rendered colorless by repeated crystallization. Keller obtained it still purer by heating the powder between two watch glasses, by which a brilliant white sublimate was obtained. According to O. Donker and C. Treumann, theobromine is contained not only in the cotyledons but also in the shells of the cacao seeds. Four kilos of the latter yielded 13.5 Gm. of pure theobromine. Theobromine is now official.

For Emminger's method of determining theobromine in cacao, see P. J., 1896, 289.

Cocoa or Prepared Cacao is also official in the N. F. IV under the title Cacao Praeparata. The description and tests are as follows:
"A powder prepared from the roasted, cured kernels of the ripe seeds of Theobroma Cacao Linne and of other species of Theobroma (Fam. Sterculiaceae), deprived of a portion of its fat. A brownish powder having a chocolate-like odor and taste, free from sweetness. Extracted with cold water Cocoa yields not less than 14 per cent. nor more than 22 per cent. of soluble matter. Extracted with ether, Cocoa yields not less than 18 per cent. of fat, and the fatty residue does not have a spicy odor or taste. The residue, insoluble in ether, when examined under the microscope, shows not more than 3 per cent. of Cocoa shells, and no foreign starch granules or other foreign substances. Cocoa contains not more than 6 per cent. of crude fiber and not more than 12 per cent. of starch. Cocoa yields not less than 3.5 per cent. nor more than 8 per cent. of ash, which has a distinctly reddish color." N. F.

Cacao, usually but erroneously known as cocoa, is often sold in powder which is sometimes adulterated with various other ingredients such as ground rice, barley flour, sugar, etc. Mixed with hot milk or water it is much employed as a drink. It has the advantages over tea and coffee that it is less stimulating to the nervous system and contains some nutriment. Chocolate is the solid substance expressed from the cacao bean after roasting. In Great Britain and the United States it is usually made, when pure, exclusively of the kernel of the cacao or chocolate nuts, which are first roasted, then deprived of their shells, and lastly reduced, by grinding between heated stones, to a paste, which is moulded into oblong cakes. Sometimes rice flour or other farinaceous substance, with foreign fats, is added, but these must be considered as adulterations. In the compounded form known as sweet chocolate, sugar is generally incorporated with the paste, and spices, especially cinnamon, are often added; vanilla is a favorite addition in America, France, and Spain. The well-known confection known as "milk chocolate" contains either whole or skim milk powder in addition to the foregoing ingredients. The U. S. Department of Agriculture standards for cocoa products are as follows:

"1. Cocoa beans are the seeds of the cacao tree, Theobroma cacao, L. 2. Cocoa nibs, cracked cocoa, is the roasted, broken cocoa bean freed from its shell or husk. 3. Chocolate, plain chocolate, bitter chocolate, chocolate liquor, bitter chocolate coatings, is the solid or plastic mass obtained by grinding cocoa nibs without the removal of fat or other constituents except the germ, and contains not more than three (3) per cent. of ash insoluble in water, three and fifty hundredths (3.50) per cent. of crude
fiber, and nine (9) per cent. of starch, and not less than forty-five (45) per cent. of cocoa fat. 4. Sweet chocolate, sweet chocolate coatings, is chocolate mixed with sugar (sucrose), with or without the addition of cocoa butter, spices, or other flavoring materials, and contains in the sugar- and fat-free residue no higher percentage of either ash, fiber, or starch than is found in the sugar- and fat-free residue of chocolate. 5. Cocoa, powdered cocoa, is cocoa nibs, with or without the germ, deprived of a portion of its fat and finely pulverized, and contains percentages of ash, crude fiber, and starch corresponding to those in chocolate after correction for fat removed. 6. Sweet cocoa, sweetened cocoa, is cocoa mixed with sugar (sucrose), and contains not more than sixty (60) per cent. of sugar (sucrose), and in the sugar- and fat-free residue no higher percentage of either ash, crude fiber, or starch than is found in the sugar- and fat-free residue of chocolate."

Hagenbuch examined several commercial brands of chocolate, and found that the amount of fat or cacao butter present varied from 12 to 45.8 per cent. (A. J. P., 1885, p. 276.) From this it would seem that manufacturers do not uniformly extract the fat from commercial chocolate.

Oil of Theobroma. Cacao Butter.—This is the fixed oil of the chocolate nut. It is extracted either by expression, decoction, or the action of a solvent. Soubeiran recommends that the seeds, previously ground, be mixed with one-tenth of their weight of water and then pressed between hot plates of tinned iron. It is advisable that the heat should not exceed that of boiling water, and even a lower heat will answer. When the method of decoction is used, the cacao should be slightly roasted before boiling. As a solvent, carbon disulphide has been found to answer well, as recommended in the preparation of the expressed oil of nutmeg. (See Oleum Myristicae.) Upon the whole, the method of expression is perhaps preferable. The presence of water in the ground seeds is said greatly to facilitate the process. The expressed oil, now made largely in Philadelphia as a by-product in the manufacture of cocoa, occurs in the shape of oblong cakes, like those of chocolate, weighing about half a pound each. It is "a yellowish-white solid, having a faint, agreeable odor, and a bland, chocolate-like taste. It is usually brittle at temperatures below 25° C. (77° F.). It is slightly soluble in alcohol, soluble in boiling dehydrated alcohol, and freely soluble in ether, chloroform or benzene. Specific gravity: about 0.973 at 25° C. (77° F.). It melts between 30° and 35° C. (86° and 95° F.). Dissolve 1 Gm. of Oil of
Theobroma in 3 mils of ether in a test tube at a temperature of 17° C. (62.6° F.), and immerse the tube into water having the temperature of melting ice. The liquid does not become turbid nor deposit white flakes in less than three minutes; and if the mixture after congealing is again brought to 15° C. (59° F.), it gradually forms a perfectly clear liquid (wax, stearin, or tallow). Saponification value: not less than 188 nor more than 195. Iodine value: not less than 33 nor more than 38."

"A yellowish-white solid, breaking with a smooth fracture. Odor resembling that of cocoa; taste bland, agreeable. Somewhat brittle at ordinary temperatures, but softening at 25° C. (77° F.). Specific gravity 0.990 to 0.998; melting point 30° to 33° C. (86°-91.4° F.); saponification value 188 to 195; iodine value 35.5 to 37.5; acid value not more than 2.0; refractive index at 40° C. (104° F.) 1.4565 to 1.4575. In ascertaining the melting point and specific gravity, seventy-two hours should be allowed to elapse between the time of melting and the time of determining the constants. When 1 gramme is dissolved at 17° C. (62.6° F.) in 3 millilitres of ether in a test-tube, and the tube placed in water at 0° C. (32° F.), the solution neither becomes turbid nor deposits a granular or flaky mass in less than three minutes; and if, after congealing, it is exposed to a temperature of 15.5° C. (60° F.), a clear solution is gradually formed (absence of certain other fats)."

Cacao butter consists chiefly of the glycerides of stearic, palmitic, and lauric acids, and, further, of small quantities of the glycerides of arachidic, linolic, formic, acetic, and butyric acids. The percentage of stearic acid obtainable is from 39.9 to 40.6. Kingzett believes it to contain in addition a peculiar acid which he calls theobromic, and to which he gives the formula C_{64}H_{128}O_{2}, but his results have not been confirmed by subsequent investigators. From its large proportion of stearin, it is one of the best fats for the preparation of stearic acid. It is said to be frequently adulterated with animal fats, which, according to E. Lamhofer, may be detected by attention to the fact that pure cacao butter dissolves entirely in ether or petroleum benzin, separating out in minute granular crystals when immersed in water of 0° C. (32° F.), the liquid portion remaining transparent for 30 or 40 minutes, when the whole solidifies. After solidification, if the oil be kept at a temperature of about 14.4° C. (58° F.), it will redissolve without turbidity. (A. J. P., 1877, p. 238.) G. Ramsperger concludes, as the result of much experimentation, that ether affords the best test of purity (see the official tests).
Uses.—Butter of cacao is used as an ingredient in cosmetic ointments, and in pharmacy for coating pills and preparing suppositories. For the last purpose it is well adapted by its blandness, and the fact that although liquefying at a temperature below that of the body, it is of firm consistence at 21.1° C. (70° F.). It is also valuable for the reason that easily decomposable substances like silver nitrate, potassium permanganate, etc., may be incorporated in it without material change and it is therefore valuable as an excipient. It was chiefly on this account that it was introduced into the U. S. Pharmacopoeia of 1860. It has the emollient properties of the fats and is used to soften and protect chapped hands or lips. F. Bringhurst prepared a lip salve by melting together 28 ounces of cacao butter, 4 ounces of yellow wax, and a drachm, each, of balsam of Peru and benzoic acid, straining, adding perfuming oils, as those of rose, bergamot, and bitter almond, in sufficient quantity, and finally, when nearly cool, an ounce of glycerin. (A. J. P., July, 1867, p. 348.)

OLEUM THYMI. U. S.

OIL OF THYME
Ol. Thymi [Thyme Oil]

"A volatile oil distilled from the flowering plant of Thymus vulgaris Linne (Fam. Labiatae), and containing not less than 20 per cent., by volume, of phenols. Preserve it in well-stoppered, amber-colored bottles, in a cool place, protected from light." U. S.

In the south of France thyme grows wild in great abundance, and is largely collected for distillation. The oil is taken from France to England, and thence reaches this country under the name of oil of origanum, having, probably from its greater cheapness, been substituted for the latter.

Thymus vulgaris is a very common plant, indigenous to Southern Europe, and cultivated in our gardens. It possesses a subcampanulate two-lipped calyx, villous in the throat; corolla limb two-lipped, the upper erect and emarginate, the lower spreading, three-cleft. It is a low under-
shrub, procumbent at the base, with ovate-linear, revolute leaves, the flowers occurring in a whorled spike. The herbaceous portion, which should be gathered when the plant is in flower, has a peculiar, strong, aromatic, agreeable odor, not lost by drying, and a pungent, aromatic, camphoraceous taste. Its active constituent is the volatile oil, which is obtained separate by distillation with water.

The oil, as prepared in Southern France, is, after one distillation, of a reddish-brown color, and called the red oil, but when again distilled is colorless, and in this condition is distinguished as the white oil. Oil of thyme is officially described as "a colorless or red liquid, having a characteristic odor and taste. It is soluble in 2 volumes of 80 per cent. alcohol. Specific gravity: 0.894 to 0.930 at 25° C. (77° F.). It is slightly laevorotatory. Shake 1 mil of the Oil with 10 mils of hot distilled water, and, after cooling, pass the aqueous layer through a wetted filter; the filtrate does not assume a blue or violet color upon the addition of a drop of ferric chloride T.S."

According to Zeller, one pound of the fresh herb yields 45.7 grains of the oil, of the dried herb 38 grains. The oil, as found in commerce, is of a reddish-brown color, and of an odor recalling that of thyme, but less agreeable. Its specific gravity is stated at 0.905, but probably varies, as the oil is a complex body. The more volatile portion, that coming over below 180° C. (356° F.) in distillation, is a mixture of cymene, C_{10}H_{14}, boiling at 175° C. (347° F.), and pinene, C_{10}H_{16}, boiling at 161° C. (321.8° F.). The less volatile and most valuable portion is chiefly thymol, C_{10}H_{14}O, a white crystalline solid, melting at 50° C. (122° F.), and possessing a pungent taste. Carvacrol is also present, at times replacing part or all of the thymol, and in addition linalool and bornyl acetate have been found in small amount. (See Proc. A. Ph. A., 1897, 637.)

The true oil of thyme, according to Bennett (P. J., 1908, lxxx, p. 803), differs from the various oils known commercially under this name, as well as the oils of origanum, in that it contains thymol, while the other oils of thyme contain the isomeric carvacrol. While it is probable that carvacrol has similar therapeutic properties to thymol, it has not been employed in medicine to any considerable extent and is far less well known.

The oil is commonly adulterated with the oil of turpentine, the white oils
being especially impure. The presence of oil of turpentine, according to Duyk (J. P. A., 1899, 41), is due to the fact that the French peasants place in the body of the still as a foundation for the herbs a layer of pine and fir branches.

The annual production of oil of thyme at Grasse, according to Fluckiger (A. J. P., 1885, 132), amounted to 40,000 kilogrammes.

Oil of thyme has been largely replaced in medicine by thymol. According to Camperdon, in doses of from three to fifteen grains (0.2-1.0 Gm.), oil of thyme causes mental excitement, and is a valuable diffusible stimulant in collapse. It is powerfully gennicidal. (See Thymol.)

Dose, three to five minims (0.2-0.3 mil).

**OLEUM TIGLII. U. S. (Br.)**

**CROTON OIL OI. Tigii**

"A fixed oil expressed from the seeds of Croton Tiglium Linne (Fam. Euphorbiaceae). Preserve it in small, well-stoppered bottles, protected from light." U. S. " Croton Oil is the Oil expressed from the seeds of Croton Tiglium, Linn." Br.

Croton Tiglium Willd. is a small tree or shrub, with a few spreading branches, bearing alternate petiolate leaves, which are ovate, acuminate, serrate, smooth, of a dark-green color on the upper surface, paler beneath, and furnished with two glands at the base. The flowers are in erect terminal ra-cemes, scarcely as long as the leaf—the lower being female, the upper male— with straw-colored petals. The fruit is a smooth capsule, about the size of a filbert, with three cells, each containing a single seed.

The tree is a native of Hindostan, Ceylon, the Moluccas, and other parts
of India. It is pervaded by an acrid purgative principle, probably analogous to that found in other plants belonging to the family of Euphorbiaceae. Rumphius says that the root is employed in Amboyna, in the dose of a few grains, as a drastic purge in dropsy, and, according to the same author, the leaves are so acrid that when chewed and swallowed they excite inflammation in the lips, mouth, and throat, and along the whole course of the alimentary canal. The wood is said in small doses to be diaphoretic, in larger, purgative and emetic. But the seeds are the most active part. These have been long used in India as a powerful purgative, and were employed so early as 1630 in Europe, under the names of grana Molucca and grana tiglia. But in consequence of their violent effects they fell into neglect, and had ceased to be ranked among medicines, when, at a comparatively recent period, attention was again called to them by the writings of some English physicians in India. They are now imported for their oil, which is the only official product of the plant. It is probable that most if not all of the Crotons are purgatives. The oil of the Mexican Croton morifolius is said to be mildly purgative in doses of two or three minims (0.12-0.2 mil). In India, under the name of Kowli seeds (Kuli seeds), are used certain beans, which have been referred by authorities to the Croton oblongifolius Roxb., and also to the C. persimilis Muill.Arg. (See Ph, Rev., Oct., 1896.) Kowli seeds reach a length of 2.1 cm., a breadth of 1.2 cm., a thickness of 0.8 cm., ovate, having pointed ends with a marked caruncle. The outer side shows the grayish-brown crusty seed coat with irregular rough longitudinal stripes; the cross-section shows a large endosperm, in the middle the embryo of considerable size with flat cotyledons. Besides the fatty oil and protoplasm, the cells of the endosperm show longitudinally very large aleurone grains, which contain a considerable number of small globoids and badly formed crystalloids.

The seeds of the C. Tiglrium resemble castor beans in size and general structure. They are oblong, rounded at the extremities, with two faces, the dorsal considerably more convex than the ventral, separated from each other by longitudinal ridges, and each divided by a similar longitudinal ridge, so that the whole seed presents an irregular quadrangular figure. Sometimes their ventral surface is flat, with a longitudinal groove, owing to the presence of only two seeds in the capsule, the groove being produced by the central column or axis. The shell is covered with a soft, yellowish-brown epidermis, beneath which the surface is black and smooth, and, as the epidermis is often partially
removed by friction during their carriage, the seeds as they come to us are frequently mottled, and sometimes nearly black. The kernel or endosperm is yellowish-brown, and abounds in oil. In India the seeds are prepared for use by submitting them to slight torrefaction, by which the shell is rendered more easily separable. In the dose of one or two grains (0.065 or 0.13 G-m.) the kernel purges severely.

The oil is obtained by expression from the seeds, previously deprived of the shell. It may also be separated by decoction in water, or by the action of ether, or carbon disulphide, which dissolves the oil and leaves it behind when evaporated. Guibourt recommends, after the first expression, to digest the residue with alcohol at a temperature of 48.8° to 60° C. (120°-140° F.), and then submit it to a new expression. The alcohol is to be separated by distillation from the oil, which is then to be mixed with the first product. Great care must be used, during this distillation, to prevent blistering the unprotected skin of the operator.

Extraction by Ether.—Having washed and dried the seeds, grind them in a coffee mill, and form a soft paste with ether. Introduce this into a narrow percolation tube, and gradually pour ether upon it until it is exhausted. Evaporate the ether by means of a water bath, and filter the remaining oil.

Extraction with Carbon Disulphide.—The seeds, well bruised, are introduced into a bottle with three times their weight of carbon disulphide, well rectified; the mixture is allowed to stand, with frequent agitation, for 24 hours; the whole is then poured upon a cloth and rapidly expressed. The residue is similarly treated with twice its weight of the disulphide, and expressed, after standing as before. The products of the two macerations are mixed, then filtered in a covered funnel, and finally submitted to distillation, by means of a water bath, in a glass retort, at the temperature of 71.1° or 76.6° C. (160° or 170° F.). The disulphide should be recovered by condensing its vapor in a refrigerated receiver. The oil is to be poured into a dish, to show that it contains none of the disulphide, and then introduced into a bottle and closely stoppered.

Properties.—The seeds consist of 64 per cent. of kernel and 36 of envelope. From the seeds imported into England, about 22 per cent. of oil is obtained by simple expression. Guibourt, by his process, obtained 52 per cent. from the kernels, equivalent to about 35 per cent. from the
seeds. Croton oil consists chiefly of the glycerides of stearic, palmitic, myristic, kluric, and oleic acids. There are also present, in the form of glycerin ethers, the more volatile acids, as formic, acetic, isobutyric, and isovalerianic acids. The volatile part of the acid yielded by croton oil contains, moreover, an acid of the oleic series, named by Geuther and Frolich tiglic or tiglinic acid \( C_5H_8O_2 \). It is isomeric with angelic acid, but the melting points (angelic acid 45° C. (113° F.), tiglic acid 64° C. (147.2° F.) and the boiling points (angelic acid 185° C. (365° F.), tiglic acid 198.5° C. (389.3° F.)) differ. Crotonic acid, \( C_4H_6O_2 \), was thought by Schlippe to be present, but later investigation does not confirm the statement. Crotonol, announced by Schlippe as the vesicating principle of the oil, has likewise been found only by the discoverer.

In 1823 John Nimmo, of Glasgow, found that about 45 per cent. of croton oil is soluble in alcohol, the insoluble 55 per cent. being inert. Recent researches have shown that the percentage of soluble portion varies greatly. (See also below.) In this soluble portion Buchheim found an acid, crotonolic acid or crotonoleic acid, which he believed to be the active principle. It is an oily substance, readily decomposable, having the character of a weak acid, and forming various salts. It is freely soluble in alcohol, and is extremely irritant to the skin and the mucous membrane. As pointed out in 1889 by Stilhnark and Robert, croton seeds contain one or more toxic albuminoids, which have been especially studied under the name of croton by Elf strand. Dimstan and Boole (Proc. Roy. Soc. London, lxiii, 1895) found that crotonoleic acid, prepared by the method of Kobert and Hirscheydt, is a mixture of inactive oily acids and a resinous substance having extraordinary power as a vesicant, for which they have proposed the name of croton resin, assigning to it the empirical formula \( C_{13}H_{18}O_4 \), and the molecular formula \( (C_{13}H_{18}O_4)_2 \), or \( C_{36}H_{36}O_8 \). It is described as a hard, pale yellow resin, nearly insoluble in water, and benzene, but readily dissolved by alcohol, ether, and chloroform. It is neither a glyceride, a ketone, nor an aldehyde.

Crotonoleic acid may be readily prepared by treating the portion of croton oil soluble in alcohol with a hot saturated solution of baryta in a water bath, washing the stiff white paste that forms with cold distilled water to remove excess of baryta and barium compounds with acetic, butyric, and tiglic acids, repeatedly treating with water, and lastly agitating with ether, which takes up only the barium oleate and
crotonoleate. The crotonoleate is separated by dissolving it out in alcohol, decomposing it carefully with sulphuric acid, and the solution containing the free acids carefully evaporated. (See also Robert's Arbeiten, 1890, p. 30.)

Crotin is described as a yellowish powder, yielding about 21 per cent. of ash, soluble in water, and possessed of such active poisonous properties that the subcutaneous lethal dose for the rabbit is from 0.05 to 0.08 Gm. per kilo. It attacks the blood corpuscles as well as the centric nervous system, and, indeed, probably affects all protoplasm. (On Some Toxic Albumins, Upsala, 1897.)

Croton oil, as found in commerce, varies greatly in color, from a pale yellow to a dark reddish-brown. That imported from India is usually pale, that expressed in Europe dark, like the deepest-colored sherry. Its consistence is rather viscid, and is increased by time. Its odor is faint, but peculiar, its taste hot and acrid, leaving in the mouth a disagreeable sensation which continues for many hours. It is officially described as "a pale yellow or brownish-yellow, somewhat viscid and slightly fluorescent liquid, having a slight, characteristic odor. Great caution is necessary in tasting it, and it must be handled carefully as it causes a pustular eruption, when applied to the skin. It is slightly soluble in alcohol, the solubility increasing with age; freely soluble in ether, chloroform, or in fixed or volatile oils. It is acid to litmus paper previously moistened with alcohol. Specific gravity: 0.935 to 0.950 at 25° C. (77° F.). When gently heated with twice its volume of dehydrated alcohol, it forms a 1 part each of cacao butter and white wax in a small glass flask, and then adding 2 parts; of croton oil, taking care to close the orifice of the flask at once with a cork. When the mixture begins to get thick, it is poured into cylindrical moulds, where it speedily solidifies. These crayons may be made of a thickness of about 8 or 9 millimeters (1/3 inch), and may be covered with tin foil to protect them from change. (N. R., May, 1877.)

The oil is most conveniently administered in the form of pill. A safe and convenient plan is to make two drops into four pills with crumb of bread, and to give one every hour until they operate. The oil may also be given in emulsion.

Crotonoleic acid has been shown by Kobert to be a very active irritant poison, much more harsh and severe in its influence than croton oil itself. Hirscheydt has found that its salts injected into the blood are
extremely powerful depressants to the circulation. It has appeared in
commerce, but after trial has been found by Hirsheydt to act badly as a
practical remedy. It probably also varies greatly in purity. Ten
milligrams were found by Hirsheydt to be very uncertain in their
purgative effect, while large doses commonly produced excessive gastro-
intestinal irritation. The superiority of croton oil over the acid probably
depends upon the fact that the acid exists in it chiefly in combination
with glycerin, and that this crotonoleic glyceride acts with comparative
kindness because of the slow decomposition and setting free of the acid
which occur in the intestines. This being the case, it follows as a
corollary that old, acid croton oil must be more irritant than the fresher
and nearly neutral oil. Robert has confirmed this conclusion by actual
trial, and asserts that the neutral oil should always be preferred in
practice, and that the acid oil should be rejected.

Dose, one-half to two minims (0.03-0.12 mil).

Off. Prep.—Linimentum Crotonis, Br.; Col-lodium Tigliii, N. F.;
Linimentum Tiglii, N. F.; Linimentum Tiglii Compositum, N. F.; Pilulsa
Aloes, Hydrargyri et Scammonii Compositse, N.F.

Olibanum. Thus. Oliban, Encens, Fr. Wéhrauch, G.—Olibanum, the frankincense of
the ancients, was erroneously ascribed by Linnaeus to Juniperusphoenicea L. (J.
lycia L.). There are two varieties of olibanum, one coming to Europe from the
Mediterranean, and the other directly from Calcutta. These varieties were formerly
considered distinct, but recent researches indicate their common origin. In 1843
Captain Kempthorne, of the East India Company's navy, saw the olibanum tree
growing upon the mountains, on the African coast, between Bunder Maryah and
Cape Guardafui. According to his statement, it grows on the bare marble rocks
composing the hills of that region, with very brittle soil or the slightest fissure to
support it, adhering by means of a substance thrown out from the base of the stem.
This rises forty feet, and sends forth near the summit short branches, covered with a
bright green, singular foliage. The juice, which exudes through incisions made into the
inner bark, has at first the color and consistence of milk, but hardens on exposure. (P.
J., iv, 37.) Sir William J. Hooker says that the African olibanum is derived from
Boswellia papyrifera Hochst., one of the Burseraceae; but thinks it highly probable
that it is furnished by more than one species which has since proven to be the case.
(P.-J., 1859, 217.) Birdwood asserts (Tr. Linn. Soc; xxvii) that no olibanum is obtained
in India, all coming from a coast district of Arabia (the same district as that described
by Theophrastus), and being the product of a new species of Boswellia, B. Carterii
Birdwood. It ia very likely that several species of Boswellia furnish the olibanum of
commerce—viz., B. Carterii Birdw. (furnishes what is known as Luban Bedowi, or
Luban Sheheri), and B. Frereana Birdw. (furnishes Luban Meyeti or Luban Matti). It
appears that the resin of B. papyrifera Hochst. is not gathered at all. The product of
B. serrata Roxb. (known as Salaigugul) is not sent into general commerce, but is employed medicinally only in India.

The Arabian or African frankincense is in the form of yellowish tears, and irregular, reddish lumps or fragments. The tears are generally small, oblong or roundish, not very brittle, with a dull and waxy fracture, softening in the mouth, and bearing much resemblance to mastic, from which, however, they differ in their want of transparency. The reddish masses soften in the hand, have a stronger taste and odor than the tears, and are often mixed with fragments of bark and small crystals of calcium carbonate which are visible under the microscope.

The Indian frankincense, or olibanum, consists chiefly of yellowish, somewhat translucent, roundish tears, larger than those of the African, and generally covered with a whitish powder produced by friction. It has a balsamic resinous odor, and an acrid, bitterish, somewhat aromatic taste. When chewed it softens in the mouth, adheres to the teeth, and partially dissolves in the saliva, which it renders milky. It burns with a brilliant flame and a fragrant odor. Triturated with water, it forms a milky, imperfect solution. Alcohol dissolves nearly three-fourths of it, and the tincture is transparent. Tschirch (Harze und Harzbehalter, 1900, p. 253) has made a thorough study of olibanum and determined all of its constituents with care. Alcohol extracts 72 per cent., consisting of resins 65 per cent. and volatile oil 6 per cent.; water soluble gum, 20 per cent.; bas-sorin, 6-8 per cent.; plant residue, 2-4 per cent. The resins were composed of boswellic acid, C_{32}H_{52}O_{4}, a resin acid of which well crystallized salts were obtained, and olibanoresin, C_{14}H_{22}O, a neutral resin.

In the essential oil Wallach identified l-pinene and dipentene, while the chemists of Schimmel & Co. found in addition phellandrene.

W. F. Daniell has described an odorous product, used as frankincense in Sierra Leone, and obtained from a large tree, growing in the mountainous districts of that region. The tree has been described by J. J. Bennett in P. J., 1854, 251, as Daniella thurifera (Fam. Leguminosae). According to Daniell, the juice exudes through openings made by an insect, and, concreting in connection with the woody particles resulting from the boring of the insect, falls at length to the ground, where it is collected by the negroes. (See A. J., P., xxvii, 338.)

Olibanum is stimulant like the other gum-resins, but is now very seldom used internally. According to Delioux, of Toulon, however, it affords a cheap, efficient substitute for the balsams of Tolu and Peru. It appears to act more favorably when combined with a little soap. Delioux has also obtained advantage from the inhalation of its fumes, when heated, in chronic bronchitis and laryngitis. (B. G. T., Fev. 28, 1861.) It is chiefly employed for fumigation and in unofficial plasters. Dose, fifteen grains (1.0 Gm.), which may be increased to a drachm (3.9 Gm.) or more.

Canadian olibanum is reported by Karl Dieterich to be an American substitute for olibanum, which comes into the drug market from Hamburg. Ita melting point is 77-78° C. (170.6°-172.4° P.). Thus occupies a place about midway between Canadian...
olibanum or gum thus. It ia a valuable American pine resin, which, however, contains no gum and therefore is not a gum resin. (Ph. Zhalle, 1912, 652-654.)

OLIVERI CORTEX. Br.

OLIVER'S BARK [Black Sassafras]

"Oliver's Bark is the dried bark of Cinnamomum Oliveri, Bailey." Br.

The genus Cinnamomum comprises some fifty-four species which are mostly tropical or subtropical evergreen shrubs or trees. They are mostly aromatic and comprise two principal groups: The one yielding camphor, and the other aromatic barks like cinnamon. Oliver's bark was official in the Ind. and Col. Add. for the Australian Colonies and is now official in the British Pharmacopoeia. The tree which furnishes this bark is Cinnamomum Oliveri Bailey (Fam. Lauraceae). It is indigenous to New South Wales and Queensland. It is much of the same habit as the trees yielding cinnamon and the bark is used as a substitute for this spice in the Australian Colonies.

"In flat pieces usually about twenty centimetres long, four centimetres wide and one centimetre thick. Cork greyish-brown, very warty. Inner surface umber-brown, satiny. Fracture short, slightly fibrous. In transverse section, umber-brown, a pale line separating the cork from the inner tissues. Aromatic odor; taste aromatic, bitter, camphoraceous." Br.

Off. Prep.—Tinctura Oliveri Corticis, Br.

Omphalea.—According to Calmody, the government chemist in Trinidad, the seeds of the Omphalea megacarpa (?), Fam. Euphorbiaceae, yield an oil which acts as a brisk cathartic in about three hours after taking, without pain or much continuance. (P. J., Feb., 1898.) Cash (J. P., 1911, xxxvi, p. 488) obtained from the Omphalea triandra seed, 56 per cent. of a pale yellow oil, with a specific gravity of 0.924, which, in doses of 0.5 Gm. exercised a cathartic and diuretic action. From the O. diandra (Megacarpa) he obtained an oil somewhat darker in color than the preceding which had a specific gravity of 0.922 and a saponification value of 190.3, and an iodine value of 119.7. This oil was also a cathartic and diuretic, although somewhat larger doses were required than in the oil from the O. triandra. From the allied plant, Garcia nutans, he also obtained a cathartic oil.

Onion. Cepa.—The bulk of Allium Cepa L. (Fam. Liliaceae) Fourcroy and Vauquelin
obtained from the ordinary onion a white, acrid, volatile oil containing sulphur; also albumen, much uncrystallizable sugar and mucilage, phosphoric acid, both free and combined with lime, acetic acid, calcium citrate, and lignin. The expressed juice is susceptible of the vinous fermentation. The oil is essentially the same in chemical composition as the oil of Allium sativum L., and consists largely of allyl sulphide, \((\text{C}_3\text{H}_5)_2\text{S}\). (See A. Pharm., 1892, 434.) Perkin and Hummel found quercetin in the outer skin of onion bulbs, and the skins have been used in dyeing.

By virtue of its volatile oil the onion taken in moderate quantities is a stimulant to the stomach and promotes digestion, but in large quantities is apt to cause gastric uneasiness. It is slightly rubefacient, said to be diuretic, and belongs among those expectorants to be employed in the advanced stages of subacute bronchitis or in chronic bronchitis. Although the onion has been asserted to exercise a marked influence on nitrogenous metabolism it can scarcely be doubted that any apparent influence which it may exert in the direction spoken of is secondary to its action upon digestion.

Onion poultices are somewhat effective as a counter-irritant and nerve stimulant in cases of bronchitis or pneumonia in young children, with nervous symptoms. According to M. V. Pog-relaky, a decoction made with the outer reddish skin of the bulb is widely used in Russia for the production of abortion. He attributes the ecbolic effect to the presence of allyl sulphide. One or two tumblerfuls of the concentrated dark brown or dark red infusion are taken at a dose.

Ononis. Rest Barrow. Ononis spinosa L.— The roots are official in several European Pharmacopoeias under the title of "Radix Ononis." The plant is common throughout Europe. The root is more or less flattened, twisted and slightly branched; from 10 to 60 cm. in length and 1 to 2 cm. in thickness; externally it is grayish-brown, deeply wrinkled; the odor resembles that of licorice, the taste being sweetish, mucilaginous, afterward bitter. Reinsch obtained from this plant ononin, \(\text{C}_{25}\text{H}_{26}\text{O}_{11}\), a glucoside. Onocerin, a di-secondary alcohol, \(\text{C}_{26}\text{H}_{42}(\text{OH})_2\), was isolated by Thoms, who proposed to change its name to onocol. (A. Pharm., 1897, 28.) Cow (A. E. P. P., 1912, IXIX, p. 393) has found that in the dog, the aqueous extract of ononis exercises a diuretic effect approaching in power that of juniper, which conclusion has been clinically confirmed by Breitenstein. It also contains tannin.

Ophioxylon. Radixmustelae. Rauwolfiase-pentina Benth. (Ophioxyylonserpentinum L.) (Fam. Apocynaceae.)—In the root of this plant, which is used in East India as a purge and anthelmintic, Wefers-Bettink found a yellow crystalline principle, ophioxylin, melting at 72° C. (161.6° F.), and possessing the formula \(\text{C}_{16}\text{H}_{12}\text{O}_{6}\); also a volatile oil. (A. J. P., 1890.) It is widely used in India as an antidote against bites of serpents, stings of insects, etc.

Opopanax.—A concrete juice or oleo-gum-resin of Opopanax chironium Kch. (Pastinaca Opopanais li., Fam. Umbelliferae). This species of parsnip has a thick, yellow, fleshy, perennial root, which ends up annually a strong branching stem, rough near the base, about 2 cm. in thickness, and from 1 to 3 m. in height. The
leaves are variously pinnate, with long sheathing petioles, and large, oblong, serrate leaflets, of which the terminal one is cordate, others are deficient at their base upon the upper side and the whole are hairy on their under surface. The flowers are small, yellow, and form large flat umbels at the termination of the branches. The plant is a native of the Levant, and grows wild in the south of France, Italy and Greece. When the base of the stem is wounded, a juice exudes, which, when dried in the sun, constitutes the opopanax of commerce. Some authors state that it is obtained from the root. A warm climate appears necessary for the perfection of the juice, as that which has been collected from the plant in France, though similar to opopanax, is of inferior quality. The drug is brought from Turkey. It is said to come also from the East Indies; but Ainslie states that he never met with it in any Indian medicine bazaar. The method of its production is not known with any certainty.

It is sometimes in tears, but usually in irregular lumps or fragments, of a reddish-yellow color, speckled with white on the outside, paler within, and, when broken, exhibiting white pieces intermingled with the mass. Its odor is strong, peculiar, and unpleasant, its taste bitter and acrid. Its sp. gr. is 1.622. It is inflammable, burning with a bright flame. It is a gum-resin, with an admixture of other ingredients in small proportion. Pelletier found in it gum, starch, wax, malic acid, lignin, a volatile oil, and traces of caoutchouc. Subsequently, Tschirch found opopanax to consist of resin, 19 per cent., ethereal oil, 6.5 per cent.; gum and plant tissues, 70 per cent.; water and loss, 4.5 per cent. (A. Pharm., 1895, 209.) Schimmel states that the oil consists of an alcohol with a sesquiterpene as the chief constituent. (Schim. Rep., 1904, 67.) Water by trituration dissolves about one-half of the gum-resin, forming an opaque milky emulsion, which deposits resinous matter on standing, and becomes yellowish. Both alcohol and water distilled from it retain its flavor; but only a very minute proportion of oil can be obtained in a separate state. Opopanax was formerly employed, as an antispasmodic and deobstruent, in hypochondriasis, hysteria, asthma, and chronic visceral affections, and as an emmena-gogue; but it is now scarcely ever used. Dose, ten to thirty grains (0.65-2.0 Gm.).

**Opuntia.** Opuntia vulgaris (Mill.). (Fam. Cactaceæ) Prickly Pear. Figue de Barbarie, Fr. IndischeFèige, G.—A common cactus composed of flattened, prickly or spinose-jointed stems, and occurring in sandy soil from Nantucket to South Carolina. For analyses of fruit of this cactus, see A. J. P., 1884, 3, and 1896, 170. It is of a lighter color than minium, and is used as a pigment.

**Oreodaphne.** Umbellularia californica (Hook et Arnott) Nutt. (Fam. Lauraceæ)—The California Bay Laurel is an evergreen tree of considerable size, rather abundant throughout the State. Its wood is much prized on account of the beauty of its grain and its immunity from the attacks of insects. The leaves yield about 4 per cent. of a neutral, straw-colored, limpid, volatile oil, which has a warm camphoraceous taste and a pungent aromatic odor, resembling somewhat that of a mixture of oils of nutmeg and cardamom. It is soluble in 1000 parts of water, and in alcohol and ether in all proportions. It is said, when inhaled, to cause dizziness and headache. Its chemical characters have been studied by John P. Heamy. (A. J. P., 1875, 105.) He finds it to consist of a pure hydrocarbon, sp. gr. 0.894, boiling at 175°
C. (347° F.), and an oxygenated, pungent portion, which boils at 210° C. (410° F.). This he calls oreodaphnol. Oreodaphene was obtained by distilling oreodaphnol with glacial phosphoric acid. For the reactions, see Heamy's paper.

**Organotherapeutic Extracts.**—The use of the extracts of various organs as medicinal agents is one of the oldest known therapeutic measures. Thus, Pliny mentions the use of the brains of animals in the treatment of jaundice, and it is probable that this drug was used also by the ancient Egyptians. The modern use of organic extracts may be dated from the investigations of Brown-Sequard. (A. de P., 1889, p. 51.) Since this time extracts of nearly every portion of the body have been tested therapeutically. From many of these extracts there is no reason to expect any beneficial influence in diseased conditions. On the other hand, it is impossible to deny that many of the glandular organs of the body deliver their secretions directly into the blood stream, and that these secretions are essential for the maintenance of health and it is a priori not unreasonable to expect that the artificial administration of these secretions will have a beneficial influence in certain diseased conditions. It is among the last group of drugs that opotherapy finds a justification for its existence. Three of these organs of internal secretion have achieved so fixed a place in medicine as to have received official recognition, namely, the hypophysis, the suprarenal capsule, and the thyroid-gland. Although the pancreas probably also delivers an internal secretion, the pancreatin of the Pharmacopoeia represents an external and not an internal secretion of the pancreatic gland. There are some which have firmly established their claims, although not yet included in the U. S. P., but the great mass of them are still in the experimental stage.

**Cerebrin. Cerebrum Siccum.**—The dried brain substance has been used by Babes and others (K. T. W., 1900) in the treatment of neurasthenia, insanity and epilepsy. The treatment, however, has no scientific foundation. Wasaermann (B. K. W., 1898, p. 4) has shown that an emulsion of the brain is capable of neutralizing the tetanus toxin. It has subsequently been shown also that this holds true for strychnine and morphine. On this evidence an emulsion of the dried brain substance has been used in the treatment of tetanus and rabies. (Kowalski, K. T. W., 1900, No. 5.) The dose of the dried brain substance is 30 to 60 grains (2-4 Gm.).

**Bronchial Gland. Glandula Bronchialis Siccum.**—The dried bronchial gland has been used in the treatment of tuberculosis and chronic bronchitis, but with no very encouraging results. The dose is 1 to 3 grains (0.06-0.18 Gm.).

**Ciliary Body. Corpus Ciliarae.**—The extract of the ciliary body, as well as the vitreous body has been used in sympathetic ophthalmia by Dor and by Wecker. (Annals d'Oculistique, August, 1902.) Oculin is a name applied to a glycerin extract of the ciliary body and vitreous humor.

**Kidneys. Renes Siccum.**—There is considerable evidence that the kidneys supply an internal secretion, but that failure of this internal secretion is the cause of uremia, as claimed by some, has certainly not been established. Although a number of authors have claimed beneficial results from the administration of the kidney substance in nephritis and uremia, it is probable that the treatment is useless. The dose
recommended is from four to fifteen grains (0.26-1.0 Gm.) several times daily. Nephritin is a proprietary extract of this class.

Lungs. Pulmones Sicci.—The dried substance of the lung has been used by Brunei (Press. Med., 1898, p. 22) in tuberculosis, emphysema, and asthma. The dose is seventy-five grains (5 Gm.) a day.

Liver. Hepar Siccum.—Gilbert and Karno (S. M., 1897, p. 184) believe that there is some substance in the liver which leads to a retention of the glycogen out of the blood in the liver, and that the administration of this substance is of benefit in the treatment of diabetes. Gyr asserts that the extract of the liver is also useful in hepaticcirrhosis (R. M. S. R., June 20, 1908), and in hemeralopia by Roncagliolo (Med. Klin; 1905, p. 909). The dose of the dried liver is one-half to one ounce (15-31 Gm.) per day.

Mammary Gland. Mammae Siccatae.—On the theory that there is some relation between the uterus and the mammary gland, the latter has been used by Shober (Phila. M. J., Nov., 1899) and others, in the treatment of menorrhagia, fibromata, dysmenorrhea, etc. The dose of the dried gland is five to ten grains (0.32-0.65 Gm.) three times a day.

Ovaries.—That the ovaries deliver an internal secretion which if not essential to life, certainly modifies in some way metabolism, is almost universally accepted. One of the strongest proofs of this is seen in the symptoms which occur at the menopause or after double oophorectomy. The corpus luteum, according to Ott and Scott (Proc. of the Soc. of Exper. Biol. and Med., 1910, viii, p. 49), has a marked stimulating effect upon the mammary gland, but the ovarian substance when deprived of this was without such action. There is strong clinical evidence that the administration of the ovarian substance will at least temporarily relieve the symptoms seen at the menopause, whether the latter is natural or artificial. Richter (D. M. W., 1899) has found that there is a marked increase in the fatty metabolism under the feeding of the ovarian substance. These investigations have been confirmed by Thumim. (Ther. Gog; 1900, p. 451.)

The ovarian substance has also been used in the treatment of neurasthenia by Vidal (Press. Med., 1900, p. 173) as well as in a host of other diseases in which there was much less likelihood of benefit following its administration. (For review of the literature, see Offergeld, D. M. W., 1911, p. 1172.)

The corpus luteum has been used for various disturbances of pregnancy on the ground that these were due to the natural intermission in this function. The dried ovarian substance is marketed in various strengths. Ovariin represents eight times its weight in fresh bovine ovarian substance; the dose is three to six grains (0.2-0.4 Gm.). Ovaraden represents two parts of the gland and may be given in doses of fifteen to thirty grains (1-2 Gm.). Other proprietary preparations of the ovarian substance are glandnovin, ovadin, ovarial, ovarigen, oopherin, ovaron, and luten. The dried corpora lutea is given in doses of one to five grains (0.065-0.32 Gm.) two or three times a day.
Parotid Gland. Parotis Siccum. Glandula Parotidis.—Believing that there is some connection between the parotid and the sexual organs, Bell (Ther. Woch., 1896, p. 659) has employed the parotid gland in the treatment of dysmenorrhea, ovarian neuralgias, and other disorders of the pelvic organs. The dried substance is usually administered in tablet form in doses of from one to three grains (0.065-0.2 Gm.) three times a day.

Parathyroids. Glandula Parathyroidea.—These are four small bodies growing near the lateral lobes of the thyroid gland. Because of their anatomical proximity it was at one time believed that their function in the body was similar to that of the thyroid body, but it is now known that these two organs are in no way physiologically connected. The parathyroid bodies, however, are among those organs whose removal is fatal. The most prominent symptom caused by parathyroidec-tomy are tetanic convulsions. Ott and Scott (Amer. Med., 1910) have found that the parathyroid extract has a powerful diuretic influence. The dried parathyroid gland has been used in the treatment of tetany. (Loewenthal, Med. Klin., 1907, p. 1012.) It has also been used by Meyer (Ther. Geö., 1913, 354) and Berkley (N. Y. M. J., Nov. 23, 1907) in treatment of paralysis agitans. The dose is one-tenth of a grain (0.006 Gm.) two or three times a day.

Prostate. Glandula Prostatae Siccae.—This substance has been used, without any reasonable justification, in the treatment of prostatic enlargement, and in prostatorrhea. The dose of the dried substance is two grains (0.125 Gm.).

Spleen. Lien Siccus.—It can hardly be considered definitely established that the spleen furnishes any internal secretion. According to Danilewsky and Salensky (A. G. P., 1895, p. 264), however, the subcutaneous injection of the splenic extract produces an increase in the percentage of hemoglobin, and in the number of red blood cells. It is also asserted that there is an increase in the number of the white corpuscles. It is possible that these effects are not due to any substance peculiar to the spleen, but to the nucleinic acid which it contains. Accordingly, the splenic extract has been used in the treatment of anemias, with more or less beneficial results. Carpenter (D. M. Ztg., 1907, p. 571) asserts that it has a specific action in malaria. H. C. Wood (A. J. M. S., 1897, p. 511) has found it useful in Graves' disease. It has also been recommended in various forms of insanity. One of the difficulties in the use of this drug is to obtain a preparation which is active and yet will be borne by the stomach. The dried powder is given in doses of four to fifteen grains (0.26-1 Gm.) three times a day. It is doubtful, however, how far it entirely represents the drug. Under the name of erythrol, an aqueous extract has been marketed. The dose of this is one to two teaspoonfuls, given generally in soup. Lienaden and opos-lieinum are proprietary preparations of spleen.

Testicles. Testes Sicci.—The basis of the famous elixir of Brown-Sequard, Liquor spermaticus, was the fluid contained in the testicles. The persistent use of the various imitations and modifications of the Brown-Sequard Elixir would argue that it must possess some therapeutic virtue. It is claimed by those who use it that it has a powerful tonic effect, not merely improving the strength, but also exercising a beneficial influence upon the metabolism, so as to lead to a permanent augmentation of power. It has been recommended for neurasthenia, diabetes, locomotor ataxia, arteriosclerosis, and a large number of other chronic complaints.
The dried testicular substance is given in doses of from ten to thirty grains (0.65-2 Gm.), but it is generally recommended as a liquid preparation, and that it should be given hypodermically. Among the preparations which contain testicular fluid as their important ingredient are the Siccus e Testibus Paratus, orchidin, Hawley lymph, testaden, testidin and teston.

Mesentery Gland. Coeliacin.—The dried mesentery gland has been used by Schwerdt (M. M. W.. 1907, p. 1230) in the treatment of scleroderma. The dose he employed was five grains (0.3 Gm.) twice a day.

Thymus Gland. Glandula Thymi Sicca.—This body, which is the ordinary sweet-bread, is found only in young animals, disappearing as adult life comes on. Physiologists are not agreed as to its exact importance or function. It appears to have some connection with the growth of bone and also of the formation of the white corpuscles of the blood. It has been used in medicine chiefly for two purposes, namely, in the treatment of exophthalmic goiter, and for the purpose of stimulating bony growth in rickets and ununitedfracture. It should be remarked that thymus contains a larger percentage of nuclein than any common food stuffs, and for this reason its use is generally forbidden to gouty patients. The dose of the fresh gland ia from one drachm to half an ounce (2-15 Gm.); of the dried gland five to forty-five grains (0.32-3 Gm.).

Bone Marrow. Medulla Ossium.—This has been used by Gullan (Lancet, 1907, p. 520), and others, in the treatment of pernicious anemia. Gullan administered it by spreading the fresh red bone marrow on bread, which is taken at meal times. It is very prone to produce nausea. The dose of the fresh marrow is one to three ounces (31-93 Gm.); of the dried marrow two to five drachms. (7.7-20 Gm.). Opo-ossin and ossagen are proprietary preparations made from bone-marrow.

Spermin.—A salt solution of the hydrochloride of the amine spermin (C₅H₁₄N₂), a normal constituent of the spermatic fluid. It is used as a nerve tonic and stimulant in all diseases due to auto-intoxication, as typhus, syphilis, etc. Dose, subeutaneously, sixteen minims (1 mil) of a two per cent. solution; by mouth, ten to thirty drops (0.6-1.8 mils) of a four per cent. solution.

Origanum. Wild Marjoram. Marjolaine sauvage, Fr. Wilder Majoran (Meiran), G.—Two species of Origanum (Fam. Labiatae) have been used in medicine. O. majorana L., or sweet marjoram, and O. vulgare L., or common marjoram. The former grows wild in Portugal and Andalusia, and is cultivated as a garden herb in other parts of Europe and in the United States. Some authors, however, consider O. majoranaoides Willd., which is a native of Barbary, and closely allied to O. majorana, as the type of the sweet marjoram of our gardens. This is by others considered to be simply a form of O. vulgare L. Sweet marjoram has a pleasant odor, and a warm, aromatic, bitterish taste, which it imparts to water and alcohol. By distillation with water it yields a volatile oil. It is tonic and gently excitant, but is used more as a condiment than as a medicine. In domestic practice its infusion is employed to hasten the tardy eruption in
measles and other exanthematous diseases.

The plant is a native of Europe and America. In this country it grows along the roadsides, and in dry, stony fields and woods, from Pennsylvania to Virginia, and is in flower from June to October; but is not very abundant, and is seldom collected for use.

Sweet marjoram imported during recent years from Europe is alleged to be adulterated by mixing with it broken fragments of leaflets of the poisonous coriaria myrtifolia.

Two kinds of oil of origanum are now known commercially: the Trieste oil, of dark color and high specific gravity, and the Smyrna oil, of lighter color, lower specific gravity, and milder taste. The former contains from 60 to 85 per cent. of carvacrol, C_{10}H_{14}O, a trace of another phenol, and cymene C_{10}H_{14}. The latter contains from 25 to 60 per cent. of carvacrol and, in addition, linalool and cymene. The specific gravity of the Trieste oil ranges from 0.94 to 0.98, while that of the Smyrna oil is from 0.915 to 0.945. (Gilde-meister and Hoffmann, Aetherische Oele, pp. 813, 814; see also Schim. Rep., 1913, 76.)

The French oil of marjoram is said to be distilled from Clinopodium Nepeta (L.) Kze. (Calamintha Nepeta Link. and Hoffm.). It is colorless, but gradually turns yellow on exposure. It is neutral in reaction, sp. gr. 0.904 at 16° C. (60.8° F.), and optical rotation [a]_D = +18° 39' in chloroform solution. On fractionating, three constituents were isolated, laevo-pinene, calaminthone, and pulegone. Calaminthone is a new ketone, C_{10}H_{16}O. (See P. J., March, 1903.)

Origanum floribundum, of Algeria, yields largely of a volatile oil containing 25 per cent. of thymol. (P. J., Feb., 1903.)

Orobanche. Epifagus virginiana (L.) Bart. (Fam. Orobanchaceae) Beech-drops. Cancer Root. Orobanche de Virginie, Fr. Krebswurz, G.—This is a parasitic, fleshy plant, found in Northeastern America, growing upon the roots of the beech tree. The plant has a bitter, nauseous, astringent taste, which is said to be diminished by drying. It has been given internally in bowel affections; but its credit depends mainly upon the idea that it is useful in obnivate ulcers of a cancerous character, to which it was directly applied. Other species of orobanche, growing in America and Europe, have been employed. They are all parasitic, fleshy plants, without verdure, and of a bitter, nauseous taste. In Europe they are called broom rape. C. Charaux believes that Chlorogenic acid which can be easily converted into caffeic acid exists in plants of the fam. Orobanchaceae and other families. The allied plants, Conopholis americana (L. f.) Wallr. (Orobanche americana L. f.) and Orobanche uniflora L., growing throughout the United States, are used for the same purposes as the species above noticed, and, like it, are called cancer root.

Oroxylon. Oroxylon indicum Vent. (Fam. Bignoniaceae)—This East India bark is said to be not only a tonic and astringent, useful in diarrhea, but also a powerful sudorific. A yellow crystalline substance, oroxylin, has been separated from the bark.
by Naylor and Chapman (P. J., Sept., 1890), and from the seeds by Hooper (P. J., vol. Ixi). The seeds have been used in veterinary medicine.

**Orthosiphon.** Orthosiphonstamineus Benth. Java Tea. (Fam. Labiatae.)—This drug occurs in commerce in the form of small, oval, finely toothed, green leaves, rolled up like tea. Van Itallie has discovered in it a volatile oil and a crystalline gluco-side, orthosiphonin, and potassium salts. (Ph. Ztg., Sept., 1886; see also Repertoire de Pharm., 1887, 191.) It is said to be a powerful diuretic, and is highly recommended in nephritic colic, gravel, uric acid diathesis, and even ascites. The dose is from fifteen to thirty grains (1.0-2.0 Gm.) a day.

**Osha Root.**—This is the root of Ligusticumfilicinum Wats. (Fam. Umbelliferae), a perennial herb indigenous in Utah and neighboring States and known as Colorado cough root. It is highly prized as an expectorant. H. Haupt found in it an acid, oshaic add, closely resembling angelic acid. (A. J. P., 1867, 1868, 1873.)

**Oxalis.** O. Acetosella L. Wood Sorrel. Acetosella. Alleluia, Surelle, Pain deCoucou, Fr. Sauerklee, Hasenklee, G.—Wood sorrel is a small, creeping plant having radical leaves and scapes from 5 to 15 cm. high. (fam. Oxalidaceae.) It is a native of Europe and naturalized in the Northern United States. Other indigenous species of oxalis possess similar properties to O. Acetosella. The whole herbaceous portion may be used.

Wood sorrel is without odor, and has an agreeable sour taste. It owes its acidity to acid potassium oxalate or potassium binoxalate (HKO₂O₄).

The fresh plant, eaten raw, is useful in scurvy.

Oxaliscrassicaulis Zucc., a Peruvian species, yields edible tubers and, by expression from its leaves, a very sour and astringent juice, which is employed, in the form of syrup, in hemorrhages, chronic catarrh, and gonorrhea, with asserted advantage.
Paeonia. Paeonia officinalis L. Peony. Pivoine Fr. Gichtrose, Pfingstrose, G. (Fam. Ranunculaceae)—The root of the garden peony consists of a thick rhizome which sends off in all directions spindle-shaped roots, which gradually taper into thread-like fibers, by which they hang together. It has a strong, peculiar, disagreeable odor, and a nauseous taste, which is at first sweetish, and afterwards bitter and somewhat acrid. The odor is lost, or much diminished, by drying. Peony root was in very great repute among the ancients as a charm and as a medicine in epilepsy. In modern times it has been used as an antispasmodic. According to Rochebrune (Toxicolog. Africaine, i), it contains an active alkaloid, paeonine. The expressed juice is milky, of a strong odor and very disagreeable taste. The seeds are roundish-oval, about as large as a pea, externally smooth, shining, and nearly black, internally whitish, inodorous when dry, and of a mild oleaginous taste. By some authors they are said to be emetic and purgative, by others antispasmodic. The dose of the fresh root or seeds is from two drachms to an ounce (7.7-31.0 Gm.), boiled in a pint of water down to half a pint, which should be taken daily. It is said to be less active when dried. Dose, of the expressed juice of the root, one fluidounce (30 mils).

W. Will obtained from an aqueous distillate of the root of the Japanese Paeonia Moutan Simson, an aromatic ketone in colorless crystals. (Ber. d. Chem. Ges., xix, 1777.) According to Nagae, this substance has the formula C₉H₁₀O₃. (Ibid., xxiv.) It has been prepared by Schimmel & Co., under the name of peonol. It has a pleasant aromatic odor, and crystallizes in large needles. No essential oil was found in the root. (Schim. Rep., Oct; 1890.) Dragendorff has found in the seed of P. peregrina Mill., a fixed oil, an alkaloid, and paeonic acid. (Jahresb., 1879.)

Palicourea. Palicourea rigida H. B. K. (Fam. Rubiaceae)—The leaves of this tree are used in Brazil as a diuretic and diaphoretic. In 1866 Peckholdt found in them an alkaloid and three organic acids. One of these acids, consisting of a yellow, oily liquid with an overpowering odor, was found to be distinctly poisonous, one drop injected into a pigeon being enough to cause death. This was called myotonic acid. A crystalline palicouric acid, an amorphous tannin, and another amorphous non-toxic bitter principle were also isolated. Santesson has confirmed the presence of an alkaloid. (A. Pharm., 235.)
**Panbotano Bark.**—The root of the Mexican leguminous tree, Calliandra Houstoni Benth., has been highly recommended by Valude as an antiperiodic, although Villejean was not able to find in it either an alkaloid or a glucoside. (Journ. de Sci. Med. de Lille, 1890.) Pouchet (Nouv. Rem., 1896), however, states that he has found in panbotano, besides saponin, an alkaloid which produces death by systolic arrest of the heart. Both Dinau (These de Paris, 1896) and Crespin confirm its antiperiodic value. (B. G. T., Aug., 1895.) A tincture representing two ounces of the root is taken in four doses during twenty-four hours.

**Pangium.** Pangium edule Reinw. (Fam. Bixaceae)—This East Indian tree, which is said to possess anthelmintic and narcotic properties, and to be capable of causing death, according to Blume, contains an alkaloid resembling menispermine.

**Pao-Pereira Bark.** Pereiro Bark.—Under this name a bark is employed in Brazil as a febrifuge. It is supposed to be the product of Geissospermum laeve (Veil.) Baill. (Fam. Apocynaceae). O. Hesse has found an alkaloid, geissospermine, C_{19}H_{24}N_{2}O_{2}+H_{2}O, in it (see P. J., viii, 648), but he seems to have been preceded in this discovery by Santos. (A. J. P., 1878, 184.) Peretti has discovered in the root a second alkaloid, pereirine, C_{19}H_{24}N_{2}O, which, according to Guimaraes (B. M. J., vol. i, 1887), in sufficient doses causes paralysis with elevation of temperature, ending in death. It has been given to man as an antiperiodic in doses of thirty grains (2.0 Gm.) a day. (See also A. J. P., 1886, 278.) Later a third alkaloid, vellosine, C_{23}H_{28}N_{2}O_{4}, was found. This forms colorless, crystals, melting at 189° C. (372.2° F.), insoluble in water, easily soluble in alcohol and ether. In concentrated nitric acid it dissolves with a purplish-red color, which is very stable.

**Papaya.** Melon Tree. Papaw.—The Carica Papaya L. (Fam. Caricaceae) is a shrub, everywhere cultivated in tropical countries for the sake of its fruit. The ovoid fruit sometimes attains a length of 30 cm. and weight 4 or 5 K. According to Peckholdt (P. J., Nov., 1879), the milky juice is contained in all parts of the tree, but in such small quantity, save in the unripe fruit, that it is always procured from the latter. One fruit will yield about 33 Gm., which is obtained by scratching through the skin in various places; the process does not interfere with the ripening of the fruit, but it is said that the seeds will not germinate. The milk has an acid reaction, an astringent bitterish taste, and a sp. gr. of 1.023. Upon standing for a few minutes it separates into two parts, an aqueous liquid and a white, somewhat coagulated pulpy mass. In the aqueous portion is an albuminous substance, possessed of enzymic properties, to which the names of papain and papayotin have been given. According to the researches of S. H. C. Martin, papaw juice contains besides papain, a milk-curdling ferment and globulin, albumin, and two phytalbumoses. No peptones occur in the juice, but leucine and tyrosine are present. (J. Chem. S., 1886, 642; see also P. J., 1885, 129.) In a representative preparation the ferment action seems to be most marked when all the proteids are associated together in the natural form. In its action upon albumin the enzyme of the papaw produces products which have a close relation to those produced by tryptic and peptic digestion. In the action of the papaw ferments on milk there is first curdling, in which the casein is separated into a soft flocculent precipitate, and afterwards a digestion of the proteids, during which process
they are converted into soluble and diffusible products. The amount of starch-converting ferment is not large, but sufficient in the fresh latex to promptly act upon starch paste, thinning it, and converting a portion at least into soluble starch and dextrin. The import of the rennet ferment and the pectase probably present require further investigation.

According to Wurtz, fibrin is dissolved whether the solvent solution be alkaline or acid. Brunton and Wyatt and also Martin affirm, however, that one-half per cent. of hydrochloric acid will prevent digestion, but Albrecht reasserts that hydrochloric acid hastens the action of the ferment, and states that the official preparation in use in Paris hospitals is an acid one. In order entirely to convert fibrin into pure peptone so that nitric acid will produce no precipitate, the proportion of the ferment should be as great as 3 per cent., and digestion must continue for forty-eight hours at 50° C. (122° F.).

Papaya juice has a tendency to spoil by undergoing a butyric fermentation, but Wurtz found that the addition to it of glycerin preserved it without interfering with its digestive power. Imported in this form, it was a thick, milky liquid. As it now occurs in commerce, papain is a grayish, fine powder, which in appearance, odor, and taste strongly suggests pepsin.

The seeds of the papaw tree contain a glucoside, caricin, which resembles sinigrin. These seeds also contain the ferment, myrosin, and by the reaction of the two a volatile pungent body is produced, suggestive of oil of mustard in odor. An alkaloid, carpaine, C_{14}H_{25}O_{2}N, has been obtained from the leaves. Physiologically, this alkaloid has the effect of a heart stimulant, quite similar to that of digitalis. (A. J. P., July and August, 1901, 336-48 and 383.)

Under the name of papayotin, papain, or papoid, the dried juice of the Carica Papaya is put upon the market. It is frequently adulterated with starch, which is not naturally present in the fruit. Its digestive power is far below the claims formerly made for it. It is asserted for it that, when the stomach is acid, it is much superior to pancreatin, because its action is not markedly affected by contact with the acid. In experiments made by H. C. Wood with a papoid from one of the most renowned manufacturers no digestion occurred, and it is probable that much of the article of commerce is inert. It has been used as an internal medicine in dyspepsia and gastric catarrh, and as a local application for the destruction of false membranes, warts, tubercles, walls of old sinuses, and even of epithelioma. (See Branch, B. M. J., 1907.)

It is not caustic nor astringent, but destroys the part by virtue of its power of dissolving not only muscular but connective tissue. Jacobi affirms (T. G., vol. ii) that diphtheritic membranes are dissolvable in a few hours by the hourly application of a mixture of one part of papain with two parts each of water and of glycerin. It is stated that from time immemorial the fresh leaves of the papaya plant have been used by the Indians to wrap meat in to make it tender, and as a dressing to foul wounds. Peckoldt says that, taken internally, the juice is reputed to cause intestinal inflammation. No recent observers have noted such influence. According to Brunton, the dose is from five to ten grains (0.32-0.65 Gm.). Injected into the venous circulation
it acts as a powerful poison, of which a single grain is sufficient to kill a rabbit.

**Paracoto.** N. F. IV. Paracoto.—"The dried bark of an unidentified tree indigenous to Northern Bolivia." N. F.

This drug was introduced into the National Formulary IV. It is not official in the U. S. or Br. Pharmacopoeia. A tincture and fluidextract are official in the N. F.. Paracoto is described as follows:

"In quills, or fragments of quills, of indefinite length, usually from 3 to 6 cm. in breadth, from 5 to 15 mm. in thickness; of a deep-brown color throughout, the outer surface nearly smooth, lightly, transversely fissured, and often very thinly scaly, the inner surface very coarsely striate; hard and heavy, but splitting and breaking readily, the fracture mealy in the outer layer, with an irregular resinous band, coarse splinterly in the inner layer with large, yellowish-brown bast fibers and stone cells and darker resin tissue. Odor strong and characteristic, nutmeg-like; taste strongly aromatic and pungent. Paracoto yields not more than 3 per cent. of ash." N. F.

Paracotoin, $O_{12}H_{8}O_{4}$, is extracted from para-coto bark, in which it exists associated with hydrocotoin, $C_{15}H_{14}O_{4}$, protocotoin, $C_{16}H_{14}O_{6}$, methylhydrocotoin, $C_{16}H_{16}O_{4}$, and methylprotocotoin, $C_{17}H_{16}O_{4}$. Paracotoin may be distinguished from cotoin by giving no reaction with ferric chloride.

Paracotoin forms yellowish crystals soluble in alcohol and water and fusing at 149° to 151° C. (300.2°-303.8° F.). For a special reason its manufacturers have warned against its use in intestinal hyperemia. Piperonylic (methylene protocatechuic) acid, $C_{8}H_{6}O_{4}$, is also present. Paracoto bark has been used in various types of dysentery and diarrhea, especially in tuberculous enteritis. Balz (of Tokio) has employed paracotoin hypodermically in the treatment of cholera in doses of three grains (0.2 Gm.). This principle has also been recommended for night sweats.

The dose of paracoto bark is five grains (0.3 Gm.). (For uses see Coto Bark, p 1344.)

**Parameria.** Parameria vulneraria Radlkofer. (Fam. Apocynaceae)—This tree yields the Balsamo de Taguloway of the Malays. (See A. Pharm., Nov., 1885.)

**Pareira.** N. F. IV (U. S. P. VIII, Br. 1898). Pareüra Brava, Pareüra Radix, Br. Pareüra Root.—"The dried roots of Chondrodendron tomentosum Ruiz and Pavon (Fam. Menispermaceae) without the presence of more than 5 per cent. of stems or other foreign matter." N. F.

Chondrodendron tomentosum is a climbing, woody vine, which attains often a considerable height, and is remarkable for the size of its leaves. These are about a foot long, broadly ovate or rounded, slightly cordate, with a smooth upper surface, and on the under surface, between the veins, covered with a fine close wool of an ashy hue. The racemose fruits are of the size of large grapes, oval and black. This plant inhabits both Brazil and Peru.
Pareira was formerly official in the U. S. VIII and Br. Pharmacopoeias, but is now official in the N. F. IV, where it is described as follows: "Nearly cylindrical, more or less tortuous, of variable length and from 1 to 6 cm. in diameter. Externally brownish-black or blackish-brown with transverse ridges on knot-like projections, occasionally fissured and longitudinally wrinkled or even furrowed. Hard, heavy and tough; when freshly cut having a waxy luster; the transverse surfaces exhibiting several successive eccentric and distinctly radiate concentric zones of projecting, secondary fibro-vascular bundles, each from 2 to 4 mm. in width, and separated by distinct concentric zones of parenchyma and stone cells. Stem deeply furrowed, grayish in color, usually covered with foliaceous patches of lichens bearing their blackish apothecia; internally grayish-yellow, with a prominent development of wood with a tendency to separate fibro-vascular bundles and without a waxy luster. Odor slight, taste very bitter.

The powder is dark brown, containing numerous starch grains and a few woody fragments; starch grains mostly simple, occasionally unequally two-to-four-compound, the individual grains ellipsoidal or oblong, 0.005 to 0.02 mm. in diameter and occasionally with central clefts or irregular markings; fragments with large, wide tracheae, the walls with numerous slit-like pores and associated with long, thick-walled, strongly lignified, porous wood fibers; stone cells in small groups, with thick porous walls and in form resembling those of the fruits and seeds; fragments of starch-bearing parenchyma; the cells of the root being thick-walled, strongly lignified and with large, longitudinal, elliptical pores; occasional fragments of blackish-brown cork. Pareira yields not more than 5 per cent. of ash."

For account of commercial history, see U. S. D., 18th ed., 1916.

The root imparts its virtues readily in water. Feneuille found in it a soft resin, a yellow bitter principle, a brown substance, a nitrogenous substance, fecula, acid calcium malate, potassium nitrate, and various other salts. He considers the yellow bitter substance as the active principle. It is soluble in water and alcohol, and precipitated from its solution by tincture of galls. Wiggers announced in 1838 the existence in pareira brava of an alkaloid, for which he proposed the name of pelosine or cissampeline. Peretti of Rome, and Pelletier afterwards, separated from the root an alkaloid characterized by assuming a beautiful purple color upon contact with strong nitric acid. (J. P. C., xxvi, 162.) It is stated to be uncrystallizable, insoluble in water, soluble in ether, alcohol, and the acids, and of an intensely bitter and sweetish taste. Fluckiger (P. J., 1870, p. 192) found an alkaloid in pareira, and, having thoroughly determined its origin, investigated its properties, and fixed its composition at $C_{18}H_{21}NO_3$, showed its identity with the bebeerine of nectandra and the buxine of Buxus sempervirens obtained by Walz. Ringer and Brooke (A. J. P., 1892, 255) proved that the true chondrodendron root contained a larger quantity of chemical and extractive principles than do the substitutes. (See also Dohme's paper, D. C., 1896, 296.)

Pareira is supposed to have a diuretic effect and to act as an antiseptic in the bladder.
It is chiefly employed for the relief of chronic inflammations of the urinary passages. In Brazil it is used in the cure of the bites of poisonous serpents, —a vinous infusion of the root being taken internally, while the bruised leaves of the plant are applied to the wound. The dose of pareira in substance is from thirty grains to a drachm (2.0-3.9 Gm.). The infusion (1 oz. in 1 pint of boiling water) is useful. The aqueous extract may be given in the dose of from ten to thirty grains (0.65-2.0 Gm.). There is an official fluidextract made with diluted alcohol in the N. F. IV.

For preparations of pareira see U. S. D., 19th cd., p. 917.

Dose, thirty to sixty grains (2.0-3.9 Gm.).

**Parietaria.** Parietaria officinalis L. Wall Pellitory. Pariétaire, Perce-muraille, Fr. Glaskraut, G. (Fam. Urticacae) —A perennial European herb, growing on old walls and heaps of rubbish. It is diuretic and refrigerant, and was formerly used in urinary complaints and dropsy, in the form of decoction or of the expressed juice.

**Parkia.** Parkia biglandulosa W. and A. (P. africana R. Br.). African Locust. Nitta or Nutta Tree, Doura. Houëlle, Nerétou.—This is an African leguminous tree, from the dried seeds of which a farinaceous food is prepared by the natives. According to De Rochebrune (Toxicolog. Africaine, 1898), it contains a peculiar crystalline alkaloid, parkine, which resembles in its physiological activity physostigmine.

**Parnassia Palustris.**—An infusion of the bark of this tree has been used in the treatment of epileptics, administered in teaspoonful doses three times daily.

**Parsley Root.** N. F. IV. Petroelini Radix. Petrosel Rad. It is described by the N. F. as " The root of Petroselinum sativum Hoffmann (Fam. Um-belliferae). The entire fusiform root, measuring up to 20 cm. in length and up to 2.5 cm. in thickness at the crown, or broken or cut into pieces; usually cut lengthwise into two or four sections; externally light yellowish, wrinkled longitudinally, somewhat annulate, root scars distinct and corky; fracture tough when damp, brittle when dry; internally, cortex whitish and characterized by numerous, reddish-brown oleoresin cells, cambium zone distinct and brownish; wood about the same thickness as the cortex, slightly radiate and light yellow. Odor aromatic; taste sweetish and pungent. The powdered drug, when examined under the microscope, shows numerous truncate or somewhat angular starch grains up to 0.03 mm. in diameter, reticulate tracheae up to 0.06 mm. in width and thin-walled, lignified fibers with simple pores. Parsley Root yields not more than 6 per cent. of ash." Dose, thirty grains (2 Gm.). (See Petroselinum).

**Parthenium.** Chrysanthenum Parthenium (L.) Bernh. Feverfew. Matricaire, Fr. Mutterkraut, G. (Fam. Compositae)—A tall, perennial, branching herbaceous plant, with bipinnately divided leaves, the divisions being ovate, and compound flowers in a corymb. It is a native of Europe, but cultivated in our gardens and naturalized in some places. The whole herbaceous part is used. The plant has an odor and taste analogous to those of chamomile, which it resembles also in the appearance of its flowers and in its medicinal virtues. It yields a greenish volatile oil which boils between
165° and 220° C. (329° and 428° F.), and separates on standing, pyrethrum camphor, \( C_{10}H_{16}O \). (Dessaignes and Chautard, J. P. C. (3), xiii, 241.)

The flowers of this and of a closely resembling species, Matricaria Anthemis parthenoides Desf., are said to be used in France, to a considerable extent, indiscriminately with those of the true chamomile plant, Anthemis nobilis, which they closely resemble, especially when double. They may, however, be distinguished, in this state, by their peculiar odor, their small receptacle, which is, moreover, rounded and flattened above, instead of being conical and somewhat pointed as in the Anthemis, and by the tubular five-toothed central florets, which in the chamomile are small, few, and scarcely visible, but in the two former species are large, very numerous, and very long.

Parthenium Hysterophorus L.—Jose Torar has found parthenine and four other alkaloids besides parthenic acid, in this Cuban plant which is used by the natives as a febrifuge and antiperiodic. Of the alkaloids, parthenine is crystallizable and is apparently the active principle. It has been extracted and studied again by H. Vin Arny (A. J. P., 1890, 121), who believes it to be a bitter glucoside and not an alkaloid. In doses of three grains (0.2 Gm.) it is said to quicken the heart, and in doses of fifteen grains (1.0 Gm.) to slow cardiac action, while fifty grains (3.2 Gm.) not only lessen the arterial pressure and respiratory frequency but reduce the bodily temperature. In doses of from seven to ten grains (0.45-0.65 Gm.) it is affirmed to be useful in neuralgia. (See Journ. de Med. de Paris, March, 1887; J. P. C., xii, 1885; A. J. P., 1897, 169.)

Parthenium integrifolium L., American Feverfew, Wild Quinine (Fam. Compositae), is an herbaceous perennial, growing abundantly in the prairies of the Southwestern States, which has been used as a tonic and antiperiodic; two ounces (62 Gm.) of the flowering tops may be given in infusion.

**Passion Flower.** N. F. IV. Passiflora. Passion Vine. "The dried herbage of Passiflora incarnata Linne (Fam. Passifloraceae), collected after some of the berries have matured." N. F.

It is described in the N. F. as follows: "Stems glabrous or slightly pubescent above, striate, from 6 to 8 mm. in diameter, of variable length, woody, hollow, the cavity about one-half the diameter; bark very thin, greenish or purplish; wood very porous and bordered on the inner side by a thin layer of pith; fracture of the wood uneven, of the stem smooth, of the bark coarsely fibrous. Leaves more or less broken in drying, rather thick, glabrous or often pubescent, when entire nearly orbicular in outline, base cordate, deeply three- to five-lobed, lobes ovate, acute, finely serrate, petioles from 1 to 5 cm. in length, with two glands near the summit. Tendrils numerous and closely coiled. Flowers solitary, axillary, peduncles as long as the petioles, usually three bracted; calyx cup-shaped, four to five lobes; lobes linear, imbricated, cuspidate, corona of the fresh flowers purplish; petals four to five, yellow; ovary oblong, stalked; stamens monadelphus in a tube about the stalk of the ovary, separated above, anthers narrow, versatile. Fruit from 4 to 5 cm. in length, an ovoid, many-seeded
berry; externally green or yellow, shriveled and wrinkled; seeds flat, ovate, yellowish to brown arilled. Taste and odor slight. Passion Flowers yield not more than 12 per cent. of ash." N. F.

This indigenous plant has been supposed to possess narcotic properties and used in neuralgias, sleeplessness, dysmenorrhea, as well as in diarrhea and dysentery. I. Ott (Medical Bulletin, Dec., 1898) finds that it is a depressant to the motor side of the spinal cord, but increases the rate of the respiration, and that it has very little effect upon the circulation, only temporarily reducing the arterial pressure. Dose, three to ten grains (0.2-0.65 Gm.).

Paulowilhelmina. Paulowilhelmina speciosa Hochst.—This acanthaceous plant is used by the Aquapine tribe on the Gold. Coast, as a fish poison, under the name of adubiri. (P. J., xx, 1890.)

Peach Leaves. Leaves of Prunus Persica (L.) Sieb. et Zucc. (Fam. Rosaceae) Pechier, Fr. Pfirsch, G.—The peach tree is supposed to have been originally brought from Persia, but flourishes everywhere in the warm temperate zone. Peaches are among the most grateful and wholesome of our summer fruits. They abound in saccharine matter, which renders their juices susceptible of the vinous fermentation, and a distilled liquor prepared from them has been much used, in some parts of the country, under the name of peach brandy. The kernels of the fruit resemble, physically and chemically, bitter almonds, for which they are frequently, and without inconvenience, substituted in commerce. The flowers, leaves, and bark also have the peculiar odor and taste of bitter almonds, and yield hydrocyanic acid. The leaves afford a volatile oil by distillation. The distilled water prepared from them was found in one instance to contain 1.407 parts of hydrocyanic acid in 1000, and in another only 0.437 parts in the same quantity. From some experiments it is inferred that the proportion of acid is greatest where there is least fruit. (A. J. P., xxiv, 72.)

Peach kernel oil made by expression has found its way into Western Europe from the Levant, and is used in Italy and Southern France largely as an adulterant of almond oil. It is described as of a light yellow color, having the taste and odor of almond oil. It thickens at -9° C. or -10° C. (15.8° F. or 14° F.), and solidifies at -18° C. (-0.4° F.). The sp. gr. at 15° C. (59° F.) is 0.915. It gives with strong nitric acid a dark brown color, with sulphuric acid a dark brown becoming lighter, with solution of zinc chloride a purplish-brown; forming with the elaidin test in two hours a mass of butter-like color and consistence. Peach kernel oil has a saponification value of 189-192 and an iodine figure of 93.5. (See Oleum Amygdalae Expressum.)

The leaves of the peach are said to be laxative, and have also been used with asserted advantage in whooping cough, irritability of the bladder, etc. The dried leaves may be employed (an ounce to a pint of hot water) in infusion. The flowers of the peach are affirmed to be laxative and vermicidal, in half-fluid-ounce (15 mils) doses when fresh, given in the form of syrup. Cases of fatal poisoning in children from their use are on record. The peach kernels are distinctly active, and when rubbed up with cold water form an emulsion which may be used in place of cherry-laurel water or other

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - P - Page 8
The Southwest School of Botanical Medicine http://www.swsbm.com
preparations of hydrocyanic acid.

**Peganum.** Peganum Harmala L. Wild Rue. (Fam. Rutaceæ)—A tall herbaceous plant growing in the Mediterranean region of Europe and Africa and extending into Thibet. In the seeds of this plant Goebel (1837) found the alkaloid harmaline, and Fritzscbe (1847) a second alkaloid, harmine, which have been re-studied by Fischer and Tauber. (A. J. P., 1886, 89.)

The seeds of peganum were used by the ancient Greeks in the treatment of eye diseases. In modern times it has been used as an emmenagogue, anthelmintic and sedative.

Harmaline or harminedihydride, C\textsubscript{13}H\textsubscript{14}N\textsubscript{2}O, is in the form of trimetric, octahedral crystals. It is soluble in alcohol and ether and slowly so in water. It melts at about 238° C. (460.4° F.) with decomposition. Flury (A. E. P., 1911, lxiv, p. 105) finds that harmaline in moderate doses produced symptoms in the dog similar to those produced by cannabis and in toxic quantities it caused salivation. Its anthelmintic effect he attributes to a paralytic action upon the muscular tissues of the worm.

**Pelargonium.** Pelargonium odoratissimum Willd. Rose Geranium. (Fam. Geraniaceæ)—The *Pelargoniums*, commonly referred to as geraniums, are indigenous to South Africa and largely cultivated as decorative plants. Some of the species are cultivated for the distillation of the volatile oil, in France, Spain, Algiers, and the Island of Reunion. According to Guibourt, several species of Pelargonium yield a volatile oil by distillation, closely analogous in odor to that of the rose: the species above named, *P. capitatum* Ait., and *P. roseum* Willd., the last being regarded as a variety of *P. radula* Ait. (Hist. Nat. des Drogues, 4e ed., iii, 52.) The oil is obtained from the leaves. Recluz obtained from thirty-five ounces of *P. odoratissimum* W., two drachms of a volatile, crystallizable oil. (Merat and De Lens, Dict. de Mat. Med., iii, 368.) According to Septimus Piesse, one cwt. yields about two ounces. (See A. J. P., xxvi, 368.) The oil which occurs in commerce, purporting to be the oil of *P. odoratissimum*, is fluid at ordinary temperatures, of a pale brownish-yellow color, and the characteristic odor of the plant, merely recalling that of the rose. This oil is now much used in perfumery. Piesse states that, as this oil is used to adulterate that of roses, so is it in its turn adulterated with the cheaper oils of speciea of Andropogon. (See p. 1517.) (A. J. P., xxvi, 368.) It appears, however, that the oil known as oil of palmarosa (see Oil of Citronella), distilled in India, is the one which is used most largely to adulterate oil of rose and oil of rose geranium. According to Baur, the oil is shipped in large copper flasks from Bombay to the Red Sea, and thence to Constantinople and Kيزانليک. For Burtell's description of the method of distilling palmarosa oil see Schim. Rep., 1909, 88. Jallard states that the true oil of rose geranium from *P. roseum* is freely soluble in 70 per cent. alcohol. The oils likely to be used to adulterate it are insoluble in this liquid. If, therefore, six drops of the suspected oil be mixed with 5 mils of 70 per cent. alcohol, there should be no separation. (A. J. P., 1878, 260; from J. P. C.) F. W. Semmler (Ber. d. Chem. Ges., xxiiii, 1098) has shown that the chief ingredient in the various geranium oils is an alcohol, geraniol, C\textsubscript{10}H\textsubscript{18}O, which boils at from 231° to 232° C. (447.8°-449.6° F.), and has a sp. gr. 0.884 at 15°.
C. (59° F.). When oxidized by chromium trioxide mixtures, it is changed into citral, 
C_{10}H_{16}O, an aldehyde found in many of the essential oils, and this when oxidized by 
silver oxide yields geranic acid, C_{10}H_{16}O_2. The geraniol is both free and combined as 
tiglic acid ester. The oil also contains citronellol. (Schim. Rep., April, 1897.) Geranium 
oil is sometimes adulterated with dimethyl sulphide, (CH_3)_2 S. (Schim. Rep., 1909, 55; 
see also Am. Perf., Jan., 1913.)

**Pengawar Djambi.** Paku Eidang. Golden Moss.—This is composed of silky, long, 
yellow or brownish hairs, very soft, which are obtained in Sumatra from the base 
of the shrub of various ferns, especially Cibotium Link. (Fam. Cyatheaceae), a peculiar 
fern related to Dicksonia. (See also S. W. P., 1910, No. 43, 661.) It has the power of 
causing rapid coagulation of blood, and, when properly used, of mechanically arresting 
hemorrhages from capillaries. It has been much used, in the physiological 
laboratories of Europe and this country, and was employed in human medicine during 
the Middle Ages under the name of Agnus Scythicus. The medieval drug was composed 
of pieces of the rhizome with the attached scales and petioles so cut as to resemble 
animals. Interest in the pengawar djambi was revived on account of the assertions of 
Junker of its usefulness during the Franco-German war. (L. M. R., Dec., 1887.) It is 
undoubtedly a very efficient styptic.

**Penthaclethra.** Penthaclethra macrophylla Benth. (Fam. Leguminosae.) Owala 
Grains.—The seeds of this plant, which grows in the Congo States, are said to contain 
an alkaloid, paucine, crystallizing in yellow foliaceous crystals, melting at 126° C. 
(258.8° F.), insoluble in ether and chloroform, having the formula C_{27}H_{38}O_5N_5. (P. J., 
ilx.) Paucinehydrochloride, C_{27}H_{39}O_5N_5 2HCl + 6H_2O, is marketed by Merck and Co., 
and is stated to be physiologically inactive.

**PEPO. U. S. (Br.)**

**PEPO [Pumpkin Seed]**

"The dried ripe seeds of cultivated varieties of Cucurbita Pepo Linne 
(Fam. Cucurbitaceae), without the presence or admixture of more than 5 
per cent. of other substances." U. S. "Melon Pumpkin Seeds, are the 
prepared fresh ripe seeds of cultivated plants of Cucurbita maxima, 
Duch. Melon Pumpkin Seeds must not be more than one month old, and 
when required for use about 100 grammes are bruised with a little 
water or milk to a creamy consistence and administered as a single 
dose." Br.

**Cucurbitae Semina Praeparata.** Br.; Melon Pumpkin Seeds; Semen Peponis, 
Semen Cucurbitae; Semences de Potirons ou de Courge, Fr.; Kurbiasamen, 
Kurbiskorner, Graumontaamen, G.; Calabaza (Semilla), Sp.
The Cucurbita Pepo, or common pumpkin, is a plant almost too well known to need description. The seeds are the part used. These are officially described as follows: "Broadly elliptical or ovate, from 15 to 23 mm. in length and from 2 to 3 mm. in thickness; externally yellowish-white, very smooth, occasionally with thin, transparent fragments of adhering pulp and with a shallow groove parallel to and within 1 mm. of the margin; fracture short, seed-coat consisting of a white coriaceous outer layer and a membranous inner layer occasionally of a dark green color; embryo whitish, straight, with a small conical hypocotyl and two plano-convex cotyledons; slightly odorous when contused; taste bland and oily. Under the microscope, sections of Pepo show an outer epidermal layer consisting of palisade-like cells, the radial walls attaining a length of 1 mm., the outer walls being usually torn off so that it appears as though the seeds were covered with very long hairs; a sub-epidermal layer consisting of from 5 to 12 rows of cells with slightly thickened, lignified and porous walls; a layer of strongly lignified stone cells, elliptical in outline and about 0.075 mm. in length; a single layer of small cells resembling those of the sub-epidermal layer; several rows of parenchyma cells with characteristic reticulate markings and separated from each other by large intercellular spaces; several layers of parenchyma cells, the inner layer being more or less collapsed and bounded on the inside by a single epidermal layer, the cells having rather thick walls; the perisperm cells are usually more or less collapsed and the endosperm consists of a single layer of cells filled with small aleurone grains; the cotyledons consist of thin-walled, isodiametric, elongated or palisade-like cells containing a fixed oil and numerous small aleurone grains." U. S.

The British Pharmacopoeia recognizes the melon pumpkin seeds, under the title of Cucurbitae Semina Praeparata. These are derived from a closely related species, Cucurbita maxima Duch., which closely resembles C. Pepo and differs in that the margins of the leaves possess rounded teeth, whereas in C. Pepo they are acute. The British definition and description are as follows: "Flat, ovate, white, and exalbuminous, consisting of two fleshy, easily separable cotyledons, freshly deprived of the yellowish outer, and brownish inner integument. Faint odor; taste very slight. Before preparation, the seeds measure from eight to twenty millimetres in length, and from nine to twelve millimetres in breadth." Br.

They contain a fixed oil, consisting of the glycerides of palmitic, myristic,
and oleic acids, with some free fatty acid, an aromatic principle, chlorophyll, sugar, starch, and, according to Dorner and Wolkowich, an alkaloid, cucurbitine. Deprived of their coating, and exhausted by ether, they yield 30 per cent. of fixed oil. (Ann. Ther., 1862, p. 176.) The researches of Dorner and Wolkowich have not received confirmation, and their alkaloid probably has no existence. Pumpkin seed oil has a sp. gr. at 15° C. (59° F.) of 0.923, and solidifies at -15° C. (5° F.). The cold drawn oil is used for culinary purposes and the lower qualities for burning. The oil dries very slowly. (Lewkowitsch, Chem. Analysis of Oils, etc., 2d ed., 1898, 372.) Sicker obtained 30 per cent. of the oil from the seeds; it was reddish-yellow in color, soluble in ether, benzene, and carbon disulphide, but insoluble in alcohol. (Proc. A. Ph., A., 1897, 545.) Willard Graham endeavored to prepare Oil of Pumpkin Seed by expression, but failed to obtain appreciable quantities even under a pressure of 3000 pounds. By extraction with acetone the ground seed yielded 25 per cent. of oil, clear reddish, limpid, and of agreeable odor and taste. Its sp. gr. at 15° C. (59° F.) was 0.9208; saponification number, 192.5; acid number, 18.9; ether number, 173.6; soluble in all proportions of carbon disulphide, ether, chloroform, and in twenty parts of absolute alcohol, and drying on standing to a tough, yellowish, transparent mass. These properties and constants agree well with a commercial specimen, evidently also obtained by extraction. The latter, however, had a lower acid number, 3.5, while the ether number was somewhat higher, 191.7. (A. J. P., 1901, 352.) J. C. Lyons used an ounce of the oil with success in a case of tapeworm (A. J. P., 1865, 253), but Wolff has found it inert when pure and free from resin, which he prepares by extracting the oil from the powdered seeds by means of petroleum benzin, then treating the remaining powder with ether, chloroform, and alcohol, which yields on evaporation a soft greenish-brown resinous liquid resembling the oleoresin of male fern. Heekel was the first to assert that the active principle is a resin, and in this he has been corroborated by L. Wolff (pamphlet, Phila., 1882), who found the resin to be efficient in doses of fifteen grains (1 Gm.), given in pill followed in two or three hours by castor oil, and who recommends an alcoholic fluidextract as the best preparation of the drug after the resin.

Power and Salway (J. Am. C. S., 1910, p. 346) found the resin as well as the oil which they separated from the seed, destitute of anthelmintic powers.

W. E. Miller (A. J. P., 1891, 585) analyzed both the shells and the
kernels of pumpkin seed. He also found a resin soluble in alcohol, and a
dark reddish fixed oil.

**Uses.**—It is said that in Italy the seeds of the Cucurbita maxima, and
in the West Indies those of C. occidentalis, have been long used in doses
of an ounce and a half as tenifuges. In the Dictionary of Materia Medica
by Merat and De Lens (ii, 493) it is stated that Hoarau had reported
that in the Isle of France the seeds of a small variety of pumpkin were
used against the tapeworm, and with never-failing success. In the year
1820, Mongeney, a physician of Cuba, published the results of his
experience with the flesh of the pumpkin in the same disease. He had
discovered the remedy by accident, and found it uniformly successful.
He gave to the patient, in the morning, fasting, about three ounces of
the fresh pumpkin in the form of a paste, and followed it at the end of
an hour by about two ounces of honey, which latter was twice repeated
at intervals of an hour. So far as we know, attention was first directed to
it in this country by Richard Soule. (B. M. S. J., Oct., 1851.) Since this
time the drug has steadily grown in favor, and, properly used, is one of
our most efficient and harmless tenifuges. The patient should be allowed
only a light supper of bread and milk, in the morning early should take
an ounce and a half of the seeds, a cup of tea or coffee an hour later,
but no food, at 10 A.M. a brisk cathartic, and two hours later a
substantial meal. We have obtained excellent results from the exhibition
of the beaten seeds in the form of an electuary strongly flavored with oil
of cinnamon or of gaultheria.

Dose, one to two ounces (31-62 Gm.).

**Perezia Root.**—This root is obtained from several Mexican plants, Perezia Wrightii
A. Gray, P. Nana A. Gray, and P. Dugesii A. Gray. (Fam. Compositae.) It contains
pipitzahoic acid, a substance which crystallizes in beautiful golden-yellow needles.
R. Anschutz and J. W. Leather obtained from the dried roots of P. adnata A. Gray
(Trixis Pipitzahoac Schaffner), an average of 3.6 per cent. of this acid, which melts at
from 103° to 104° C. (217.4°-219.2° F.), sublimes readily, and is easily soluble in
alcohol, ether, chloroform, benzene, and glacial acetic acid. The authors confirm the
formula given to the acid in 1855—viz., $\text{C}_{15}\text{H}_{20}\text{O}_3$. It is a quinone, and bears great
resemblance, when recrystallized from diluted alcohol, to oxythymoquinone, which,
recrystallized from the same liquid, is scarcely distinguishable from it. (A. J. P., 1884,
185, and Ph. Rund., 1883, 245; A. Pharm., 1887, 183.)

Under the name of perezol the 0.5 per cent. alcoholic solution of pipitzahoic acid has
been recommended by Duyk as an alkalimetrical indicator. By acids it is at once
decolorized; with alkalies it becomes reddish. Boric, and perhaps other acids, and
acetates, borates, bicarbonates, and carbonates act with respect to the solution like alkalies. For a paper on pipitza hoic acid by Altamirans, see Analen del Institute Mex., Nat. 7, p. 21, or P. J., 1905, 553.

**Periploca.** Periploca graeca L.—From the bark of this asclepiadaceous shrub, growing in the neighborhood of the Black Sea, has been separated by Lehmann (A. Pharm., 1897, p. 157) a colorless glucoside, periplocin, $C_{30}H_{48}O_{12}$, soluble in 125 parts of water, freely soluble in alcohol. According to the experiments of Burschinski (St. P. M. W., 1897), it is an active cardiac poison belonging to the digitalis group. It has been used as a cardiac tonic by Cholewa (Th. M., 1904, p. 292), Silberberg (Ln. Dis., Odessa, 1909), and others, as a practical remedy in the treatment of heart disease. Silberberg asserts that it is better suited for intravenous injection than strophanthin. The dose is from one one-hundred-and-twentieth to one-sixtieth of a grain (0.0005-0.0011 Gm.).

**PETROSELINUM. U. S.**

**PARSLEY FRUIT** Petrosel. [Parsley Seed]

"The dried ripe fruit of Petro selinum sativum Hoffman (Fam. Umbelliferae), without the presence or admixture of more than 5 per cent. of foreign seeds or other matter. Preserve Parsley Fruit carefully in tightly-closed containers, protected from light." U. S.

Ache, Persil, Fr.; Petersilie, G.; Prezzemolo, It.

Petroselinum sativum Hoffman (Apium petroselinum L.).—The common parsley, which is used extensively as a culinary herb, is a hardy biennial bearing pinnately-compound leaves, which in the cultivated varieties are greatly divided. During its early stages the leaves are arranged in rosettes and the plant is six inches or less above the ground; the flowering and fruiting plant, however, is from 2 to 3 feet in height. It is a native of Sardinia and was introduced into England in 1548, and is naturalized in salt marshes on the coast of California. It has been cultivated as a sweet herb since earliest times and was used by the ancient Greeks and Romans as a part of their festive garlands on account of retaining its color so long.

Parsley-root is recognized by the N. F.; it is spindle-shaped, about 1 cm. in thickness, externally white and marked with close annular wrinkles, internally fleshy and white with a yellowish central portion. It has a pleasant odor and sweetish slightly aromatic taste, but loses this property by long boiling and by time. It was formerly used as a diuretic
in dropsical affections, but has been shown by Cow (A. E. P. P., 1912, lxx, p. 393) to possess very feeble powers.

The fruit, which has been admitted into the U. S. P. IX consists of two dry, seed-like, mericarps, which are in the fresh state joined along the central commissure. It is officially described as follows: "Mericarps usually separated, ovoid-crescent shaped, from 2 to 3 mm. in length and about 1 mm. in diameter; externally grayish-brown, becoming grayish or brownish on aging, having 5 yellowish, filiform, prominent ribs, alternating with the coarsely roughened furrows; in transverse section nearly hemispherical, the commissural surface with 2 vittae or oil-tubes, the dorsal surface usually with a single vitta, occasionally 2 vittae in the groves between the primary ribs; endosperm large, oily, enclosing a small embryo; odor and taste characteristic and aromatic, especially when bruised. Under the microscope, sections of Parsley Fruit show an epidermal layer with thick cuticularized walls having numerous small centrifugal projections; several layers of small, thin-walled parenchyma cells, being usually considerably collapsed and occasionally containing a rosette aggregate of calcium oxalate; a single, large, brown, elliptical vitta or oil-tube between each of the primary ribs and surrounded by a layer of comparatively large yellowish-brown, tangentially elongated cells; a single fibro-vascular bundle more or less surrounded by a few or occasionally numerous sclerenchymatous fibers; inner epidermis of narrow, thin-walled elongated cells closely cohering with the brownish tabular cells of the seed-coat; commissural surface usually with 2 large vittae, a very few stone cells and showing a slight separation of pericarp and seed-coat; endosperm of polygonal, thick-walled parenchyma cells containing fixed oil and numerous, small aleurone grains usually containing a small rosette aggregate of calcium oxalate. The vittae usually contain yellowish oil globules or a resin-like mass adhering to the walls, and occasionally are divided by a radial wall. The powder is grayish-brown; mostly of large, irregular fragments; cells of endosperm with aleurone grains, each usually containing a rosette aggregate of calcium oxalate, from 0.003 to 0.007 mm. in diameter; fragments with light yellow vittae and the yellowish-brown cells of the pericarp; fragments with narrow tracheae and more or less lignified sclerenchymatous fibers." U. S.

All parts of the plant contain a volatile oil, to which it owes its odor and mainly its taste, as well as its use in seasoning. This oil consists of a hydrocarbon, C_{10}H_{16}, probably pinene, and apiol. Braconnot obtained
from the herb a peculiar substance, resembling pectic acid in appearance, which he named apiin. It is procured by boiling the herb in water, straining the liquor, and allowing it to cool. The apiin then forms a gelatinous mass, which requires only to be washed with cold water. (Ber. d. Chem. Ges., 1876, 1121) found that by repeated dissolving of this gelatinous mass in alcohol and precipitation by water it could be purified and then obtained from concentrated alcoholic solution in silky needles of the formula \( \text{C}_{27}\text{H}_{32}\text{O}_{16} \). Joret and Homolle found the seeds to contain a volatile oil, a crystallizable fatty matter, pectin, what they believe to be the apiin of Braconnot, chlorophyll, tannin, a coloring matter, extractive, lignin, various salts, and, in addition to these, a peculiar substance to which they gave the name of apiol. This, however, is a mixture only partly consisting of true apiol which is the dimethoxymethylene ether of allyl-tetra-oxo-benzene, \( \text{C}_{12}\text{H}_{14}\text{O}_{4} \). (See Oleoresina Petroselini.)

Off. Prep.—Oleoresina Petroselini, U. S.

**Peucedanum.** Chucklusa. Hog Fennel. Sulphurwort.—This is the root of Peucedanum officinale (Fam. Umbelliferae), originally an European plant but now growing in North America. The active constituent of the root is peucedanin, \( \text{C}_{16}\text{H}_{16}\text{O}_{4} \), stated to be diuretic and emmenagogue.

**Peucedanum palustre** Mchnch. Marsh Parsley. Marsh Smallage. Persil de Marais, Fr. Radix Olsnitii. Sumpfsilge, Elsenich, G.—The root of this European umbellifer is, when dried, of a brown color externally, having a strong aromatic odor, and an acrid, pungent, aromatic taste. Peschier found it to contain a volatile oil, a fixed oil, and a peculiar acid which he calls selinic. It has been used for epilepsy in Russia. Dose, from twenty to thirty grains (1.3-2.0 Gm.) thrice daily, rapidly increased to four times the amount. (J. P. C., 1859.)

**Pharbitis.**—A genus constituted by Choisy, 1833, its species referable to Ipomoea or Convolvulus. Ipomoea hederacea (L.) Jacq. (Pharbitis Nil Choisy).—The seeds of this Japanese plant have been chemically examined by K. Hirano and also by Y. Inoko, who find that they contain a large proportion of a resinous substance, seemingly identical with convolvulin, and acting as a cathartic in doses of from seven to ten grains (0.45-0.65 Gm.). (Sei-i-kwai, 1891.)

**Phaselin.**—This substance is represented as the active constituent of the bean of Dilkas Mexicano, a South American plant. It is used similarly to papain as a digestive in doses of eight to fifteen grains (0.5-1.0 Gm.).

**Phaseolus.** Phaseolus vulgaris L. Common Kidney or String Bean. (Fam. Leguminosae)—Of this species there are some 70 cultivated varieties. Soltzien found
an alkaloid, phaseoline, in the legumes of the common bean. He, during a toxicological analysis, traced the source of the alkaloid which might, under other circumstances, have been mistaken for a ptomaine, to the beans found in the stomach under examination. The new substance is not crystallizable in the free state, but it crystallizes as a hydrochloride. (A. Pharm., 1884.)

**Phyllanthus.** Phyllanthus Niruri L.—Ottow isolated from this widely distributed euphorbia-ceous plant phyllanthin, C\textsubscript{30}H\textsubscript{37}O\textsubscript{8}, which crystallizes in colorless needles, is intensely bitter, insoluble in water, but soluble in alcohol, petroleum benzin, chloroform, and ether.

**Physalis.** Physalis Alkekengi L. Alkekengi. Common Winter Cherry. Alkekenge, Coqueret, Fr. J udenkirscheSchlutte, G.—A perennial herbaceous plant, belonging to the Solanaceae growing wild in the south of Europe, cultivated in our gardens and said to be escaping locally. The fruit is a round red berry, about as large as a cherry, enclosed in the inflated calyx, and containing numerous flat kidney-shaped seeds. All parts of the plant are bitter, especially the leaves and the capsules enveloping the fruit. The berries are very juicy, and have an acidulous, bitterish taste. By drying they shrink, and become a brownish-red color. A bitter principle, physalin, has been isolated by Dessaignes and Chautard by extracting an infusion of the plant with chloroform. It is a yellowish, bitter powder, very slightly soluble in cold water and freely soluble in alcohol and chloroform, especially with the aid of heat. Its composition is C\textsubscript{14}H\textsubscript{16}O\textsubscript{5}. (J. P. C., 3e ser., xxi, 24.) The berries are said to be aperient and diuretic, and have been recommended in suppression of urine, gravel, and other diseases of the urinary passages. Gendron recommends them very highly as a febrifuge. (A. G. M., xxiii, 536.) They also have been highly commended in gout. An extract of alkekengi berries to which lithium salt has been added is sold under the name of lithal. From six to twelve berries, or half an ounce of the expressed juice, may be taken for a dose; and much larger quantities are not injurious. They are consumed to a considerable extent in some parts of Europe as food.

The berries of Physalis viscosa L., of this country, are said by Clayton to be diuretic.

**PHYSOSTIGMA. U. S.**

**PHYSOSTIGMA Physostig.** [Calabar Bean, Ordeal Bean]

"The dried ripe seeds of Physostigma venenosum Balfour (Fam. Leguminosae), yielding not less than 0.15 per cent. of the alkaloids of Physostigma." U. S.

Physostigmatis Semina, Br. 1898; Chopnut; Ordeal Bean of Calabar; Faba Calabarica; Feve du Calabar, Fr. Cod.; Kalabarbohne, G.; Haba del calabar, Eseve, Sp.
Physostigma venenosum is a climbing plant, with a ligneous stem, and frequenting especially the banks of streams, into which it often drops its fruit when ripe, and it is said that the people of Calabar derive their supply principally from the borders of the streams down which the fruits are carried. The rhizome is spreading, with numerous rootlets, often having attached to them small succulent tubers. The flowers are in axillary, multiflorous, pendulous racemes. The corolla is papilionaceous, of a pale pink color, with a purplish tinge. The legume when ripe is about seven inches long, and contains two or three seeds. It ripens at all seasons, but is most abundant during the rainy season from June to September. The seeds are the part used. The plant, which is indigenous to Western Africa, has been introduced into India and Brazil, and is said to flourish in the latter country. The market supplies are obtained from the regions surrounding the mouth of the Niger and the lower portion of the Calabar River, the chief port of export being Lagos (Ap. Ztg., xxvi, p. 568; xxvii, p. 137). Only one other species (P. mesoponticum Taub.), also of tropical Africa, is known. For a paper on the botanical description, history, etc., of Physostigma venenosum by J. U. Lloyd, see West. Drug., 1897, 249.

This bean was brought to the notice of the scientific public by Daniell, in 1846. Considerable attention was attached to the subject, and specimens of the bean were obtained by Christison from the Gold Coast. These were planted in the Botanical Garden at Edinburgh, and produced a perennial creeper. In the year 1859, specimens of the plant were sent from Calabar, which came under the observation of Balfour, of Edinburgh, who was thus enabled to ascertain its botanical character.

Properties.—The seeds are officially described as follows: " Oblong or ellipsoidal, somewhat compressed reniform, from 15 to 30 mm. in length and from 10 to 15 mm. in thickness; externally reddish or chocolate brown, smooth, somewhat wrinkled near the brownish-black groove, the latter being about 2 mm. in width and extending almost the entire length of the convex edge and in which are found frequently the remains of the white membranous funiculus, the margins of the seed-coat on both sides of the groove somewhat elevated, of a yellowish-red or brownish-red color and somewhat thickened; embryos large, white, with short hypocotyl and two concavo-convex cotyledons; taste at first starchy, afterwards acrid. The powder is grayish-white, starch grains numerous, from 0.005 to 0.15 mm. in diameter, ellipsoidal or somewhat reniform, and usually with a distinct cleft and frequently with radiating
or irregular fissures; fragments of seed-coat with very thick, reddish-brown cells, being either palisade-like or very irregular and resembling stone cells, but the walls are not lignified; an occasional fragment with tracheae showing reticulate thickenings. Physostigma yields not more than 3 per cent. of ash."

Physostigmine was official in the Br. Pharm., 1885, and was thus described: "In colorless or pinkish crystals, slightly soluble in water, but readily soluble in alcohol and in diluted acids. The aqueous solution has an alkaline reaction, when warmed with or when shaken with dilute solution of potash becomes red, and when evaporated to dryness over a water bath leaves a bluish residue, the acidified solution of which is beautifully dichroic, being blue and red." Br., 1885.

Calabar beans are occasionally substituted by a number of more or less similar seeds of African plants. Hartwich (S. W. P., 1905, p. 441) calls attention to a false physostigma found in the Hamburg drug market which is derived from Pentaclethra macrophylla Benth., a leguminous tree indigenous to tropical Africa. The seeds are dark reddish-brown, from 5 to 7 cm. long, about 5 cm. broad and about 1 cm. thick. They are flattened-oval or roundish-triangular.

Physostigma yields its virtues to alcohol, and imperfectly to water. The shell constitutes, according to Edwards, 30 per cent., the kernel 70 per cent., of the bean. Jobst and Hesse (J. P. C., March, 1864, p. 277) first isolated an active principle, which they found exclusively in the cotyledons. They obtained it by exhausting an alcoholic extract of the seeds with water, adding magnesia to neutralization, which is indicated by the liquid becoming brown, then concentrating, and treating with ether. The ethereal solution was shaken with a little weak sulphuric acid. The liquid separated into two layers—the upper, ethereal, containing no alkaloid, and the lower, a solution of the sulphate in water. The latter was separated, treated with magnesia, and afterwards with ether, which yielded the alkaloid on evaporation. The substance thus obtained they proposed to name physostigmine. In 1865 Vee and Leven (C. R. A. S., 60, 1194) obtained, by treating the seeds in nearly the same manner, an alkaloid to which they gave the name eserine, which formed colorless tabular crystals of a bitter taste, readily soluble in ether, alcohol, or chloroform, but sparingly in water. The crystals contain 1 molecule of water, which they lose at 100° C. (212° F.), and the anhydrous alkaloid then fuses at from 102° to 103° C. (215.6 °-
217.4° F.). Eserine is now generally accepted as identical with physostigmine. In 1867, Hesse (Ann. Ch. Ph., 141, 82) obtained the same alkaloid in a still purer state, perfectly colorless and tasteless, fusing at 45° C. (113° F.), and decomposing at 100° C. (212° F.) with red coloration. He gives it the formula C$_{15}$H$_{21}$O$_2$N$_3$.

A peculiarity of the alkaloid is that an aqueous solution of it, or of one of its salts, exposed to the air in the presence of potassium or sodium hydroxides, or lime, becomes red, owing to the absorption of oxygen. The coloring matter is taken up by chloroform. The color is not permanent, but gradually changes to yellow, green, or blue. This test will detect less than the hundred-thousandth part of the alkaloid. The same property is possessed by the alcoholic extract of the bean. This is the cause of the color changes taking place in solutions dispensed in ordinary glass bottles. The change may be retarded by previously rinsing out the bottle with diluted hydrochloric acid, and subsequently with distilled water, or it may be entirely prevented by coating the inner surface of the dispensing vial with paraffin.

Harnack and Witkowski (A. E. P. P., v; also x) in 1876 obtained still another alkaloid, which they named calabarine. It is soluble in alcohol and water, nearly insoluble in ether, melts at 132° C. (269.6° F.), and differs in physiological character from physostigmine. It is now generally known under the name of eseridine. The formula C$_{15}$H$_{23}$O$_3$N$_3$ has been given to it by Eber (Ph. Ztg., 1888, p. 611), which differs from that of physostigmine, it will be seen, by H$_2$O only, and it is stated that the one can be changed into the other by the action of dilute acids. It has properties like eserine but in a milder degree. Eseramine, C$_{16}$H$_{25}$O$_3$N$_4$, is another alkaloid of feeble activity which is present. It was announced by Ehrenberg in 1893 (Verhand. d. Gesellsch. Deutsche Natur. u. Aertzte, 1893, ii, p. 102). There is much reason for believing that calabarine is a decomposition product derived from physostigmine. (Husemann, A. E. P. P., 1878, 14; Harnack, A. E. P. P., x.)

Still another alkaloid announced by Salway is physorenine, C$_{14}$H$_{18}$O$_3$N$_2$. It is a powerful myotic like eserine. It is believed to be an intermediate product in the decomposition of eserine by alkalies, which results in the formation of a new base called eseroline, C$_{13}$H$_{18}$ON$_2$. Another decomposition product of eserine is produced by an excess of
ammonia and is called eserine blue, \( C_{17}H_{23}O_{2}N_{3} \).

Hesse obtained also a neutral fatty body, physisosterin, by exhausting the cotyledons with petroleum benzine. It is closely allied to cholesterin, but its chloroform solution is devoid of rotatory power. Its formula is \( C_{26}H_{44}O + H_{2}O \), and its melting point is 133° C. (271.4° F.).

**Uses.**—The action of physostigma is practically that of its dominant alkaloid physostigmine, but the effects are more or less modified by the other alkaloids; thus calabarine is a stimulant to the spinal cord and in this regard antagonistic to physostigmine, while isophyso-stigmine possesses the physiological properties of the dominant alkaloid upon the unstriped muscle, but apparently not upon the other structures of the body. For this reason whenever the systemic action is desired the alkaloid should be given the preference over preparations of the whole drug. On the other hand, as a stimulant to the unstriped muscle of the intestines, as in constipation, the whole drug may properly be used.

Poisoning.—Calabar bean has been used from time immemorial by the natives of Africa as an ordeal, and, when given by their head men, usually proves fatal to the accused, unless free vomiting occurs. A draught containing 19 seeds pounded and infused in water is said to have killed a man in an hour. In the experiments of Fraser, it was found that the integuments of the seeds, as well as the shell, are distinctly purgative. It is probable that in the fresh bean they are also emetic, and that the priests or chiefs who administer the ordeal take advantage of this in regulating the effects of the poison to suit their own purposes; sometimes, however, even the pure alkaloid causes vomiting. (Gubler.) Of seventy children poisoned in Liverpool by eating Calabar beans which had been thrown upon a waste heap, vomiting occurred, or was produced by emetics, in all except one, in whom four kernels caused death. The nausea and vomiting came on in about half an hour, the nervous symptoms in less than an hour.

There are generally diminution of reflexes, coarse muscular tremors which may be sufficiently violent to suggest convulsions, contraction of the pupil, and progressive diminution of motor power. In the fatal cases death is generally due to paralytic asphyxia.

In the treatment of physostigma poisoning the stomach should be thoroughly washed out either with an emetic or the stomach pump.
tannic acid or compound solution of iodine given as a chemical antidote. Atropine, which is a partial physiological antagonist, should be given in doses of about one-fiftieth of a grain (0.0013 Gm.), and strychnine and other stimulants employed as indicated.

Dose, one to three grains (0.065-0.2 Gm.).

**Phytelephas.**—Phytelephasmacrocarpa Ruiz. and Pav., or negrito-palm, of Ecuador, yields the Tagud nut, from which is derived the hard white substance, vegetable ivory or corajo. The nuts contain a fixed oil which is said to enter commerce. (J. P. C., xvi.) The ground nuts have been recently used as an adulterant in cattle powders.

The U. S. P. has in the past recognized both the root and the berries of the Phytolacca decandra L. This is an indigenous plant, with a large, branching, perennial root, often 20 to 25 cm. in diameter, which is fleshy, fibrous, whitish within, and covered with a thin brownish cork. The stems, which are annual, frequently grow to the height of 6 to 15 dm., and divide into numerous spreading branches, which are green when young, but becoming purple especially in the upper portions after the berries have ripened. The leaves are alternate, ovate-oblong, entire, pointed, smooth ribbed beneath, and on short foot-stalks. The flowers are small and in long racemes. The raceme of flowers becomes a cluster of dark purple, almost black, shining berries flattened above and below, and divided into ten loculi, each containing one seed.

Poke is abundant in all parts of the United States, flourishing along fences, by the borders of woods, in newly cleared fields, and especially in the muck thrown up from the ditches or swamps. It also grows spontaneously in Northern Africa and Southern Europe, where, however, it is supposed to have been introduced from America. Its flowers begin to appear in July, and the fruit ripens in autumn. The magnitude of the poke weed, its large rich leaves, and its beautiful clusters of purple berries, often mingled upon the same branch with the green unripe fruit and the flowers still in bloom, render it one of the most striking of our native plants. The young shoots are much used as food early in the spring, boiled in the manner of asparagus. The ashes of the stems and leaves yield, according to Bracconot, not less than 4.2 per cent. of potassium hydroxide. In the plant the potassium is combined with an acid resembling malic acid. The leaves, berries, and root are used in medicine, but the latter is the most active. It should be dug up late in November, cut into thin transverse slices, and dried with a moderate heat. As its virtues are diminished by keeping, a new supply should be procured every year. The berries should be collected when perfectly ripe, and the leaves about the middle of the Bummer, when the foot-stalks begin to redden.
The berries (Phytolaccae Fructus, U. S., 1890, Phytolaccae Baccae, U. S., 1880, Poke Berry) contain a succulent pulp, and yield upon pressure a large quantity of fine purplish, red juice. They have a sweet, nauseous, slightly acrid taste, with little odor.

The dried root is "cylindrical, somewhat tapering, sparingly branched, from 3 to 7 cm. in thickness, mostly in transverse or longitudinal slices; externally yellowish-brown, finely longitudinally or spirally wrinkled and thickly annulate with lighter colored, low ridges; fracture fibrous, characterized by alternating layers of fibro-vascular tissue and parenchyma, the layers of the latter being much retracted. Odor slight; taste sweetish, afterwards highly acrid. Phyt'olacca yields not more than 14 per cent. of ash." N. F.

From the analysis of Edward Donnelly, the root appears to contain tannic acid, starch, gum, sugar, resin, fixed oil and lignin, besides various inorganic substances. (A. J. P., xv, 169.) Claussen (Pharm., 1879, p. 466) prepared from the seeds of Phytolacca decandra, by extraction with alcohol, evaporation to dryness, and taking up with chloroform or ether, after washing the residue with petroleum benzin, a neutral principle in silky lustrous crystals, insoluble in water, soluble in alcohol, ether, and chloroform, which he named phytolaccin. A. Terel (C. R. A. S., 91, 856) obtained from the berries an acid (phytolaccic acid) as an uncrystallizable yellowish-brown mass of gummy consistency. It was soluble in water and alcohol, slightly soluble in ether, of acid reaction, and gelatinizing with hydrochloric and sulphuric acids. W. F. Wagner (A. J. P., 1887, p. 69) found tannin in the berries, but not in the root. W. A. Partee (A. J. P., 1888, p. 123) made a proximate examination of poke root and found crystals deposited from a solution of an alcoholic extract in absolute alcohol; he also discovered traces of tannin, glucose, and indications which pointed to the presence of a glucosidal principle. Frankforter and Ramaley (A. J. P., 1897, 281) have again analyzed the root with care. They find nearly 10 per cent. of a non-reducing sugar, free acid, identified as formic acid, but no certain proof of either alkaloid or glucoside. The very bitter resin amounted to 1 per cent.; phytolaccine, an alkaloid, has been said to exist in minute quantities in the root.

Uses.—Phytolacca is emetic, purgative and somewhat narcotic. As an emetic it is very slow in its operation, frequently not beginning to cause vomiting in less than one or two hours after it has been taken, and then continuing to act for a long time upon both the stomach and the bowels. The vomiting produced by it is said not to be attended with much pain or spasm, but narcotic effects have been observed by some physicians, such as drowsiness, vertigo, and dimness of vision. In overdoses it produces excessive vomiting and purging, attended with great prostration of strength, and sometimes with convulsions, and has, in several instances, proven fatal. According to Robert Bartholow, phytolacca causes in the lower animals convulsions and death from paralysis of respiration. It is not fit for use as an emetic, but has been employed as an alterative in chronic rheumatism, granular conjunctivitis, and even in cancer. Locally it has been used in the form of ointment (a drachm to the ounce) in the treatment of psora, tinea capitis, sycosis, and favus. It occasions at first a sense of smarting and heat in the parts to which it is applied. Alcohol, diluted alcohol, and water, extract the virtues of the poke root. A fluidextract is included in the National
Formulary.

Dose, emetic, ten to thirty grains (0.65-2.0 Gm.), alterative, one to five grains (0.065-0.32 Gm.).

**Phytolacca Acinosa** Roxh. (Fam. Phytolaccaceae)—This plant has long been used in Japan as a diuretic, and is said to be violently poisonous. C. Nagai has separated from it an amorphous resin, phytolaccotoxin, which appears to be a spinal convulsant, and at the same time stimulant to the circulation, probably through the vasomotor centers. (Sei-i-kwai. Med. Journ., April, 1891.)

**Pichurim Beans.** *Semen Pichurim. Sassafras Nuts. Feves Pichurim, Noix de Sassafras, Fr. Pichurimbohnen, Sassafrasnusse, G.*—The seeds of *Nectandra Puchury-major* Nees v. E., and *N. Puchury - minor Nees (Ocotea Puchury-minor Mart.) (Fam. Lauraceae), yielding respectively "Fabae Pichurim majores," or larger pichurim seeds, and "Fabae Pichurim minores," smaller pichurim seeds. The two species are closely allied and both have been known to botanists as *Ocotea Pichurim* H. B. K. (*Laurus Pichurim* Willd.). The trees grow in Brazil, Guiana, Venezuela, and other parts of South America, and are sometimes spoken of as Brazilian or South American Sassafras. Carson, of the University of Pennsylvania, had specimens of the fruit and other parts of the trees sent him, sufficient to verify the ascription of the pichurim beans to this source. (A. J. P., xxvii, 385.) The seeds of commerce usually consist of the separated cotyledons. They are plano-convex, from 3 to 5 cm. in length and nearly 2 cm. in width. Externally they are smooth and blackish-brown, being internally light brown. They have an aromatic odor combining that of nutmegs and sassafras, and a spicy pungent taste.

Pichurim beans contain a concrete volatile oil, a fatty matter of the consistency of butter, besides resin, fecula, gum, sugar, and lignin. The fatty matter, which is known as pichurim fat, amounts to about 30 per cent. and contains laurostearin, 

\[
C_3H_5C_{12}H_{23}O_2, \quad \text{and pichurim camphor which appears to be identical with laurel camphor. A liquid product brought from South America and known as the native oil of laurel or sassafras, or aceite de sassafras, is obtained by incising the trunk of the Nectandra puchury. This, as described by Procter (A. J. P., 1851, p. 1) is a reddish oleoresin with a specific gravity of 0.898, a characteristic odor, and an aromatic somewhat camphoraceous taste. It is believed to be the same as that with which the copaiba from Mara-caibo is adulterated. It may be distinguished from copaiba by its ready solubility in alcohol of 0.838 'and by the fact that its volatile oil is acted on by potassium.}

Muller, by distilling the oil in contact with sulphuric acid, obtained a greenish-yellow oil possessing the peculiar odor of the beans. By fractional distillation he separated—1, a colorless oil, boiling at 150° 0. (302° F.) ; 2, a colorless oil, boiling between 165° C. (329° F.) and 170° C. (338° F.); both of these oils consisting principally of hydrocarbons, OioHig; 3, a greenish-yellow viscid oil, boiling between 235° C. (455° F.) and 240° C. (464° F.), and having the composition C_{38}H_{58}O_2; 4, a deep blue oil, having a faint odor, boiling between 260° C. (500° F.) and 265° C. (509° F.).
In medicinal properties the pichurim beans resemble the common aromatics, and may be employed for the same purposes. In South America they are said to be used as a substitute for nutmeg, and have even been called by that name. They are rare in this country. The oil obtained from the tree is said to impart its odor to the perspiration and urine, and to be useful in rheumatism, gout, etc. The bark is sometimes employed as a tonic and febrifuge.

**Picrasma.** Picrasma quassioides (Ham.) Benn. (Fam. Simarubaceae)—The wood of this tree, which grows in the subtropical Himalayas, and resembles closely the Ailanthus in its appearance, has an intensely bitter taste, and has been proposed as a substitute for quassia. W. Dymock and C. J. H. Warden have found in it a crystalline principle which they believe to be quassin, and to exist in the probable proportion of from 0.02 to 0.03 per cent. The same investigators believe that the drug has in it a peculiar alkaloid. (P. J., xx, 1889.) A principle analogous to quassin was isolated by Shimoyamo from the bark of *P. elantoides*. (Ap. Ztg., 1892, 439.)

**PICRORHIZA. Br.**

**PICRORHIZA**

"Picrorhiza is the dried rhizome of Picrorhiza Kurroa, Royle." Br.

Kutki, Katki, Kuru, Kuruwa, Kaur, Karru, Kutaki, Kali-kutki, or Black Kutki, Katukurogani.

Picrorhiza Kurroa Royle (P. Kurrooa Benth.), more properly known as *P. Lindleyana* (Wall. Wettst.), is a low, hairy perennial herb (Fam. Scrophulariaceae), indigenous to the Alpine Himalayas. The rootstalk or the rhizome has long' been used in India and has been frequently spoken of by European and Mahometan writers as black hellebore, but is essentially different.

**Properties.**—Picrorhiza occurs "in cylindrical pieces two to five centimetres long, and four to eight millimetres thick, sometimes terminating in a stem or scaly leaf-bud; brittle. Cork greyish-brown, wrinkled, with transverse leaf scars and small buds. Fracture short. In transverse section internally dark and porous, with a thin, greyish cork and narrow ring of tangentially elongated wood-bundles. No odor; taste very bitter." Br.

Picrorhiza resembles externally the rhizome of Gentiana Kurroo Royle (Fam. Gentianaceae), the latter, however, is uniformly brown internally,
whereas the rhizome of Picrorhiza is darker or black, whence its name kali or black kutki. It is the dried rhizome of an Alpine-Himalayan plant, Kurroa. From this rhizome H. Warden has separated a glucoside, picrorhizin, which is freely soluble in water and alcohol and appears to be the bitter principle of the drug; also a red-brown, resinous, tasteless body, picrorhizetin, and, perhaps, cathartic acid (Pharmacog. Indica, vol. 3).

Uses.—The natives of India attribute active antiperiodic power to picrorhiza, which appears to be a powerful bitter tonic with slight laxative action. It is given in doses of from one to twenty grains (0.065-1.3 Gm.) as a tonic and from forty to fifty grains (2.6-3.2 Gm.) as an antiperiodic, usually in combination with aromatic.

PILOCARPUS. U. S.

PILOCARPUS Pilocarp. [J aborandi]

"The dried leaflets of Pilocarpus J aborandi Holmes, known in commerce as Pernambuco Jaborandi, or of Pilocarpus microphyllus Stapf, known in commerce as Maranham Jaborandi (Fam. Rutaceae), without the presence or admixture of more than 5 per cent. of the stalks bearing the leaflets and stems of the same plant, or other matter, and yielding not less than 0.6 per cent. of the alkaloids of Pilocarpus." U. S.

It is unfortunate in our opinion that this drug was omitted from the Br. Pharm., 1914; it was official in the Br. Pharm., 1898, under the title "J aborandi Folia."

Pilocarpus was first introduced to the notice of the European profession by Coutinho (J. P. C., 4e ser., xx, 51) under the name of Jaborandi, a name which has adhered to the drug, although the terms Jaborandi, laborandi and Jamborandi are used in South America to designate various pungent, sudorific plants, most of which belong to the genus Piper, but some of which have no botanical relation at all with the
peppers. Although the leaves of the Piper J aborandi have been sent into commerce as J aborandi, none of the true jaborandis of South America have any physiological relations with the official drug, which, in South America is known as Arruda do Mato or as Arruda brava or, rarely, as J amguarandi or J aurandi.

The genus Pilocarpus consists of woody shrubs belonging to the Rutaceae and inhabits tropical and subtropical America, including Cuba, Guadeloupe, Martinique, and probably other islands. For elaborate botanical and histological studies of the commercial species of Pilocarpus, see the articles by A. Duvall, B. Sc. Pharm., iii, pp. 41 and 98; Geiger, Ber. d. D. Phar. Ges., 1897, p. 356; Hartwich, Apoth. Zeit., 1900; Holmes P. J., 1903, p. 713; and 1904, p. 54; Schneider, Jour. of Pharmacology (N. Y. C. P.), 1897, No. 6; Tunman, S. W. P., xlvii, p. 177.

The following species of the genus have been used in medicine:

P. J aborandi Holmes (P. officinalis Poehl). —This plant inhabits the northern and northeastern part of Brazil whence its leaves find their way through Sergipe, Alagoa, Sobral and Ceara, etc., to Liverpool and Hamburg, the chief centers of European commerce in the drug. Like those of P. selloanus its leaves are two or three jugeate and are especially separated from those of the P. pennatifolius by the fact that all of the leaflets except the terminal one have their bases cordate, while the bases of all the leaflets of P. pennatifolius are attenuate. This species is practically no longer obtainable in commerce, only occasional lots being imported.

P. pennatifolius Lemaire (P. simplex Baillon) inhabits the southern portion of Brazil and Paraguay, whence its leaves were formerly largely exported through Buenos Ayres and Rio Janeiro; at present they seem to have almost disappeared from commerce. The leaves are grayish-green in color, oval, elliptical, obtuse, attenuate at the summit, which is feebly emarginate, and also attenuate at their base but not petiolated. The species is recognized in the Belgian Pharmacopoeia.

In the original specimens of J aborandi seen by Coutinho, and also in other specimens received from the doctor's family by F. V. G-reene, U. S. N., some of the leaves are hairy, although most of them are smooth, and it seems probable that the species does contribute somewhat to the J aborandi of commerce.
P. selloanus Engler, formerly official in the U. S. P., appears to be a variety of P. pennatifolius Lemaire, from which it differs almost solely in the length of its flower stalk, which is six times as long as the flower bud, while that of P. pennatifolius, is but three to four times as long as the bud. P. selloanus seems to be the more southern plant of the two, and ia especially abundant in Paraguay.

P. trachylophus Holmes.—The leaves of this species are smaller than those of the P. Jaborandi, and are oblong, elliptical, obtuse, and emarginate at the summit with cordate bases, symmetrically and shortly petiolate. The plant grows in Northeastern Brazil, especially in the provinces of Ceara and Maranhao, and the leaves, although they contain so little of the alkaloid (about 0.2 per cent.) as to be of small value, have been sent into commerce in considerable quantities. Their color upon the surface is vivid green, below yellowish-green. The under surface is covered with short hairs.

P. microphyllus Stapf grows in the northeastern part of Brazil, whence the leaves, much mixed with the debris of the petioles, of the twigs and of the fruit, are sent to Liverpool and Hamburg. These leaves are alternate, im-paripinnate having from one to five pairs of leaflets, or are often apparently simple owing to the failure of the lateral leaflets to develop. The leaflets are opposite, slightly pubescent, their petioles being marked by a deep longitudinal furrow. They vary very much in form, the base usually being attenuate and feebly cordate or unequal.

P. spicatus A. Saint-Hilaire (P. parviflorus Martins et Nees), inhabits the southern and northern portions of Brazil and can be recognized at once by its having simple leaves which are from 3 to 11 cm. long and from 1 to 4 cm. broad, and are tender or coriaceous and more or less pubescent and dotted. They are brownish-green above, paler beneath, and attached by a short twisted petiole. They appeared in commerce in 1895 under the name of Arocati jaborandi. P. subcoriaceus Engler is probably a variety of this species. P. racemosus Vain, a native of Martinique, Cuba, Guadeloupe and probably other of the West Indian Islands, appeared first in commerce in 1903 as a new variety of jaborandi under the name of Guadeloupe jaborandi. The leaves are proportionately broader than those of Pernambuco jaborandi, more obovate in outline, of a purer green color, and are trifoliate or apparently simple. Considerable diversity of result has been obtained by chemists in the examination of the Guadeloupe jaborandi. Rocher (A. J.)
P., 1900) obtained 1 per cent. of total alkaloids of which 0.6 per cent. was believed to be pilocarpine, the remainder jaborine. In the laboratory of Wright, Layman and Umney, only 0.34 per cent. of total alkaloids were reported as existing, while in an assay by A. J. Cowenley (P. J., 1903, lxxxii) 0.6 per cent. of total alkaloids was obtained, about 50 per cent. of which was believed to be isopilocarpine. The commercial cultivation of jaborandi (may some day be successful, as the P. pennatifolius has been found to grow freely in Sicily and produce a leaf containing a fair proportion of alkaloid. Pilocarpus is usually bought by assay. The variation in the percentage of alkaloid, according to the observations of A. Duval, depends not merely on the original contents of the drug but upon the fact that the alkaloid disappears when the pilocarpus is kept for some length of time in a moist atmosphere. Pilocarpus was at one time adulterated with spurious jaborandis, other foreign leaves, stems, dirt and mouldy leaves. At the present time the commercial article is of good quality. There are, however, reports of the leaves of other plants being substituted. Weigel states that under the name of "Foeliles de Bois d'inde," the leaves of the logwood plant were substituted for Paraguay jaborandi. The most common adulterant appears to be in lots of P. microphyllus, which often contain leaves of the leguminous plant, Tunatea decipiens (Holmes), O. Kze. (Swartzia decipiens Holmes). In general appearance the two leaves resemble one another, both being imparipinnate and having the leaflets about the same size and shape, but in P. microphyllus the leaflets are opposite and the petioles are only slightly pubescent, while in the Tunatea the leaflets are alternate, and the petioles very pubescent. Then again, the absence of secreting hairs, the deep green of the upper and lighter green of the lower surface of the leguminous leaf serve easily to distinguish it from the true drug.

The following description of the drug is adapted from that of F. V. Greene, U. S. N., who had unquestionable specimens of the original jaborandi of Coutinho. The package contained several stems branched at an angle of about 20°, these branches being furnished with alternate leaves, which are imparipinnate, with from two to five opposite leaflets (Planchon has met with leaves having as many as seven or nine, and, more rarely, eleven leaflets) articulated to the rachis by short petiolules, thickened at the base. The leaflets, which are coriaceous in texture, vary considerably in size and outline. As a rule, they may be considered as oblong-lanceolate, and are entire, emarginate, with an unequal base. The midrib rises very little above the upper surface of the leaflet, but is
very prominent and sharp on the lower. The veins, which are rather more prominent on the lower surface, leave the midrib at an angle of about 60°, pursue a parallel course across the leaflet, and finally turn up and anastomose within about a quarter of an inch of the margin. The leaflets are pellucidly punctate; the dots are the receptacles of secretion, are numerously and irregularly distributed over the whole surface, and are plainly visible when the leaflet is held up to the light. According to Conroy, the leaflets yield 0.76 per cent., the leafstalks only 0.37 per cent. of alkaloid. The fruit consists of five carpels, of which not more than two or three are usually developed to maturity; when ripe, the carpels dehisce into two valves, and then remind one strongly of miniature cockle shells with the valves open exposing the animals. The black, shining, reniform seeds (one for each carpel) have a lancet-shaped hilum, a sharp ridge on the back near the apex, and a smooth, pale yellow endocarp surrounding it.

Paraguay jaborandi from P. pennatifolius and P. selloamis is an inferior variety of the drug, which reaches European commerce from Buenos Ayres and from Rio Janeiro, and is believed to be collected in Paraguay. The leaves are thinner than those of the Pernambuco jaborandi, and have only two or three, never four, pairs of leaflets. It is also noticeable in the Paraguay variety that the lateral veins are not prominent, that the base is so tapered that the widest portion is above the middle, and that the upper surface is grayish-green.

Properties.—The Pernambuco and Maranham jaborandis are official, being described as follows:

'Pernambuco Jaborandi.—Leaflets when entire, oval, oblong, or elliptical, from 4 to 10.5 cm. in length and from 2 to 4 cm. in breadth and with short, stout petiolules; summits more or less rounded or acute and emarginate; bases rounded or acute and mostly unequal; margins entire and narrowly revolute; very smooth, shiny, coriaceous and glandular-punctate; upper surfaces grayish to brownish-green, midribs mostly depressed, under surfaces yellowish- or greenish-brown and slightly pubescent. on the prominent midvein; peculiarly aromatic when crushed; taste bitterish, becoming somewhat pungent and having a sialogogue effect.

'Maranham Jaborandi.—Leaflets rhomboid-ally oval to obovate or elliptical from 1.5 to 5 cm-in length and from 1 to 3 cm. in breadth, the
lateral ones nearly sessile, the terminal ones on margined petiolules, from 0.5 to 1.5 cm. in length; of a nearly uniform grayish or yellowish-green color, rather thin but otherwise resembling Pernambuco Jaborandi.

"Under the microscope, transverse sections of Pilocarpus show the upper epidermal cells with a yellowish layer of cutin from 0.005 to 0.01 mm. in thickness; palisade cells, 1 to 3 rows deep, being filled with chloroplastids; among the palisade cells occur large, nearly circular, oil-secretion reservoirs from 0.08 to 0.15 nun. in diameter; the dorsal pneumatic layer, from 10 to 20 rows in depth, the cells occasionally containing rosette aggregates of calcium oxalate from 0.01 to 0.025 mm. in diameter; distributed in the center of the leaf are the collateral fibro-vascular bundles each surrounded by a more or less interrupted circle of several rows of thick-walled, slightly lignified bast-fibers, tracheae associated with strongly lignified wood-fibers; among the cells of the lower epidermis occur numerous stomata. On surface view the stomata are broadly elliptical, from 0.025 to 0.04 mm. in length, being uniformly smaller in Maranham Jaborandi. Upon both surfaces of Pernambuco Jaborandi occur a number of non-glandular, one-celled hairs, more or less bent or curved, from 0.08 to 0.5 mm. in length, thick-walled and with numerous, slight, centrifugal projections.

The powder is dark green or greenish-brown; epidermal cells on surface view 5-or 6-sided; stomata broadly elliptical, from 0.02 to 0.04 mm. in length, usually with four neighboring cells; fragments of fibro-vascular bundles showing tracheae with simple or bordered pores or spiral thickenings, associated with thick-walled and strongly lignified wood-fibers; bast-fibers few, walls thick and only slightly lignified; calcium oxalate in rosette aggregates, from 0.01 to 0.025 mm. in diameter; fragments of laminae showing large, oil-secretion reservoirs and usually containing one or more globules of oil; non-glandular hairs having thick walls, usually more or less broken, are occasionally found. Pilocarpus yields not more than 7 per cent. of ash." U. S.

An alkaloid was isolated in 1875 from Jaborandi almost simultaneously by A. W. Gerrard and M. Hardy. To this the name of pilocarpine was given. Gerrard at the same time stated that there were at least two alkaloids in the leaves, and this view seemed to be confirmed when jaborine was discovered. He also obtained a volatile oil, tannic acid, a peculiar volatile acid, and potassium chloride. Pilocarpine may be
prepared as follows. The leaves are exhausted with 80 per cent. alcohol containing 8 grammes of hydrochloric acid in a liter, the tincture is distilled and evaporated to the consistence of a liquid extract, and this is mixed with a small quantity of water, and filtered. The filtrate is treated with a slight excess of ammonia, and then with a large quantity of chloroform. The chloroform solution is agitated with water, to which hydrochloric acid is added, drop by drop, in sufficient quantity to neutralize the alkaloid, the hydrochloride of which is obtained in long needles on evaporating the aqueous solution, while foreign principles remain dissolved in the chloroform. By dissolving the crystals in water, treating the solution with ammonia and chloroform, and evaporating the latter solution, pilocarpine is obtained as a soft viscous mass, which is only slightly soluble in water, but is freely soluble in alcohol, ether, and chloroform.

Kingzett originally assigned pilocarpine the formula C_{23}H_{24}O_{4}N_{4}+4H_{2}O. Hamack and Meyer, on the other hand, give it as C_{11}H_{16}O_{2}N_{2}. The latter has been accepted, and is recognized by the U. S. Pharmacopoeia. It was later definitely established as correct by the synthesis of pilocarpine afterwards effected by Hardy and Calmels. (C. R. A. S., cv, pp. 68 to 71; also A. J. P., 1887, p. 632.) By the action of hydrochloric acid or of barium hydroxide, pilocarpine, C_{11}H_{16}O_{2}N_{2}, is changed into pilocarpidine, C_{10}H_{14}O_{2}N_{2}, by the loss of a methyl group.

Now Hardy and Calmels have converted β-pyridine-a-lactic acid, into pilocarpidine, the methyl iodide of which by oxidation is converted into pilocarpine. The synthetical pilocarpidine and pilocarpine yield gummy derivatives similar to those obtained by Harnack and Meyer from the natural products. The physiological action of synthetical pilocarpine is identical with that of the natural alkaloid. Knudsen, E. Merck, and Petit and Polonovski all dispute the conclusions of Hardy and Calmels, and state that they failed to get pilocarpine by the synthetic method of these investigators. (Proc. A. Ph. A., 1897, 716.) Petit and Polonovski (J. P. C. (6), v, 481) obtained pilocarpic and pilocarpidic acids from pilocarpine and pilocarpidine. Harnack and Meyer first stated that jaborine is easily formed from pilocarpine, and may be produced by simply heating the latter alkaloid. They also showed that pilocarpine has physiological effects analogous to those of nicotine, while jaborine resembles atropine in its effects.

Uses.—The therapeutic virtues of jaborandi appear to be due entirely to
the alkaloid pilocarpine and the crude drug is very rarely employed.

When an overdose of jaborandi, or its principle alkaloid, has been taken, the symptoms begin with flushing of the face and neck, soon followed by free sweating and salivation, both of which may be extremely profuse. Frequently there is nausea and sometimes vomiting, the pulse is usually somewhat more rapid than normal, the pupils contracted, and often there is diarrhea. In patients with circulatory disturbances, pulmonary edema may occur, and prove rapidly fatal. The antagonism between pilocarpine and atropine is about as complete as between any two drugs, and the most certain treatment for cases of poisoning by jaborandi, after evacuating the stomach, is the prompt administration of a full dose of atropine, or some substance containing it.

Dose, of jaborandi, from twenty to forty grains (1.3-2.6 Gm.).

Off. Prep.—Fluidextractum Pilocarpi, U. S.

**PILULÆ.**

**PILLS**

Pilules, Fr.; Pillen, G.; Pillole, It.; Pildoras, Sp.

These are globular masses of a size convenient for swallowing. They are well adapted for the administration of medicines which are unpleasant to the taste or smell, or insoluble in water, and which do not require to be given in large doses. Deliquescent substances should not be made into pills, and those which are efflorescent should be previously deprived of their water by crystallization. Care should be taken not to combine materials the mutual reaction of which may result in a change of physical conditions.

Some substances have a consistence which enables them to be made immediately into pills. Such are the softer extracts and certain gum-resins, and the addition of a little water to the former, and of a few drops of alcohol to the latter, will give them the requisite softness and plasticity, if previously wanting. Substances which are very soft, or in the liquid state, are formed into the pilular mass by incorporation with dry and inert powders, such as wheat flour, starch, and powdered gum arabic, or with crumb of bread. Powders must be mixed with soft, solid
bodies, as extracts, confections, soap, etc., or with tenacious liquids, as syrup, molasses, honey, mucilage or glycerin and the last-mentioned substance has been especially recommended in connection with a little alcohol. Heavy metallic powders are most conveniently made into pills with the former; light vegetable powders with the latter. Mucilage is very often used, but pills made with it are apt when kept to become hard and of difficult solubility in the liquids of the stomach, and if metallic substances are mixed with it the mass does not work well. A mixture of syrup and powdered gum arabic is not subject to the same inconveniences, and is an excellent material for the formation of pills. Honey evaporated to about half its bulk has been highly recommended. Confection of rose and glucose are among the best excipients, when the pills are to be kept long. For the same purpose of keeping the pills soft, the addition of a small portion of some fixed oil or deliquescent salt has been recommended, but glycerin is still better. Glycerin incorporated with one-twenty-fifth of its weight of powdered tragacanth is said to cause pills to remain soluble for almost any length of time. The official mucilage of tragacanth is an excellent excipient. Martindale prepares a mass by heating together with constant stirring to 115.5° C. (240° F.) five parts by weight of glycerin and one of flour, or, when a very firm mass is required, equal parts of flour and glycerin. It has been objected that pills made with glycerin could not be handsomely gilded or silvered, the luster of the metal disappearing. This is true, however, only of very recent pills, or of those in which an excess of glycerin has been used. Many powders require only water. Such are all those which contain ingredients capable of forming an adhesive or viscid solution with the liquid. Care should always be taken that the substance added is not incompatible with the main constituents of the pill.

The materials should be accurately mixed together, and beaten in a mortar until formed into a perfectly uniform and plastic mass. This should be of such a consistence that the pills may preserve their form, without being so hard as to resist the solvent power of the gastric fluids. As pills frequently become very hard by time, it is often convenient to keep the mass in a state fit to be divided when wanted for use. This may be done by wrapping it in waxed paper, putting it in covered pots, and occasionally moistening it as it becomes dry, or, more effectually, by keeping it in glass or well glazed jars, accurately closed with rubber cloth. The mass is made into pills by rolling it with a spatula, or with a flat, smooth piece of hard wood, into a cylinder of precisely the same thickness throughout, and of a length corresponding to the number of
pills required. It is then divided as equally as possible by the hand, or, more accurately, by a machine. (See Remington's Practice of Pharmacy, 5th edition, p. 1217.) The pills receive a spherical form by being rolled between the fingers or by the use of one of the pill rolling machines. Mialhe describes a little instrument for rolling pills, composed of two circular plates, one about 12 inches, the other 6, in diameter, the former having a ledge at the border one-third of an inch high, the latter with a similar ledge, varying, according to the size of the pills, from less than a line to nearly two lines, and with a strap on the back by which it can be fitted to the hand. This is to be moved in a rotary manner upon the larger plate, holding the divided portions of the pill mass. Similar pill rollers made of wood are now in use. In order to prevent the adhesion of pills to one another, or to the sides of the vessel in which they may be placed, it is customary to agitate them with some dry powder, which gives them an external coating, that serves also to conceal their taste. For this purpose magnesium carbonate, rice flour, or starch may be used. Magnesium carbonate is sometimes incompatible with one of the ingredients of the pills, and licorice root is then preferable, though it occasionally becomes mouldy with very damp pills. The powder of lycopodium, which has been long in use in Europe, is now considerably employed in this country, and is perhaps one of the best substances for the purpose. It is the custom in some sections of the United States, particularly on the Pacific coast, to give the pill a coating of gold or silver leaf. This is done by agitating the pills, prepared without dusting powder, and with their surface still damp, or coated with a very small quantity of mucilage, with gold or silver leaf, in a hollow spherical wooden box made by turning two hemispheres out of hard wood, fitting each other, and provided with a short handle.

It was proposed by Garot to cover pills with gelatin, which answers the purpose of concealing their taste and odor and counteracting deliquescence or chemical change from exposure to the air, but it sometimes interferes with their solubility in the stomach. This method of coating is largely used at the present time. One of the best machines that have been devised for gelatin coating pills extemporaneously on the small scale is that of H. Maynard, of Chicago. This consists of a circular plate in which are affixed twenty fine needles; the pills are rolled into depressions, and are easily impaled on the points of the needles; they are then dipped into a solution of gelatin, gently rotated, and allowed to cool. Another plan, less effectual, but more convenient, is to introduce the pills into a spherical box, to drop on them enough syrup
simply to moisten their surface, then to give a rotary movement to the box until the pills are uniformly covered, and finally to add by degrees either powdered French chalk, elm bark, or some similar substance, shaking the box with each addition, and continuing the process until nothing more will adhere to the pills. The investing material may be rendered agreeable to the taste and smell by aromatic additions, if deemed advisable. Calloud found that a good powder for coating pills, because little disposed to attract moisture, is made by boiling one part of flaxseed and three parts of white sugar with sufficient Water until a thick mucilage is formed, evaporating this carefully to dryness, and then pulverizing. The same writer has since suggested, as still more effective, a powder made by forming a mucilage with one part of tragacanth and two parts of water, pressing this through linen, mixing it with twenty parts of sugar of milk, spreading the paste thus made in thin layers to dry, and then powdering. The pills may be simply moistened with water and then shaken in the powder. L'Hermite proposed first to agitate the pills in a mortar with a little concentrated solution of gum, and afterwards to put them into a box containing dry and very finely powdered sugar, to which a rotary motion is given. If the coating be not sufficiently thick, the process may be repeated. (J. P. C., xxv, 460.) For a list of excipients for pills by J. Cohn, see Proc. A. Ph. A., 1900, 469 from Ph. Ztg., 1900, 221; also G. Gugge, A. Ph. A. Year Book, 1914, p. 81.

Gelatin coating on the larger scale is accomplished by the use of the vacuum apparatus of J. B. Russell (see Remington's Practice of Pharmacy), or by simply rotating the pills in contact with a solution of gelatin in large spherical vessels, such as are used for sugar coating.

The sugar coating of pills is now conducted upon a large scale by manufacturers, who send immense quantities both of popular and of official pills into the market thus protected. The process employed is similar to that of the confectioners in coating almonds. After having been thoroughly dried, the pills are put into a hemispherical tinned copper basin, which is suspended from the ceiling and moved quickly backward and forward with an eccentric motion, so as to cause a constant attrition among the pills. First a little very thick syrup, or syrup of gum, is introduced in order to give a thin coating to their surface, and afterwards very finely powdered and very dry white sugar is sifted or thrown over them, the motion being constantly maintained. The sugar is fixed by the moist surface of the pills, and the coating
made compact and smooth by the attrition. The process is aided by a
gentle heat, but the heat must be guarded, lest the pills be much
softened, and thus lose their shape and even discolor the coating.
Dexterous manipulation is necessary in order that the process may
succeed thoroughly. For practical remarks on the sugar coating of pills,
see an essay by H. C. Archibald in A. J. P., 1867, p. 199, and by Wm. R.
Warner, dr., and T. S. Wiegand in A. J. P., 1902, 32. On a larger scale a
pill coater of copper of peculiar construction, heated by steam pipes, is
now used.

Still another method of coating pills, proposed by E. K. Durden is to
cover the pills with collodion, which completely conceals the taste. The
solution employed by Durden had the sp. gr. 0.810, and two dippings
gave a sufficient coating. (A. J. P., xxi, 183.) It is, however, yet to be
determined whether a coating of collodion would yield readily to the
solvent powers of the gastric juice. Blanchard covers pills with a solution
of Tolu balsam in ether, but H. C. Baildon objects to this, that it takes
too long to dry, and suggests as a substitute a solution of a drachm
of the balsam in three drachms of chloroform, which dries sufficiently in
twenty minutes. If old and solid Tolu balsam be selected, it will be less
liable to the objection of drying slowly. This balsam is officially employed
in coating the U. S. pills of ferrous iodide. A solution of mastic in ether
has also been used for coating pills, and the white of egg has been
recommended for the same purpose.

Pills are sometimes coated with substances which do not dissolve in the
stomach, with the object of permitting the passage of the undissolved pill
into the intestines; for this purpose keratin coating has been largely
used. (See Keratin, Part II, and Remington's Practice of Pharmacy, sixth
edition.) Salol has also been employed, by melting it in an enamelled
pan at a temperature of about 50° C. (122° F.) and dropping in the pills,
rotating until covered, and then transferring to a dry pan, still rotating
(to prevent adhesion) until cold.

An improved (method of salol coating for pills intended for enteric use
has been contributed by J. C. and B. L. DeG. Peacock (Proc. P. Ph. A.,
1915, p. 258). The particular points to be observed are the amount of
salol to be used and the shape and size of the vessel used in melting the
salol.

W. Q. Toplis (Proc. P. Ph. A., 1915, p. 262) proposes stearic acid as an
enteric coating for pills and gives details of the method to be followed in producing a satisfactory article.

Pills which are to be kept long should be well dried, and put into bottles with loosely fitting stoppers to prevent mouldiness. Though the U. S. Pharmacopoeia, in almost every instance, orders the mass to 'be divided into pills, yet it should be understood rather as indicating the number of pills to be made from a certain quantity of the mass, -when particular directions are not given by the physician, than as requiring the division to be made immediately after the materials have been mixed. It will be found convenient by the apothecary to retain a portion of the mass undivided, especially when it is desirable to keep the pills soft. The British Pharmacopoeia furnishes formulas for pill masses, using the title of "Pilula " instead of "Massa," the title of the class adopted by the U. S. Pharmacopoeia; there is, in our opinion, a decided advantage in selecting a name for the class which is not likely to be confused with that used for the divided pills.

Pills containing silver nitrate, potassium permanganate or other easily oxidizable substances, should be made by diluting with kaolin or talc and massing with petrolatum or mixtures of petrolatum and paraffin. All organic matter should be excluded.

Compressed pills are made directly from the medicinal substance without the aid of an excipient. The drug, if not already in granular powder, is made so, and then forced into pill shape by means of a powerful press. For certain substances which are crystalline in structure, such as quinine bisulphate, potassium bromide, and potassium iodide, and which have some cohesiveness and yet are of easy solubility, the process is a good one. An apparatus was contrived by J. P. Remington for compressing pills (see 16th ed., U. S. D., and Practice of Pharmacy, 5th ed., page 1233). It is made of cast steel; the base has two counter-sunk depressions with a short post in the center of each, and a lenticular depression is made in the upper surface of each post. A steel cylinder having a central aperture of the diameter of the post is placed in the depression, the proper quantity of powder is introduced, and the plunger, which has a corresponding lenticular depression on its lower surface, is placed on the powder and is struck a quick blow with a mallet; the powder is compressed, and the pill adheres to the cylinder; by removing the cylinder and holding it over a box and tapping the plunger again lightly, the pill is forced out and falls into a box.
Compressed tablets, are now used to an enormous extent, being made by various manufacturers with machinery of ingenious construction; the fact of their requiring no excipient, the ease with which they can be tested, and their permanent character (in most cases being just as valuable years after they were made as when fresh) have caused their extensive employment. Care should be taken, however, not to use them in those few cases where very prompt action is required, as the powerful compression to which they are subjected renders them less quickly effective than the same drug administered in the form of a loose powder.

For a description of some of the more important forms of pill compressing machines with illustrations, see Remington's Practice of Pharmacy, sixth edition.

**PILULÆ ALOES. U. S. (Br.)**

**PILLS OF ALOES Pil. Aloes**

*Pilula Aloes*, Br.; Aloes Pill; Pill of Barbados Aloes, Pill of Socotraine Aloes; Pilules d'Aloes et de Savon, Fr. Cod.; Pilules Aloetiques Savoneuses, Fr.; Alcepillen, G.

"Aloes, in fine powder, thirteen grammes [or 201 grains]; Soap, in fine powder, thirteen grammes [or 201 grains]; Water, a sufficient quantity, to make one hundred pills. Mix the powders intimately, then incorporate sufficient water to form a mass, and divide it into one hundred pills." U. S.

"Aloes, in powder, 58 grammes; Hard Soap, in powder, 29 grammes; Oil of Caraway, 3 millilitres; Syrup of Glucose, 10 grammes or a sufficient quantity. Mix to form a mass." Br.

In the Br. Pharm., 1898, confection of rose was used as the excipient. It is now replaced by syrup of glucose.

The former British process for Pill of Socotraine Aloes was the same except that Socotraine was substituted for Barbados Aloes, and the volatile Oil of Nutmeg for Oil of Caraway.

The soap, in this formula, not only serves to impart a proper consistence to the aloes, but is thought to qualify its operation and diminish its
liability to irritate the rectum. Five of the U. S. pills, containing ten
grains (0.65 Gm.) of aloes, may be given with a view to their purgative
effect, but the preparation is usually employed as a laxative in habitual
costiveness.

Dose, one, two or three pills at bedtime. The British pill mass is of very
nearly the same strength as that of the U. S. Pharmacopoeia.

PILULA ALOES ET ASAFOETIDÆ. Br.

PILL OF ALOES AND ASAFOETIDA

Pilulae Aloes et Asafoetidae, N. F.; Pilules d’Aloes et d’Asefetide, Fr.; Aloe und
Asfetida-Pillen, G.

A process for these pills was not retained in the U. S. P. IX, but are
recognized by the N. F. IV (see Part III); the British process is as follows:

Aloes, in powder, 30 grammes; Asafetida, 30 grammes; Hard Soap, in
powder, 30 grammes; Syrup of Glucose, 10 grammes, or a sufficient
quantity. Mix to form a mass." Br.

In the Br. Pharm., 1898, confection of rose was used as the excipient. It
is now replaced by syrup of glucose.

Pills made from this mass are peculiarly adapted, by the stimulant and
carmínative properties of the asafetida, to ease of costiveness attended
with flatulence and debility of the digestive organs.

Dose, about four grains (0.26 Gm.) of the mass.

PILULA ALOES ET FERRI. Br.

PILL OF ALOES AND IRON

Pilulae Aloes et Ferri, N. F.; Pilulæ Italicae Nigrae; Pilules d’Aloes et de Fer, Fr.;
Pilulae Aloeticae ferratae, P. G.; Eisenhaltige Aloepillen, Aloe und Eisenpilletten,
Italienische Pillen, G.,

"Exsiccated Ferrous Sulphate, 10 grammes; Aloes, in powder, 20
grammes; Compound Powder of Cinnamon, 35 grammes; Syrup of
Glucose, 35 grammes, or a sufficient quantity. Mix to form a mass." Br.
These pills were deleted from the U. S. P. IX, but were introduced without change into the N. F. IV.

This pill differs from the preparation of the same name in the British Pharmacopoeia in the substitution of aromatic powder for the compound powder of cinnamon. It is essentially an old preparation of the Edinburgh Pharmacopoeia, was omitted in the original British, and reintroduced and continued in the present edition. The Br. Pharm., 1898, improved this mass by substituting exsiccated ferrous sulphate for the crystallized salt formerly employed, and by the use of syrup of glucose instead of confection of rose. It is said that the laxative power of aloes is increased, and its tendency to irritate the rectum diminished, by combination with ferrous sulphate. This pill is especially adapted to amenorrhea with debility of the stomach and constipation.

Dose, of the Br. mass, from three to eight grains (0.2-0.5 Gm.); of the N. F. pills, from one to three pills.

**PILULA ALOES ET MYRRHÆ. Br.**

**PILL OF ALOES AND MYRRH**

Pilulae Aloes et Myrrhae, N. F., Rufus's Pills; Pilule d'Aloes et de Myrrhe, Pilules de Rufus, Fr.; Rufussche Pillen, G.

"Aloes, in powder, 44 grammes; Myrrh, in powder, 22 grammes; Syrup of -lucose, 34 grammes, or a sufficient quantity. Mix to form a mass." Br.

These pills were deleted from the U. S. P. IX, but were introduced without change into the N. F. IV.

This composition has been long in use, under the name of Rufus's Pills. It is employed, as a warm stimulant cathartic, in general debility attended with constipation, and in retention or suppression of the menses.

Dose, of the Br. mass, from four to eight grains (0.26-0.5 Gm.); of the N. F. pills, three to six pills.
PILULE ASAFÆTIDÆ. U. S.

PILLS OF ASAFETIDA Pil. Asafoet.

Pilules d'Asefetide, Fr.; Asafoetida-Pillen, G.

"Asafetida, twenty grammes [or 309 grains]; Soap, in fine powder, six grammes [or 93 grains]; Water, a sufficient quantity, to make one hundred pills. Beat the solids together with water, so as to form a mass, and divide it into one hundred pills." U. S.

Each of these pills contains three grains (0.20 Gm.) of asafetida. They are a convenient form for administering asafetida, the unpleasant odor and taste of which render it very offensive in the liquid state.

Dose, one to three pills.

PILULAE CATHARTICÆ COMPOSITÆ. U. S.

Antibilious Pills; Pilules cathartiques composees, Fr.; Abfuhrpille, G.

"Compound Extract of Colocynth, eighty grammes [or 2 ounces av., 360 grains]; Mild Mercurous Chloride, sixty grammes [or 2 ounces av., 51 grains]; Resin of Jalap, in fine powder, twenty grammes [or 309 grains]; Gamboge, in fine powder, fifteen grammes [or 231 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand pills. Mix the powders intimately, then incorporate a sufficient quantity "of diluted alcohol to form a mass, and divide it into one thousand pills." U. S.

This cathartic compound was first made official in the second edition of the U. S. Pharmacopoeia. It was intended to combine smallness of bulk with efficiency and comparative mildness of purgative action and a peculiar tendency to the biliary organs. Such an official preparation was much wanted in this country, in which bilious fevers, and other complaints attended with congestion of the liver and portal circle generally, so much abound. The object of smallness of bulk is accomplished by employing extracts and the more energetic cathartics; that of a peculiar tendency to the liver, by the use of calomel, and that of efficiency with mildness of operation, by the union of several
powerful purgatives. It is a fact, abundantly proved by experience, that drastic cathartics become milder by combination, without losing any of their purgative power. It is highly important that these pills be prepared in exact compliance with the directions, and that the compound extract of colocynth and the resin of Jalap used be of good quality. When they fail, the result is generally ascribable to the substitution of jalap for the resin, or to the use of a compound extract of colocynth made with nearly inert scammony, inferior aloes, and insufficient colocynth, and altogether badly prepared.

Each pill weighs about 3 grains (0.194 Gm.), and contains 2.70 grains (0.175 Gm.) of active ingredients. A single pill will generally be found to operate as a mild laxative. In a full dose, the preparation acts vigorously on the bowels, producing bilious stools, generally without much pain or disorder of the stomach. It may be employed in most instances where a brisk cathartic is required, but is particularly applicable to the early stages of bilious fevers, to hepatitis, jaundice, and all those derangements which depend on congestion of the portal circle. It should not be used in habitual constipation.

Dose, one to three pills.

**PILULA COLOCYNTHIDIS COMPOSITA. Br.**

**COMPOUND PILL OF COLOCYNTH**

Pilulae Colocynthidis Compositae, N. F.; Cochia Pills; Pilules de Coloquinte composees, Fr. Cod.; Pilules cochees mineures, Fr.; Zusammengesetzte Koloquinten-Pillen, G.

"Colocynth Pulp, in powder, 20 grammes; Aloes, in powder, 35 grammes; Scammony Resin, in powder, 35 grammes; Potassium Sulphate, in powder, 5 grammes; Oil of Cloves, 5 millilitres; Distilled Water, a sufficient quantity. Triturate the Oil of Cloves with the Potassium Sulphate; add the Colocynth Pulp; mix; add the Aloes and Scammony Resin; mix; add Distilled Water, and mix to form a mass." Br.

This is not, like the old London pills of the same name, merely another form of the compound extract of colocynth, though containing essentially the same materials—one great difference being that colocynth and aloes are used in substance in the pill, instead of in the state of extract. Potassium sulphate is used to promote the more
complete division of the aloes and scammony. The preparation is actively cathartic. This pill is also official in the N. F. IV.

Dose, from five to ten grains (0.32-0.65 Gm.).

**Off. Prep.**—Pilula Colocynthidis et Hyoscyami, Br.

**PILULA COLOCYNTHIDIS ET HYOSCYAMI. Br.**

**PILL OF COLOCYNTH AND HYOSCYAMUS**

Pilulae Colocynthidis et Hyoscyami, N. F.: Pilules de Coloquinte et d'Extrait de Jusquiam, Fr.; Koloquinten-Bilsenkrautpillemasse, G.

"Compound Pill of Colocynth, 50 grammes; Extract of Hyoscyamus, 25 grammes; Distilled Water, a sufficient quantity. Mix to form a mass." Br.

This was an official pill of the Edinburgh College. It is asserted that the compound pill and compound extract of colocynth are almost entirely deprived of their griping tendency by combination, as above, with extract of hyoscyamus, without losing any of their purgative power.

Dose, from five to twenty grains (0.32-1.3 Gm.).

This pill is also official in the N. F. IV).

**PILULA IPECACUANHA CUM SCILLA. Br.**

**PILL OF IPECACUANHA WITH SQUILL**

Pilules d'Ipecacuanha et de Scille, Fr.; Brechwurzel-Meerzwiebelpillen, G.

"Compound Powder of Ipecacuanha, 30 grammes; Squill, in powder, 10 grammes; Am-moniac'nm, in powder, 10 grammes; Syrup of Glucose, a sufficient quantity. Mix to form a mass. This Pill contains about 5 per cent. of Opium." Br.

This is an old-fashioned combination of expectorants, intended for chronic bronchitis, but scarcely in keeping with modern practice.

Dose, from five to ten grains (0.32-0.65 Gm.).
PILL OF IPECACUANHA WITH URGINEA

"Compound Powder of Ipecacuanha, 30 grammes; Urginea, in powder, 10 grammes; Ammoniacum, in powder, 10 grammes; Syrup of Glucose, a sufficient quantity. Mix to form a mass. This Pill contains about 5 per cent. of Opium." Br.

This is the same as Pill of Ipecacuanhae with Squill, except that Indian Squill or Urginea is used in place of the Mediterranean variety.

COMPOUND PILLS OF RHUBARB Pil. Rhei Co.

Pilula Rhei Composita, Br.; Pilules de Rhubarbe composees, Fr.; Rhabarber und Aloepillen, G.

"Rhubarb, in No. 80 powder, thirteen grammes [or 201 grains]; Aloes, in fine powder, ten grammes [or 154 grains]; Myrrh, in fine powder, six grammes [or 93 grains]; Oil of Peppermint, five-tenths of a mil [or 8 minims]; Water, a sufficient quantity, to make one hundred pills. Mix the oil of peppermint intimately with the powders, then incorporate sufficient water to form a mass; divide it into one hundred pills." U. S.

"Rhubarb, in powder, 25 grammes; Aloes, in powder, 20 grammes; Myrrh, in powder, 14 grammes; Hard Soap, in powder, 14 grammes; Oil of Peppermint, 2 millilitres; Syrup of Glucose, 25 grammes, or a sufficient quantity. Mix to form a mass." Br.

This is a tonic laxative, useful in constiveness. If made in quantity the pills should be kept in loosely stoppered bottles. The use of glycerin favors the formation of mouldiness through the attraction of moisture, and it was replaced in the formula of the Br. Ph., 1898, by syrup of glucose.

Dose, of the compound rhubarb pills, two to four pills, or from five to fifteen grains (0.32-1.0 Gm.) of the mass, twice a day.
PILULA SCILLÆ COMPOSITA. Br.

COMPOUND SQUILL PILL

"Squill, in powder, 25 grammes; Ginger, in powder, 20 grammes; Ammoniacum in powder, 20 grammes; Hard Soap, in powder, 15 grammes; Syrup of Glucose, 20 grammes, or a sufficient quantity. Mix to form a mass." Br.

This preparation was dropped at the 1880 revision of the U. S. Pharmacopoeia.

This is a stimulating expectorant compound, depending for its virtues chiefly on the squill, and applicable to the treatment of chronic bronchitis. The mass should be freshly made when wanted, as the squill which it contains is liable to be injured by keeping.

Dose, from five to ten grains (0.32-0.65 Gm.).

PILULA URQINEÆ COMPOSITA. Br.

COMPOUND URGINEA PILL

"Urginea, in powder, 25 grammes; Ginger, in powder, 20 grammes; Ammoniacum, in powder, 20 grammes; Hard Soap, in powder, 15 grammes; Syrup of Glucose, 20 grammes, or a sufficient quantity. Mix to form a mass." Br.

This pill is the same as the Compound Squill pill, except that the Indian Squill, Urginea, replaces the ordinary variety.

Dose, from five to ten grains (0.32-0.65 Gm.).

Pimenta was dropped from the U. S. and Br. Pharmacopoeias but admitted to the National Formulary IV.

The tree yielding pimenta is a native of the West Indies, Mexico, and South America, and is abundant in Jamaica, whence its fruit received the name of Jamaica pepper. The allspice plant is cultivated in Central America and the surrounding countries, but more than half the supply to the United States comes from Jamaica, where the tree is so abundant as to form in the mountainous districts whole forests, and to require no further cultivation than the clearing out of the under-brush. The berries are gathered after having attained their full size, but while yet green, and are carefully dried in the sun. When sufficiently dry, they are put into bags and casks for exportation. The fruits of four other species of the genus Pimenta, found in Venezuela, Guiana, and the West Indies, are employed in their native countries as spices.

It is described by the N. F. as: "Sub-globular, from 4 to 7 mm. in diameter, summits with four calyx teeth forming a minute ring; externally dark brown, somewhat rough and glandular-punctate; pericarp brittle, about 1 mm. in thickness; two-celled and two-seeded; dissepiments thin; seeds plano-convex, slightly reniform, externally reddish-brown, smooth, somewhat wrinkled and shiny. Odor and taste, particularly of the pericarp, aromatic and distinctive. The powder is reddish-brown or dark brown and, when examined under the microscope, shows irregular fragments and numerous starch grains, the latter being either simple or compound, the individual grains spherical, from 0.003 to 0.015 mm. in diameter, plano-convex or polygonal, and frequently with a central circular marking or cleft; stone cells numerous, of tabular, pyriform or variable shape and with thick, porous, and strongly lignified walls, the lumina frequently filled with a yellowish-or reddish-brown amorphous substance, fragments with oil secretion reservoirs containing globules of a yellowish-brown oil; parenchyma cells with reddish-brown tannin masses. Stem fragments very few, and characterized by more or less curved, thick-walled, non-glandular hairs, rosette aggregates of calcium oxalate, from 0.006 to 0.017 mm. in diameter, tracheid-like tissues of the wood and long narrow bast fibers. The yield of crude fiber does not exceed 25 per cent. when estimated as directed in the U. S. Pharmacopoeia. Pimenta yields not more than 6 per cent. of ash." N. F.

The odor of Pimenta berries is thought to resemble that of a mixture of cinnamon, cloves, and nutmeg. Hence the name of allspice, by which they are best known in this country. They impart their flavor to water, and all their virtues to alcohol. The infusion is of a brown color, and reddens litmus paper.

Pimenta yields a volatile oil by distillation having the sp. gr. of from 1.04 to 1.05 at 15° C. (59° F.). (See Oleum Pimentae) Bonastre obtained from them a volatile oil, a green fixed oil, a fatty substance in yellowish flakes, tannin, gum, resin, uncrystallizable sugar, coloring matter, malic and gallic acids, saline matters, moisture, and lignin. The green oil has the burning aromatic taste of pimenta, and is supposed to be the acrid principle. Upon this, therefore, together with the volatile oil, the medicinal properties of the berries depend, and, as these two principles exist most largely in the shell or cortical portion, this part is most efficient. According to
Bonastre, the shell contains 10 per cent. of the volatile and 8 of the fixed oil, the seeds
only 5 per cent. of the former and 2.5 of the latter. Berzelius considered the green
fixed oil of Bonastre as a mixture of volatile oil, resin, fixed oil, and perhaps a little
chlorophyll. Dragendorff, in 1871, announced the existence of an alkaloid in allspice. It
is present in exceedingly small quantity, and has somewhat the odor of coniine. W. W.
Abell obtained from 448 Gm. of pimenta leaves one-half of one per cent. of volatile oil
resembling oil of bay; he also found tannic acid. (A. J. P., 1886, 163.) A convention of
hygienists at Vienna decided that ground allspice should not yield more than 6 per
cent. of ash, of which not more than 0.5 per cent. should be soluble in hydrochloric
acid.

Pimenta is sometimes adulterated by the larger and less aromatic berries of the
Mexican Myrtus Tobasco Mocino.

Uses.—Pimenta is an aromatic spice, used in medicine chiefly as an adjuvant to
tonics and purgatives. It is particularly useful in cases attended with much flatulence.
It is, however, much more largely employed as a condiment than as a medicine.

It is one of the ingredients in compound tincture of guaiac of the National Formulary
IV. Aqua PimentaeBr., 1898, was formerly official—it was a distilled water.

Dose, ten to forty grains (0.65-2.6 Gm.).

**Pimento Water** (Aqua Pimentae). Eau de piment de la Jamaïque, Fr.;
 Nelkenpfefferwasser, G.—It was prepared by the Br. 1898 as follows; "Pimento,
bruised, 8 ounces (Imperial) or 250 grammes; water, 2 gallons (Imp. meas.) or 10
litres. Distil one-half." Br., 1898. Pimento water is an agreeable aromatic water, used
as a vehicle.

**Pimpinella.** N. F. IV. Pimpernel Root. Pimpinella Saxifraga L. Small Burnet
 Saxifrage. Saxifraga. Radix Pimpinellae, P. G. Grand Boucage, Fr. Pimpinell,
 Bibernell, G.—" The dried rhizome and roots of Pimpinella Saxifraga Linne, or
Pimpinella magna Linne (Fam. Umbelliferae)." N. F.

This is a perennial umbelliferous European plant growing on sunny hills, and in dry
meadows and pastures. It is also naturalized, growing along roadsides and in waste
places in the northern United States and Canada. The root has a strong, aromatic,
yet unpleasant odor, and a sweetish, pungent, biting, aromatic, bitterish taste.
Pimpinella is described by the N. F. aa "cylindrical or slightly tapering, from 10 to 20
cm. in length and from 1 to 1.5 cm. in diameter at the crown, frequently branching,
sometimes split longitudinally or broken into pieces; the upper or rhizome portion
annulate, with undeveloped stem buds and a few attached stem remains which should
not be over 5 cm. in length; roots longitudinally wrinkled, slightly annulate, cortex
thin, easily detached; fracture short when dry, tough and flexuous when damp;
externally light yellowish-brown; internally porous; cortex broad and whitish with
numerous groups of projecting radial bast fibers and reddish-brown oleoresin cells;
wood yellowish, usually with a few indistinct fibers, medullary rays interrupted,
cambium zone distinct. Odor aromatic; taste sweetish, pungent and acrid.

"The powdered drug, when examined under the microscope, shows numerous simple or two- to four-compound starch grains, the individual grains being from 0.004 to 0.01 mm. in diameter; secretion canals from 0.05 to 0.06 mm. in diameter; tracheae reticulate or scalariform, from 0.035 to 0.07 mm. in breadth; fibers, thin-walled numerous, thick-walled with simple pores few (P. magna).

"Pimpinella yields not more than 5 per cent. of ash." N. F.

Its active constituents are volatile oil and an acrid resin. The yellow volatile oil has an odor recalling parsley, and a biting taste. Buchheim obtained from the alcoholic extract a crystalline principle, which he called pimpinellin, \( \text{C}_{13}\text{H}_{10}\text{O}_{5} \). It is insoluble in water and petroleum ether, but soluble in alcohol. It is considered diaphoretic, diuretic, and stomachic, and has been used in chronic catarrh, asthma, dropsy, amenorrhea, etc. The dose in substance is about half a drachm (2.0 Gm.), and in infusion two drachms (7.7 Gm.). The root is used also as a local stimulant in toothache, etc.

**Pinckneya.** Pinckneya pubens Rich. Fever Tree (Fam. Rubiaceae)—A large shrub or small tree, growing in South Carolina, Georgia, and Florida, in low and moist places along the sea-coast. It is botanically allied to the Cinchonas. The bark is bitter and has been used with alleged advantage in intermittent fever. E. H. Naudain (A. J. P., April, 1885) found in it a glucoside, pinckneyin, but no alkaloid.

**Pineapple.** Ananas sativa Schult. f. (Fam. Bromeliaceae)—Some years ago V. Marcano discovered that the juice of the ordinary pineapple has the power of digesting proteid vegetable and animal substances. R. II. Chittenden (Trans. Connecticut Academy, vol. viii, 1891) found that the fresh pineapple juice is a very constant and powerful digestant of albuminous matters; that the ferment is decidedly active in the presence of either acids or alkaline carbonates, but is most energetic in neutral solution; that the ferment is most active between 50° and 60° C. (122° and 140° F.); still digests at 30° C. (86° F.), but is destroyed at a temperature of 70° C. (158° F.); that the digestion takes place with rapidity; that the ferment, to which the name bromelin has been given, is more nearly related to trypsin than to pepsin, forming during its action not only proteoses and peptone, but also leucine and tyrosine.

E. V. Flack subjected pineapples grown in Cape Colony to analysis. He found in the fresh fruit: Crude fat 1.11 per cent., proteins 0.49 per cent., crude fiber 0.33 per cent., nitrogen-free extract 13.51 per cent., ash 0.70 per cent., silica, 0.069 per cent., lime 0.047 per cent., potash 0.358 per cent., phosphoric oxide 0.024 per cent., and moisture 83.86 per cent. (Chem. News, 1912, 99.)

**Pinguicula Vulgaris** and **Pinguicula Alpina** L. (Fam. Lentibulariaceae)—These perennials of the northern United States and Canada are used as a folk medicine in the treatment of wounds and as a purgative. It has been asserted that P. vulgaris contains a proteolytic ferment; this has been used in combination with the extract of thyme in the treatment of whooping-cough under the name of "diatussin." The dose of
diatussin for a child of five years is one to three drops twice a day.

**Pini-Pini.** Arra Diabo.—This is the bark of *Jatropha urens* (Fam. Euphorbiaceae).—This Brazilian plant has been long used by the natives of Southern America as a blistering agent. Very little is known of its constituents and it is but lately that it has come into notice as a caustic and blistering medium.

**PIPER. U. S.**

**PEPPER [Black Pepper]**

"The dried, unripe fruit of *Piper nigrum* Linne (Fam. Piperaceae), without the presence or admixture of more than 2 per cent. of stems or other foreign matter." U. S.

Piper Nigrum, Br. 1898; Common Pepper; Poivre noir, Fr. Cod.; Poivre, Fr.; Schwarzer Pfeffer, G.; Pepenero, It.; Pimienti negra, Sp.; Fifil uswud, Arab.; Lada, Malay; Maricha, J av.; Sahar, Palembang.

The pepper vine (*Piper nigrum*) is a perennial plant, with a round, smooth, woody, articulated stem, swelling near the joints, branched, and from eight to twelve feet or more in length. The leaves are entire, broad-ovate, acuminate, seven-nerved, coriaceous, very smooth, of a dark green color, and attached by strong sheath-like footstalks to the joints of the branches. The flowers are small, whitish, sessile, covering thickly a cylindrical spadix, and succeeded by globular berries, which are red when ripe.

The plant grows wild in Cochin-China and various parts of India. It is cultivated on the coast of Malabar, in the peninsula of Malacca, in Siam, Sumatra, Java, Borneo, the Philippines, Japan, and many other places in the East; also to some extent in the West Indies. The best pepper is affirmed to be produced in Malabar, but Europe and America derive their chief supplies from Sumatra and Java. The plant is propagated by cuttings, and is supported by props, or trees planted for the purpose, upon which it is trained. In three or four years from the period of planting, it begins to bear fruit. The plant sometimes begins to bear as early as the first year after planting, increases in its yield to the fifth or sixth year, when it produces eight or ten pounds, and begins to lose its productiveness about the fifteenth year. The berries are gathered as soon as one is seen to turn red—i.e., before they are all perfectly ripe—and upon being dried, become black and wrinkled. The greatest
production is in Sumatra, and the ports of export are principally Singapore and Penang, the Malabar pepper coming from Tellicherry. In England, at least, it is customary to mix peppers of different origin in grinding, taking Malabar for weight, Penang for strength, and Sumatra for color. (Bulletin U. S. Dept. of Agric., No. 13, 1887.) The importations from the Strait Settlements to the United States of unground black and white pepper is on an average about 20,000,000 pounds annually. Owing to the widespread cultivation of pepper a large number of varieties exist; these receive their names from the place of their production or their ports of shipment, as Singapore, Acheen, Penang, Siam, Tellicherry, Trang, Lampong, etc. For a description of the most important of these varieties with the percentage of active constituents contained in each, see J. W. Gladhill, A. J. P., Feb., 1904; Kraemer and Sindall, A. J. P., 1908, p. 1; also Blyth, Foods: Their Composition and Analysis.

White pepper is the ripe berry, deprived of a part of its pericarp by maceration in water and subsequent friction, and afterwards dried in the sun. It occurs as yellowish more or less broken grains with a smooth shiny surface from which the epicarp or outer layer of the fruit has been removed. It is sold in the market either as a whole white pepper or as broken white pepper; the whole peppers are very likely to have some of the epicarp or hull remaining. The removed hull is sold separately under the name of "pepper hulls;" it forms a light to dark brown powder, with a very pungent odor and taste and contains large amounts of the oleoresin of pepper, but according to Gladhill, no piperine. The hulls are sometimes sold mixed with broken white pepper. This mixture contains more oleoresin and less piperine than does the pure pepper; the percentage of the two active constituents varying according to the percentage of drugs in the mixture. White pepper is much less pungent but more aromatic than black pepper.

Long Pepper is obtained from Piper officinarum DC., and P. longum L., the former species yielding the principal commercial supplies and being grown in Java, India, and the Philippines. The plants are distinguished in having their flowers in dense, short, terminal, and nearly cylindrical spikes and their fruits, consisting of very small one-seeded berries or drupes, embedded in a pulpy matter. The fruit is green when immature, and becomes red as it ripens. It is gathered in the former state, as it is then hotter than when perfectly ripe. The whole spike is taken from the plant, and dried in the sun. The fruit of the P. officinarum is cylindrical,
2 to 6 cm. long and 4 to 7 mm. in diameter, indented on its surface, of a dark-gray color, a weak aromatic odor, and a pungent fiery taste. The fruits of *P. longum* are shorter and thicker. Dulong found its chemical composition to be closely analogous to that of black pepper. Like that, it contains pipeline, a concrete oil or soft resin upon which its burning acridity depends, and a volatile oil to which it probably owes its odor. Its medicinal virtues are essentially the same as those of black pepper, but it is inferior to that spice, and is seldom used except as an adulterant. West African or Ashantee Pepper is the fruit of *P. Clussii*, C. DC., which grows abundantly in tropical Africa. It does not come into Western commerce, although much used in Africa. The berry is described as resembling cubeb, but less rugose, and with a more slender pedicel, and having the odor and taste of black pepper. Stenhouse found piperine in this variety of pepper.

Kissi Pepper is a fruit yielded by the *Piper Famechoni*, Heckel, of Upper Guinea. The berries, which grow in cylindrical clusters, are small, blackish-brown, ovoidal, with a cubeb-like pedicel at their base. Their powder is very aromatic, with an especially pleasant taste. They have been found by A. Barille to contain 4.5 per cent. of volatile oil and 3.7 per cent. of piperine. (J. P. C., 1903, 106.)

**Properties**—The dried berries are "nearly globular, from 3.5 to 6 mm. in diameter, epicarp very thin, easily separable from the sarcocarp; externally blackish-brown or grayish-black, coarsely reticulate; unilocular, 1-seeded; seed nearly white, hollow, adhering to the pericarp; odor aromatic, slightly empyreumatic; taste aromatic and very pungent. The powder is a mixture of blackish-brown fragments of the pericarp and nearly white fragments of the endosperm and embryo; starch grains spherical or somewhat angular, from 0.001 to 0.003 mm. in diameter, mostly in the polygonal cells of the endosperm; stone cells of the epicarp varying from nearly isodiametric or palisade-like to long tapering or somewhat irregular in shape, with thick porous walls and large lumina frequently containing a reddish-brown pigment; stone cells of the endocarp unevenly thickened, the outer walls being usually rather thin, and the lumina usually filled with a reddish-brown substance; oil cells with suberized walls and containing a yellowish oil, from which monoclinic prisms of piperine occasionally separate. Pepper yields not less than 6 per cent. of non-volatile extract, soluble in ether. It contains not less than 25 per cent. of starch. Pepper yields not more than 7 per cent. of ash. The amount of ash in Pepper, insoluble in
diluted hydrochloric acid, does not exceed 2 per cent. of the weight of Pepper taken."

U. S.

They yield their virtues partially to water, entirely to alcohol and ether. Pelletier found them to contain a peculiar principle called piperine (see Part II), an acrid concrete oil or soft resin of a green color, a balsamic volatile oil, isomerio with oil of turpentine, a colored gummy substance, an extractive matter, like that found in leguminous plants capable of being precipitated by infusion of galls, starch, a portion of bassorin, tartaric and malic acids, lignin, and various salts. William Johnston (Konig's Nahrungs- und Genussmittel, 3d ed., Bd. i, 1046) finds that piperidine, C₅H₁₁N, is an invariable constituent of pepper in amounts varying from 0.21 to 0.77 per cent.

Piperidine is of great chemical interest as being a simple derivative of pyridine, which seems to underly the molecular structure of so many alkaloids. Piperidine is a hexalhydropyridine and can easily be obtained from pyridine by the action of tin and hydrochloric acid. Conversely piperidine can be changed into pyridine when sulphuric acid at 300° C. (572° F.) or gentle oxidizing agents act upon it. Coniine, it will be remembered, is a normal propylpyridine. Moore and Row (J. P., 1898) have shown that piperidine resembles coniine in its physiological effects.

The taste and medicinal activity of pepper depend mainly on the concrete oil or resin, and on the volatile oil. The concrete oil is of a deep green color, very acrid, and soluble in alcohol and ether. The volatile oil is limpid, colorless, becoming yellow by age, of a strong odor, and of a taste less acrid than that of pepper itself. It consists of terpenes including' dipentene, phellandrene, etc., and it forms a liquid but not a solid compound with hydrochloric acid. According to Weigle (Ap. Ztg., 1893, 626), pepper contains; besides cellulose, starch, and coloring matter, (1) Volatile oil, smelling strongly of pepper, but without pungency; (2) a thick oil, tasteless and nearly odorless; (3) odorless piperine whose solutions possess the pungency of pepper. Weigle believes that in the fresh fruit the volatile oil acts as a solvent for the
piperine and he thus accounts for their pungency.

For a paper on commercial peppers, by J. W. Gladhill, see A. J. P., 1904, 71.

Adulterations.—On account of its extensive use as a condiment, pepper has been largely adulterated, especially when sold in the form of a powder. Chief of the adulterants are pepper-hulls, ground olive pits, wheat middlings, and roasted cereals. Among the other substances sometimes used have been ground beans or peas, corn starch, flaxseed, mustard hulls, and coffee hulls. The adulterated articles are usually fortified with the addition of Cayenne pepper. At the present time, by virtue of the National and state Food Laws, black pepper is seldom adulterated. Adulterations can be detected by the microscope with more or less ease (see P. J., lxxi, 269; P. J., June, 1890; Bull. U. S. Dept. of Agriculture, No. 13, Part II, pp. 183, 1887; A. J. P., 1887, 146); but when pepper has been adulterated to the amount of 10 per cent. the discovery of the fraud is best made by determining the proportion of ash, of ether extract and of piperine present. The ash should never be above 6.5 per cent. for black and 3 per cent. for white pepper; the ether extract should be between 7.5 and 10 per cent. for black and 6 to 9 per cent. for white pepper, the U. S. standard being not less than 6 per cent. in which not less than 3.25 per cent. nitrogen shall be present. Piperine should be present in from 5.5 to 9 per cent. in good black pepper. The amount of oleoresin in any pepper can readily be determined by subtracting the weight of piperine from that of the mixture. Penang pepper is sometimes made to resemble the higher priced white peppers by coating the grains with an earthy matter (lime or clay). According to A. Mennechet, the fruits of Myrsine africana and of Embelia Ribes may sometimes be detected in the powder of pepper by extracting with ether and adding a little water, followed by a few drops of ammonia, when after shaking, a deep lilac-red color will appear in the aqueous layer. (J. P. C., xiv, 587.)

Uses.—Black pepper is a warm carminative stimulant, capable of producing general arterial excitement, but acting with greater proportional energy on the part to which it is applied. From the time of Hippocrates it has been used as a condiment and in medicine. Its chief medicinal application is to excite the languid stomach and correct flatulence. It was for years occasionally administered for the cure of intermittents, but its employment for this purpose had passed from the
profession to the laity, till a few years since revived by an Italian physician, to be again consigned to forgetfulness. Piperine has also been employed in the same disease, and has even been thought superior to quinine sulphate, but experience has not confirmed this favorable opinion. That, in its impure state, when mixed with a portion of the acrid principle, it will occasionally cure intermittents, there can be no doubt, but it is not comparable to the preparations of cinchona, and is certain fly less active than the official oleoresin of pepper. In intermittent fever, pepper may be found a useful adjuvant to the more powerful febrifuge. It may be given whole or in powder, but is more energetic in the latter state.

Dose, of pepper, five to twenty grains (0.32-1.3 Gm.).

**PiperNovae-Hollandiae** Miq. (Fam. Piperaceae)—The berries of this Australian pepper contain a volatile oil, and are said to be useful in gonorrhea and allied diseases.

Piper Ovatum Vahl.—From the leaves of this plant, found growing in Trinidad, Dunstan and Carr (Chem. News, 1895, 278) extracted a crystalline principle, piperovatine, \( C_{16}H_{21}NO_2 \). It is insoluble in water, but soluble in alcohol. It is said to act as a depressant of both motor and sensory nerves, and as a stimulant to the spinal cord.

**Pipi Root.**—The root of the *Petiveria alliacea* L. (Fam. Phytolaccaceae), which more than sixty years ago attracted notice in Europe, is said to have re-entered commerce. It is described as consisting of irregularly bent pieces, 3 to 6 mm. thick, externally grayish-brown, upon transverse section showing a brownish bark with white dots, and a lighter colored radiating ligneous wood. The cork layer consists of 3 or 4 rows of cells, the thick primary bark encloses crystals of calcium oxalate; the woody cord contains tracheids with narrow dotted tracheae, two-rowed medullary rays and in the center a thin pitli. The genus *Petiveria* grows in tropical America, extending into Mexico and Texas. The shrubby plants are mostly acrid and have an alliaceous odor. It is reported to be a stimulant, expectorant and diaphoretic. (A. J. P., Aug., 1887.)

**Piscidia.** *Piscidia Erythrina* L., Jamaica Dogwood. Dogwood Bark. *Ecorce du Bois de chien. Ecarce de Piscdie. Mulungu. Murungu.*—This is a leguminous tree growing throughout the West Indies and the neighboring countries, being found in Florida, Texas, Mexico, and the northern portion of South America, and yielding to commerce a very valuable wood. From time immemorial the bark has been used for catching fish. The leaves, twigs, and root bark are collected, macerated with the residue from...
the distillation of rum or with lime water, then transferred into baskets, and the latter
dragged up and down the water until the fish are stupefied.

In 1844 William Hamilton called the attention of the profession to the plant (P. J.,
Aug., 1844) as a powerful narcotic and analgesic. The bark of commerce is in pieces of
5 to 10 cm. in length and about 8 cm. in width, having a thickness of 1.5 cm. The
outer surface of some of the pieces is of a dark gray-brown, while others are of a
yellow-brown, with no shade of gray present. The bark is frequently studded with
flattened protuberances of a lighter color than the surrounding cork. The central part
of the bark is much lighter colored, and, when wet or freshly broken, is of a peculiar
blue-green color. The inner part of the bark is of a dark brown color and very fibrous.
It has a strong odor resembling opium when broken into pieces. It is acrimonious, and
produces a burning sensation in the mouth and pharynx.

E. Hart obtained a neutral principle, C_{29}H_{24}O_{8}, to which he gave the name piscidin.
(A. J. P., 1883, 369; see also Ibid., Sept., 1898.) Paul C. Freer and A. M. Clover have
examined Hart's piscidin and found it to consist of two distinct chemical compounds.
The first of these forms colorless, highly refracting rectangular prisms, melting at
201° C. (393.8° F.); composition C_{25}H_{20}O_{7}. The second separates from alcohol in fine
yellow needles, melting at 216° G. (420.8° F.); composition C_{20}H_{18}O_{6}. The authors
found also in the aqueous extract of the bark piscidic acid, soluble in water; insoluble
in chloroform, benzene or ligroin. It forms acicular crystals, which melt at 182° to
185° C. (359.6°-3650 F.); composition H_{2}C_{11}H_{10}O_{7}. (A. Pharm., Feb., 1901.)

The action of the drug upon the lower animals has been studied by J. Ott and A. C.
Nagle with similar results. (Jamaica Dogwood, Parke, Davis & Co., 1881.) The
conclusions reached are: 1. It is narcotic to frogs, rabbits, and men. 2. It does not
affect the irritability of the motor nerves. 3. It does not attack the peripheral ends of
the sensory nerves. 4. It reduces reflex action by a stimulant action on the centers of
Setschenow. 5. It produces a tetanoid state by a stimulant action on the spinal cord,
and not by a paralysis of Setschenow's centers. 6. It dilates the pupil, which dilatation
passes into a state of contraction upon the supervision of asphyxia. 7. It is a
salivator. 8. It increases the secretion of the skin. 9. It reduces the frequency of the
pulse. 10. It increases arterial tension by stimulation of the vasomotor center. 11.
This increase of pressure is soon succeeded by a fall, due to a weakening of the heart
itself.

The exact practical value of the drug has not been determined, nor are the results
produced in man, by doses approaching toxic, known. Hamilton took a drachm, when
suffering with severe toothache, on going to bed. He first felt a violent sensation of
heat internally, which gradually extended to the surface, and was followed by profuse
perspiration, with profound sleep for twelve hours. On awaking, he was quite free from
pain, and without the unpleasant sensations which follow a dose of opium. Various
practitioners have reported good results from its use as an anodyne in neuralgia,
nervousinsomnia, whoopingcough, etc., but in other hands it has failed to do good. H.
C. Wood found it in one case of neuralgia to produce great nausea and gastric distress
without evincing the slightest narcotic effect. (For formula for fluidextract by

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - P - Page 56
The Southwest School of Botanical Medicine http://www.swsbm.com
Lemberger, see U. S. D., 19th ed., p. 1616; also D. C., 1881, 179.) The dose of the fluidextract is a fluidrachm (3.75 mils), to be carefully increased.

**Pithecolobium.**—Pithecolobium Saman Benth. (Fam. Leguminosae.) — A shade-tree, growing from Mexico to Brazil, and planted for shade in Japanese coffee plantations, which yields a poisonous alkaloid, pithecolobine-saponin, whose physiological action is analogous to that of sapotoxin.

**Plantain.** Plantago major L. Rib Grass. Ribwort. Ripple Grass. Plantain, Fr. Wegerich, G. (Fam. Plantaginaceae).—The leaves are saline, bitterish, and acrid to the taste; the root is saline and sweetish. The common plantain weed was formerly considered refrigerant, diuretic, de-obstruent, and somewhat astringent. The ancients esteemed it highly, but it is at present never used, except externally in domestic practice as a stimulant application to sores. The leaves are applied whole or bruised in the form of a poultice. Plantago media L., or hoary plantain, and P. lanceolata L., or rib grass, which are also naturalized in America, possess properties similar to those of P. major, and may be used for the same purposes.

For results of examination of the leaves of P. major, see Kosenbaum (A. J. P., 1886, 418.) J. F. Strawinski found in the rhizome a substance which he believes to be either phlobaphene or proto-catechuic acid. (A. J. P., 1898, 189.)

Bourdier (A. Pharm., ccxivi) has found in a number of species of plantago, including the P. major, a glucoside aucubin, which was isolated from the Aucuba japonica.

Semen psyllii is the name given to the seeds of several species of European Plantago. The best are those of Plantago Psyllium L., or fleawort, which grows in the south of Europe and in Northern Africa. They are ovoid, about 3 mm. in length, and 1 to 1.5 mm. in width, convex on one side, concave on the other, dark-brown and on flat side reddish-brown, shining, inodorous, and nearly tasteless, but mucilaginous when chewed. They are demulcent and emollient, and may be used internally and externally in the same manner as flaxseed, which they closely resemble in medicinal properties. Spogel seed, used in India as a demulcent in intestinal irritation, is derived from P. Isphagula Roxb., probably a variety of P. ovata Forsk. (See Journ. Med. de Paris, Sept., 1887.)

**Plumbago Europea** L. Leadwort. Dentellaria. (Fam. Plumbaginaceae.) — A perennial, herbaceous plant, growing in the south of Europe. It has an acid taste, and, when chewed, excites a flow of saliva. This is particularly the case with the root, which has been long used to relieve toothache; hence its French name dentelaira. A decoction of the root in olive oil has been highly recommended for itch. A crystallizable, acid principle, called plumbagin, has been extracted from the root by Dulong. (J. P. C. (2), xiv, 441.) Plumbago zeylanica is said to be a very powerful diaphoretic.

**Plumiera.** Pagoda Tree.—The bark of Plumiera sucuuba Spruce (Fam. Apocynaceae), a plant growing in South America which the natives of Brazil have long used in the
treatment of fevers. It is asserted also to be an anthelmintic and emmenagogue. Plumier, the French botanist, first brought this plant to the attention of the medical profession. The important constituents of the plant are Plumierin (agoniadin), \( \text{C}_{21}\text{H}_{24}\text{O}_{12} + \text{H}_2\text{O} \), and plumieric acid, \( \text{C}_{20}\text{H}_{24}\text{O}_{12} \). The \( P. \text{acutifolia} \), said to contain an alkaloid, \( \text{C}_{57}\text{H}_{72}\text{N}_{33} \), has been used in the treatment of gonorrhea.

PODOPHYLLI INDICI RESINA. Br.

INDIAN PODOPHYLLUM RESIN [Podophyllum Emodi Resin]

"Indian Podophyllum Resin is a powdered resin prepared by the same process as that described under ‘Podophyli Resina,’ employing Indian Podophyllum Rhizome in place of Podophyllum Rhizome. It possesses the characters and responds to the tests described under 'Podophylli Resina.'" Br.

(See Podophylli Indici Rhizoma.)

The rhizome of the Indian Podophyllum has become a commercial article and appears to have been largely used in the making of podophyllin. The question as to the relative yield of the Indian and American plants is a matter of great importance to the manufacturer, it usually being stated that the Indian rhizome is twice as active. Some years since Dymock and Hooper obtained 12 per cent. of resin from \( P. \text{Emodi} \); Umney, working with large quantities (\( P. \text{J.} \), Sept., 1902), got out 11.4 per cent.; since then John Barclay (\( P. \text{J.} \), 1903, lxx) was not able to obtain a greater yield than 6.69 per cent. Umney, commenting on this, believes that of late years the Indian plant gives a much smaller product than formerly, probably on account of the time of year in which it is now dug. In regard to the therapeutic interchangeability of the two resins it has been demonstrated by the researches of Dunstan and Henry and J. C. Umney that the active substances in true Podophyllin are all present in the Indian resin, but it is not assured that the proportion of these active principles is the same in the two resins. At one time it was claimed that the resin from the Indian species was more active than that obtained from the American plant, but this appears not to be correct. In the present state of our knowledge, the manufacturer is certainly not justified in putting upon the market a resin made from the Indian plant unless it is plainly marked as the Indian Podophyllin. Distinguishing between the two resins has become a question of importance. The presence of a yellowish-green color does not, as has been affirmed, prove that a podophyllin is impure or of Indian origin.
The test of solubility is also uncertain. The Indian Podophyllin, properly prepared, is freely soluble in alcohol. It is commonly stated that the true Podophyllin will dissolve in ammonia (1 to 100). The Indian species is seemingly much less soluble in ammonia than this, but a properly prepared official resin does not always come up to this standard. E. J. Millard (P. J., Ix) states that the Indian resin strikes with strong sulphuric acid an orange to red color, the official resin yellow coloration, tending to brown, but especially commends the following test:

To six grains (0.4 Gm.) of the resin in a test tube add one fluidrachm (3.75 mils) of diluted alcohol sp. gr. 0.920, and eight or ten drops (0.4-0.5 mil) of solution potash, B. P.; shake gently by rotating the test tube. In case of the Indian resin, the mixture becomes in a few seconds a semi-solid gelatinous mass, so that the test tube can be safely inverted. If this does not occur quickly, the mixture should be heated until it just begins to boil, and when cool it will be found to have gelatinized. The official resin similarly treated gives a dark fluid that shows no signs of gelatinizing even after standing for days. The Indian Podophyllum Resin is used for the same purposes as the American. (See Resina Podophylli.)

Dose, one-fourth to one grain (0.016 to 0.065 mil); of the tincture (Tinctura Podophylli Indici), five to fifteen minims (0.3-0.9 mil).

**PODOPHYLLI INDICI RHIZOMA. Br.**

**INDIAN PODOPHYLLUM RHIZOME**

[Podophyllum Emodi Rhizome]

“Indian Podophyllum Rhizome is the dried rhizome and roots of Podophyllum Emodi, Wall; *.

Podophyllum Emodi (Fam. Berberidaceae) is a perennial herb which is indigenous to Thibet and Afghanistan. It somewhat resembles our American Podophyllum. The stem rises to a height of six or twelve inches before the leaves, which attain a diameter of six to ten inches when fully expanded. The latter are curiously reflexed, droop umbrella-like and are often spotted. The plant produces in May a large sub-sessile pinkish-white flower which arises from the axil of one of the leaves, maturing before the latter are fully expanded. The fruit is about the size of a small lemon, of a bright orange color, being fully ripe in about
August or September.

The contorted rhizome of Podophyllum Emodi is from six to eight mm. in thickness, crowded above with numerous buds or short branches, marked by depressed oval or circular sears, and giving off numerous simple rootlets from the whole of the under surface. The terminal bud is enclosed in whitish papery sheaths. The color is earthy-brown. The fracture is white, short, and mealy, or yellow and horny, exhibiting a circular arrangement of yellow vascular bundles, and bounded on the outside by a thin brown cortical layer.

"Rhizome cylindrical or flattened, contorted, earthy-brown; usually about ten millimetres thick; below with numerous root-scars, or with stout roots, and crowned with the short remains of aerial stems, bearing cup-shaped scars. In transverse section, pale-brown and starchy or homy, with a ring of radially elongated wood-bundles. Slight odor; taste bitter and acrid." Br.

It is used for the same purposes as podophyllum.

**Off. Prep.**—Podophylli Indici Resina, Br.; Tinctura Podophyllii Indici (from Resin), Br.

**PODOPHYLLUM. U. S. (Br.)**

**PODOPHYLLUM Podoph.**

*Podophyllum peltatum* (May-apple) is an indigenous herbaceous plant. The rhizome is perennial, creeping, usually several feet in length, about one-quarter of an inch thick, brown externally, smooth, jointed, and furnished with roots at the joints. The stem is about a foot high, erect,
round, smooth. The basal leaves are centrally peltate, with six or seven wedge-shaped lobes, irregularly incised at their summits, yellowish-green on their upper surface, paler and slightly pubescent beneath. The flower-bearing stems bear from one to three similar leaves. The flower is nodding, and appears between two leaves at the apex of the stem or at the base of the upper leaf when three leaves are present. The calyx is composed of three oval, obtuse, concave, deciduous sepals. The corolla has from six to nine white, fragrant petals, which are obovate, obtuse, concave, with delicate transparent veins. The stamens are from thirteen to twenty, shorter than the petals, with oblong, yellow anthers, of twice the length of the filaments. The stigma is sessile, and rendered irregular on its surface by numerous folds or convolutions. The fruit is a large oval berry, crowned with the persistent stigma, and containing a sweetish fleshy pulp, in which about twelve ovate seeds are embedded. It is, when ripe, of a lemon-yellow color, diversified by round brownish spots. Two species of the genus Podophyllum are known as growing in China while Podophyllum Emodi, which inhabits the interior ranges of the Himalayas and is very abundant in Cashmere, is recognized in the Br.

The plant has been found on Mount Togakushi, in Japan, and is extensively diffused through the Eastern United States, growing luxuriantly in moist shady woods and in low marshy grounds from Canada, to Minnesota and southward to Florida and Texas. It is propagated by its creeping rhizome, and is often found in large patches. The flowers appear about the end of May and the beginning of June, and the fruit ripens in the latter part of September. The leaves are said to be poisonous. The fruit has a subacid, sweetish, peculiar taste, agreeable to some palates, and may be eaten freely with impunity. From its color and shape, it is sometimes called wild lemon. The rhizome is the official portion, and is said to be most efficient when collected after the falling of the leaves. It shrinks considerably in drying.

**Properties.**—The dried rhizome is much wrinkled lengthwise, is yellowish or reddish-brown externally, and furnished with roots of a similar but somewhat paler color. It was determined, by an experiment of Wm. Saunders, that these roots contain as much active matter as the rhizome itself. It is officially described as follows: "Rhizome horizontal, nearly cylindrical, jointed, compressed on the upper and lower surfaces, sometimes branched; in pieces from 3 to 20 cm. in length, the internodes from 2 to 9 mm. in diameter; externally dark brown, longitudinally..."
wrinkled or nearly smooth with irregular, somewhat V-shaped scars of scale leaves, nodes annulate, upper portion marked with large, circular, depressed stem-scars and sometimes with buds or stem-bases; at or near the nodes on the lower portion occur numerous root-scars or roots from 2 to 7 cm. in length and about 2 mm. in thickness; fracture short; internally, bark light brown, wood with small yellowish, vascular bundles, pith large and white; odor slight; taste sweetish, disagreeably bitter and acrid. Under the microscope, a transverse section of the rhizome of Podophyllum shows an outer layer of one or two rows of reddish-brown cells; parenchyma of cortex and pith with numerous single, spherical, polygonal, or 2- to 6-compound starch grains, or rosette aggregates of calcium oxalate; vascular bundles from 24 to 34, arranged in a circle between cortex and pith. The powder is light brown, with a pronounced and characteristic odor; starch grains numerous, spherical, polygonal or 2- to 6-compound, the individual grains from 0.003 to 0.015 mm. in diameter; calcium oxalate crystals few, in rosette aggregates from 0.05 to 0.08 mm. in diameter and occasionally in raphide's from 0.03 to 0.09 mm. in length; tracheae with simple pores or reticulate thick-enings; fragments of starch-bearing parenchyma and reddish-brown cork cells. Podophyllum yields not more than 3 per cent. of ash.

"Rhizome nearly cylindrical, of very variable length, usually about five millimetres thick; dark reddish-brown, smooth or only slightly wrinkled; enlarged at intervals of about five centimetre's, the upper surface of each enlargement being marked by a depressed circular scar, below which, on the under surface, are rather stout, brittle, brown roots, or the scars corresponding to them. In transverse section, either nearly white and starchy, or pale yellowish-brown and horny. Characteristic odor; taste slightly bitter and acrid." Br.

The root in its aggregate state is nearly inodorous, but in powder has a sweetish not unpleasant odor. The taste is at first sweetish, afterwards bitter, nauseous, and slightly acrid. Both the decoction and the tincture are bitter, but alcohol is said to be the best solvent of the active matter. V. Podwyssotzki (Ph. Z. R., Bd. xx, 777) announced the active principle to be solely a neutral crystalline principle, picropodophyllin. This principle is associated with an inactive resin-acid, picropodophyllic acid, and the combination of the two he named podophyllotoxin. Picropodophyllin is in colorless, silky, extremely delicate needles, very soluble in chloroform, readily soluble in 95 per cent. alcohol, but very
slightly in 75 per cent. alcohol. It is soluble in ether, and crystallizes from a warm saturated solution on cooling. It is insoluble in water, turpentine, or benzine. Podophyllotoxin is a bitter, white, resinous powder, soluble in weak alcohol and hot water. It may be precipitated from its alcoholic solution by water in large quantity. (P. J., 1882, 1011.) Podwyssotzki also obtained podophylloquercetin, the coloring principle, which is closely allied to quercetin and is the cause of the varying color of resin of Podophyllum. His results have since been corrected and supplemented by R. Kursten (A. J. P., 1891, 485), who has obtained the several principles in a purer state. The results of Kursten's investigation are as follows: The podophylloxytoxin prepared by Podwyssotzki's method was not constant in composition, and its melting point varied from 100° to 125° C. (212°-257° F.); further, the podophylllic acid of that author is composed mainly of a crystallizable, active, but very impure substance.

Podophyllotoxin, C$_{23}$H$_{24}$O$_{9}$, is obtained by extracting the coarsely powdered rhizome with cold, light petroleum, until freed from fat; after drying in the air, the extraction is continued with chloroform, until the liquid comes away almost free from yellow color. As it is not possible to work with alcohol-free chloroform, too prolonged extraction with chloroform would yield a more impure extract. The chloroform extract is distilled and the residue is dried over a not too warm water bath, partially dissolved in benzene, filtered, and the filtrate allowed to remain from three to eight days, when a brownish-yellow mass of well-formed, thick, strongly refractive prisms is produced. This is purified by washing with a 50 per cent. alcohol, then with ether, recrystallizing first from boiling benzene, and finally from solution in hot 45 per cent. alcohol; the compound is thus obtained in long, well-formed prisms which melt at 94° C. (201.2° F.).

Podophyllotoxin, when oxidized in an alkaline solution in the cold by means of potassium permanganate, yielded, besides a little carbonic anhydride and a brown amorphous substance, principally two compounds, the more considerable of which was podophyllic acid, obtained as well-formed, colorless crystals from solution in a mixture of benzene and alcohol. The compound is without action on animals. It melts at from 158° to 160° C.(316.4°-320° F.). Its aqueous solution, neutralized with aqueous potassium hydroxide, gives no precipitate with gold, calcium, or barium chlorides; silver nitrate gives a white precipitate, soluble in much water; copper acetate gives a blue precipitate. The copper salt was prepared as beautiful light green prisms
Picropodophyllin results from the action of alkalies on podophyllotoxin; thus, on heating the latter with aqueous ammonia, a well-crystallized product is obtained, which at first was recrystallized from strong alcohol; but this was found to be unnecessary, as the melting point, 227° C. (440.6° F.), was not affected by it. Picropodophyllin has the same composition as podophyllotoxin, but they differ in melting point and in their action on polarized light,—the former inactive, the latter laevo-rotatory; the former is less soluble in all liquids than the latter; the latter gives Millon's reaction, the former does not. By oxidation and reduction the two compounds yield the same products.

Dunstan and Henry (Proc. Chem. Soc., March, 1898) find that the constituents of the Indian Podophyllum (Podophyllum Emodi) and of the American Podophyllum (Podophyllum peltatum) are identical. The chief constituent is the podophyllotoxin of Podwyssotzki and Kiirsten. It is strongly laevo-rotatory, and acts as a powerful purgative and intestinal irritant. They found that when heated with alkalies, it is converted by hydration into the salt of an unstable gelatinous acid, podophyllic acid, $\text{C}_{15}\text{H}_{16}\text{O}_{7}$, of which several salts were obtained and analyzed. This acid very readily loses water, and furnishes the crystalline picropodophyllin of Podwyssotzki and Kiirsten, which is isomeric with podophyllotoxin. It passes again into podophyllic acid when warmed with aqueous alkalies. Podophyllotoxin and pieropodophyllin furnish identical decomposition products; when oxidized with nitric acid, oxalic acid is the principal product; when fused with alkalies, orcinol and acetic acid are produced. Both substances contain three methyl groups and no hydroxyl. It is likely that picropodophyllin is the lactone of podophyllic acid. Picropodophyllin is therapeutically inactive. The yellow coloring matter of Podophyllum, called by Podwyssotzki podophylloquercetin, was proved by the authors to be identical with quercetin, the yellow coloring matter of querciton bark. An uncrystallizable resin, podophylloresin, was also isolated and found to exert a purgative action. A fatty oil has been separated from the rhizome of Podophyllum by Dohme and Engelhardt. (See Proc. A. Ph. A., 1904, 340.) Gordin and Merrell (Proc. A. Ph. A., 1902, 343) proposes to judge of the quality of resin of Podophyllum by an assay based on the percentage of crude picropodophyllin and the following requirements: Pure podophyllin must be completely soluble in about twice its weight of cold alcohol. 2. It should contain about 64 per cent. ether-soluble and
about 74 per cent. chloroform-soluble matter. 3. It should yield about 22 per cent. crude picropodophyllin when assayed by the method described by them.

Manlius Smith recommended that the resin should be prepared by forming an alcoholic tincture of the root, evaporating the tincture until most of the alcohol is driven off, and throwing the residue into water, by which the resin is precipitated. The concentration should not be carried too far, as otherwise the resin separates in clots, which cannot be easily washed. According to Smith, the resin, when pure, is white, and purges actively. It has been called Podophyllin for many years. (A. J. P., xxiv. 306. See Resina Podophyllii.) The proportion of resin contained in the root of the P. peltatum appears to vary very much, the variation possibly depending upon the season of the year at which the drug has been gathered. John Barclay (P. J., 1903, Feb., 164) obtained a percentage of 1.6 to 3.86 per cent., stating that these figures were confirmed by the results of the manufacturers of Podophyllin on a large scale, but J. C. Umney states that in five years' experience working with batches of 1000 pounds, the rhizome averaged a yield of 6.6 per cent. Both observers noticed that the Indian rhizome (P. Emodi) contains a much larger proportion of resin, the average according to Umney being 11.4 per cent. How far the proportion of podophyllotoxin varies in the different rhizomes does not seem to have been determined. (See B. B. Dott, P. J., 1903, Mar. 460.) (P. J., 1911, lxxvii, p. 156.)

From the leaves of P. peltatum Thos. J. Husband, Jr., obtained berberine and a resin which was free from purgative properties, 8 grains producing no other effect than slight headache. (A. J. P., 1869.)

B. F. Carter (A. J. P., 1886, p. 449) also examined the leaves. He found tannin, uncrys-tallized sugar, coloring matter, and 6 per cent, of resin. This latter seems to be of twofold character, ether dissolving the soft resin, while the hard resin remains behind. The resin has a bitter taste and a much milder action than that of the rhizome. Fused with potassium hydroxide a small amount of protocatechuic acid seems to be formed.

A method of assay for Podophyllum has been proposed by W. M. Jenkins (J. I. and, E. C., 1914, p. 671) which is based upon a shaking out method using a mixture of chloroform and alcohol.
Uses.—Podophyllum is a slow but active and certain cathartic producing copious liquid discharges often with much griping. It has been attributed with cholagogic properties and is used in various forms of hepatic torpor but its virtues in this direction are probably no greater than that of other active purgatives. In small doses it is frequently used in chronic constipation, especially in conjunction with aloes or cascara.

In overdoses Podophyllum acts as an irritant poison; an amount estimated at five grains of the resin caused death in a woman sixty years old (N. Y. M. E., April, 1890); the symptoms were vomiting and purging, followed some hours after their cessation by coma, full soft pulse, slight elevation of temperature, and haemo-globinuria.

Dose, five to ten grains (0.32-0.65 Gm.), but it is rarely exhibited in the crude form.

F.; Pilulæ Aloes, Hydrargyri et Podophyli (from Resin), N. F.; Pilulæ Aloini Compositæ (from Resin), N. F.; Pilulæ Catharticae Vegetabile (from Resin), N. F.; Pilulæ Colocynthidis et Podophyli (from Resin), N. F.; Pilulæ Laxativæ Post Partum (from Resin), N. F.

Polygala. Polygala polygama Walt. (P. rubella Muhl.) (Fam. Polygalaceae) Bitter Milkwort. American Bitter Polygala. Polygale. Lai-tier, Fr. Kreutzblume, Milchwurz, G.—Bitter polygala is an indigenous, perennial plant, which was formerly official. It has a strong and permanent bitter taste, which it yields to water and alcohol. In small doses bitter polygala is tonic, in larger, laxative and diaphoretic. It appears to be closely analogous in medicinal virtues to Polygala amara L., of Europe, which is used for a similar purpose. From the seeds of the P. butyracea Heck. and Schlag., an African plant, the natives prepare an edible fat. (See P. J., xx, Aug., 1889.)

Polymnia. Polymnia uvedalia L. Bear's Foot. (Fam. Compositae)—A tall, branching plant, growing in rich soil from New York to Missouri and southward. Great virtues as a remedy in malarial splenic enlargements have been attributed to this plant.

Polypodium. Polypody. Fern Root.—Various species of this genus of ferns are asserted to have medicinal properties. Polypodium vulgare L., very common both in Europe and America, was believed by the ancients to be an active cholagogue purgative, and has been used in modern times as an expectorant in chronic catarrh and asthma. Dose, from one to eight drachms (3.9-31 Gm.), usually given with a cathartic. The rhizome, as it usually occurs in commerce, is from 2 to 12 cm. in length and 3 to 8 mm. in thickness, somewhat contorted, covered with brown, easily separable scales, which should be removed before being used. Its color is reddish-brown, with a tinge of yellow, its odor disagreeably oleaginous, its taste peculiar,
sweetish, somewhat bitter, and nauseous. P. adiantiforme, of Porto Rico, is believed by the natives to be a powerful antisyphilitic. It must be used freely for several months in the advanced stages of the disease. P. friederichsthalianum, of Central America, has had similar properties attributed to it.

**Pongamia.** Pongamia glabra Vent. (Fam. Leguminosae)—Pongamia or kurung oil is expressed from the seeds of an East Indian tree. It is deep yellow to reddish-brown, fluid at 15.6° C. (60° F.), but below that it is solid with sp. gr. of 0.9352 (P. J., 72, p. 492). It is especially commended in pityriasis versicolor and other parasitic skin diseases. (P. J., February, 1883.)

**Poplar Buds.** N. F. IV. Populi Gemmae. Balsam Poplar Buds. Balm of Gilead Buds.—" The air-dried, closed winter leaf-buds of Populus nigra Linne or Populus balsamifera Linne (Fam. Salicaceae), collected early in the spring. Preserve the buds in tightly-closed containers of glass or tin." N.F.

In most trees of the genus Populus, the leaf-buds are covered with a resinous exudation, which has a peculiar, agreeable, balsamic odor, and a bitterish, balsamic, somewhat pungent taste. It is abundant in the buds of Populus nigra L., or the black poplar of Europe, which are official in some parts of that continent. They contain resin and a peculiar volatile oil. The buds of P. balsamifera L., the Balsam Poplar or Tacamahac, growing in the northern parts of North America and Siberia, are also highly balsamic; and a resin is said to be furnished by the tree. The buds are obtained from P. canadensis Ait and are often called Balm of Gilead buds. Poplar buds are described in the N. F. IV as "conical, pointed, up to 2 cm. in length and from 2 to 5 mm. in thickness, consisting of closely imbricated scales, externally brown and glossy, glutinous with fragrant resin. Odor pleasant, balsamic; taste aromatic and bitter." The virtues of the poplar buds are probably analogous to those of the turpentines and balsams. They have been used in pectoral, nephritic, and rheumatic complaints, in the form of a tincture, and a liniment, made by macerating them in oil, has been applied externally in local rheumatism. The unguentum populeum, Pommade de Bourgeons de Peuplier, is made, according to the directions of the French Codex, from 100 Gm. each of the dried contused leaves of white poppy, belladonna, henbane, and black nightshade, and 800 Gm. of dried poplar buds. The leaves are moistened with 400 Gm. of alcohol and allowed to stand twenty-four hours in a closed vessel; 4000 Gm. of lard is now added and the mixture heated gently during three hours, stirring frequently, the crushed poplar buds are then added and allowed to digest for ten hours at a gentle heat, and the whole strained and cooled slowly. This is an anodyne ointment, employed in Europe in painful local affections. It has been ascertained that poplar buds are capable of imparting a principle to ointments which obviates their
tendency to rancidity. Poplar buds are an ingredient of Syrupus Pini Strobi Compositus, N. F. and of Syrupus Pini Strobi Compositus cum Morphina, N. F.

The bark of P. tremuloides Michx., or American aspen, and of P. tremula L., or European aspen, is possessed of tonic properties, and has been used in intermittent fever. In the bark of the latter Braconnot found salicin, C_{13}H_{18}O_7, and another crystallizable principle which he named populin, C_{20}H_{22}O_8 + 2H_2O. It is in these, probably, that the febrifuge properties of the bark reside. They may be obtained by precipitating a saturated decoction of the bark with solution of lead subacetate, filtering, precipitating the excess of lead by sulphuric acid, again filtering, evaporating, adding animal charcoal towards the end of the evaporation, and filtering the liquor while hot. Salicin gradually separates, upon the cooling of the liquor, in the form of crystals. If, when this principle has ceased to crystallize, the excess of sulphuric acid in the liquid be saturated by a concentrated solution of potassium carbonate, the populin will be precipitated. If this be pressed between folds of blotting paper, and redissolved in boiling water, it will be deposited, upon the cooling of the liquid, in the crystalline state. The leaves of P. tremula are also said to yield more populin than does the bark. It is probable that both principles exist in the bark of P. tremuloides and other species. Schaak (A. J. P., 1892, 226) found a bitter principle in the bark of P. alba L., which was most likely populin. Populin is very light and white, of a bitter, sweetish taste, analogous to that of licorice. It is soluble in 1896 parts of cold and about 70 parts of boiling water, and is more soluble in boiling alcohol. It loses its two molecules of water of crystallization at 100° C. (212° F.), and at 180° C. (356° F.) it fuses to a colorless liquid, from which at a higher temperature benzoic acid may be sublimed. Acetic acid and the diluted mineral acids dissolve it, and, upon the addition of an alkali, let it fall unchanged. Piria first showed it to be benzoyl salicin, C_{13}H_{17}(C_7H_5O)O_7 + 2H_2O. He then decomposed it and prepared salicin from it. Populin has been prepared synthetically by Schiff and by Dobbin and White. (P. J., 73, p. 233.) When populin is boiled with baryta water or milk of lime, the benzoic acid precipitated by ferric chloride, the excess of iron removed by lime, and the excess of lime by carbon dioxide, the remaining liquid yields salicin on evaporation. The same conversion may be effected by heating populin with an alcoholic solution of ammonia to 100° C. (212° F.). Piria obtained from populin 28.9 per cent. of benzoic acid. (P. J., xv, 378.) T. L. Phipson, basing his experiments upon the results of Piria, has succeeded in preparing populin artificially by combining salicin and benzoic acid. Nothing more is necessary than to dissolve the two substances in alcohol, and to concentrate the solution. Crystals are formed having all the char-aeters of populin, and consisting of salicin and benzoic acid combined in the proportion of their equivalents. (Chem. News, Dec. 6, 1862, 278.) Dobbin and White make populin from salicin and benzoic acid chloride. (Y. B. P., 1904, 506.) The flower-buds of P. tremuloides yielded a bitter resin to R. Glenk. It was of yellowish-brown color, strong, hop-like odor, and had a melting point of 51° C. (123.8° F.). (A. J. P., 1889, 240.)

fully grown, unripe fruit of *Papaver somniferum* Linne (Fam. Papaveraceae). Separate and reject the seeds before using the fruit in pharmaceutical preparations." N. F.

Poppy capsules were official in the Br. Pharmacopoeia, 1898; they have been admitted to the N. F. IV. In England the poppy has been largely cultivated for its capsules, which are gathered as they ripen, and taken to market enclosed in bags. The N. F. directs them to be collected before they are quite ripe, as they then contain, more of the active milky juice. When ready for collecting they are a yellowish-green color. They are occasionally imported, but, as no effect is produced by them which cannot be as well obtained from opium, they are little employed.

Dried poppy capsules vary in size from the dimensions of a small egg to those of the fist. They differ also in shape according to the variety of the poppy from which they are procured. On the Continent two sub-varieties of the white poppy are recognized, the long, and the round or depressed. Of these, according to Aubegier, the long are richest in morphine, and his conclusions are confirmed by Meurein, who also found the largest capsules most efficient. Those commonly found in commerce are spheroidal, flattened below, and surmounted by a crown-like expansion—the persistent stigma—which is marked by numerous diverging rays that rise somewhat above the upper surface and appear to be prolongations of partial septa, or partitions, proceeding along the interior circumference of the capsule from the top to the bottom. In the recent state, the seeds, which are very numerous, adhere to these septa, but in the dried capsule they are loose in its cavity, and the N. F. directs that they should be separated before the capsule is used. They are described in the N. F. as "globular or ovoid, usually from 3 to 3.5 cm. in diameter, but varying in size, more or less sunken or depressed on the sides, contracted at the base into a sort of neck immediately above a tumid ring at the point of attachment with the stalk; crowned at the summit with the seven- to fifteen-rayed stigma disk; outer wall of pericarp smooth, hard, grayish-yellow to brownish-yellow, often marked with black spots; interior surface rugose, finely striated transversely, and bearing thin, brittle, membranous placentae which extend from the sutures toward the center, and bear on their faces and edges numerous, minute, conspicuously reticulated, reniform white seeds. Odorless; taste slightly bitter.

"Macerate 1 Gm. of the powdered Capsules for two hours with 10 mils of water containing 1 per cent. of hydrochloric acid, and filter; the filtrate yields distinct precipitates with iodine T.S. and with potassio-mercuric iodide T.S.

" The powdered drug is grayish-yellow, and, when examined under the microscope, exhibits fragments of the epicarp composed of thick-walled polygonal cells, the cells of the outer layer non-porous, up to 0.05 mm. in diameter and with occasional stomata, the latter up to 0.035 mm. in length; the cells of the inner layer of the epicarp often with numerous simple pores; portions of the soft, spongy sarcocarp consisting of isodiametric or irregular parenchyma and branching milk ducts, the latter up-to 0.06 mm. in width, of variable length and with thin, non-porous walls; fragments of the inner wall of the pericarp and the outer wall of the placental tissue composed of polygonal or somewhat elongated cells with porous walls, up to 0.06 mm. in width and up to 0.3 mm. in length, the walls of the latter cells often slightly lignified; spiral and
annular tracheae up to 0.035 mm. in width and reticulate tracheae up to 0.06 mm. in width; sclerenchyma cells few with simple or oblique pores; starch grains few, small, somewhat rounded; fragments of the reticulately pitted seed-coat very few or absent. Poppy Capsules yield not more than 10 per cent. of ash.” N. F. IV.

On the continent of Europe, the poppy is cultivated largely for its seeds, which yield about fifty per cent. of an excellent fixed oil on expression. Poppy seed oil is of a pale golden color, liquid at 5.5° G. (42°F.), easily dried, inodorous, and of a pleasant flavor. It is bleached by exposure in thin layers to the sun. (P. J., March, 1874, p. 731.) It belongs to the class of drying oils, ranking after linseed and hemp seed oils in power.

Dried poppy heads, though analogous to opium in medicinal properties, are exceedingly feeble. They are nevertheless asserted to have proved fatal, in the form of decoction, to a child. The case, reported by F. L. Winckler, was that of a babe, in the stomach of which he found a little morphine, but no meconic acid. (N. R. Pharm., 1867, xvi, 38.) They are sometimes employed in decoction, as an external emollient and anodyne application, and, in emulsion, syrup, or extract, are used internally, in Europe, to calm irritation, promote rest, and produce generally the narcotic effects of opium.

The dose is from ten to twenty grains (0.65-1.3 Gm).

**Portulaca.** Portulaca oleracea L. Garden or Common Purslane. (Fam. Portulacaceae) —This fleshy annual, common in cultivated and waste grounds, has been considered a cooling diuretic, and recommended in scurvy and urinary affections. The seeds have been considered anthelmintic, but are inert.

**Potentilla.**—Potentilla reptans L., the creeping cinquefoil of Europe, growing in waste places from Massachusetts to Ohio, and Potentilla canadensis L., one of the common cinquefoils of America (Fam. Rosaceae), have each been used as astringents in diarrhea, chronic catarrhs, night sweats, etc. According to J. C. Peacock (A. J. P., 433, 1900), dried P. norvegica L. contains four, and P. canadensis thirteen, per cent. of tannic acid. (See P. J., 1911, 350.)

**Primula.**—The leaves of the various species of this genus produce irritation when handled, due to a secretion in the glandular hairs. For a study of primula dermatitis, see Forster, J. A. M. A., 1910, Iv, p. 642. From the roots of Primula grandiflora, Bongault and Alland have separated a crystalline polyatomic alcohol, primulite, which is said to be identical with the hepatonic alcohol, volemit. (C. R. A. S., 135, 796.) Two glucosides, primverin and primulaverin, and an enzyme, primverase, were isolated by Goris and Mascne. (Chem. Cb., 1910, No. 3.)

**Prinos.** Black Alder. Winterberry. Feverbush. Prinos, Fr., G.—The U. S. P. formerly recognized under this name the bark of Ilex verticillata (L.) A. Gray (Prinos verticullatus L.) (Fam. Aquifoliaceae). This shrub, of which there are 3 well recognized varieties, grows in the United States from Canada to Florida, and west to Missouri and Wisconsin, frequenting low, wet places. The berries, which have a bitter,
sweetish, somewhat acrid taste, are sometimes used medicinally for the same purposes as the bark. The dried bark occurs in "thin, slender fragments, about 1 Mm. thick, fragile, outer surface brownish aah-colored, with whitish patches and blackish dots and lines, the corky layer easily separating from the green tissue; inner surface pale greenish or yellowish; fracture short, tangentially striate; nearly inodorous, bitter, slightly astringent." U. S., 1880. It has no odor, but a bitter and slightly astringent taste. Boiling water extracts its virtues. William J. Lerch failed to find berberine in it. (A. J. P., 1873, 251.)

Black alder has been considered tonic and astringent, and has been used in diarrhea and as a substitute for Peruvian bark, but has no anti-periodic properties. In cases of flabby or ill-conditioned ulcers it is popularly used both locally and internally in decoction (two ounces in three pints of water boiled to a quart); dose, from two to three fluidounces (60-90 mils).

**Prioria.** Prioria Copaifera Griseb. (Fam. Leguminosae)—The oil tree is a native of the West Indies. The seeds are edible and in Panama are sold under the names of Cativa or Amanza muger. The tree yields an exudate which is known as the gum of the oil tree. This is a thick, adhesive liquid, resembling copaiba, usually turbid on account of a greenish substance, which, however, finally subsides, leaving a clear, brownish-yellow liquid. For chemical study, see A. J. P., Jan., 1898.

**Protea.** Protea mellifera Thunb. (Fam. Proteaceae.) Sugar Bush.—A plant growing in South Africa, from the leaves of which Merring Beck in 1886 obtained proteacin. Merck and Hesse subsequently named the principle leucodrin. Hesse found the leaves to yield from 2 to 5 per cent. of hydroquinone associated with proteacic acid. (P. J., 1896, 426.)

Prunus domestica or the cultivated prune or plum tree is so well known as to render a minute description unnecessary. The varieties of the tree produced by cultivation are very numerous. Nearly one hundred are to be found in the British gardens. Though at present growing wild in various parts of Europe, it is thought to have been brought originally from Asia Minor and Syria. It is the partly dried ripe fruits only that are official in the N. F. IV. They are officially described as "oblong, ellipsoidal, more or less compressed, 3 to 4 cm. long; externally brownish-black, shriveled; the sarcocarp sweet and acidulous; putamen hard, smooth or irregularly ridged; the seed, shaped like that of the almond but smaller and of a bitter-almond taste." N. F. IV. The prunes brought to our market come chiefly from the south of France, the best from Bordeaux. They are derived from the variety of the tree named juliana by Linnaeus. The fresh fruit, called PrunedeSaint-Julien by the French, is of an oval shape, nearly an inch in length, and of a deep violet color. It is prepared by drying in the sun, after having been exposed to the heat of an oven. The finest prunes, used on the tables of France, are prepared from the larger kind of plums, such as the Saint Catharine, and
Reine Claude or greengage. An inferior sort is brought from Germany.

Prunes have a feeble odor, and a sweet mucilaginous taste, which is generally also somewhat acid. They contain uncrystallizable sugar, malic acid, and mucilaginous matter. The following is given as the average of nine analyses of dried prunes. Water 29.30 per cent., nitrogenous material 2.35 per cent., fat 0.53 per cent., free acid 2.72 per cent., sugar 44.35 per cent., other nitrogen-free material 17.89 per cent., woody fiber (not including the stone) 1.48 per cent., ash 1.38 per cent. (Konig, Nahrungsmittel, ii, 397, 1880.) In Hungary a kind of brandy (Zwetschenbranntwein), containing about 40 per cent. of alcohol, is obtained from them, which in some districts is largely consumed. Bonneberg, a German chemist, has extracted from prunes crystallizable sugar equal to that of the cane.

Prunes are laxative and nutritious, and, stewed with water, form an excellent diet in costiveness. Imparting their laxative properties to boiling water, they serve as a pleasant and useful addition to purgative decoctions. Their pulp is used in the preparation of laxative confections. Too largely taken, they are apt to occasion flatulence, griping, and indigestion. Prunes were dropped from the former U. S. Pharmacopoeia, but admitted to the National Formulary IV because confection of senna, which was the only preparation in which prunes entered, was not admitted to the U. S. P. IX, but confection of senna is now official in N". F. IV.

Prunella.  Prunella vulgaris L.  Self-heal. Heal-all. Carpenter Weed. Brunella vulgaris. Paquerette, Fr. Braunelle, Braunheil, G.—A small perennial labiate herb, which is common both in Europe and the United States. It was formerly used in hemorrhages and diarrhea, and as a gargle in sorethroat.

PRUNUS VIRGINIANA. U. S. (Br.)

WILD CHERRY Prun. Virg.  [Wild Black Cherry Bark]

"The stem-bark of Prunus serotina Ehrhart (Prunus virginiana Miller) (Fam. Rosaceae), collected in autumn and carefully dried. Preserve Wild Cherry in tightly-closed containers, protected from light." U. S. "Wild Cherry Bark is the bark of Prunus serotina, Ehrft., collected in autumn." Br.

Pruni Virginianae Cortex, Br., Wild Cherry Bark; Virginian Prune Bark; Rum, Whisky, or Cabinet Cherry, Wild Black Cherry; Ecorce de Cerisier de Virgiuie, Fr.; Wild-kirschenrinde, Amerikanischer Zierstrauch, G.

The genus Prunus now includes the plums, almonds, peaches, apricots, and cherries, and comprises about one hundred and twenty species. They are generally distributed in the temperate regions of the northern
hemisphere. In the United States there are about forty indigenous species.

The name *P. virginiana* was applied by Miller (Diet., ed. 8, No. 3), and not Linnaeus, to *P. serotina* Ehr. *P. virginiana* L., commonly called wild cherry or choke cherry, is distinguished from *P. serotina* Ehr., known more properly as wild black cherry, by the following characteristics: *P. virginiana* L. has deciduous calyx lobes; oblong-obovate pointed endocarp (or stone); leaves broadly oval to oblong-ovovate, and usually abruptly acuminated; inner bark with a rather disagreeable odor. *P. serotina* Ehr. has persistent calyx lobes; the endocarp (or stone) oblong-ovovate, usually gradually acuminate; leaves oblong or lanceolate-oblong, usually gradually acuminate; the inner bark and leaves possess an aromatic odor. The British name, "Virginian Prune Bark," for the bark is misleading; Virginian Peach Bark or Virginian Almond Bark would have been no more of a misnomer. The official species is, according to Michaux, one of the largest productions of the American forest. Trees were observed by that botanist on the banks of the Ohio, from eighty to one hundred feet high, with trunks from twelve to fifteen feet in circumference, and undivided to the height of twenty-five or thirty feet. But as usually met with in the Atlantic States the tree is much smaller. In the open fields it is less elevated than in forests, but sends out more numerous branches, which expand into an elegant oval summit. The trunk is regularly shaped, and covered with a rough blackish bark, which detaches itself semicircularly in thick narrow plates. The leaves are alternate, oval-oblong, or lanceolate-oblong, acuminate, unequally serrate, smooth on both sides, of a beautiful brilliant green; the petioles are furnished with one or more reddish conspicuous glands. The flowers are small, white, and occur in long-erect or spreading racemes. They appear in May, and are followed by globular drupes, about the size of a pea, and when ripe of a shining blackish-purple color. For a paper on the structure of species of Prunus, by E. S. Bastin, see Proc. A. Ph. A., 1895, 211.

This tree is distributed from Ontario south to Florida, and westward to Dakota, Nebraska, Kansas, Indian Territory, and Eastern Texas. It extends along the mountain ranges of Western Texas, Mexico, and Pacific regions of Central America, Colombia, and Peru. In the United States it was once common throughout the Appalachian region. In the neighborhood of Philadelphia it affects open situations, growing solitarily in the fields and along fences, and seldom aggregated in woods.
or groves. It is highly valued by the cabinet-makers for its wood, which is compact, fine-grained, susceptible of polish, and of a light red tint which deepens with age. The leaves have been found by Procter to yield volatile oil and hydrocyanic acid on distillation, and in such proportion that a water distilled from them might with propriety be substituted for the cherry-laurel water. (Proc. A. Ph. A., 1858, 325.) The fruit has a sweetish, astringent, bitter taste, and is much used in some parts of the country to impart flavor to spirituous liquors. The bark is obtained indiscriminately from all parts of the tree, though that of the roots is thought to be most active. The revisers of the Pharmacopoeia believe with J. S. Perot that the bark is stronger when collected in autumn than in the spring; from a portion gathered in April Perot obtained 0.0478 per cent. of hydrocyanic acid, and from another in October 0.1436 per cent., or about three times as much. (A. J. P., xxiv, 111.) The bark should be preferred recently dried, as it deteriorates by keeping. A. B. Stevens (Proc. A. Ph. A., 1895, 226; 1896, 215), after testing many specimens, reached the conclusion that bark procured from different parts of the same tree varied in the yield of hydrocyanic acid, the value being in this order: 1, root; 2, twigs; 3, trunk; the bark from young trees yielding more glucoside than that from old trees. Jos. L. Lemberger (A. J. P., 1872, 303) believes that tannic acid is most abundant in the bark in October and November. On the other hand, Grace E. Cooley (A. J. P., August, 1897) concludes that there is more tannic acid in the bark during the active growth of the spring than in the autumn. She further states that in the spring and autumn the bark contains its maximum percentage of starch; so that if the bark, whether powdered or whole, contains much starch in its parenchymatous cells, it has been collected after the time of leaf-fall in the autumn or before the unfolding of the leaves in the spring. Occasionally barks find their way into commerce as Prunus Virginiana which yield no odor of hydrocyanic acid when moistened and are probably obtained from other than the official wild cherry. (See Bastin, A. J. P., 1895, and Finnemore, P. J., 72.)

Moser points out that collectors frequently mistake P. virginiana L. or choke cherry for P. serotina Ehrh. or black cherry, which is the official source of wild cherry bark. He presents a description of the two trees and of the characteristic features of their barks. (A. J. P., 1909, lxxxi, p. 579.) Farwell reports that the bark of P. demissa (Nutt.) Walpers, a tree from west of the Rocky Mountains, has been found in commerce. It is much darker and the lenticels are much more prominent. The
Preparations made from it resemble the official wild cherry bark in color, odor and taste.

Properties.—Wild cherry bark is officially described as follows: "Usually in transversely curved pieces from 2.5 to 8 cm. in length and from 0.5 to 4 mm. in thickness; outer surfaces light brown or greenish-brown, smooth, except for numerous lenticels from 3 to 4 mm. in length; inner surfaces light brown, longitudinally striate and occasionally fissured; fracture short, granular; odor distinct, bitter almond-like when macerated in water; taste astringent, aromatic, and agreeably bitter. Under the microscope, sections of Wild Cherry show a tendency for the separation in radial segments or bands of the phloem tissues from the rather broad medullary rays; periderm usually of a few layers of cells; outer bark from young twigs with 1 or 2 nearly continuous layers of cells, the latter being of very irregular shape, often branching and with thick lamellated, porous walls; medullary rays extending in more or less scythe-shaped groups from the cambium to the outer bark, from 1 to 10 cells in width, some of the cells occasionally being modified to stone cells; between the medullary rays occur numerous small groups of stone cells, resembling those of the outer bark and occasionally modified to sclerenchymatous fibers; calcium oxalate mostly in crystal fibers consisting of monodinocic prisms, from 0.015 to 0.04 mm. in diameter, also in rosette aggregates from 0.01 to 0.04 mm. in diameter; starch grains numerous, occurring in the medullary rays and parenchyma. The powder is light brown; when examined under the microscope it exhibits bast-fibers and stone cells with thick, strongly lignified walls; crystal fibers with monodinocic prisms and rosette aggregates of calcium oxalate, from 0.01 to 0.04 mm. in diameter; starch grains nearly spherical, from 0.003 to 0.004 mm. in diameter." U. S.

"In curved pieces or irregular fragments not more than three millimetres thick. Frequently covered with a smooth, thin, reddish-brown, papery cork, or, if this has been removed, exhibiting a greenish-brown cortex; marked with transversely elongated lenticels. Fracture short, granular; fractured surface reddish-grey. Inner surface reddish-brown, striated or reticulately fissured. In the bark numerous groups of sclerenchymatous cells of characteristic shape, but no typical bast fibers; in the parenchymatous cells minute starch grains and prismatic crystals of calcium oxalate. Slight odor; taste astringent, aromatic and bitter, recalling that of bitter almonds." Br.
In the fresh state, or when treated with water, it emits an odor resembling that of peach leaves. Its taste is agreeably bitter and aromatic, with the peculiar flavor of the bitter almond. It imparts its sensible properties to water, either cold or hot, producing a clear reddish infusion closely resembling Madeira wine in appearance. Its peculiar flavor and its medicinal virtues are injured by boiling, in consequence partly of the volatilization of the principles upon which they depend, partly upon a chemical change effected by the heat. From an analysis by Stephen Procter, it appears to contain starch, resin, tannin, gallic acid, fatty matter, lignin, red coloring matter, salts of calcium, potassium, and iron. He obtained also a volatile oil, associated with hydrocyanic acid, by distilling the same portion of water successively from several different portions of the bark. William Procter proved that, as in the case of bitter almonds, the volatile oil and hydrocyanic acid do not exist ready formed in the bark, but are the result of the reaction of water with amygdalin, which he ascertained to be one of its constituents. In order, however, that this change may take place, he affirmed that the agency of another principle, probably analogous to, if not identical with, emulsin or the synaptase of Robiquet, was also essential, and, as this principle becomes inoperative at the boiling temperature, one can understand how decoction may interfere with the virtues of the bark. (A. J. P., x, 197.) The bitterness appears to be due to the fluorescent substance described below which confirms Procter, who found the bitterness of an extract of the bark to remain after it had been wholly deprived of amygdalin. Stevens and Judy (A. J. P., 1895, 482, 534) found that the thick bark contains more amygdalin and consequently yields more HCN than the thin bark. The thick bark contains amygdalin, etc., 4.12 per cent., and HCN from 0.32 to 0.35 per cent.; the thin bark, amygdalin, etc., 3.16 per cent., and HCN from 0.24 to 0.27 per cent. F. B. Power and Henry Weimer, on the other hand, state that the bark does not contain crystallizable amygdalin, that the ferment principle is not emulsin, and that it cannot be isolated by an analogous process. The bitter principle, which appears to be the fluorescent substance, has the character of a glucoside, and crystallizes in colorless needles. (West. Drug., 1887, p. 331.)

R. Rother (A. J. P., 1887, p. 286), in searching for the fluorescent principle of wild cherry bark, obtained a reddish crystalline substance, soluble in water, chloroform, ether, and alcohol, the solution of which fluoresced strongly on addition of ammonia. Bother says that it does not agree in crystalline form with mandelic acid, but may be a derivative of
Uses.—Wild cherry bark has the stomachic effects of the simple bitters but is comparatively infrequently employed for this purpose. On the theory that hydrocyanic acid is a cough sedative, wild cherry bark has been popularly employed in the treatment of bronchitis of various types, but is of doubtful service.

Dose, from thirty to sixty grains (2.0-3.9 G-m.).

Psoralea.—Of this genus (Fam. Leguminosae) various species are useful. The tubers of P. esculenta L. are employed by the Indians of the Northwestern United States, and by the settlers, as articles of food, being the prairieturnip or prairie potato, the tipsinah and taahgu of the Indians. C. Richardson found in it nearly 70 per cent. of starch, and 5 per cent. of a new, rapidly crystallizing sugar, which has not been further investigated. P. glandulosa L., culen, yolochiahiti, of the Mexican Pharmacopoeia, yields a leaf which is used as a tonic or anthelmintic, and an emetic root. P. bituminosa L., of Europe, and P. physodes Dougl., of California, are popularly considered tonic and emmenagogue, the former being presented under the name of Herba Trifolii Bituminosi. P. pedunculata (Mill.) Vail. (P. melilotoides Michx.) (Congo root, Bob's root, Samson's snakeroot), of Virginia, has been recommended as an aromatic bitter tonic, especially useful in chronic diarrhea. The part employed is the root, from which MacNair obtained about 2 per cent. of a volatile oil, having the specific gravity 0.93, a pungent and bitter taste, and a neutral reaction; also a bitter principle, but not tannin. For further description, see A. J. P., July, 1889; also 14th and 16th editions of U. S. D. P. corylifolia L., of India, yields an oleoresin which is used in the treatment of leucoderma and other skin diseases. (P. J., Sept., 1881.) Mann and Griffiths obtained from the seeds of P. coryfolia 13.7 per cent. of a thick brownish oil and 37.2 per cent. of an alcoholic extract which yielded by purification 9.2 per cent. of a resinoid. (P. J., 1912, 260.)

Ptelea. Ptelea trifoliata, L. and the variety Mollis T. and G. Wafer Ash. Wing Seed. Shruby Trefoil. Hop Tree. Ormea trois feuilles, Fr. Hopfenbaim, Kleebaum, G. (Fam. Rutacece.)—This is a shrub with 3-foliate leaves growing in rocky places from Long Island to Minnesota and southward. The root bark has a peculiar somewhat aromatic odor, and a bitter, persistently pungent, and slightly acrid, yet not disagreeable taste.
Steer obtained from it an oleoresin of an acrid and bitter taste and the alkaloid berberine. An alkaloid, arginine, C_{6}H_{14}O_{2}N_{4}, is stated also to be present in the root. (A. J. P., 1867, 337.) It was formerly employed among the physicians of the Western States in the treatment of dyspepsia, and generally in diseases requiring a mild, non-irritating, bitter tonic.

**Pulmonaria.** Pulmonaria officinalis L. Lungwort. Pulmonaire, Fr. Lungenkraut, G. (Fam. Boraginaceae)—An herbaceous perennial, European plant, sometimes cultivated. The leaves have been employed in catarrh, hemoptyisis, and consumption, but their virtues are doubtful.

**Pulsatilla.** N. F. IV. PasqueFlower. Meadow Anemone—"The dried herb of Anemone Pulsatilla Linne, Anemone pratensis Linne, or of Anemone Ludoviciana (Nuttall) Heller (Fam. Ranunculaceae), without the presence of more than 5 per cent. of foreign matter." N. F.

The plants are common throughout Europe and should be employed in the fresh condition. The drug is collected at the time of flowering of the plants which extend from March to May. The drug is frequently sold in the dry condition and should be carefully preserved.

The genus Anemone is composed of small herbal plants growing in almost all the temperate countries of the world, and probably possessed very generally of the acrid rubefacient properties of the Ranunculaceae.

Pulsatilla was official in the U. S. P. 1890 and has been admitted to the N. F. IV. It has been introduced to make the tincture of pulsatilla of the strength of 10 per cent., with a menstruum of 3 volumes of alcohol with 1 volume of water. It is described by the N. F. as follows:

"Leaves and flowering scapes matted, silky-villous; basal leaves with petioles up to 30 cm. in length, the latter hollow, often purplish in color, the blades twice or thrice deeply three- or four-parted or pinnately cleft, the lobes linear and acute, the base of the petiole more hairy than above and frequently attached to the short root-stock; flowering scapes up to 30 cm. in length, solid in the lower portion and hollow in the upper part, with sessile, involucral dissected leaves near the flower, occasionally with remains of the dull purple hairy sepals and the dense-woolly, plumose-tailed akenes. Nearly odorless; taste very acrid.

The powder, when examined under the microscope, shows numerous simple, thick-walled hairs up to 2.5 mm. in length and up to 0.02 mm. in thickness; tracheae up to 0.03 mm. in breadth with spiral markings or with simple or bordered pores; fragments of epidermal tissue with stoma, the latter being broadly elliptical and up to 0.05 mm. in length; some epidermal cells with wavy vertical walls; calcium oxalate crystals and starch grains few or absent. Pulsatilla yields not more than 10 per cent. of ash." N. F.
an American species, growing in Minnesota and other parts beyond the Mississippi, has been employed with supposed advantage by W. H. Miller of St. Paul, in chronic diseases of the eyes, in cutaneous eruptions, and in syphilitic affections. A. W. Miller found anemonin in it. (A. J. P., 1862, p. 300; see also A. J. P., xliv, 299.) A. nemorosa L., which is common in Europe, is said to act as a poison to cattle, producing bloody urine and convulsions. It is stated also to have proved, when applied to the head, a speedy cure for tinea capitis. It is probable that the American A. quinquefolia, at first described as a variety of A. nemorosa, has similar properties. The American Pasque Flower (A. patens L., var. Wolfgangiam (Bess.) Koch), formerly known as A. patens L. var. nuttaliana Gray, was recognized as a source of pulsatilla. This plant is also designated as Pulsatilla hirsutissima (Pursh.) Britt.

Beckurts obtained from pulsatilla anemone camphor by treating in each case the aqueous distillate of A. nemorosa, A. pratensis, and A. pulsatilla with chloroform. It is unstable, splitting easily into anemonin and anemonic acid, the latter, when treated with alkalis, yielding anemoninic acid, C₁₀H₁₂O₆. (P. J., 1885, 365.) The formula of anemonin is C₁₀H₈O₄. It is decomposed at temperatures above 152° C. (305.6° F.), and dissolves in alkalis with yellow color, changing at the same time into anemonic acid, O₁₀H₁₀O₅. When treated with nascent hydrogen in an acid solution, anemonin yields hydroanemonin, O₁₀H₁₂O₄, which crystallizes from boiling petroleum in large colorless laminae which contain 1 molecule of HgO, melt at 78° C. (172.4° F.), and distill without decomposition at from 210° to 212° C. (4100-4140 F.) under a pressure of 10 mm. Hydroanemonin is much more stable than anemonin.

Medicinal Properties and Uses.—Pulsatilla is a violent irritant, producing when taken in sufficient amount excessive vomiting and purging, with pain, hematuria, tremors, dyspnea, and collapse. The statements of the physiological action of anemonin vary so much that there can be little doubt that different experimenters have used different substances under the same name. Noel and Lambert (A. J. P., 1897) affirm that it has no action upon the heart but affects powerfully the central nervous system, producing in the lower animals progressive paralysis of spinal origin. On the other hand, Bronevski (Med. Press., Aug., 1886) affirms that anemonin affects very powerfully not only the nerve centers but the heart itself. The strength of commercial anemonin is variable. Broudgeest gives the fatal dose for the rabbit as 200 mgm. per kilo, while in Noel and Lambert's experiments 0.16 gramme per kilo was required to kill a guinea-pig. Authors place the dose for man at from five-sixths to one and one-half grains (0.05-0.096 Gm.) a day, in divided amounts.

It has been claimed for pulsatilla that it acts powerfully upon the genitalia in men and women, and is useful in dysmenorrhea and ovarian irritation; also epididymitis and orchitis. Our own experience with it is in accord with that of many practitioners—that unless given in infinitesimal dose, with much ceremony, it fails to achieve any good in these various cases, so that the effect which sometimes follows its use in hysterical women is of psychical origin. Noel and Lambert especially commend a fluidextract made from the fresh herb, of which they state that from seventy-five to one hundred and twenty-five minims (4.6-7.8 mils) may be exhibited in the course of twenty-four hours. The dose of the dried powder is commonly given as from two to three grains
(0.13-0.2 Gm.), but probably much larger amounts can be safely taken.

**PULVERES**

**POWDERS**

The form of powder is convenient for the exhibition of substances which are not given in very large doses, are not very disagreeable to the taste, have no corrosive property, and do not deliquesce rapidly on exposure.

With regard to keeping powders in well-stoppered bottles, it is asserted by Herouard, a French pharmacist, that this plan, instead of preserving some powders, tends to their more speedy and certain change. Whatever pains may be taken in drying drugs previously to powdering them, most of them during the process attract moisture, so as to put themselves in this respect in equilibrium with the surrounding air; and, if enclosed in this state in air-tight vessels, they are exposed to injurious influence from their own absorbed water, which, vaporized in hot weather, is in the colder seasons condensed on the inner surface of the vessel and determines a movement of fermentation, and even cryptogamic growths appear in some instances. The best method of preservation, the author thinks, is to enclose the powders in strong paper bags of a 'blue or gray color, so as to exclude the light, while the air has exit or entrance through the porous walls. Whatever may be our theoretical opinions on the point, Herouard asserts the fact, as the result of observation, that powders keep best in this way, and his statement coincides with our own experience. The powders may be more likely to cake or harden into aggregate masses; but this disadvantage is easily counteracted by a new pulverization when required. (J. P. C., Aout, 1862, p. 98.) From these statements the inference may be drawn that, where powders are kept in air-tight bottles, they should be thoroughly dried, after pulverization, before being enclosed, and many, such as ergot, rhubarb, etc., should be kept in paper boxes or cartons.

In relation to substances most liable to injury from these causes, the best plan is to powder them in small quantities as wanted for use.

Powders may be divided into the simple, consisting of a single substance, and the compound, of two or more mixed together. The latter
only are embraced under the present head. In the preparation of the compound powders, the ingredients, if of different degrees of cohesion or solidity, should be pulverized separately and then mixed. Deliquescent substances, and those containing fixed oil in large proportion, should not enter into the composition of powders intended to be kept,—the former because they render the preparation damp and liable to spoil, the latter because they are apt to become rancid and impart an unpleasant odor and taste. When deliquescent substances are extemporaneously prescribed, the apothecary should enclose them before delivery in waxed paper or other impervious covering; and the same remark is applicable to volatile powders, as ammonium carbonate and camphor. The lighter powders may in general be administered in water or other thin liquid; the heavier, such as those of metallic substances, require a more consistent vehicle, as syrup, molasses, honey, or one of the confections. Resinous powders, if given in water, require the intervention of mucilage or sugar. For many powders the cachet de pain affords the best method of administration.

These very useful articles are wafers made of unleavened bread in such a manner that they offer a concavity, so that when two are placed face to face there is a space in which a powder may be contained. They are of different sizes and capacities, the largest readily holding as much as ten grains of quinine. In filling them, one wafer is placed upon a board, and the requisite amount of medicine is put in it; then a second wafer, whose interior margin has been wetted, is laid upon the first and pressed down upon it. When taken, they should be dipped in water, placed immediately upon a teaspoon containing a little water, and swallowed with a gulp of fluid. For most powders of disagreeable taste, cachets afford the best method of administration.

Gelatin capsules are extensively used for the administration of drugs in powdered form and are admirably adapted for this purpose if the dose is not too large, as they are readily filled and easily taken by the patient.

In the act of powdering, the whole substance in the mortar should not be beaten until completely pulverized, as the portion already powdered interferes with the action of the pestle upon the remainder, while the finer matter is apt to be dissipated, so that there is a loss of time and of material. The proper plan is to sift off the fine powder after a short continuance of the process, then to return the coarser parts to the mortar, and to repeat several times this alternate pulverization and
shifting, until the process is completed. Care should be taken to mix thoroughly the several portions of fine powder thus obtained.

**PULVIS AMYGDALÆ COMPOSITUS. Br.**

**COMPOUND POWDER OF ALMONDS**

Confectio Amygdalæ; Conserva Amygdalarum; Confection of Almond; Conserve d'Amandes, Fr.; Mandelconserv, G.

"Sweet Almonds, 60 grammes; Refined Sugar, in powder, 30 grammes; Gum Acacia, in powder, 10 grammes. Blanch and dry the Almonds; reduce them to a coarse powder; mix the Gum Acacia and Sugar; add to the powdered Almonds; mix." Br.

This is the old Almond Confection in powder form. It is intended to afford a speedy method of preparing the almond mixture, which, when made immediately from the almonds, requires much time, and which cannot be kept ready made. But from its liability to be injured by keeping, it was omitted from the U. S. Pharm., which directs the emulsion of almond to be made immediately from the ingredients.

Off. Prep.—Mistura Amygdalae, Br.

**PULVIS AROMATICUS. U. S. (Br.)**

**AROMATIC POWDER Pulv. Arom.**

Pulvis Cinnamomi Compositus, Br.; Compound Powder of Cinnamon; Poudre des Epicea, P. des Aromates, Poudre aromatique, Fr.; Aromatisches Pulver, Gewurzpulver, G.

"Saigon Cinnamon, in No. 60 powder, thirty-five grammes [or 1 ounce av., 103 grains]; Jamaica Ginger, in No. 60 powder, thirty-five grammes [or 1 ounce av., 103 grains]; Cardamom Seed (deprived of pericarps), fifteen grammes [or 231 grains]; Myristica, freshly grated, fifteen grammes [or 231 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Triturate the cardamom seed and the myristica with a portion of the saigon cinnamon, until they are reduced to a fine powder; then add the remainder of the cinnamon and the ginger, and rub them together until they are thoroughly mixed." U. S.

Properties.—"Light reddish-brown; with a strong, distinctive, aromatic odor; when examined under the microscope it exhibits characteristic starch grains of ginger, being ellipsoidal or ovoid, slightly beaked and from 0.005 to 0.06 mm. in diameter; numerous yellowish-brown, brownish-red and occasional blackish fragments, the cellular structure of which is not distinct; occasional stone cells, the lumina being filled usually with a reddish-brown amorphous substance or containing air; occasional fragments with sclerenchymatous fibers; calcium oxalate crystals, in short raphides, few." U. S.

The Aromatic Powder of the U. S. P. IX does not differ essentially from that formerly official. The British and American powders now closely resemble, each other. The U. S. process contains nutmeg and the British does not. The cardamom seeds should always be deprived of their pericarps before being weighed, and the powder, when prepared, should be kept in well-stoppered bottles.

Uses.—The aromatic powder is stimulant and carminative, and the U. S. preparation may be given in the dose of from ten to thirty grains (0.65-2.0 Gm.), in cases of enfeebled digestion with flatulence; but it is chiefly used as a corrigent and adjuvant of other medicines. A mixture of aromatic powders in the form of a cataplasm is much used as a mild rubefacient, especially in nausea and vomiting, being applied over the epigastrium. Such a mixture is commonly called spice plaster and will be found in the N. F. IV (Part III), under the title Pulvis Aromaticus Rubefacien. It contains clove, cinnamon, ginger, and capsicum, and the mixed powder may be distributed in a thin flannel bag, quilted in position, and the whole wet with bathing whisky when applied and covered with oiled silk.

Aromatic Sugar.—Wm. L. Turner proposed a mode of obtaining the effects of the aromatic powder in certain cases where the use of the powder itself would be inconvenient. He prepared an aromatic sugar by submitting eight ounces of the freshly prepared powder to percolation with stronger alcohol to exhaustion, pouring the percolate over eight ounces of sugar, and evaporating at a low heat. The sugar thus prepared may be added to mixtures, solutions, etc., requiring aromatic addition. (A. J. P., 1869, p. 118.)
Dose, ten to twenty grains (0.65-1.3 Gm.).

**Off. Prep.**—Fluidextractum. Aromaticum, U.S.

**PULVIS BUTEÆ SEMINUM. Br.**

**POWDER OF BUTEA SEEDS**

"Soak Butea Seeds in Distilled Water; carefully remove the integuments; dry and powder the kernels." Br.

**Uses.**—(See Butea Semina.)

**PULVIS CATECHU COMPOSITUS. Br.**

**COMPOUND POWDER OF CATECHU**

Pulvis Qambir Compositus, N.F.; Poudre de Cashcuttie composee, Fr.; Zusammengesetztea Katechupulver, G.

"Catechu, in powder, 40 grammes; Kino, in powder, 20 grammes', Krameria Root, in powder, 20 grammes; Cinnamon Bark, in powder, 10 grammes; Nutmeg, in powder, 10 grammes. Mix." Br.

This preparation is also official in the N. F..

The dose of this agreeable preparation is from fifteen to thirty grains (1-2 Gm.).

**PULVIS GLYCIRRHIÆ COMPOSITUS.**

**U. S., Br.**

**COMPOUND POWDER OF GLYCIRRHIZA**

Pulv. Glycyrrh. Co. [Compound Licorice Powder]

Poudre de Reglisse composee, Poudre pectorale, Fr.; Pulvis Liquiritiae Compositus, P. G.; Brustpulver, Pulvis Pectoralia Kurellae, G.

"Senna, in No, 80 powder, one 'hundred and eighty grammes [or 6 ounces av., 153 grains]; Glycyr rhiza, in No. 80 powder, two hundred and thirty-six grammes [or 8 ounces av., 142 grains]; Washed Sulphur,
eighty grammes [or 2 ounces av., 360 grains]; Oil of Fennel, four grammes [or 62 grains]; Sugar, in fine powder, five hundred grammes [or 17 ounces av., 279 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Mix the oil of fennel thoroughly with about one-half of the sugar, then add the remainder of the sugar and the other ingredients, and mix thoroughly. Finally, pass the powder through a No. 80 sieve, pulverize the residue if any should be left on the sieve, add to the sifted powder, and mix thoroughly. Keep it in well-closed containers." U. S.

"Senna Leaves, in powder, 16 grammes; Liquorice Root, in powder, 16 grammes; Fennel Fruit, in powder, 8 grammes; Sublimed Sulphur, 8 grammes; Refined Sugar, in powder, 52 grammes. Mix." Br.

Properties.—"Greenish-yellow to greenish-brown with a fennel-like odor; when mounted in water or hydrated chloral T.S. and examined under the microscope, Compound Powder of Glycyrrhiza shows fragments of glycyrrhiza with their characteristic yellow fibers associated with crystal fibers, large tracheae with elliptical, bordered pores and cells containing numerous, spherical starch grains varying from 0.002 to 0.02 mm. in diameter; also fragments of senna as shown by their characteristic, more or less bent, unicellular, non-glandular hairs, from 0.1 to 0.35 mm. in length, fragments of epidermis with elliptical stomata and their 2 neighboring cells and fragments with crystal fibers; upon the addition of potassium hydroxide T.S. to aqueous mounts of the powder, some of the fragments are immediately colored a yellowish-red, changing to a reddish-brown. Introduce 0.1 Gm. of Compound Powder of Glycyrrhiza into a test tube, moisten it with 2 mils of alcohol, then add 10 mils of water, boil the mixture, allow it to cool and then filter; the filtrate is of a pale yellowish-brown color, which changes immediately to a yellowish-red on the addition of a drop of potassium hydroxide T.S. Compound Powder of Glycyrrhiza is free from an odor of hydrogen sulphide." U. S.

This official preparation, which was introduced into the U. S. P., 1880, was identical with that of the German Pharmacopoeia, and in the 1885 revision of the British Pharmacopoeia the preparation was made nearly to correspond, being slightly deficient in senna. The U. S. P., 1890, replaced the powdered fennel with oil of fennel, increasing the proportion of powdered licorice correspondingly which is an improvement,—as powdered fennel is variable in quality; great care should be used, however, to employ only fresh oil of fennel. The object of
the oil of fennel is patent, but the advantage to be gained by the use of washed sulphur in the proportion of only 8 per cent. must be purely imaginary. In our opinion, an improvement would be the substitution of two grammes each of powdered cinnamon and cloves for four grammes of the sugar, to correct the griping effect which is frequently produced.

Dose, thirty to sixty grains (2.0-3.9 Chn.), used as an agreeable laxative.

**PULVIS J ALAPÆ COMPOSITUS. U. S., Br.**

**COMPOUND POWDER OF J ALAP**

Pulvis Purgans, Pulvis Jalapæ Tartratus, Pulvis Catharticus; Poudre de Jalap composee, Fr.; Jalapenpulver mit Weinstein, G.

"J alap, in No. 60 powder, thirty-five grammes [or 1 ounce av., 103 grains]; Potassium Bitartrate, in fine powder, sixty-five grammes [or 2 ounces av., 128 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Mix the powders intimately by trituration and pass the product through a No. 60 sieve." U. S.

"J alap, in powder, 30 grammes; Acid Potassium Tartrate, in powder, 60 grammes; Ginger, in powder, 10 grammes. Mix." Br.

**Properties.**—"Very light brown; when examined under a microscope it exhibits numerous, sharp-angular, colorless fragments mostly somewhat rectangular and with straight edges varying from 0.03 to 0.3 mm. in length, slowly soluble in water or hydrated chloral T.S. and polarizing light with a strong display of colors (fragments of crystals of potassium bitartrate), numerous starch grains of jalap, readily distinguished without the use of iodine T.S., usually single, occasionally 2- to 3-compound, and varying from 0.003 to 0.035 mm. in diameter; occasional fragments of laticiferous vessels and parenchyma with yellowish-brown walls, or tracheae with bordered pores, and rosette aggregates of calcium oxalate from 0.01 to 0.035 mm. in diameter, that occur in jalap." U. S.

The rubbing of the bitartrate with the jalap is thought to favor its more minute division, while it increases its hydragogue effect. A combination of these two ingredients, though with a larger proportion of cream of
tartar (see J alapa), forms a good cathartic in dropsy.

Dose, of the powder, from thirty grains to a drachm (2.0-3.9 Gm.).

**PULVIS KALADANÆ COMPOSITUS. Br.**

**COMPOUND POWDER OF KALADANA**

"Kaladana, in powder, 30 grammes; Acid Potassium Tartrate, in powder, 60 grammes; Ginger in powder, 10 grammes. Mix." Br.

This powder is used as a cathartic.

Dose, from ten to sixty grains (0.65-3.9 Gm.).

**PULVIS KINO COMPOSITUS. Br.**

**COMPOUND POWDER OF KINO**

Pulvis Kino et Opii Compositus, N. F., Compound Powder of Kino and Opium; Pulvis Kino cum Opio, Br. 1804; Powder of Kino and Opium; Poudre de Kino Opiacee, Fr.; Kinopulver mit Opium, G.

"Kino, in powder, 75 grammes; Opium, in powder, 5 grammes; Cinnamon Bark, in powder, 20 grammes. Mix. This Powder contains 5 per cent. of Opium." Br.

The N. F. powder is practically identical with the Br..

This is an anodyne astringent powder, useful in some forms of diarrhea, but of which the composition would be better left to extemporaneous prescription, as the proportion of the ingredients should vary with the circumstances. Twenty grains contain one grain of opium.

Dose, from five to twenty grains (0.32-1.3 Gm.).

**PULVIS RHEI COMPOSITUS. U. S., Br.**

**COMPOUND POWDER OF RHUBARB Pulv. Rhei Co.**

Magnesia and Rhubarb, Gregory's Powder; Poudre de Rhubarbe composee, Fr.; Pulvis Magnesise cum Rheo, P. G.; Kinderpulver, Pulvis Infantum, s. P. Antacidus, G.
"Rhubarb, in No. 60 powder, twenty-five grammes [or 386 grains]; Magnesium Oxide, sixty-five grammes [or 2 ounces av., 128 grains]; Jamaica Ginger, in No. 60 powder, ten grammes [or 154 grains], to make one hundred grammes [or 3 ounces av., 231 grains]. Rub the rhubarb and ginger together, then gradually add the magnesium oxide and continue the trituration until they are thoroughly mixed, then pass through a No. 60 sieve." U. S.

"Rhubarb Root, in powder, 22 grammes; Light Magnesia, 66 grammes; Ginger, in powder, 12 grammes. Mix." Br.

Properties.—" A pinkish-white, mobile powder, becoming darker on exposure to moisture; when examined under the microscope it exhibits flue particles of magnesium oxide, numerous starch grains and characteristic fragments of vegetable tissues; starch grains of ginger, more or less elliptical or ovoid, frequently with a prominent beak, from 0.005 to 0.06 mm. in diameter; starch grains of rhubarb, single or compound, either spherical or polygonal, often with a central cleft, from 0.002 to 0.02 mm. in diameter; mounts made with hydrated chloral T.S. give a strong effervescence and show more clearly the fragments of reticulate tracheae, the reddish-brown parenchyma of rhubarb with numerous small starch grains or rosette aggregates of calcium oxalate, varying from 0.05 to 0.1 mm. in diameter. With solutions of the alkalies many of the fragments of rhubarb become of a deep red color." U. S.

This is a good laxative antacid, well adapted to bowel complaints, especially in children.

Dose, for an adult, from one-half to one drachm (2.0-3.9 Gm.); for a child two or three years old, from five to ten grains (0.32-0.65 Gm.).

**PULVIS SCAMMONIÆ COMPOSITUS. Br.**

**COMPOUND POWDER OF SCAMMONY**

"Scammony Resin, in powder, 50 grammes; Jalap, in powder, 35 grammes; Ginger, in powder, 15 grammes. Mix." Br.

This does not appear to us a very eligible preparation.
Dose, from ten to twenty grains (0.65-1.3 Gm.).

**PULVIS TRAGACANTHÆ COMPOSITUS.** Br.

**COMPOUND POWDER OF TRAGACANTH**

"Tragacanth, in powder, 15 grammes; Gum Acacia, in powder, 20 grammes; Starch, in powder, 20 grammes; Refined Sugar, in powder, 45 grammes. Mix." Br.

This is applicable to the general purposes of the demulcents, but is chiefly employed in Great Britain as a vehicle for heavy insoluble powders.

Dose, one-half to one drachm (2.0-3.9 Gm.).

**Punaria Ascochingae.**—This plant was said to belong to the Compositae and was native in Argentine; was asserted to be free from alkaloids, but to contain a glucosidal resin which is its active principle. Zehden (Med.Woch., 1906, No. 35) found it useful in asthma when the powder, made up into pastilles called asthma carbon, is burned and inhaled.

Holmes (P. J., 1908, lxxx, 316) says there is no plant known by this name and that the same substance was introduced many years ago and was really obtained from Brachycladi stuckertii.

**Pycnanthemum.** P. flexuosum (Walt.) Bsp. (P. linifolium Pursh.) Dysentery Weed.—This American mint is popularly used in bowel complaints; its hot infusion is diaphoretic. (See A. J. P., 1894, 65, 169; Ph. Rund., 1896, 32.)

A volatile oil was obtained by E. R. Miller by distilling the leaves and flowering tops of P. pycnanthemooides (See Proc. Alabama Pharm. Assoc. 1910, 58.)

**PYRETHRUM. U. S. (Br.)**

**PYRETHRUM Pyreth. [Pellitory Root]**

"The dried root of Anacyclus Pyrethrum (Linne) Dc Candolle (Fam. Compositæ). Preserve Pyrethrum in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." U. S. "Pyrethrum Root is the dried root of Anacyclus Pyrethrum DC." Br.
Pyrethri Radix, Br.; Pyrethrum Root; Radix Pyrethri Romani; Spanish Chamomile, Long-wort, Pellitory of Spain; Pyrethre officinal, Fr. Cod.; P. vrai, Salivaire, Fr.; Bertram-wurzel, Romische Bertramwurzel, G.; Pelitre (Raiz de), Sp.

Anacyclus Pyrethrum is perennial, and sends up numerous stems, usually trailing at the base, erect in the upper portion, eight or ten inches high, and terminated by one large flower. The leaves are doubly pinnate, with narrow, nearly linear segments of a pale-green color. The florets of the disk are yellow; the rays white on their surface, and reddish or purple beneath and at their edges.

The plant is a native of Northern Africa, the Levant, and the Mediterranean coast of Europe, being also cultivated. The root is the part used under the name of pellitory, or pellitory of Spain.

The German Pharmacopoeia formerly recognized the root of Anacyclus officinalis Hayne (A. Pyrethrum Schrader), a plant cultivated in Magdeburg. The roots are smaller and thinner, attaining a length of 25 cm. and a thickness of 5 cm. They are externally grayish-brown; the bark is not radiating and does not contain many stone cells, such as are present in the official pyrethrum. The taste resembles that of the official drug but is even more pungent.

Properties.—Pyrethrum is officially described as "nearly cylindrical, slightly tapering, usually in pieces from 2.5 to 10 cm. in length and from 5 to 20 mm. in diameter; externally dark brown, deeply longitudinally furrowed and somewhat wrinkled, occasionally bearing short, tough, hair-like rootlets, crown more or less annulate, and occasionally tufted with coarse fibers or with long, soft-woolly, nearly straight, 1-celled hairs; fracture short; bark dark brown with 1 or 2 circular rows of resin ducts, closely adhering to the light yellow, radiate, porous wood, in the medullary rays of which occur 1 to 3 rows of resin ducts; odor distinct; taste sweetish, pungent, very acrid, tingling and producing a strong sialagogue effect. The powder is light to dark brown; when examined under the microscope it exhibits numerous spherical or irregular masses of inulin, the nature of which is especially seen with polarized light, and lignified fragments of the woody tissues and stone cells associated with cork; inulin in spherical granules or irregular masses, from 0.01 to 0.1 mm. in diameter, which is not affected by the addition of iodine T.S.; trachea; with simple pores and reticulate or scalariform thickenings, usually associated with wood parenchyma and with few or no wood fibers; stone cells in groups, the cells more or less tabular in outline and
with thick, yellowish porous walls; cork in yellowish-brown or dark brown fragments. Pyrethrum yields not more than 5 per cent. of ash." U. S.

"Usually from five to ten centimetres long, and from ten to fifteen millimetres thick; un-branched, nearly cylindrical, or frequently tapering towards both extremities; the crown often bearing a tuft of nearly colorless hairs. Outer surface brown and longitudinally wrinkled. Fracture short. In transverse section, numerous, narrow, yellowish wood-bundles alternating with wider, brownish-grey medullary rays; in the cortex and medullary rays scattered, yellowish-brown oleo-resin ducts; in the parenchymatous tissue inulin, but no starch. Characteristic odor; taste pungent, salivant." Br.

Its analysis by Koene gives, in 100 parts, 0.59 of a brown, very acrid substance, of a resinous appearance, and insoluble in potassium hydroxide (this is stated to contain pelletonin), 1.06 of a dark brown, very acrid, fixed oil, soluble in potassium hydroxide; 0.35 of a yellow acrid oil, also soluble in potassium hydroxide; traces of tannin; 940 parts of gum; inulin; 7.60 parts of potassium sulphate and carbonate, potassium chloride, calcium phosphate and carbonate, alumina, silica, etc., and 19.80 of lignin, besides loss. (See A. J. P., viii, 175.) Buchheim (A. E. P. P., v, 458) claims to have discovered as the active principle an alkaloid, pyrethrine, which, treated with alcoholic potassium hydroxide, splits up like piperine, and yields pyrethric acid. Schneegans (Proc. A. Ph. A., 1897, 736) has obtained this pyrethrine in long branched needles united in tufts, melting at 46° C. (114.8° F.), with an extremely burning taste. It is soluble in absolute alcohol, acetone, ether, strong acetic acid, chloroform, and carbon disulphide, yields a yellow solution, which soon changes to red.

A false pellitory root has been identified by E. M. Holmes as the product of Corrigiola telephiifolia. It is readily distinguished from the true root by its being softer and more flexible, by its having a distinctly sweetish taste, and especially by the transverse section of the root, which is of a yellowish-white color, with from three to five pale opaque concentric rings, each alternating with a narrower translucent horny ring.

Uses.—Pellitory is a powerful irritant, used
Quamacai.—The wood of Paullinia Thalictrifolia (fam. Sapindaceae), a native of Brazil, has been used in beri-beri and rheumatic affections. It is also used externally in diaphoretic baths.

QUASSIA. U. S. (Br.)

QUASSIA Quass. [Bitter Wood]

"The wood of Picrasma excelsa (Swartz) Planchon, known in commerce as Jamaica Quassia, or of Quassia amara Linne, known in commerce as Surinam Quassia (Fam. Simarubaceae)." U. S. "Quassia Wood is the wood of the trunk and branches of Picraena excelsa, Lindl." Br.

Quassiae Lignum, Br.; Jamaica Quassia, Quassia Wood; Bitter Wood; Bitter Ash; Quassie Amere ou Bois amer de Surinam, Fr. Cod.; Bois de Quassie, Quassie de la Jamaicue, Fr.; Lignum Quassia, P. G.; Quassiaholz, Fliegenholz, G.; Quassia, Quassia della Giammaica, It.

"In logs of varying length, or in chips or raspings; yellowish white, tough and dense, but easily split. In longitudinal section, elongated cells containing single crystals of calcium oxalate; in transverse section, medullary rays mostly two or three cells wide. No odor; taste intensely bitter." Br.

The genus Picrasma is represented by eight species, which are found in the warmer regions of the Old and New World. They all possess a bitter wood and bark.

Picrasma excelsa (Swartz) Planchon (Picraena excelsa Lindley), as its name implies, is a lofty tree, sometimes attaining the height of not less
than one hundred feet, with a straight, smooth tapering trunk, which is often three feet in diameter near its base, and is covered with a smooth, gray bark. The leaves are pinnate, the leaflets being petiolate and oblong pointed and arranged in opposite pairs, with a single leaflet at the end. The flowers are small, of a yellowish-green color, and disposed in panicles. They are polygamous and pentandrous. The fruit is a small black drupe. This species inhabits Jamaica and the Caribbean Islands, where it is called bitter ash. Most of the commercial quassia is obtained from this tree.

Quassia amara, or bitter quassia, is a small branching tree or shrub, with alternate leaves, consisting of two pairs of opposite pinnae, with an odd one at the end. The leaflets are elliptical, pointed, sessile, smooth, of a deep green color on their upper surface, and paler on the under. The common footstalk is articulated and winged. The flowers, which are hermaphrodite and decandrous, are bright red, and terminate the branches in long racemes. The fruit is a two-celled capsule containing globular seeds. Quassia amara is a native of Surinam, and is found in Brazil, Guiana, Colombia, Panama, and the West Indies, as also in some tropical countries of the Old World. Its root, bark, and wood were formerly official. They are excessively bitter, as in fact are all parts of the plant. For the botanical description and history of Quassia amara, see J. U. Lloyd, West. Drug., 1897, 7; also Gilling (P. J., 1908, lxiii, p. 30).

Properties.—Quassia is at first whitish, but becomes yellow by exposure, and sometimes has blackish spots or markings, due to the presence of the mycelium of a fungus. The two varieties are thus officially described:

"Jamaica Quassia.—Usually in chips, raspings or shavings, occasionally in small cubes or billets; yellowish-white or bright yellow, with a few light gray pieces somewhat coarsely grained; fracture tough, fibrous; odor slight; taste bitter. Under the microscope, sections of Jamaica Quassia show large tracheae either single or in groups of 2 to 5, the walls being marked by numerous, small, bordered pores, and the contents being often of a yellowish color; medullary rays mostly 1 to 5 cells wide and from 10 to 20 rows deep; calcium oxalate, in crystal fibers near the medullary rays, in 4- to 6-sided prisms, from 0.006 to 0.03 mm. in length; wood fibers with thin walls and oblique pores; starch grains few, spherical or ellipsoidal, from 0.01 to 0.015 mm. in diameter.
“Surinam Quassia.—The crude drug and microscopic sections closely resemble the Jamaica variety; tracheae usually single or in pairs, sometimes in groups of 3 or 4; medullary rays in narrower and larger groups than in the Jamaica variety, from 1 to 4 cells wide and from 10 to 30 rows deep; calcium oxalate crystals few or entirely absent, thus distinguishing the variety from Jamaica Quassia." U. S.

Quassia imparts its active properties, with its bitterness and yellow color, to water and alcohol. Its virtues depend upon a peculiar bitter crystallizable principle, denominated quassin, which was first discovered by Wiggers, who assigned it the formula $C_{10}H_{12}O_3$. Quassin is white, opaque, unalterable in the air, inodorous, and of an intense bitterness, which in the solutions of this principle is almost insupportable. The bitterness is pure, and resembles that of the wood. When heated, quassin melts like a resin. It is but slightly soluble in water, 100 parts, at 54° C. (129.2° F.) dissolving only 0.45 part, and that slowly. By the addition of salts, especially of those with which it is associated in quassia, its solubility is strikingly increased. It is also but slightly soluble in ether, but is very soluble in alcohol, more so in that liquid hot than cold, and the more so the purer it is. Quassin is perfectly neutral, though both alkalies and acids increase its solubility in water. It is precipitated by tannic acid from its aqueous solution, which is not disturbed by iodine, chlorine, corrosive sublimate, the salts of iron, sugar of lead, or even lead subacetate.

Oliveri and Denaro (A. J. P., 1885, p. 29) obtained quassin in a thoroughly pure, crystallized state, and made a complete study of it. They give it the formula $C_{32}H_{44}O_{10}$. It melts at 210° to 211° C. (410°-411.8° F.), and is very soluble in alcohol, chloroform, and acetic acid, but only sparingly so in ether. Its aqueous solution becomes yellow on exposure to the air, is dextrorotatory, excessively bitter, and reduces Fehling's solution. When quassin is heated to 90° C. (194° F.) for some hours with diluted sulphuric acid (4 per cent.) it yields quasside, $C_{32}H_{42}O_9$, a white, amorphous, bitter substance, formed from quassin by removal of $H_2O$; no glucose could be detected in the mother liquors. Bromine forms a derivative which seems to have the formula $C_{32}H_{41}Br_3O_9$. If quassin is heated with concentrated hydrochloric acid in sealed tubes for four hours at 100° C. (212° F.), methyl chloride is formed and a colorless substance deposited, which the authors call
quassic acid, C\textsubscript{28}H\textsubscript{38}O\textsubscript{6}(COOH)\textsubscript{2}. This is far less soluble in alcohol than quassin, and crystallizes in silky needles, which melt at 245° C. (473° F.), and reduce Fehling's solution and ammoniacal silver nitrate in the cold. The authors consider quassin as the methyl ether of this quassic acid, as follows:

\[ \text{C}_{28}\text{H}_{38}\text{O}_{6}(\text{COOCH}_3)_2 = \text{C}_{32}\text{H}_{44}\text{O}_{10} \]

The real nature of quassin is at present somewhat doubtful, it being probably that distinct substances have been confounded by chemists. Dymock and Warden believe that they have obtained quassin from the wood of Picrasma quasioides (Ham.) Benn. of India. According to the researches of Massute (A. J. P., 1890, p. 338), Quassia amara contains four principles, which, are different from those of Picrasma excelsa. By shaking an alcoholic extract of quassa wood with chloroform he obtained a mixture of crystals, from which, eventually, four bitter principles, differing in melting point and solubility, were separated. One of these melting at 210° to 211° C. (410°-11.8° F.), and another melting at 239° to 242° C. (462.2°-467.6° F.), were in too small a quantity to be further examined, but the former agreed in melting point and crystalline form with the quassin of Wiggers (C\textsubscript{32}H\textsubscript{40}O\textsubscript{10}). Of the other two, one melted at 215° to 217° C. (419°-422.6° F.), and is represented by the formula C\textsubscript{35}H\textsubscript{46}O\textsubscript{10}, while the other melted at 221° to 226° C. (429.8°-438.8° F.), and is represented by C\textsubscript{37}H\textsubscript{50}O\textsubscript{10}. From the wood of Picrasma excelsa two crystalline compounds were separated by Massute, both having lower melting points than either of the compounds from Q. amara. One was in needles, melted at 204° C. (399.2° F.), and had the composition C\textsubscript{35}H\textsubscript{46}O\textsubscript{10}, while the other was in prisms, melted at 209° to 212° C. (408.2°-413.6° F.), and had the composition C\textsubscript{36}H\textsubscript{46}O\textsubscript{10}. Both of these are homologues of a third crystalline principle, C\textsubscript{29}H\textsubscript{34}O\textsubscript{10}, melting point 212° to 216° C. (413.6°-420.8° F.), which occurs with them. When the picrasmin, C\textsubscript{35}H\textsubscript{46}O\textsubscript{10}, above referred to, melting at 204° C. (399.2° F.), is heated with hydrochloric acid, it is changed like quassin into an acid, which in this case has the formula C\textsubscript{33}H\textsubscript{42}O\textsubscript{10} + 5H\textsubscript{2}O, and is called picrasmic acid. It appears, therefore, that each wood represents a different series of homologous compounds.

**Uses.**—Quassia was introduced into medicine about the middle of the 18th century by a negro of Surinam, named Quassi, who acquired
considerable reputation in the treatment of the malignant fevers of that
country by a secret remedy, which he was induced to disclose to
Rolander, a Swede, for a valuable consideration. Specimens were taken
to Stockholm by this gentleman in the year 1756, and the medicine soon
became popular in Europe. The name of the negro has been perpetuated
in the generic title of the plant. But the quassia of Surinam is now
comparatively little used, it having been superseded by the product of
Picrasma excelsa from the West Indies.

Quassia is among the most powerful of the simple bitters, useful in
failure of appetite due to gastric debility, and in overdoses capable of
sufficiently irritating the stomach to produce vomiting. Its active
principle, quassin, has been studied by Comparden, who asserts that in
moderate doses it acts as a stimulant to the salivary, hepatic, and renal
secretions, and in overdoses causes burning pain in the oesophagus,
with headache, nausea, vertigo, vomiting, diarrhoea, and muscular
cramps. It is also stated that if given in doses of six-tenths of a grain
(0.04 G-m.) before meals it increases markedly the alvine discharges,
and that it is especially useful in constipation from debility of the
muscular and intestinal coats. The dose of pure quassin is three-tenths
of a grain (0.02 Gm.).

An infusion of quassia, two ounces in a pint of water, affords a valuable
and safe injection for seat-worms.

Syrupus Quassiae.—This syrup is used in the preparation of a harmless
fly-poison. Macerate, during twenty-four hours, 1000 parts of quassia
wood with 5000 parts of water, then boil for half an hour, set aside for
twenty-four hours, and press; mix the liquid with 150 parts of molasses,
and evaporate to 200 parts. A weaker decoction of quassia does not kill
the flies. From this the Fly Water or Fly Plate is prepared as follows: Mix
when needed, and dispense without filtering, 200 parts of syrup of
quassia, 50 parts of alcohol, and 750 parts of water. It is used by
moistening with the mixture a cloth or filtering paper on a plate.

Quassia is given in infusion, tincture, extract, or fluidextract. Some
dyspeptic patients who have become habituated to its bitterness, chew
the wood occasionally with benefit.

Dose, five to ten grains (0.32-0.65 Gm.).

Quebracho Colorado and Quebracho Gum are respectively the wood and the dried juice or aqueous extract of the Schinopsis Lorentsi (Gries.) Engl. (fam. Anacardiaceae), a large tree growing in the Argentine Republic. The wood is very heavy, hard, and of a reddish-brown color. (See A. J. P., 1879, p. 152; also Penzoldt, loc. cit.; P. J., xii.) Quebracho Colorado has been used as a substitute for the true quebracho, but is essentially different from it, and probably is a simple astringent and gastro-intestinal stimulant, although Penzoldt claims that it is similar in its action, but much weaker than quebracho blanco. The extract, which contains about 70 per cent. of tannin, is extensively used in the tanning of leather. In appearance it is somewhat intermediate between kino and logwood extract. Perkin and Gunnel have determined the yellow coloring matter of the wood of quebracho Colorado to be identical with fisetin, $C_{15}H_{10}O_{6}$, the coloring matter of young fustic, Rhus Cotinus L. It occurs in glistening yellow needles, dyeing similarly to quercitin, and yields compounds with mineral acids. Its benzoxy and acetyl derivatives have also been prepared. Fused with alkalies it yields protocatechuic acid and probably resorcinol. Ellagic and gallic acids have also been obtained from the wood, these being probably formed during the isolation of the fisetin. (A J. P., Nov., 1896, 626.)

There are about sixty-five species of oak found in the United States. Many of these are applied to important practical purposes. Quercus Robur, or European oak, has a very wide distribution. It is the common British oak, constitutes a large part of the European forests, and has spread itself over almost the whole northern section of Asia and along the northern coast of Africa. There are two distinct varieties of it, one, pedunculata, with sessile or shortly stalked leaves and the acorns on long peduncles; the other, sessiflora, with the leafstalks more or less elongated and the acorns either sessile or provided with a very short peduncle. The dried bark of the smaller branches of this tree were formerly recognized by the Br. Pharmacopoeia under the name of Quercus Cortex.

Of all the American species, the white oak approaches the nearest, in the character of its foliage and the properties of its wood and bark, to Q. pedunculata, of Great Britain. Its trunk and large branches are covered with a whitish bark, which serves to distinguish it from most of the other species. The leaves are regular and obliquely divided into oblong, obtuse, entire lobes, which are often narrowed at their base. When full grown, they are smooth and light green on their upper surface, and glaucous beneath. Some of the dried leaves remain on the tree during the whole winter. The acorns are large ovoid or ellipoidal, contained in rough, shallow, grayish cups, and supported singly or in pairs upon peduncles nearly 2.5 cm. in length.
The white oak abounds from Ontario to Maine and Minnesota, and extends southward. It is the most highly valued for its timber of all the American oaks, except the live oak, *Q. virginiana* Mill. (*Q. virens* Ait.), which is preferred in ship building. The bark is sometimes used for tanning, but the barks of the red and Spanish oaks are preferred. All parts of the tree, with the exception of the epidermis, are more or less astringent, but this property predominates in the fruit and bark.

White oak bark, deprived of its epidermis, is of a light-brown color, of a coarse, fibrous texture, and not easily pulverized. It occurs "in nearly flat pieces, from 2 to 10 mm. in thickness; externally light brown, becoming darker with age, rough-fibrous; fracture uneven, coarsely fibrous. Odor distinct; taste strongly astringent; not tingeing the saliva yellow when chewed. Quercus yields not more than 7 per cent. of ash." N. F. IV. The medicinal value of oak bark depends on the presence of a considerable proportion of tannin. The proportion of this ingredient varies with the size and age of the tree, the part from which the bark is derived, and even the season when it is gathered. It is most abundant in the young bark, and the English oak is said to yield four times as much in spring as in winter. H. Davy found the inner bark most abundant in tannin, the middle portion or cellular integument much less so, and the epidermis almost wholly destitute as well of this principle as of extractive. Kraemer examined the tannin of white oak bark (A. J. P., 1890, p. 236) and assigned to it the formula \(C_{29}H_{27}O_{13}\), which was later confirmed by Trimble (Tannins). The tannin yields upon sublimation a principle resembling pyrocatechin and upon fusion with potassium hydrate a phenol similar to protocatechinic acid. Dilute solutions of white oak tannin are colored olive-brown with ferric chloride T.S. and possess a slight fluorescence.

The tannic acid of the oak barks is known as quercitannic acid, and has, according to Lowe (Zeit. An., Chem., 20, p. 208), two forms, one soluble in water, of the formula \(C_{26}H_{27}O_{14}\), and the other difficultly soluble, \(C_{26}H_{24}O_{12}\). Both are changed by the loss of water into oak red, \(C_{26}H_{22}O_{11}\). Neither is a glucoside. Gerber discovered in European oak bark a peculiar bitter principle upon which he conferred the name of quercin. This quercin Husemann considers to have been only impure quercite (or oak sugar).

*Quercus velutina* Lam., or black oak, is one of our largest trees, frequently attaining the height of eighty or ninety feet. Its trunk is covered with a deeply furrowed bark, of a black or dark brown color. The leaves are ovate-oblong, pubescent, slightly sinuated with oblong, aculeate lobes. The fructification is biennial. The acorn is globose, flattened at top, and placed in a saucer-shaped cup.

Black oak bark has a more bitter taste than that of the other species, and may be distinguished also by staining the saliva yellow when it is chewed. Its cellular integument contains a coloring principle, capable of being extracted by boiling water, to which it imparts a brownish-yellow color, which is deepened by alkalies and rendered brighter by acids. Under the name of quercitrin, large quantities of this bark, deprived of its epidermis and reduced to coarse powder, are sent from the United States to Europe, where it is used for dyeing wool and silk of a yellow color. The coloring principle is called quercitrin. Herzig (J. Chem. S., 1893, 413) found that its...
composition is expressed by the formula \( C_{21}H_{22}O_{12} + 2H_2O \), and this is confirmed by Rudolph. (Ph. Post, 1893, 529.) The reaction for its decomposition is

\[
C_{21}H_{22}O_{12} + H_2O \rightarrow C_{15}H_{10}O_7 + C_6H_{10}O_6
\]

the products being quercetin and isodulcite in equal molecules.

Quercitrin forms yellowish crystals, which, pulverized, yield a citron-yellow powder. It is neutral in reaction, is odorless, and in the dry condition tasteless, but in hot aqueous or alcoholic solution has a bitter taste. It fuses at 160° to 200° C. (320°-392° F.) to a resinous mass. It is almost insoluble in cold water, sparingly soluble in hot water, and easily soluble in alcohol and alkaline solution. Besides this principle, the bark contains much quer-citannic acid; but it is less used in tanning than the other barks, in consequence of the color which it imparts to the leather, and it was dropped from the U. S. P., 1890, on account of its decoction staining so decidedly.

Quercitrin has been found in various other plants, as in the leaves of Rutagaveolens, and the flower buds of Capparis spinosa, Sophora japonica, and Æsculus Hippocastanum, or horse chestnut. (Chem. Gaz., May 2, 1859, p. 161.) As this principle is capable of assuming various colors under various chemical influences, the idea has been advanced that it might be the coloring principle of flowers.

Acorns, besides the bitter and astringent principles of the bark, contain a peculiar saccharine matter (quercite), which is insusceptible of the vinous fermentation. (J. P. C., 3e ser., xx, 335.) They are sometimes used as a tonic or astringent, and a decoction made from roasted acorns has been long employed in Germany as a remedy in scrofula. Before roasting they should be deprived of their shells, and the cotyledons, according to Dausse, should lose, during the process, 28 per cent. of their weight. (Ph. Cb., Oct. 9, 1850, p. 687.) From half an ounce to an ounce may be prepared and taken like coffee at breakfast (Richter).

The National Formulary IV admitted quercus mainly in order to provide a process for the fluid-extract, FluidextractumQuercus, N. F., which was formerly in the U. S. VIII; it is made with a menstruum of five volumes of alcohol, four volumes of water and one volume of glycerin, followed by diluted alcohol. The medical value of oak-bark depends solely upon its tannin. Because of its cheapness it is often used where an external astringent wash is desired. Thus it is employed as an injection in leucorrhœa and hemorrhoids, as a wash for flabby ulcers and similar purposes.

**QUILLAIÆ CORTEX. Br.**

**QUILLAIA BARK**

"Quillaia Bark is the dried inner part of the bark of Quillaja Saponaria, Molina." Br. "The dried bark of Quillaja Saponaria Molina (Fam.
Rosaceae), deprived of the periderm." N. F.

**Quillaja**, N. F.; Soap-tree Bark; Soap Bark; Quillaia, Pharm. 1880; Panama Bark; Panama (Bois de), Fr. Cod.; Ecorce do Quillaya, Fr.; Seifenrinde, G.

The name of this genus is said to be derived from the popular name of the tree Quillay, which in turn comes from the Chilian word quillean, to wash.

Quillaja Saponaria Molina is a tree of moderate size, with alternate oval or oblong leaves having entire or slightly denticulate margins. Staminate and pistillate flowers grow on the same branch, are axillary, pedunculate, and without corolla. The calyx of the pistillate flower persists in fruit, and has its limb deeply divided into five oval acute segments. The bark is thick, the wood very hard. This tree was first described by the famous Abbe Giovanni Ignazio Molina in the Saggio sulla Storia naturale del Chili, published at Bologna, in 1782; second edition, 1810. (Translated into German, I. D. Brandis, Leipsic, 1786; into French, Gruvel, Paris, 1789; into English, London, 1809; also Middletown, Conn., 1880.) It is first noticed by systematic writers in the second (Gmelin's) edition of the Syst. Nat., tome ii, p. 767. The tree is a native of Peru and Chili, but is now cultivated in Northern Hindostan, where it is said to resist well the frosts of winter, and to be flourishing.

**Properties.**—Soap bark is officially described in the Br. as "in flat pieces, from three to eight millimetres thick, but varying considerably in length and width. Outer surface brownish-white, or, where the outer bark has been incompletely removed, reddish or blackish-brown, and longitudinally striated. Inner surface white or yellowish-white and smooth. Fracture splintery and laminated, the tangential surfaces of the lamina; often exhibiting glistening prismatic crystals of calcium oxalate. In transverse section, chequered with delicate radial and tangential lines; medullary rays four cells wide; numerous irregular groups of bast fibres of varying size; scattered starch grains from four to six microns in diameter. Powdered Quillaia Bark is strongly sternutatory; water vigorously shaken with it forms copious persistent froth. Odor not marked; taste astringent and acrid. Ash not more than 15 per cent." Br.

It is described in the N. F. IV as "in flat pieces of variable length, from 3 to 8 mm. in thickness, or in small chips; outer surface brownish-white, often with small patches of cork attached, otherwise nearly smooth;
inner surface yellowish-white, nearly smooth, with occasional circular depressions, conical projections of transverse channels; fracture uneven and strongly fibrous, the laminae oblique to each other. Odor slight; taste acrid. The powder is strongly sternutatory, and contains calcium oxalate in monoclinic pyramids and prisms from 0.035 to 0.2 mm. in length. Quillaja yields not more than 10 per cent. of ash. N. F.

The fracture exhibits, when slightly magnified, glistening prismatic crystals. Quillaja bark is histologically distinguished and its powder recognizable, by the large and numerous prismatic calcium oxalate crystals, which are from 0.035 to 0.200 mm. long.

When bruised and macerated in water quillaja bark imparts to that liquid the property of frothing like soap when agitated. This has been found by Fleury, Jr., and Boutron-Chalard to be owing to the existence of a saponin in the bark. The bark contains neither tannic acid nor any bitter principle. The formula of saponin, given by Rochleder, was $C_{32}H_{54}O_{18}$, and Schiaparelli agreed with him. Stiitz, however (Ann. Ch. Ph., 218, 231), gives it as $C_{19}H_{30}O_{10}$, and this is now accepted for the saponin of quillaja bark. Saponin is slowly decomposed by dilute acids into sapogenin, $C_{14}H_{22}O_{2}$, and a glucose. R. Robert (Chem. Central., 1893, i, 32) gives a list of one hundred and forty plants which contain bodies of the saponin class. He arranges them under several formulas which seem to form an homologous series. Thus, $C_{17}H_{26}O_{10}$ he terms Saponin I (senegin or quillaia sapotoxin); $C_{18}H_{28}O_{10}$ is Saponin II (Schnedeborg's digitonin or sapororubrin); $C_{19}H_{30}O_{10}$ is Saponin III (quillain or quillaiac acid); $C_{20}H_{32}O_{10}$ is cyclamin, Paschki's digitoxin, or sarsaparill-saponin; $C_{22}H_{36}O_{10}$ is sarsasaponin; $C_{26}H_{44}O_{10}$ is parillin.

G. Melliers states that there is present in quillaja bark a carbohydrate which he has identified as saccharose (P. J., Feb., 1901, 161.)

**Uses.**—In diluted form quillaia saponin is irritant to all tissues, and when concentrated it kills by its local action both muscular and nervous tissue. As was first discovered by H. Kohler, when injected into the leg of the frog in minute quantity it produces not only motor weakness but a rapid loss of sensibility, so that reflex movements can no longer be caused by irritating the foot. The paralysis seems to affect especially the
peripheral nerve endings, since irritation of the nerve trunk, although incapable of causing contraction of the muscles supplied by it, elicits pain, cries and other evidences of sensibility. Muscles with which saponin comes in contact become unexcitable and pass into a condition resembling post mortem rigidity. According to Kohler, this occurs without change in the microscopic structure, but Przybyszewski found that in the neighborhood of the injection where the saponin was abundant the muscles underwent structural changes similar to those of myositis. In the frog saponin produces not only local symptoms, but after a time widespread paralysis, with final arrest of the cardiac movements. Given internally to mammals it causes violent gastro-intestinal irritation, progressive loss of power, disturbance of respiration and circulation, and usually clonic and tonic convulsions, which are probably secondary to the perturbations of the cardiac and respiratory functions.

Injected into the circulation in rabbits and dogs, according to the researches of Przybyszewski, it causes fall of the arterial pressure, with great disturbance of the respiration and finally cardiac arrest. According to Kohler, the action of the drug upon the heart is antagonistic to that of digitalin, so that the application of sufficient quantities of saponin to the frog's heart which has been arrested by the local application of digitalin will bring about a return of pulsations, while, on the other hand, digitalin is capable of putting aside cardiac arrest from saponin. As has been shown by Ransom (D. M. W., xxvii), saponin has a powerfully destructive action upon the red blood corpuscles, due to an extraordinary tendency which it has to unite with their cholesterin. The action of saponin upon the respiratory centres is very great, the injection of large doses being followed by immediate arrest of respiration, the heart continuing to beat for some time. As it exists in agrostemma seeds, saponin has several times caused death in the human species. The symptoms have been headache, vertigo, vomiting, hot skin, rapid feeble pulse, progressive muscular weakness, and finally coma. Following out the experiments of Kobert, Ulenburg and Keppler tried saponin as a local anesthetic, but found that it was not practically convenient for use; nor were the essays of Kobert with the glucoside as an antipyretic more encouraging.

According to Kobert (Gaz. Méd. de Paris, xiv, 2, 1883), saponin of commerce is composed chiefly of two substances, quillaic acid and sapotoxin. For method of preparation, see T. G., vol. ii, 540. The quillaic
Acid is said to be extraordinarily poisonous, three-one-thousandths of a grain for each pound of body weight injected into the veins of a cat being sufficient to cause death, although thirty grains administered by the mouth are safely borne. Lohmann (P. J., 73, 477) affirms that chemically pure saponin is not injurious when taken by the stomach.

Both the active principles, quillaiac acid and sapotoxin, of quillaja bark are violent local irritants. In a case of poisoning by quillaiac acid (T. G., xi) the symptoms were violent vomiting, with epigastric pain, increased diuresis and cystic irritation, accompanied by cold sweats, feeble pulse, threatened syncope, and other evidences of collapse.

Sapotoxin, when in sufficient concentration and amount, is a fatal poison to all forms of protoplasm. Given to the lower animals in very large toxic dose it produces violent convulsions with death from failure of the respiration. When in smaller quantities it causes violent dysenteric diarrhea, with ecchymotic hyperaemia, oedema, and necrotic destruction of the intestinal mucous membrane. The smallest lethal doses are said to produce great weakness, death occurring after some days through collapse and general paralysis without intestinal symptoms. In such cases, when the drug is administered hypodermically, a severe hemorrhagic inflammation occurs at the place of injection. Fatty preparations of sapotoxin applied to the sound skin produce redness and burning with, after repeated applications, painful pustulation. Both sapotoxin and quillaiac acid have the power of breaking down the red blood corpuscles, but it is not apparent that such destruction plays an important role in poisoning by these substances except at the point of injection after hypodermic use.

On account of the active principles of soap bark being the same as those of senega, and to some extent of sarsaparilla, Kobert has proposed the use of quillaja as a cheap substitute for these much used drugs. As a stimulating expectorant he uses a decoction (five parts to two hundred) in doses of a tablespoonful for the adult. As a substitute for syrup of senega Power suggests the syrup of quillaja, prepared by adding four parts of the fluidextract (made by the process for fluidextract of arnica root) to sufficient syrup to make twenty-five parts. (P. J., Oct., 1886.)

Quillaja is much used in the arts for washing silk, cloth, and other fabrics, for which soap would not be suitable. It is an emulsifying agent, but unless ordered by the physician should never be used by the
pharmacist in the preparation of emulsions, on account of its active medicinal properties.

It has also been largely used in the production of foam on non-alcoholic carbonated beverages. This use has been criticized as harmful and it is now prohibited by law in many jurisdictions.

**Off. Prep.**—Liquor Picis Carbonis, Br.; Tinctura Quillajae, N. F. (Br.).

**Quina Morada.**—This drug, growing in Bolivia and the Argentine Republic, and there credited with the therapeutic values of cinchona is produced by *Pogonopus Tubulosus* (Rich.) K. Sch. (Fam. Rubiaceae). It has been studied by Arata and Canzoneri, who find in it a blue fluorescent substance, moradin, and an alkaloid, moradine. (P. J., April, 1890.)

**Quinoa.**—The *Chenopodium Quinoa* Willd. (Fam. Chenopodiaceae), is largely cultivated in Southern Peru and Southern Chili, often above the height at which barley and rye will ripen, for the sake of its seeds. These are about the size of white mustard seeds, but flatter, and afford a flour resembling somewhat oatmeal. The starch grains are very small, and constitute about 40 per cent. of the grain, which also contains 5 per cent. of sugar, 7% of casein, and 11 of albumen and other protein compounds. One variety, the red quinoa, contains a bitter principle in the seed husks, and is used to some extent as an emetic and antiperiodic. (A. J. P., 1872, 559.)
Randia. Randia dumetorum Lam. (Fam. Rubiaceae)—The fruit of this East India shrub is used by the natives as a fish poison, and is said to act in man as an irritating emetic. According to the Pharmacographia Indica, each fruit contains about four grains (0.26 Gm.) of saponin, besides valeric acid. The tincture has been used by James Sawyer (L. L., 1891) as an antispasmodic.

Ranunculus. Crowfoot. Renoncule. Fr. Hahnenfuss, G;—Most of the plants belonging to the genus Ranunculus have similar acrid properties, and, from their close resemblance, are confounded under the common name of buttercup. R. bulbosus L. was formerly in the Secondary List of the U. S. Pharmacopoeia; but R. sceleratus L. had attracted more attention in Europe, and R. acris L. and R. flammula L. were recognized by the Dublin College. In all these species the plant itself is a violent irritant, producing when chewed excessive inflammation in the mouth and throat, and, when swallowed, toxic gastritis which may be fatal. The acrid principle appears to be volatile; according to Bigelow, it is yielded to water in distillation. Clarus discovered, in R. sceleratus L., besides the acrid volatile oil, a nearly inert resin, and a narcotic principle called anemonin or anemone camphor, C_{15}H_{12}O_{6}. The volatile oil is soluble in ether, and is decomposed, on standing, into a white amorphous substance having acid properties (anemonic acid), C_{15}H_{14}O_{7}, and into anemonin. Brit. and For. Med.-Chir. Rev; 1859, 181.) Rochebrune states that he has separated from R. aquatilis L., R. flammula L.; R. sceleratus L. and R. bulbosus L., crystalline alkaloids to which he has given the name of ranunculinne, although their identity is doubtful. These alkaloids are violent irritants and active cardiac poisons. (Toxicolog. Africaine, i.) Before the introduction of cantharides the green buttercup plants were much employed as vesicants.

Reseda. Reseda Luteola L. Weld. Dyer's Weed. Herbe Jaune. Gaude, Fr. Wau, Gelbkraut, Harnkraut, Gr. (Fam. Resedaceae)—An annual European plant, naturalized on roadsides and ballast from Massachusetts to Pennsylvania. The plant grows to a height of 6 dm., possesses alternate lanceolate leaves and small greenish-yellow flowers. It is inodorous, and has a bitter taste, which is very persistent. Volhard showed that allyl thiocyanate, C_{3}H_{5}SCN (volatile oil of mustard), was present in the root, and Chevreui obtained from it by sublimation a peculiar yellow
coloring matter, which he called luteolin. Hiasiwetz and Pfaundler (1805) assign to it the formula \( \text{C}_{15}\text{H}_{10}\text{O}_6\text{H}_2\text{O} \) and find it to be tetrahydroxyflavone. This forms yellow crystals of silky luster, insoluble in water, soluble in alcohol. It dissolves in alkalis with deep yellow color. It is used especially in silk dyeing. A. G. Perkin (J. Chem. S., 1896) investigated the salts of luteolin, and called attention to the similarity of its properties to those of fisetin. In medicine it has been employed as a diaphoretic and diuretic, but it is now used only for dyeing purposes.

**RESINA. U. S., Br.**

**ROSIN Resin. [Resin,Colophony]**

"The residue left after distilling the volatile oil from the concrete oleoresin obtained from Pinus palustris Miller and from other species of *Pinus* (Fam. Pinaceae)." U. S. "Resin is the residue left after the distillation of the oil of turpentine from the crude oleo-resin (crude turpentine) of various species of Pinus." Br.

After the distillation of the volatile oil from the turpentine (see *Terebinthina*), a resinous matter remains, which on the continent of Europe is called colophony, but with us is commonly and now officially known by the name of rosin. It is the Resina of the U. S. and British Pharmacopoeias. It is sometimes called resina flava, or yellow rosin. When this, in a state of fusion, is strongly agitated with water it acquires a distinct appearance, and is denominated resina alba, or white rosin. The ports from which rosin is shipped are Wilmington, N. C., Charleston, S. C.; and Savannah, Ga. The exports of rosin in 1904 amounted to 2,585,108 bbls., valued at $6,621,870; and in 1905 to 2,310,275 bbls., valued at $7,069,084.

Common or yellow rosin, in its purest state, is beautifully clear and pellucid, but much less so as usually found in commerce. Its color is yellowish-brown with a tinge of olive, and more or less dark, according to its purity and the degree of heat to which it has been exposed in its preparation. Sometimes it is almost black. It is rather heavier than water. It is completely liquid at 152.5° C. (306° F.), begins to emit bubbles of gas at 157.5° C. (316° F.), and is decomposed at a red heat.
The official description is as follows: “Rosin usually occurs in sharp, angular, translucent, amber-colored fragments, frequently covered with a yellow dust, brittle at the ordinary temperature; fracture shiny and shallow-conchoidal; odor and taste slightly terebinthinate. It is freely soluble in alcohol, ether, benzene, glacial acetic acid, or fixed or volatile oils; it is also dissolved by dilute solutions of the fixed alkali hydroxides. Its alcoholic solution is acid to litmus. Specific gravity: 1.07 to 1.09 at 25° C. (77° F.). It is easily fusible and burns with a dense yellowish smoke. Incinerate about 2 Gm. of Rosin; not more than 0.05 per cent. of ash remains. The acid number of Rosin is not less than 150.” U. S.

"Translucent, of a light amber color, compact, brittle, pulverisable; fracture shining; odor and taste faintly terebinthinate. Soluble in alcohol (90 per cent.), in ether, benzene, and carbon disulphide. Readily fusible; burns with a dense yellow flame and much smoke, leaving no appreciable ash." Br.

The composition of rosin is expressed by the formula $C_{44}H_{62}O_{4}$, which is the formula ascribed to abietic anhydride. Jean, however (Chem. News, xxvi, 207), has separated two other resinoid substances in addition to abietic acid. Lewkowitseh (Chem. Analysis of Oils, etc., 2d ed., 236) states that rosin also contains varying quantities of unsaponifiable matter—viz., hydrocarbons due to the partial breaking up of the acid on distilling the pine rosin. This may vary from 5 to 9 per cent. in the American rosin. For a paper on abietic acid by Mead and Kremers, see Proc. A. Ph. A., 1893, 198. By shaking coarsely powdered rosin with dilute alcohol and warming, it is converted into abietic acid, $C_{44}H_{64}O_{5}$, obviously an hydroxide of the first. Rosin may be considered, therefore, as abietic acid anhydride, $C_{44}H_{62}O_{4}$. Rosin, when it is boiled with alkaline solutions, forms greasy salts of abietic acid, the so-called rosin soaps which are used in admixture with other soaps. As the acid is dibasic, these salts contain two atoms of alkali metal in combination. Rosin, distilled by itself, yields the so-called “rosin-oil,” of which two fractions are taken separately—the first that distilling under 360° C. (680° F.), and the second that over 360° C. (680° F.)—and some 31 per cent. of fixed gases. The lighter fraction is known commercially as rosin essence, and is, according to Renard (J. Chem. S., Aug., 1884, p. 843), composed of hydrocarbons, representing almost all series, from the paraffin series to the terpenes, including pentane and hexane, amylene and hexylene, toluene, xylene, and cumene, the tetra- and hexa-
hydrides of all three of these, terebenthene and cymene. Several aldehydes and acids of the fatty series, such as isobutyric and valeric, were also recognized. The heavier fraction, or rosin oil in the stricter sense of the word, is composed of polymers of the hydrocarbons CnH_{2n-2}, which readily resinify by the absorption of oxygen. This accounts for the use of rosin oil as an adulterant of linseed oil in the manufacture of printers' ink. When distilled with superheated steam, rosin yields benzene and toluene. Sylvic acid, formerly considered to be a constituent of rosin, is now regarded as a decomposition product of abietic acid. Similarly pinic and pimaric acids, announced as found in rosin, are impure products, although the latter acid, or one of the same name, is found in galipot resin. Propionic acid has, according to Renard, been obtained in abundance from the tar produced by the destructive distillation of rosin. (A. Pharm., 1886, p. 939.)

A. Tschirch and B. Studer determined the nature of the constituents of American rosin. According to Mohr, the principal plant yielding the turpentine from which the American rosin is obtained is Pinus palustris Mill.; to some extent also, P. heterophylla Ell.; rarely P. echinata, P. Taeda and P. scropida. The sample under examination (presumably from P. palustris) was completely soluble in the ordinary solvents for resin, including petroleum benzin, in which some other varieties of rosin are only partly soluble. Its alcoholic solution is strongly acid in reaction. Its sp. gr. at 15° C. (59° F.) was 1.090. Its composition was proved to be as follows:

1. Acids soluble in ammonium carbonate: α-abietinic acid, C_{19}H_{28}O_{2}, forming an insoluble lead salt, 30 per cent. β-abietinic acid, C_{19}H_{28}O_{2}, not forming a lead salt, 22 per cent. 2. Acid soluble in sodium carbonate: γ-abietinic acid, C_{19}H_{28}O_{2}, insoluble in ammonium carbonate, 31.06 per cent. 3. Volatile oil, 0.4 to 0.7 per cent. 4. Resen, 5 to 6 per cent.

The impurities amounted only to 0.1 per cent., the loss in operation, however, to 10 per cent. Fahrion having proposed a method for the differentiation of different rosins, based upon their relative solubility in petroleum benzin, the authors determined the amount of solvent necessary to dissolve 1 Gm. of rosin, freshly powdered, and old powder; also abietinic acids and the resen in petroleum benzin, with the following results:
Rosin, old powder, 1 Gm. required... 400 mils
Rosin, fresh, 1 Gm. required.......... 60 mils
α-Abietinic acid, 1 Gm. required...... 500 mils
β-Abietinic acid, 1 Gm. required...... 100 mils
γ-Abietinic acid, 1 Gm. required...... 100 mils
Resin ..................... 50 mils

These results show that all the resin-acids, as well as the rosin, are more or less soluble in petroleum benzin, and that fresh rosin is more readily soluble than the isolated acids, a peculiarity which has also been noticed in the case of other bodies. On the other hand, old rosin is much less soluble in petroleum benzin than is fresh rosin. (A. Pharm; Oct., 1903, 495-522.)

White rosin differs from the preceding only in being opaque and of a whitish color. These properties it owes to the water with which it is incorporated, and which gradually escapes upon exposure, leaving it more or less transparent. A new and very interesting class of derivatives from colophony or rosin has been prepared by Eugen Schaal, of Feuerbach, Germany, and introduced into commerce under the name of ester gums. These are the glyceryl, methyl, and ethyl esters of abietic acid, made by heating the resin acid and the alcohol under pressure until saponification takes place. The product is then distilled off under reduced pressure. These "ester gums" are being used to advantage as substitutes for copal, damar, and kauri gums in varnish making.

Uses.—Rosin is important as an ingredient of ointments and plasters, but is rarely used internally. It has been given in chronic enteritis, five grains of the powder. According to Olmstead, it has the property of preventing the oxidation of fatty substances, and thus contributes to the preservation of ointments. (A. J. P., xxii, 325.)

"J alap Resin is a mixture of resins obtained from J alap” Br.

"J alap, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each a sufficient quantity. Moisten the powder with five hundred mils [or 16 fluid-ounces, 435 minims] of alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced in weight to two hundred and fifty grammes [or 8 ounces av., 358 grains], and add the latter slowly, with constant stirring, to three thousand mils [or 101 fluidounces, 212 minims] of water. When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of one thousand mils [or 33 fluidounes, 6½ fluidrachms] each of hot water. After having drained off all of the liquid, transfer the resin to a porcelain dish and heat it to dryness on a water-bath.” U. S.

"Exhaust coarsely powdered J alap with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash with Distilled Water, and dry at a gentle heat." Br.

Extract of J alap was formerly official. It has been dropped from both the U. S. and British Pharmacopoeias. Resin of J alap has taken its place in both authorities.

Properties.—Resin of jalap is officially described in the U. S. Pharmacopoeia as in "yellow to brown colored masses or fragments, breaking with a resinous, glassy fracture and translucent at the edges,
or as a yellowish-gray to yellowish-brown powder, having a slight, peculiar odor, and a somewhat acrid taste. It is permanent in the air. Resin of J alap is soluble in alcohol in all proportions; insoluble in carbon disulphide, benzene, or fixed or volatile oils. Its alcoholic solution is faintly acid to litmus. Add 1 Gm. of the powdered Resin to 10 mils of chloroform in a stoppered flask and shake the mixture occasionally during one hour. Then filter, evaporate the filtrate in a tared dish and dry the residue to constant weight at 100°C (212°F); it weighs not more than 0.3 Gm. Add 1 Gm. of the powdered Resin to 10 mils of ether in a stoppered flask and shake the mixture occasionally during one hour. Then filter, evaporate the filtrate in a tared dish and dry the residue to constant weight at 100°C (212°F); it weighs not more than 0.12 Gm. (rosin, orizaba, or other resins). It is slowly but completely soluble in 5 times its weight of ammonia water, and the solution does not become gelatinous on standing. When this solution is acidified with hydrochloric acid, only a slight turbidity appears (rosin, guaiac, or other resins). When Resin of J alap is heated at 100°C (212°F.), no material loss in weight is observed (water). When Resin of J alap is triturated with distilled water, the latter does not become colored, none of the Resin dissolves (soluble impurities), and the water does not have a bitter taste (aloin). Shake 0.02 Gm. of Resin of J alap with 5 mils of ether, filter and evaporate the ethereal filtrate on a piece of filter paper; no greenish-blue color is produced by the application of a drop of ferric chloride T.S. to the filter paper (guaiac). One Gm. of Resin of J alap when dissolved in 50 mils of alcohol, containing 1 mil of phenolphthalein T.S., requires not more than 0.5 mil of half-normal alcoholic potassium, hydroxide V.S. to produce a red color (acid resins). Dissolve 0.02 Gm. of Resin of J alap in 2 mils of glacial acetic acid and add a few drops of sulphuric acid; the mixture does not acquire a pink color (rosin).” U. S.

“In dark-brown opaque fragments, translucent at the edges; brittle, breaking with a resinous fracture; readily reduced to a pale-brown powder. Characteristic odor; taste acrid. Readily soluble in alcohol (90 per cent.). When 1 gramme of the powdered Resin is triturated with 20 millilitres of water and filtered, the filtrate is almost colorless. "solution of 0.1 gramme in 10 millilitres of solution of sodium hydroxide, boiled for a few moments and cooled, when acidified with hydrochloric acid may become opalescent but not immediately turbid (absence of certain other resins). Not more than 15 per cent. of the powdered Resin is soluble in ether (absence of scammony resin).” Br.
The U. S. resin, although pure enough for practical purposes, is still colored. To obtain it colorless, the powdered jalap should be mixed, before percolation, with an equal quantity of finely powdered animal charcoal, and, previously to the introduction of this mixture into the percolator, half the quantity of animal charcoal, similarly powdered, should be packed in the bottom of the percolator. The coloring matter is thus left behind, and the resulting tincture, treated as directed in the process, yields the resin as white as starch. Resin of jalap consists of two portions, one of which is hard and insoluble in ether, the other is soft and soluble in that menstruum, the former constituting about 90 per cent. It is insoluble in oil of turpentine. (Squire.) For its chemical properties, see Jalapa. It was at one time supposed that the purgative properties resided chiefly, if not exclusively, in the hard resin, but experiments by John C. Long appear to prove that the soft resin is equally energetic.

Guaiac, rosin, and other resinous substances are said to be sometimes fraudulently added to the resin of jalap. Guaiac may be detected by the green color it produces when a few drops of solution of sodium or calcium chloride are added to an alcoholic solution of the suspected resin. (J. P. C., 3e ser., x, 357.) When pure jalap resin is dissolved in an alkaline solution, it is not precipitated by the addition of sulphuric or hydrochloric acid, having been converted, through the agency of the alkali, into an acid soluble in water. All the adulterating resins yield precipitates under the same circumstances. The resins of scammony and of fusiform jalap act in this respect like the true jalap resin, but are distinguishable by being wholly soluble in ether, while jalap resin is not. (N. R. Pharm., No. 1, 1854.)

Power and Rogerson (P. J., 1909, lxxxiii, p. 7) find that the products heretofore obtained from jalap as the active principle possesses the attributes of a homogeneous substance. They found the resin of jalap to be a body of very complex composition, but did not determine any single principle to which its purgative action might be attributed. (See Jalap for the chemistry of the resins.)

It is now generally believed that the resin of jalap is the sole purgative principle of jalap, the gummy extractive being either simply diuretic or wholly inert. To obviate the occasional harshness of the resin, it has been advised to triturate it with milk sugar, potassium sulphate, almond
emulsion, or other substance calculated to separate its particles. It may be conveniently made into pills with mucilage or alcohol. (Hasselby, P. J., 2d ser., vii, 231.)

Dose, two to five grains (0.13-0.32 Gm.).

**Off. Prep.**—Pilulas Catharticae Compositae, U. S.; Pilulae Catharticae Vegetabiles, N. F.

**RESINA PODOPHYLLI. U. S. (Br.)**

**RESIN OF PODOPHYLLUM** Res. Podoph. [Podophyllin]

**Podophylli Resina**, Br.; Podophyllum Resin; Resin of May-Apple; Resine de Podophyllum Peltatum, Fr. Cod.; Podophyllinum, P. G.; Podophyllin, Podophyllumharz, G.; Podofillina, It.; Podofilino, Sp.

“Podophyllum, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Hydrochloric Acid, ten mils [or 162 minims]; Alcohol, Water, each, a sufficient quantity. Moisten the powder with five hundred mils [or 16 fluidounces, 435 minims] of alcohol, and pack it in a cylindrical percolator; then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced to the consistence of a thin syrup, and pour this slowly, with constant stirring, into one thousand mils [or 33 fluidounces, 6½ fluidrachms] of water, mixed with the hydrochloric acid and cooled to a temperature below 10° C. (50° F.). When the precipitate has subsided, decant the supernatant liquid, and wash the precipitate twice, by decantation, with fresh portions of one thousand mils [or 33 fluidounces, 6½ fluidrachms] of cold water. Spread it in a thin layer upon a strainer and dry the Resin by exposure to the air, in a cool place, protected from the light. Should it coalesce during the drying, or aggregate into lumps having a glossy surface, break it into pieces, and powder it in a mortar. Preserve it in well-closed containers, protected from light.” U. S.

"Podophyllum Rhizome, in No. 40 powder, 1000 grammes; Alcohol (90
per cent.), Distilled Water, Hydrochloric Acid, of each a sufficient quantity. Exhaust the Podophyllum with the Alcohol by percolation; recover the greater part of the alcohol by distillation; pour the resulting liquid into eight times its volume of Distilled Water acidified with one twenty-fourth of its volume of Hydrochloric Acid, constantly stirring; after twenty-four hours collect the deposited resin, wash with Distilled Water, and dry at a temperature not exceeding 40° C. (104°F.)." Br.

The British Pharmacopoeia (1885) abandoned the use of hydrochloric acid, as it is not necessary if the tincture is evaporated to the consistence of thick honey. Hydrochloric acid was directed in the 1898 revision as it seems to aid the precipitation when the tincture is not so concentrated. The color and yield of resin of Podophyllum may be made to vary by adding alum, acids, or other substances to the water. It darkens if dried with the aid of heat, and its color is indeed no indication whatever of its quality. The average yield of resin is about 5 per cent.

Resin of Podophyllum has usually a light-brown color, an acrid bitter taste, and a slight odor of the rhizome. It consists of two resins, one soluble both in ether and alcohol, the other in alcohol only. The resin extracted by ether constitutes, according to John W. Cadbury, 75 per cent. of the whole (A. J. P., July, 1858, p. 301), according to Harvey Alien, 80 per cent. (Ibid., May, 1859, p. 206.)

For further description of the composition of these resins see Podophyllum. Gordon and Merrell (Proc. A. Ph. A., 1902, p. 343) have proposed a method of valuing resin of podophyllum, based upon the content of picro-podophyllin and submit a method of assay.

Properties.—It is officially described as "an amorphous powder varying in color from light brown to greenish-yellow, turning darker when subjected to a temperature exceeding 25° C. (77° F.), or when exposed to light. It has a slight, peculiar odor and a faintly bitter taste. It is very irritating to the eyes, and to mucous membrane. It is soluble in alcohol with only a slight opalescence. The alcoholic solution is faintly acid to litmus. Not less than 75 per cent. of Resin of Podophyllum is soluble in ether and not less than 65 per cent. is soluble in chloroform. A hot aqueous solution of Resin of Podophyllum deposits most of its contents on cooling, and if the cooled liquid is filtered, the filtrate has a bitter taste, and turns brown upon the addition of a few drops of ferric chloride T.S. It is soluble in potassium or sodium hydroxide T.S., forming
a deep yellow liquid, which gradually becomes darker on standing, and from which the Resin is reprecipitated by acids. Add 0.4 G-m. of Resin of Podophyllum to 3 mils of 60 per cent. alcohol, introduce 0.5 mil of potassium hydroxide T.S., and gently shake the mixture; it does not gelatinize (difference from Resin obtained from Podophyllum Emodi). Resin of Podophyllum yields not more than 1.5 per cent. of ash." U. S.

"An amorphous powder, varying in color from pale yellow to deep orange-brown. Taste bitter. Entirely or almost entirely soluble in alcohol (90 per cent.) and in solution of ammonia; precipitated from the former solution by water, from the latter by acids. Partly soluble in ether. Ash not more than 1 per cent." Br.

The official resin is soluble in alkaline solutions, from which it is precipitated by acids, in this respect differing strikingly from the resins of jalap and scammony. It is insoluble in oil of turpentine. For discussion of the solubilities of the fresh resin, see G.- M. Beringer (A. J. P., 1894, 11). The name Podophyllin, given to it by the eclectic practitioners, who have long' been in the habit of using this resin, is inappropriate, and should be abandoned.

Lohmann (Proc. N. J. Pharm. Assoc., 1896, 51) states that the fresh drug does not yield as large a percentage of resin as the same drug would if tested after being stored for several years; his experiments led him to the conclusion that in the order of value of resin of podophyllum obtained by various methods, that made by precipitation with water alone came first, that made by the U. S. P. process second, and that made by precipitation with solution of alum last. Dohme and Kelly (D. C., 1903, 251), replying to statements in a paper by Lohmann (Proc. A. Ph. A., 1903, 317) regarding the yield of resin from Podophyllum, state that: 1, the yield from the method of pouring an alcoholic extract into water was 5 per cent.; 2, from pouring an alcoholic extract into acidulated water 5.5 per cent., and 3, from pouring an alcoholic extract into acidulated water containing 5 per cent. of alum, 4.9 per cent. See also Podophyllum. The color by process 1, is grayish-white; 2, light brown; 3, greenish-yellow. The value of resin of podophyllum is accurately estimated by the percentage of podophyllotoxin that it yields. Nearly all of the resin of podophyllum in commerce is made by the alum process, has a deep yellow color and is not wholly soluble in alcohol.

There has been much difference of opinion as to the relative activity of
the two resins composing it, some maintaining that both are active, others that the activity resides mainly, if not exclusively, in the resin soluble in ether. It is difficult to resist the evidence of the experiments of Cadbury, who states in the paper above referred to that, while half a grain of the ethereal resin acted energetically, and a cathartic effect was produced by even one-fourth of a grain, the portion insoluble in that menstruum was given in the dose of one grain without any effect whatever. Moreover, this evidence was subsequently confirmed by the experiments of F. B. Power. (A. J. P., xlvi, 227.) It is asserted by Power, and confirmed by Maisch (Ibid; 226), that the purgative principle of Podophyllum is soluble in hot water. The researches of Power (A. J. P., I, p. 369), Maisch (P. J., 1880, p. 621), Quereschi (Ber. d. Chem. Ges., xii, p. 683), and Podwyssotzki have established the fact that Podophyllum does not contain berberine or any alkaloid, and that its activity is due to principles in the resins. (See Podophyllum.)

**Uses.**—Resin of Podophyllum is a mixture of the active and inert principles of the rhizome. Resin of Podophyllum is a powerful cathartic, occasionally producing some griping and nausea, but capable of being favorably modified by combination, and of being very usefully employed in connection with other cathartics, to give them increased energy. It was at one time supposed to be especially cholagogue, but this belief has been of late discredited. A small proportion of extract of belladonna or hyoscymus mitigates its irritant action. Care must be taken in handling it in quantity, as it is a powerful irritant, frequently producing conjunctivitis.

Dose, one-eighth to one-fourth of a grain (0.008-0.016 Gm.).

**RESINA SCAMMONIÆ. U. S. (Br.)**

**RESIN OF SCAMMONY Res. Scamm.**

"Scammony Resin is a mixture of resins obtained from Scammony Root or from Orizaba J alap Root." Br.
Scammoniae Resina, Br., Scammony Resin; Resin de Scammonee, Fr. Cod.; Scammoniaharz, G.; Kesina di scammonia, It.

"Scammony Root in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Moisten the scammony root with sufficient alcohol, pack it in a cylindrical percolator, then add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the percolate ceases to produce more than a slight turbidity when dropped into water. Distil off the alcohol until the percolate is reduced to the consistence of thin syrup, and pour this slowly, with constant stirring, into one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms] of hot water. When the precipitate has subsided, decant the supernatant liquid, wash the precipitated Resin twice by recantation with fresh portions of one thousand mils [or 33 fluid-ounces, 6 1/2 fluidrachms] each of hot water and dry the Resin on a water bath." U. S.

"Exhaust the coarsely powdered Root with Alcohol (90 per cent.). Recover most of the alcohol by distillation; pour the concentrated solution thus obtained into eight times its volume of Distilled Water; allow the resin that separates to subside, wash it with Distilled Water, and dry at a gentle heat." Br.

The U. S. IX and Br. Pharmacopoeia 1914 are in accord on the advisability of preparing Resin of Scammony from the dried root. This result has been brought about by the practical inability to secure pure resin of scammony from the countries in which the plant grows. Adulteration and sophistication for centuries have at last wrought havoc and the pharmacopoeias have been compelled to make scammony resin from scammony root. For an account of the collection of scammony and the sophistications and adulterations, see U. S. D., 19th edition, page 1099.

Resin prepared from the root and scammony obtained by evaporating the milky juice of the plant are practically identical. The elaborate researches of H. Spirgatis (A. J. P., xlvi, 421) appear to have established the identity of the two products. A. Hess, however (A. J. P., 1875, p. 210), states that the resin obtained from the root contains tannic acid.
The advantage of the preparation is that the resin is obtained free from the inert matters with which it is often associated in the scammony of commerce. When pure virgin scammony can be procured, any preparation is unnecessary. Obtained according to the U. S. process, the resin is of a dirty greenish-brown color, with a feeble odor and taste of scammony, and is very soluble in ether, alcohol, and boiling proof spirit. When purified with animal charcoal it has a pale brownish-yellow color, and is without odor or taste, and retains its purgative property.

"Resin of Scammony consists of brownish, translucent masses or fragments, breaking with a glossy, resinous fracture; odor characteristic and agreeable. It is soluble in alcohol in all proportions, and not less than 95 per cent. is soluble in ether (distinction from resin of jalap and resin of false scammony). When triturated with water, it does not form an emulsion. Ammonia water and solutions of the alkali hydroxides dissolve it with the aid of gentle heat, and from these solutions the Resin is not re-precipitated by dilute acids. Its solution in alcohol does not give a blue color with ferric chloride T.S. or with solution of hydrogen dioxide (guaiac). Sulphuric acid does not turn red when stirred in a porcelain dish with an equal weight of Resin of Scammony (rosin). Resin of Scammony yields not more than 1 per cent. of ash." U. S.

"Brownish, translucent, brittle fragments, breaking with a resinous fracture; readily reduced to a pale-brown powder. Characteristic, agreeable odor; taste acrid. Readily soluble in alcohol (90 per cent.). When 1 gramme of the powdered Resin is triturated with 20 millilitres of water and filtered, the filtrate is almost colorless. A solution of 0.1 gramme in 10 millilitres of solution of sodium hydroxide, boiled for a few moments and cooled, when acidified with hydrochloric acid, may become opalescent but not immediately turbid (absence of certain other resins). Not less than 75 per cent. soluble in ether." Br.

The resin of scammony is liable to adulteration. Jalap resin may be detected by its partial insolubility in rectified ether, which dissolves that of scammony in all proportions. Sulphuric acid is the best test for common rosin or colophony, producing instantaneously with this substance an intense red color, while with the resin of scammony it causes no immediate change. For the tests for guaiac, the reader is referred to that article on p. 536. (See also A. J. P., xxiv, 158.) The presence of other resins may be known by the precipitates yielded when
sulphuric acid is added to the alkaline solution, the resin of scammony agreeing with that of jalap in not affording a precipitate under such circumstances. Chas. Bullock has found the resins of scammony, of jalap, and of Podophyllum to be insoluble in benzene, thus enabling any resin soluble in this liquid, which may be employed in the sophistication, to be readily detected. When rubbed with unskimmed milk, the resin of scammony forms a uniform emulsion, which is not distinguishable from rich milk itself. This is a very excellent mode of administration. The resin should always be given either rubbed up with some mild powder or in emulsion.

L. Lutz (Pharm. Ztg., 1912, xxiii, p. 232) states that the behavior of the resin with iodine when examined microscopically affords a method of distinguishing resin from a number of its substitutes and adulterants.

Uses.—Scammony resin is an energetic cathartic, likely to occasion griping, and sometimes operating with harshness. It was known to the ancient Greek physicians, and was much employed by the Arabians, who used it as a purgative and externally in skin diseases. On account of its occasional violence, it is seldom administered, except in combination with other cathartics, the action of which it promotes, while its own harshness is mitigated. It should be given in emulsion with mucilage, sugar, almonds, licorice, or other demulcent, and its disposition to gripe may be counteracted by the addition of an aromatic.

Dose, from four to eight grains (0.26-0.5 Gm.).

RESINÆ

RESINS

The official Resins, with a single exception, constitute a peculiar class of preparations, made by exhausting the substances from which they are obtained by alcohol, and then precipitating the resinous matter from the
tincture by the addition of water, which abstracts the alcohol by its stronger affinity. It is obvious that the resins thus prepared are different substances from the alcoholic extracts, which contain all the ingredients of the medicine which alcohol is able to take from it. This set of substances has been much employed by the practitioners styling themselves "eclectics," but with great lack of discrimination. They have applied names to these resinous precipitates which, in their proper scientific use, are employed to designate neutral proximate principles of plants, generally representing more or less completely the effects of the plants respectively on the system; as we say columbín, quassin, santonín, etc., themselves proper proximate principles, and representing the virtues, in part at least, of calumba, quassia santonica, etc., from which they are obtained, and from which they derive their names. By applying similar names to their precipitated resins, such as podophyllin, iridin, cimicifugin, etc., i.e., to the impure resins obtained by precipitating the tinctures of Podophyllum, iris versicolor, cimici̇fuga, etc., they justify the suspicion either that they ignorantly believe them to be in fact the active principles of these medicines respectively, or that, knowing better themselves, they seek to impose such a conviction upon the ignorant. The fact is that the substances thus obtained, and thus named, are impure resins, which may possibly contain more or less of the active principles mixed with them, but are not entitled to names which imply that they are distinct proximate principles themselves.

Resins are solid, brittle, of a smooth and shining fracture, or in powder and generally of a yellowish-brown color. When perfectly pure, they are probably inodorous and often insipid; but, as usually found, they have a slight odor, and a somewhat acrid or bitterish taste. Their sp. gr. varies from 0.92 to 1.2. They are fusible by a moderate heat, decomposed at a higher temperature, and in the open air take fire, burning with a yellow flame and much smoke. Insoluble in water, they are addition of water. With pure potassium and sodium hydroxides they unite to form soaps, which are soluble in water, and the same result takes place when they are heated with solutions of the alkaline carbonates. Concentrated sulphuric acid dissolves them with mostly soluble in ether and the volatile oils, and in alcohol; and their alcoholic and ethereal solutions afford precipitates upon the mutual decomposition, and nitric acid converts them into artificial tannin. They readily unite by fusion with wax and the fixed oils.

Losch recommends the following process for rendering the resins as
white as possible. Boil together 5 parts of the resin, 1 of carbonate of potassium or of sodium, and 20 of water, until a perfectly homogeneous mass is obtained; allow this to cool, and pass into it sulphurous acid, which saturates the alkali, and precipitates the resin in white flakes. Finally, wash the precipitate well with water, and dry it. (J. P. C., June, 1856, p. 465.)

**Rhamnus Cathartica.** N. F. IV. Buckthorn Berries. Baccce Spinae Cervinae.—"The dried, ripe fruit of Rhamnus cathartica Linne (Fam. Rham-nacece), without the presence of more than 5 per cent. of the unripe fruit or other foreign matter." N. F.

The R. cathartica. Linn, or common buckthorn, grows in Europe along with R. Frangula, and has become naturalized in this country. Its bark is probably often sold for the official Frangula. It is distinguished by its more spreading, thorny habit, and its dioecious flowers, which are thickly clustered in the axils and have their parts in fours. The leaves are more acute, have their margins finely serrate and their lateral veins mostly proceeding from the proximal half of the midrib. The fruit is black.

The berries which are ripened in September, are of the size of a pea, round, somewhat flattened at top, black, smooth, shining, with four seeds in a green, juicy parenchyma. Their odor is unpleasant, their taste bitterish, acrid, and nauseous. Their blackish, expressed juice was formerly recognized in the Br. Ph. under the name of *Rhamni succus.*

It is reddened by the acids, and from deep green is rendered light by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the color called by painters sop-green. The dried fruit of another species, R. infectoria, yields a rich yellow color, and is employed in the arts under the name of French terries.

The National Formulary IV describes buckthorn berries as follows: “Flattened, globoid or ovoid, from 4 to 8 mm. in diameter; externally purplish-black, wrinkled from shrinking of the mesocarp in drying; three-to-four-celled, each cell containing a brown, triangular-convex, seed-like nutlet; in the fully dried, ripe fruit the pedicel is usually lacking. Odor faint, unpleasant; taste at first sweetish, then nauseating and bitter; it colors the saliva purplish-red. When macerated in water the drupe readily assumes its original globular shape, about 1 cm. in diameter. The expressed pulp is colored red by acids and greenish-yellow by alkalies. Shake out an aqueous infusion of Rhamnus Cathartica with ether, separate the ethereal solution and shake it with 5 per cent. ammonia water; the ammonia solution assumes a cherry-red color. The unripe fruit, which is to be rejected, is green to greenish-brown, firm, furrowed, pedicel usually attached; very bitter; it colors the saliva greenish-yellow. Rhamnus Cathartica yields not more than 5 per cent. of ash." N. F.

The blackish, expressed juice of Buckthorn berries was formerly recognized in the Br. Ph. under the name of Rhamni Succus. It has the color, odor, and taste of the
parenchyma, is reddened by the acids, and from deep green is rendered light green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the color called by painters sap-green. The dried fruit of another species, R. infectoria, yields a yellow color, and is employed in the arts under the name of French berries.

Tschirch and Polacco, in 1900, investigated the constituents of buckthorn berries and found certain yellow coloring substances. The researches of N. Waljaschko and N. Krassowski since demonstrated that the fruits of R. cathartica contain the same yellow coloring matters as are contained in the fruits of R. infectoria and R. tinctoria, namely, quercetin and rhamnin, both existing in R. cathartica in the form of glucosides, which are split up by the action of an enzyme contained in the fruits: Rhamnin, for example, from the glucoside xanthorhamnin. The yellow coloring matters of Tschirch and Polacco, therefore, cannot be regarded as pure substances. They also extended the investigations of the former concerning the purgative substances contained in buckthorn fruits, with results confirming the theory advanced by Tschirch. They found the fruits to contain about 2 per cent. of emodin-substances and as cleavage products of the glu-cosides obtained by the action of ferments from the emodin-substances: Emodin, identical with frangula emodin and rhamnosid; the emodin of rhamnoxanthin (C\textsubscript{21}H\textsubscript{20}O\textsubscript{8} + H\textsubscript{2}O), which is isomeric but not identical with frangulin; rhamnonigrin, and a resin like body containing emodin. Other constituents found in buckthorn berries are: fixed oil, succinic acid, glucose, galactose, rhimnose, and a pentose, but of the four sugars only glucose was present in the free state, the others being derived from the glucosides. (Ph. Ztg., 1909, No. 16, 159.) Tschirch and Bromberger (Schw. Woch. f. Ch. v. Ph., 1912, p. 193) report the following constituents found in a 15 Kilo sample upon which they did considerable work: Rhamno-sterin, C\textsubscript{18}H\textsubscript{28}O\textsubscript{2}; rhamno-fluorin, C\textsubscript{14}H\textsubscript{12}O\textsubscript{6}; emodin, C\textsubscript{15}H\textsubscript{10}O\textsubscript{2}; iso-emodin, C\textsubscript{15}H\textsubscript{10}O\textsubscript{5}; chrysophanol (C\textsubscript{14}H\textsubscript{5}O\textsubscript{2})CH\textsubscript{3}(OH)\textsubscript{2}. A fluidextract and a syrup of buckthorn berries are contained in the N. F.

The dose of the dried berries is from ten to twenty grains (0.65-1.2 Gm.). Among other species of Rhamnus which have claimed attention are R. Wightii, W. & A., a common shrub of Madras and Bombay (P. J., Feb., 1888), and R. californica, Eschsho. (R. humboldtiana, Roem. and Schult.), of Mexico, which S. E. Sosa states sometimes produces paralysis in children (El Estudio, 1890). (See also Cascara Sagrada.)

**RHEUM. U. S. (Br.)**

**RHUBARB**

"The rhizomes and roots of Rheum officinale Baillon, Rheum palmatum Linne, and the var. tanguticum Maximowicz (Fam. Polygonaceae), and probably other species of Rheum grown in China and Thibet, deprived of most of the bark tissues and carefully dried. Preserve Rhubarb in tightly-closed containers, adding a few drops of chloroform or carbon..."
tetrachloride, from time to time, to prevent attack by insects." U. S.
"Rhubarb is the rhizome of Rheum officinale, 'Baill., and other species of
Rheum, collected in China and Thibet, deprived of most of the cortex,
and dried." Br,

**Rhei Rhizoma**, Br.; Rhubarb Root; Rhubarbe de Chine, Fr. Cod.;
Rhubarbe, Fr.; Rhabarber, G.; Rabarbaro, It.; Ruibarbo, Sp.; Hainounq,
Chin.; Schara-modo, Thibet.

Notwithstanding the length of time that rhubarb has been in use, it has
not yet been determined from what precise plant the Asiatic drug is
derived, the remoteness of the region where it is collected, and the
jealous care with which the monopoly of the trade is guarded, having
prevented accurate information.

The terms rha and rheon, from the former of which were derived the
names rhabarbarum and rhubarb, and from the latter the botanical
title Rheum, were applied by the ancients to a root which came from
beyond the Bosphorus, and which is supposed, though upon somewhat
uncertain grounds, to have been the product of Rheum rhaponticum L.,
growing on the banks of the Caspian Sea and the Volga. This species
was also at one time believed to be the source of the medicine now in
use; but the true rhubarb has long been known to be wholly distinct
from the Rhapontic, and derived from a different source. It was not until
the year 1732 that any probable information was obtained as to its real
origin. At that time plants were received from Russia by Jussieu in
France, and Rand in England, which were said to be of the species
affording the genuine rhubarb, and were named by Linnaeus, under
this impression, Rheum Rhabarbarum, a title which has since given
way to Rheum undulatum. Subsequently, Kaau-Boerhaave obtained
from a merchant, who dealt in the rhubarb of Tartary, some seeds
which he said were those of the plant producing the root sold by him.
These, having been planted, yielded two species of Rheum. R.
undulatum, and another which Linnaeus named R. palmatum. Seeds
transmitted by Mounsey from St. Petersburg to Hope, and planted in
the botanic garden at Edinburgh, produced the latter species, and the
same was also raised at Upsal from a root received by Linnaeus from De
Gorter, and was described in 1767 by the younger Linnaeus, two years
after the appearance of Hope's paper in the Philosophical Transactions.
Thus far the evidence appears equally in favor of R. palmatum and R.
undulatum. Colonel Przewalski concluded from personal observation
that *R. palmatum* produces rhubarb; but the specimens of the root which he brought to St. Petersburg were stated by Dragondorff to be essentially different from true rhubarb. Claims have also been made from time to time for various other species of *Rheum* as sources of the drug. Pallas, upon exhibiting the leaves of *R. palmatum* to some Bucharian merchants, was told that the leaves of the rhubarb plant were entirely different in shape, and the description he received of them corresponded more closely with those of *R. compactum* than any other known species. Seeds of this plant were, moreover, sent to Miller from St. Petersburg as those of the true Tartarian rhubarb. Wallich, superintendent of the botanical garden at Calcutta, received seeds that were said to be those of the plant which yielded the Chinese rhubarb, growing on the Himalaya Mountains and the highlands of Tartary. These produced a species not previously described, which Wallich named *R. Emodi*, from the native title of the plant. It is the *R. australe* of Don and of Colebrooke, and has been ascertained to afford a root which, though purgative, is very unlike the official rhubarb. In 1867, French missionaries in Southeastern Thibet forwarded to Soubeiran of Paris, live specimens of a plant which they asserted to yield the true rhubarb, and Baillon subsequently described the flowering plant under the name of *R. officinale*. Its root resembles the true rhubarb, but the most careful cultivation has failed to obtain an identical product, and it cannot yet be considered as settled how far the commercial drug is obtained from it, Senier found that, as raised in England, the root of *R. officinale* yielded less than half the percentage of extract obtained from the East Indian drug. In ten grain doses the extract was decidedly cathartic.

Tschirch in discussing the origin of Chinese Rhubarb has come to the conclusion that that obtained from Szetschwan, "southern" rhubarb, is derived from *Rheum officinale*, while that obtained from Kukunoor, "northern" rhubarb, is the product of *Rheum palmatum tanguticum* (A. Pharm., 1907, p. 680; and S. W. P., 1910, xlvi, 292).

Hosseus (P. J., 1911, 87, p. 429) as a result of study of material furnished by Tafel, a Tibetan explorer, concludes that the best medicinal rhubarb is derived from *R. palmatum*. He believes that the belief that some of it comes from *R. officinale* or other species is due to the fact that Tibetans dig up the root of these other species of rhubarb for the purpose of deceiving Europeans.
All the plants of this genus are perennial and herbaceous, with large branching roots, which send forth vigorous stems from four to eight feet or more in height, surrounded at their base with numerous very large petiolate leaves, and terminating in lengthened branching panicles, composed of small and very numerous flowers, resembling those of the Rumex or dock. There is some difficulty in arranging the species, in consequence of the tendency of the cultivated plants to form hybrids, and it is frequently impossible to ascertain to which of the wild type's the several garden varieties are to be referred. Lindley, Flora Medica, states that R. rhaponticum, R. hybridum, and R. compactum, and their hybrids, are the common garden rhubarbs.

R. officinale Baillon is described in the Pharmacographia "as a perennial, noble plant, resembling the common garden rhubarb, but of larger size. It differs from the latter in several particulars: the leaves spring from a distinct crown rising some niches above the surface of the ground; they have a subcylindrical petiole, which, as well as the veins of the under side of the lamina, is covered with a pubescence of short erect hairs. The lamina, the outline of which is orbicular, cordate at base, is shortly 5- to 7-lobed, with the lobes coarsely and irregularly dentate; it attains 4 to 4½ feet in length, and rather more in breadth. The first leaves in spring display before expanding the peculiar metallic red hue of copper."

Besides the species already mentioned, R. leucorrhizum, growing in the Kirgheeze desert in Tartary, R. capsicum, from the Altai Mountains, R. webbianum, R. speciforme, and R. moorcraftianum, natives of the Himalaya Mountains and R. crassinervium and R. hybridum, cultivated in Europe, but of unknown origin, yield roots which have either been employed as purgatives or possess properties more or less analogous to those of official rhubarb, though they have not entered into general commerce. In Java, the root of an indigenous species is used as a purgative. According to the analysis of J. H. Schmidt, it contains more chrysophan and emodin, and less chrysophanic and rheotannic acids, than does the official drug.

According to Aitchison (Nature, July 9, 1885), a rhubarb plant has been found in Northern Afghanistan in which there are usually only three enormous root leaves four feet long and five feet broad, lying flat upon the ground. The fruit is large and of a brilliant scarlet. The root is said to possess purgative properties, but the fruit is preferred, and is given in
the form of a decoction.

Rhubarb is produced abundantly in the elevated lands of Tartary, about the lake Koko Nor, and is said to be cultivated in the neighboring Chinese province of Shensee, and in that of Sechuen. From these sources it is generally supposed that our supplies of Russian and Chinese rhubarb were exclusively derived; but the root is also collected in Bootan and Thibet, on the north of the Himalaya Mountains, and it is probable that the plant pervades the whole of Chinese Tartary. It flourishes best in a light sandy soil. It is stated by Bell, who, on a journey from St. Petersburg to Pekin had an opportunity of observing it in a growing state, that it is not cultivated by the Tartars, but springs up spontaneously, in tufts, wherever the seeds have fallen upon the heaps of loose earth thrown up by the marmots. In other places the thickness of the grass prevents their access to the soil. The root is not considered sufficiently mature for collection until it has attained the age of six years. It is dug up twice a year in Tartary, in the spring and autumn; in China not till the winter. After removal from the ground, it is cleaned, deprived of its cortical portion and the smaller branches, and then divided into pieces of a convenient size. In China these are bored with holes, and strung upon cords to dry—according to Bell, about the tents and on the horns of sheep; according to Sievers, under sheds, by which the rays of the sun are excluded, while the air has free access. The Chinese are said first to place the pieces on a stone slab heated by fire beneath, and afterwards to complete the drying process by exposing them to the sun and air. In Bootan the roots are hung up in a kind of drying room, in which a moderate and regular heat is maintained. Much time and attention are devoted to the preparation of the root, and Sievers states that a year sometimes elapses from the period of its collection before it is ready for exportation. A large proportion of its weight is lost in drying, according to some accounts four-fifths, according to others not less than seven-eighths. It is probably in order to favor the drying that the periderm is removed. Rhubarb which has been dried by artificial heat is known commercially as high dried and often can be recognized by its more or less blackened surface, and its heavy, scarcely fragrant odor. The trade in rhubarb is said to have formerly centered in the Chinese town of Sinin, where a Bucharian company or family was established which possessed a monopoly of this trade in consideration of a tribute paid to the government. At present rhubarb is chiefly purchased for the European trade at the town of Hankow, on the upper Yangtse, the yearly export reaching over 5000 peculs (pecul =...
There were formerly two varieties of Asiatic rhubarb, the Russian and the Chinese, but at present little or no rhubarb finds its way overland to Europe. As long back as 1687, the Russian government subjected the export of rhubarb from China into Russia to official surveillance, and finally monopolized the trade entirely. At Kiakhta a very rigorous inspection of the drug was enforced, the selected pieces being finally sewed into linen sacks pitched and coated with hide. All the pieces which did not pass examination were committed to the flames, and the remainder was sent to St. Petersburg. This variety was sometimes called Turkey rhubarb, from the circumstance that it was formerly derived from the Turkish ports, whither it is said to have been brought from Tartary by caravans through Persia and Anatolia. Inferior parcels of the root, which could not pass the inspection of the Russian authorities, were said to enter Russia by Tashkend, and to be known to the druggists of that country by the name of Tashkend rhubarb. Russian rhubarb no longer occurs in commerce. The description of it is given in the U. S. D., 19th edition, page 1061.

CHINESE RHUBARB (India Rhubarb, Rheum Sinense vel Indicum) is in cylindrical or roundish pieces, sometimes flattened on one or both sides, of a dirty brownish-yellow color externally, appearing as if the cortical portion of the root had been removed by scraping, and the surface rendered smooth and somewhat powdery by attrition. The best pieces have a rather close and compact texture, and, when broken, present a ragged uneven surface, variegated with intermingled shades of dull red, yellowish, and white, which are sometimes diversified or interrupted by darker colors, and especially marked with dark lines so arranged as to form an internal ring of star-like spots. The pieces are generally perforated with small holes, intended for convenience of suspension during the drying process, and portions of the suspending cord are not unfrequently found remaining in the holes. According to Elborne (P. J., xv, 497), Chinese rhubarb is the product of R. palmatum and R. officinale, the first variety has a red-grained fracture with white latticework veins, while the second variety has a longitudinal ramification of white veins with a black-grained fracture. Chinese rhubarb has a peculiar somewhat aromatic odor, and a bitter, astringent taste, is gritty when chewed, imparts a yellow color to the saliva, and affords a yellowish powder with a reddish-brown tinge. With the pieces of good quality others often come mingled, defective from decay or improper preparation. These are usually lighter, and of a dark or russet color. Like all the other varieties of rhubarb, this is liable to be
attacked by insects, and in almost every large parcel pieces may be found which have suffered from this cause. The Shensi variety is preferred, that of Sechuen and Kansuh are less valuable.

Chinese rhubarb is the only kind recognized by the U. S. P., and is officially described as "sub-cylindrical, barrel-shaped, or conical pieces known in commerce as 'rounds,' or in plano-convex pieces known in commerce as 'flats' or in irregularly formed pieces, frequently with perforations. It is hard and moderately heavy; attaining a length of 17 cm. and a diameter of 10 cm., often cut in pieces of variable form and size; outer surfaces yellowish-brown, mottled, with alternating, longitudinal striae of grayish-white parenchyma and reddish or brownish medullary rays; small stellate groups of fibro-vascular tissue and occasionally reddish-brown cork patches, smooth and sometimes covered with a bright, brownish-yellow powder; fracture uneven and granular, presenting a characteristic mottled appearance; odor aromatic, characteristic; taste characteristic, slightly bitter and astringent, gritty when chewed and tingeing the saliva yellow. Under the microscope, sections of Rhubarb show numerous thin-walled parenchymatous cells containing either a large number of starch grains or a single large rosette aggregate of calcium oxalate; scattered among the parenchyma are stellate groups of compound fibro-vascular bundles, the latter composed of narrow medullary rays separating the wedges, having large tracheae in the outer part and separated by a prominent cambium from an internal phloem or sieve; among the grayish-white parenchyma of the inner bark occur narrow, yellowish-brown, irregular medullary rays. Not more than 15 per cent. of the drug should show a hollow or dark central area. The powder is bright orange-yellow to yellowish-brown; becoming red with alkalies; when examined under the microscope it exhibits calcium oxalate in rosette aggregates, mostly from 0.05 to 0.1 mm. in diameter, occasionally attaining a diameter of 0.15 mm.; starch grains numerous, somewhat spherical, single or 2- to 4-compound, each with a single cleft, from 0.002 to 0.02 mm. in diameter; tracheal fragments few, mostly reticulate, occasionally spiral. Boil 0.1 Gm. of powdered Rhubarb with 10 mils of an aqueous solution of potassium hydroxide (1 in 100); allow it to cool, filter, acidulate the filtrate with hydrochloric acid and shake it with 10 mils of ether; on standing the ethereal layer is colored yellow. Shake this ethereal solution with 5 mils of ammonia water; the latter is colored cherry-red (presence of emodin) and the ethereal layer remains yellow (presence of chrysophanic acid). Rhubarb, when exhausted with diluted alcohol,
yields not less than 30 per cent. of dry extract. Rhubarb yields not more than 13 per cent. of ash." U. S.

"In compact, firm, cylindrical, barrel-shaped, conical or plano-convex pieces, often perforated, the perforation sometimes containing a fragment of cord. Surface rounded or slightly angular, but not shrunken, marked with reddish-brown lines embedded in a whitish ground-substance; usually covered with a bright brownish-yellow powder. Fracture granular and uneven, the pinkish-brown fractured surface exhibiting numerous reddish-brown points and lines on a white ground-substance. For a short distance within the cambium the structure is radiate; within this there is a more or less distinct ring of closely approximated vascular bundles with central bast and radiating, reddish-brown medullary rays; in the parenchymatous cells abundant starch grains, an amorphous yellow substance and very large cluster-crystals of calcium oxalate. In powdered Rhubarb large cluster-crystals of calcium oxalate, often more than 100 microns in diameter, simple or compound starch grains, the single grains seldom exceeding 20 microns in diameter, fragments of reticulated vessels and of parenchymatous tissue, and small yellowish masses and globules which assume a reddish-pink color with solution of ammoniac it is free from added starch and from sclerenchymatous cells and fibres. Characteristic, somewhat aromatic odor; taste bitter, slightly astringent. Ash not more than 15 per cent." Br.

EUROPEAN RHUBARB.—In various parts of Europe, particularly in England, France, Belgium, and Germany, the rhubarb plants have been cultivated for many years, and considerable quantities of the root were at one time brought into the market. At present it appears not to be imported into the United States.

English Rhubarb.—This formerly came in two forms. In one the root was cut and perforated in imitation of the Russian. The pieces were of various shapes and sizes, sometimes cylindrical, but more commonly flat, or somewhat lenticular, and of considerable dimensions. In the other, the so-called stick rhubarb, the pieces were somewhat cylindrical, five or six inches long by an inch or less in thickness, and more or less irregular upon the surface, as if they had shrunk unequally in drying. English rhubarb (from Rheum rhaponticum) is lighter than the Asiatic, more spongy, and often somewhat pasty under the pestle. It is redder, and when broken exhibits a more compact and regular marbling, the
pinkish lines being arranged like rays from the centre towards the circumference. The "star-like spots" are either wanting or very few and scattered. The powder also has a brighter yellow tint. The odor is feeble and less aromatic than that of the Asiatic varieties; the taste is astringent and mucilaginous, with little bitterness, and the root, when chewed, scarcely feels gritty between the teeth, and but slightly colors the saliva. Few crystals of calcium oxalate are discoverable by means of the microscope. Much English rhubarb is obtained from R. officinale, and is put on the market in flat, concave, and convex pieces weighing from three to four ounces each. Externally the convex surface has deep longitudinal furrows and a longitudinal ramification of conspicuous veins, giving rise to an appearance of net-vein markings. In the centre of the concave surface is a small hole similar to that formerly seen in Russian rhubarb. On the inner surface the stellate markings resemble very closely those found in the East Indian rhubarb. The fracture of this form is not red, but shows a whitish parenchymatous tissue with blackish veins. When rapidly grown in rich soil, English rhubarb is lighter, more spongy, and less active than when slowly grown without high cultivation. It is probable that the powder is used to adulterate that of true Asiatic rhubarb, but of this we have no positive evidence.

French Rhubarb. Rhapontic Rhubarb. Crimea Rhubarb.—The rhubarb produced in France is, according to Guibourt, chiefly from R. rhaponticum, R. undulatum, and R. compactum, that of R. palmatum, which most closely resembles the Asiatic, having been found to degenerate so much as not to be a profitable object of culture. Most of the French rhubarb is produced in the neighborhood of L'Orient, in the department of Morbihan, and the spot where it grows has, from this circumstance, received the name of Rheumpole. Two kinds were described by Guibourt, both under the name of Rhapontic root—one proceeding from the R. rhaponticum, growing in the gardens in the environs of Paris; the other, from this and the two other species above mentioned, cultivated at Rheumpole.

Rhapontic rhubarb is still found to some extent in European markets. Tschirch has proposed a ready method for detecting the admixture. It depends on the insolubility in ether of the crystalline principle rhaponticin or ponticin. (A. Pharm., 1905, p. 443; and S. W. P., xliii, p. 253.) Hesse has also made an elaborate study on the chemistry of rhapontic root grown in Austria. (J. f. prakt. Chem., 1908, lxvii, p. 320.)
The rhapontic root differs in section from true rhubarb by its distinctly radiated structure, unbroken by the peculiar arrangement (star-like spots) of the vascular tissue which occurs in true rhubarb.

**Choice of Rhubarb.**—In selecting good rhubarb, without reference to the commercial variety, those pieces should be preferred which are moderately heavy and compact, of a bright color, brittle, presenting when broken a fresh appearance, with reddish and yellowish veins intermingled with white, of an odor decidedly aromatic, of a bitter and astringent not mucilaginous taste, feeling gritty and staining the saliva yellow when chewed, and affording a powder either bright yellow, or yellow with but a slight reddish-brown tinge. When very light, rhubarb is usually rotten or worm-eaten; when very heavy and compact, it is of inferior species, culture, or preparation. Rotten, worm-eaten, or otherwise inferior rhubarb is often powdered, and colored yellow with turmeric, and the shavings left when Chinese rhubarb is trimmed for powdering, or to imitate the Russian, are applied to the same purpose. The stellate markings observed in the cut or broken surface of the Chinese rhubarb has been believed by various pharmacologists to be of great practical value in determining the true character of the rhizome and especially in enabling a distinction between the Chinese and European rhubarb to be made. There has been a general concurrence with the statements of Tschirch that the star spots are never present in the root, occurring only in the rhizome. In an elaborate re-examination of this subject by Jakabhasy, however, the star spots were found in the root as well as in the root stock and also in the European as well as in the Asiatic rhubarb. Nevertheless, Jakabhasy states that it is possible to distinguish the two rhubarbs by the fact that in the European Rhubarb the star spots occur in greater number on the longitudinal section while in the Chinese rhubarb they are present on the transverse section, where they form a circle. He believes also that the superabundance of starch and the lack of crystals in the star spots are diagnostic of the European drug. When the rhubarb is powdered these characteristics are not available, under which circumstances the percentage of ash seems to be valuable. The Chinese rhubarb, unless of very inferior quality yields from 8 to 25 per cent.; the European 1.3 to 6 per cent. of ash. According to Jakabhasy, Shensi is the best, Shanghai the poorest, and Canton the intermediate variety of Chinese rhubarb. Of the European the English is the most, the French next, and the Austrian the least active.
Chemical Properties.—Rhubarb yields all its activity to water and alcohol. The infusion is of a dark reddish-yellow color, with the taste and odor of rhubarb, and the residue, after sufficient maceration, is whitish, inodorous, and insipid. By long boiling the virtues of the medicine are impaired. The first examination of rhubarb yielding results of value was that of Schlosberger and Ddpping. Besides extractive, tannic and gallic acids, sugar, starch, pectin, lignin, calcium oxalate and various inorganic salts, they discovered three coloring principles, holding an intermediate place between resin and extractive matter, being freely soluble in alcohol, and slightly so in water. Two of these were uncry stallizable, and denominated brown resin and red resin, or phaeoretin and erythroretin; the other, crystallizable in granular crystals, and identical with chrysophanic acid; previously discovered by Rochleder and Heldt in the yellow lichen, or Parmelia parietina of Sprengel. Chrysophanic acid crystallizes in golden-yellow needles or plates melting at 102° C. (215.6° F.), and is soluble in ether, alcohol, or benzene. Alkalies also dissolve it, forming fine dark red solutions. Its formula is $C_{15}H_{10}O_4$, and it is now recognized as a derivative of anthracene, $C_{14}H_{10}$, and as closely related to alizarine, $C_{14}H_8O_4$. It bears to methyl-anthracene, $C_{14}H_9(CH_3)$, the same relation that alizarine bears to anthracene. Hence, on distilling it with zinc dust, methyl-anthracene is formed from it by reduction.

De La Rue and Muller (J. Chem. S., x, 298) extracted from rhubarb emodin, which crystallizes in orange-colored prisms. Its formula is $C_{15}H_{10}O_5$, and it is a trioxymethylanthraquinone. The relations of both this compound and chrysophanic acid to alizarine and anthracene will be better shown by writing their molecular formulas, as follows:

\[
\begin{align*}
C_{14}H_4(CH_3)(OH)_3O_2 & \quad \text{Emodin.} \\
C_{14}H_5(CH_3)(OH)_2O_2 & \quad \text{Chrysophanic Acid} \\
C_{14}H_6(OH)_2O_2 & \quad \text{Alizarine.} \\
C_{15}H_{10}O_4 & \quad \text{Anthracene.}
\end{align*}
\]

Kubli (Ph. Z. R., 6, p. 603) obtained results both confirmatory and explanatory of those already given. He found a glucoside, chrysophan, $C_{27}H_{30}O_{14}$, which, under the influence of dilute acids or ferments, splits
up into chrysophanic acid and sugar, according to the reaction
\[ C_{27}H_{30}O_{14} + 2H_2O = C_{15}H_{10}O_4 + 2C_6H_{12}O_6 \]
also a characteristic tannic acid, rheo-tannic acid, \( C_{27}H_{30}O_{14} \), which is decomposed by dilute acids into rheumatic acid, \( C_{20}H_{16}O_9 \), and sugar. Chrysophan is a yellowish powder, abundantly present in rhubarb, soluble in water or alcohol, not in ether; rheo-tannic acid is a reddish brown powder, sparingly soluble in cold water. Kubli found further a colorless neutral compound, sparingly soluble in hot water, of the formula \( C_{10}H_{12}O_4 \), which he did not name. He stated that chrysophanic acid is not found in rhubarb, but is produced when the root is digested in water through the breaking up of the glucoside chrysophan, probably under the action of a ferment. This ferment he believes to be soluble in water, but insoluble in alcohol, and that on this account an alcoholic extract of the root can be evaporated without the formation of chrysophanic acid. On the other hand, it is to the presence of this ferment that he attributes the progressive deposition of chrysophanic acid from an extract of rhubarb prepared with diluted alcohol. (Ph. Z. R., xxiv, 193.) O. Hesse (Proc. A. Ph. A., 1896, 549) found in addition to chrysophanic acid, \( C_{15}H_8O_2(OH)_2 \), and emodin, \( C_{15}H_7O_2(OH)_3 \), a third crystalline principle, which he named rhein, and ascribes to it the formula \( C_{15}H_6O_2(OH)_4 \). Hesse calls attention to the relation these formulas bear to one another. Rhein forms microscopic yellowish-brown scales, is insoluble in water, ether, and benzene, but sparingly soluble in alcohol. It dissolves readily in aqueous solutions of the alkalies and alkaline carbonates, forming deep purple-red solutions. Hesse also finds an amorphous resinous substance, upon which, he states, the entire activity of rhubarb depends. Dragendorff states that from 11 to 17 per cent. of arabic acid and pectose are present in rhubarb. Hunkel (Ph. Archiv., Nov., 1900, 201) reviewed the investigations of various chemists and isolated tanoid by the process of Lowe and a phenolic body (unnamed) which had not been previously described.

The most important researches upon the constituents of rhubarb were made by Tschirch and Heuberger (A. Pharm., Nov. 21, 1902, 596, 630, and Ph. Ztg., Aug. 3, 1904, 651). Their conclusions are that rhubarb contains primarily two classes of substance's. 1. Tannoglucosides; 2. Anthraglucosides. These two classes cannot be sharply separated from each other and are therefore associated together in all extractions. Both of these are characterized by their ready decomposition and conversion into secondary products, such conversion resulting even during the
treatment of the drug with ordinary solvents. Thus, the ether extraction has been found to contain the products of the hydrolysis of the anthraglucosides, namely, chrysophanic acid, emodin and rhein. It is however not proven (indeed not even probable) that the tannoglucosides combine with the anthraglucosides to form so-called double glucosides. On the contrary, the indications are that these two classes of glucosides occur beside each other; furthermore, the relatively large quantity of tannoglucosides and their hydrolytic products is noteworthy and that, therefore, the activity of rhubarb is not attributable solely to the anthraglucosides; but the activity of the latter must be materially modified by that of the tannoglucosides. To what degree the primary tanno- and anthraglucosides have become hydrolyzed in the drug itself, it is difficult to determine; it is certain, however, that the drug contains a considerable quantity of free oxy-methylanthraquinones, while it is probable that the formation of the secondary glucosides results during the extraction and manipulation of the extract.

Tschireh sums up the results of the investigation as follows: Aweng's Double Glucoside is in its essentials identical with tannoglucoside, but contains some anthraglucoside. Aweng's Frangulic Acid is a secondary product of the decomposition of tannoglucoside, containing variable quantities of anthraglucoside as impurity. Kubli's Rheumtannic Acid and Hunkel's Tanoid are identical with tannoglucoside, but less pure. Kubli's and Hunkel's Rheum Acid is identical with rheum red, and therefore a product of the hydrolysis of tannoglucoside. Schlossberger and Dopping's Aporetin and Phaeoretin are impure, difficultly soluble tannoglucoside. Erythroretin is a mixture of chrysophanic acid, emodin and rhein. Garot's Erythroser is chrysamic acid. Rhein, yielding only a diacetyl derivative, cannot be regarded as being tetraoxymethylanthraquinone. It has the composition $C_{15}H_8O_6$ (not $C_{15}H_{10}O_6$, Hesse) which formula corresponds to a methylene ether of a tetraoxygenanthraquinone. Dragendorff's, Greenish's and Elborne's Cathartic Acid is an impure tannoglucoside, containing anthraglucosides and some albuminoid substances. Gilson's Chrysophan belongs to the anthraglucosides. Aweng's Secondary Glucosides are secondary, mostly difficultly soluble hydrolytic products of the primary tanno- and probably also of the anthraglucosides.

Finally, Tschirch determined that rhubarb contains no resins whatever; that the rheo-tannoglucosides and their products of decomposition and
hydrolysis are devoid of purgative activity, and that such activity is due solely to the anthraglucosides and their derivatives. Rhubarb contains no other body besides the latter that has peristaltic effect on the intestinal tract.

As regards the rheo-tannoglucoside, its medicinal activity is confined to the tonic and mildly astringent effect produced on administering the drug. Tsehirch (Ph. Ztg., Aug. 3, 1904, 651) recommended a method for assaying rhubarb based on the volumetric estimation of the free oxymethylanthraquinones, dependent on the ease with which the anthraglucosides can be hydrolyzed with sulphuric acid. See also Proc. A. Ph. A., 1905, 627.

There are other interesting principles in rhubarb. Some have been disposed to attribute its odor to a volatile oil, but this has not been isolated. The calcium oxalate is interesting from its quantity, and from the circumstance that, existing in distinct crystals, it occasions the grittiness of the rhubarb between the teeth. The proportion seems to vary exceedingly in different specimens. According to Scheele and Henry, it constitutes nearly one-third, and Queckett found between 35 and 40 per cent., while Brandes obtained only 11, Schrader only 4.5 parts in the hundred, and Dragendorff, in five samples analyzed, from 1.2 to 5.6 per cent. Little or no difference of composition has been found between the Russian and the Chinese rhubarb. The European contains but a small proportion of calcium oxalate, and is therefore less gritty when chewed. It has, however, more tannin and starch than the Asiatic.

When powdered rhubarb is heated, odorous yellow fumes rise, which are probably in part the vapor of chrysophanic acid. Its infusion is reddened by the alkalies, in consequence of their union with this acid, and their reaction on the other coloring principles. It yields precipitates with gelatin, most of the acids, ferric salts, lead acetate, mercurous nitrate, silver nitrate, stannous chloride, lime water, and solutions of quinine. Nitric acid occasions at first a turbidity, and afterwards the deposition of a yellow precipitate. The substances producing precipitates may be considered as incompatible with the infusion.

For a method of detecting the presence of turmeric in powdered rhubarb by the influence of chloroform on the coloring principles of each of these substances, and of distinguishing through the same agency between the true Chinese rhubarb and that of European origin, the reader is
referred to a paper, by W. L. Howie, contained in A. J. P. (Jan., 1874, 16), from P. J. (Nov. 15, 1873); see also P. J., 1898, 126.

**Uses.**—Rhubarb contains cathartic principles of the anthraquinone series. It differs from drugs of this group—such as aloes, cascara, etc.—in that it has a larger percentage of tannic acid. On account of the considerable quantity of tannin its purgative action is often followed by constipation. This sequence of effects has led to its use in the treatment of diarrheas, especially of the inflammatory type, on the theory that the catharsis it caused would evacuate the irritant materies morbi, and that its subsequent astringency would check the excessive secretion. The logic is plausible, but erroneous. As the action of its cathartic principles is limited to the lower bowel it has very little influence in cleaning out the smaller bowel which is the more frequently involved in acute diarrheas. In inflammations of the colon, such as dysentery, its use might appear more reasonable, but even here it is greatly inferior to less irritant laxatives because it acts chiefly by virtue of its local irritant influence. Rhubarb is also widely prescribed in atonic dyspepsia attended with constipation. It is frequently combined with an alkali, either magnesia or soda.

It sometimes occasions griping. Its coloring principle is absorbed, and may be detected in the urine. By its long-continued use the perspiration, especially that of the axilla, is said to become yellow, and the milk of nurses cathartic. It gives a yellow color to the alvine discharges.

By the roasting of rhubarb its cathartic property is diminished, probably by the volatilization of the purgative principle, while its astringency remains unaffected. When so treated it is termed torrefied rhubarb. This mode of treatment has been sometimes resorted to in cases of diarrhea. By long boiling the same effect is said to be produced.

Powdered rhubarb has been usefully applied to indolent and sloughing ulcers. It is said to have proved purgative when sprinkled over a large ulcerated surface, and the same effect is asserted to have been produced by rubbing it, mingled with saliva, over the abdomen.

European rhubarb must be administered in double or treble the dose of true rhubarb to produce an equal effect. Few medicines are used in a greater variety of forms. It is most effectual in substance. It is frequently given in the shape of pill, combined with an equal proportion of soap.
when its laxative effect is desired. The infusion is much used in cases of
delicate stomach, and is peculiarly adapted to children. The syrup,
tincture, and fluidextract are also useful preparations. They are all
official. The formula for mixture of rhubarb and soda which was largely
used in New York at one time will be found in the National Formulary
IV. The name was changed to Mistura Rhei Composita.

Dose, as a purgative, from twenty to thirty grains (1.3-2.0 Gm.); as a
laxative and stomachic from five to ten grains (0.32-0.65 Gm.).

**Rhizophora Mangle.**—The red bark of the South American mangrovetree has been
used for many years by the natives as a febrifuge but more recently Duque and
Moreno (S. M., 1905, p. 479) have claimed that it is a specific in leprosy. They
administer a beginning dose of one fluidrachm (3.75 mils) of the fluidextract twice a
day which is gradually increased until the patient is taking a fluidounce and a half (45
mils) daily.

**Rhododendron.** Rhododendron Chrysanthemum Pall. Yellow-flowered
(Fam. Ericaceae.)—The leaves of this rhododendron have long been employed in
Siberia as a remedy in rheumatism, and to a less extent in gout and syphilis. They
yield their virtue to water and alcohol, and, according to von Archangelski, contain
three proximate principles; rhododendrol, C_{10}H_{12}O_{2}; rhododendrin, C_{16}H_{22}O_{7}; and a
glucoside resembling digitalin and very toxic. The dose of the dried leaves is said to be
two drachms (7.7 Gm.), given in infusion.
G. F. Kuehnel found in leaves of the "great laurel," Rhododendron maximum L., a common shrub in the Alleghenies from New York to Georgia, arbutin, ericolin, and ursone. (A. J. P., 1885.)

**RHŒADOS PETALA. Br.**

**RED POPPY PETALS**

"Red-Poppy Petals are the fresh petals of Papaver Rhoeas, Linn." Br.

Corn Poppy, Corn Rose; Coquolicot, Fr. Cod.; Pavot rouge, Fr.; Wilder Mohn, Klapperrose, Llatschroaen, G.; Rosolaccio, It.; Amapola (Flor de), Sp.

The red or corn poppy, Papaver Rhoeas, is distinguished by its hairy stem, which is branched, and rises about a foot in height, by its incised pinnatifld leaves, by its urn-shaped capsule, and by the full, bright, scarlet color of its petals. It is a native of Europe, where it grown wild in great abundance, adorning especially the fields of grain with its brilliant flower. It has been naturalized in this country.

Its capsules contain the same kind of milky juice as that found in P. somniferum, and an extract has been prepared from them having the properties of opium; but the quantity is too small to repay the trouble of its preparation. Filhol has shown that the extract contains morphine, but in a proportion exceedingly minute compared with that in which it exists in opium. The petals are the official portion. They have a characteristic odor, and a mucilaginous, slightly bitter taste. By drying, they lose their odor, and assume a violet-red color. "Transversely elliptical, about five centimetres wide, bright scarlet, smooth and lustrous; margin entire. Characteristic, somewhat unpleasant odor; taste slightly bitter." Br.

Chevallier believed that he had detected a very minute proportion of morphine in an extract obtained from them; but Attfield seems to have determined satisfactorily the non-existence of morphine in the petals, having sought this alkaloid by three different processes, using a pound of the petals in each experiment, and failed to detect the least evidence of its presence. (P. J., Oct., 1873, p. 291.) Their operation on the system is exceedingly feeble, and they are valued more for their beautiful scarlet color, which they communicate to water, than for their medicinal virtues. According to Leo Meier, the coloring principles of the flowers are
two acids, which he denominates rhoeadic and papaveric acids. (See A. J. P., xviii, 211.) A syrup is prepared from them, which was formerly prescribed as an anodyne in catarrhal affections, but is now little esteemed except for its color.

An alkaloid was discovered in this species of poppy by O. Hesse, who proposed to name it rhoeadine. It seems to pervade all parts of the plant, from which, as the first step in its preparation, an aqueous extract is prepared. This is treated with sodium carbonate, and repeatedly agitated with ether; the ethereal liquid is shaken with a solution of sodium bitartrate, and the mixture is precipitated by ammonia. The precipitate is washed with cold water, dried, and boiled with alcohol, by which coloring matter and another alkaloid in small quantity, probably thebaine, are removed. The residue, consisting mainly of rhoeadine, is purified by combining it with acetic acid, treating with animal charcoal, and precipitating with ammonia. The alkaloid is in small white prismatic crystals, tasteless, fusible at 232.2° C. (450° F.), becoming brown at the same temperature and partially subliming. It is almost insoluble in water, alcohol, ether, chloroform, benzene, ammonia, solution of sodium carbonate, and lime water, but is dissolved by dilute acids, which produce colorless solutions. Its composition is represented by the formula C₂₁H₂₁O₆N. It does not appear to be poisonous. Hydrochloric and sulphuric acids, moderately concentrated, decompose and dissolve it, with the production of a purple color, which disappears under the action of the alkalies, but is restored by acids. One part of the alkaloid so treated produces a purple color with 10,000 parts of water, rose color with 20,000 parts, and a perceptible redness with 800,000 parts. This change is dependent upon the liberation from the rhoeadine of a red coloring matter, while the isomeric rhceagenine remains. This forms small white tasteless prisms, which fuse at 223° C. (433.4° F.) and do not sublime, but are decomposed at higher temperature's. This is a very delicate test, by means of which the alkaloid may be detected in all parts of *Papaver Rhoeas*, in the ripe capsules of the opium poppy, and in opium itself. It is said also to exist in Merck's prophyroxine. (A. J. P., 1867, p. 122.) According to Hesse, the milky juice also contains meconic acid.

**Off. Prep.**—Syrupus Rhoeados, Br,
Rhus.—The genus Rhus contains various species which have the property—probably even without direct contact—of so violently irritating susceptible skins as to produce severe dermatitis. Of these poisonous species there are six which are indigenous to the United States.

R. vernix L. (R. venenata DC.) — Swamp Sumac, Poison Sumach, Poison Elder is our most poisonous species. It is a handsome shrub or small tree, usually ten or fifteen feet high. The bark of the trunk is dark gray, of the branches lighter, of the extreme twigs and petioles pale to deep red. The leaves are pinnate, with three to six pairs of opposite leaflets, and an odd terminal one. These are oblong or oval, entire or slightly sinuate, acuminate, smooth, and, except the one at the end, nearly sessile. The flowers are polygamous, very small, greenish, and in loose or slender axillary panicles. The berries are small, roundish, and greenish white. The tree grows in swamps and low grounds from Canada to Carolina, and flowers in June and July. It was confounded by the older botanists with R. vernicifera DC., of Japan, the Japanese lacquer tree, which has similar poisonous properties. Its activity is said to depend upon urushic acid.

Rhus Michauxii Sargent (R. pumila Michx.) is a rare Southern species, growing in upper Carolina and Georgia, and not more than a foot in height. It is characterized by its pubescent branches and petioles, by its pinnate leaves, with many pairs of oval, nearly acuminate, incised-dentate leaflets, downy beneath, and by its silky fruit. According to Pursh, it is the most poisonous of the genus.

Rhus diversiloba Torrey and Gray (R. Lobata Hooker) is found on our Pacific border. It is there generally known as Poison Oak, and closely resembles the common poison ivy or poison oak—(R. Toxicodendron L.).

Rhus Metopium L. (Metopium Linnaea, Engelm.), Mountain Manchineel, Coral Sumac, is a West Indian species, growing also in the "hummock" lands of Southern Florida. It is a small tree, the bark, when wounded, exuding a gum-resin (hog gum) to which medicinal properties are ascribed. The leaves are pinnate with fine leaflets. To the acid red fruit is due the name Coral Sumac. It is exceedingly poisonous.

Rhus Toxicodendron (R. radicans L.), Poison Oak, Poison Ivy, whose fresh leaves were formerly official in the U. S. Pharmacopoeia under the name of Rhus Toxicodendron, U. S., 1890, is a woody vine climbing by numerous aerial rootlets to considerable heights and showing considerable variation. The leaves are 3-foliate, the leaflets being ovate or rhombic, 2.5 to 15 cm. long, entire or sparingly dentate or sinuate, acute or short-acuminate, the lateral sessile or short-stalked, are inequilateral, the terminal ones stalked. The flowers are green, 3 mm. broad, in loose axillary panicles, 2 to 8 cm. long; the fruit globose-oblong, whitish or cream colored, resembling that of R. Vernix.

The milky juice, of the poisonous species of Rhus, becomes black on exposure to the air, and leaves upon linen or other cloth a stain, which cannot afterwards be removed by washing with soap and water, or by alcohol either hot or cold, but deepens by age. It has been proposed as an indelible ink. Ether dissolves it; applied to the skin it frequently causes inflammation and vesication.
While there is a fairly general agreement that the toxic constituent of the poisonous species of Rhus is a non-volatile substance, there is much evidence that there is a volatile poison also in this plant. (Bessey, A. J. P., 1914, p. 112.) Several authors are inclined to explain the poisoning which results to sensitive persons who pass near Rhus plants without touching them, by saying that the poison resides in the pollen and the plant hairs. The latter may be carried by air currents or may be transported on clothes, or tools, or animals, which after brushing against the plant are able to transfer the poison to susceptible persons. Warren (A. J. P., 1913, p. 548) was unable to detect a poisonous principle in the pollen grains of Rhus Vernix. See also Tschirch and Stevens, A. J. P., 1906, p. 63. Besides the unidentifiable poisonous principle of rhus there is present an iron greening tannin, chlorophyll, wax, fixed oil, resin, sugar, albumen, pectin, gum, starch, and oxalic acid.

The poisonous rhus when taken internally appears to be possessed of narcotic besides irritant properties, vomiting, drowsiness, stupor, dilated pupils, convulsive movements, delirium, and fever having been present in poisoning by them. (Am. J. M. S., April, 1866; also M. Rep., Nov., 1867.) The tincture of rhus has been used especially by homeopathic practitioners in the treatment of sub-acute and chronic rheumatism, and the practice has found imitation.

Some years ago H. C. Wood made extended trials of the remedy, using a homeopathic tincture obtained from a homeopathic pharmacy, in various doses (homeopathic, small, and large), upon a large number of cases of subacute, chronic, and acute rheumatism, in the Philadelphia Hospital, but he was not able to perceive that the patients progressed more rapidly when taking it than when they were simply nursed. The best preparation would undoubtedly be a concentrated alcoholic tincture, made from the green drug; strength of one to four. The dose, of a 25 per cent. tincture given by H. C. Wood was from one to five minims (0.06-0.3 mil), three times a day. The solid extract is an ineligible preparation, owing to the extreme volatility of the active principle of the crude drug.

Rhus canadensis Marsh. (R. aromatic Ait) (Fam. Anacardiaceae).—This indigenous plant, growing in dry soil from Maine and Southern Ontario to Florida and westward, has been highly recommended in the treatment of nocturnal incontinence of urine by a number of clinicians of repute. (See G. H. M. C., 1889; also Annals of Gyncaec., 1890.) For elaborate description of the bark, see Newer Materia Medica. The adult dose is twenty or thirty minims (1.3-1.8 mils) of the fluidextract of the bark, three times a day, given in aromatized solution.

Rhus glabra called variously smooth sumach, Pennsylvania sumach, and upland sumach, is an indigenous shrub from four to twelve feet or more in height. The leaves
are upon smooth petioles, and consist of numerous opposite leaflets, with an odd one at the extremity, all of which are lanceolate, acuminate, acutely serrate, glabrous, green on their upper surface, and whitish beneath. In the autumn their color changes to a beautiful red. The flowers are greenish red, and disposed in large, erect, terminal compound thryses. The fruit is in clusters of small crimson berries.

The shrub is found in Canada and almost all parts of the United States, growing in old neglected fields, along fences, and on the borders of woods. The flowers appear in July, and the fruit ripens in the early part of autumn. The bark and leaves are astringent, and are largely used, especially the leaves, in tanning leather and in dyeing. The sumach for the manufacture of extract for tanners' use is largely cultivated in Virginia, where the annual crop reaches from 7000 to 8000 tons, and is collected at any time between the first of July and the appearance of frost.

The berries have a sour, astringent, not unpleasant taste, and are often eaten by the country people with impunity. They are described in the National Formulary IV as follows:

"Nearly globular, ovoid, more or less reniform, somewhat compressed, about 5 mm. in length and 2 mm. in diameter; externally dark red, velvety with short hairs, summit with remains of the short style, base occasionally with the five-cleft calyx and a short pedicel; endocarp, smooth, shiny, light red; one-celled, one-seeded; seeds dark brown, smooth. Inodorous; taste acidulous and slightly astringent. The powder is brownish-red, and, when examined under the microscope, exhibits irregular fragments; non-glandular hairs, more or less elliptical or ovoid or spatulate, about 0.15 mm. in length and from 0.045 to 0.08 mm. in width, filled with a pink or red cell sap in which occasionally occur rod-shaped crystals; glandular hairs with a short one-celled stalk and multicellular head, from 0.045 to 0.075 mm. in length; fragments of endosperm numerous; fragments of endocarp showing very small stone cells with irregularly thickened walls, readily determined by the use of aniline sulphate T.S. and sulphuric acid; fragments of embryo with rather small cells containing a fixed oil; occasional reddish colored fragments of epidermis and underlying spiral tracheae of the mesocarp. Mix 1 Gm. of powdered Rhus Glabra with 10 mils of hot water, shake the mixture occasionally until cold, filter, and allow the filtrate to evaporate spontaneously in a watch crystal; numerous, feather-shaped crystals separate which polarize light strongly with a distinct play of colors. Rhus Glabra yields not more than 4 per cent. of ash." N. F.

W. J. Watson ascertained that free malic acid and acid calcium malate coexist in the berries, which contain also, upon the same authority, tan-nic and gallic acids, fixed oil, extractive, red coloring matter, and a little volatile oil. (A. J., P., xxv, 194). A medicinal wine has been prepared from the fruit. (M. S. R., Feb. 9, 1867.) For a paper on the relative proportion of the constituents found in the husk and seed portion of the fruit by Frankforter and Martin, see A. J. P., 1904, 151.

Excrescences are produced under the leaves resembling Chinese galls in character, and containing large quantities of tannic and gallic acids. These have been used as a substitute for the imported galls by Walters of New York, who thought them in every
respect preferable. They may be collected at little expense, as they are produced very abundantly, especially in the Western States.

Henry Trimble collected some galls from the leaves of R. glabra and found that they contained 61.70 per cent. of tannin, reckoned on the weight of the air-dried galls, or 70.90 per cent. of the weight of absolutely dry material. (A. J. P. 1890, p. 564.)

From the experiments of Stenhouse (A. J. P., xxxiv, 252), it appears that the tannic acid of sumach is identical with that of galls, being, like it, resolved, under the influence of sulphuric acid, into glucose and gallic acid, and this change is supposed to take place spontaneously in sumach when long kept.

The percentage of tannin in Virginia, sumach rises at times as high as 27 per cent., but falls a few per cent. below this as the season advances. Samples of leaves gathered along the Mississippi near Dubuque, Iowa, in July and August, yielded 16.36 per cent. and 15.75 per cent. respectively. (A. J. P., 1888, p. 389.) The proportion of tannic acid in the European sumach falls from 6 to 8 per cent. below the percentage of the Virginia sumach, yet the European is much preferred by tanners and dyers. By using Sicilian sumach it is possible to make the finer white leathers so much used for gloves and fancy shoes, while by the employment of the American product the leather has a yellow color, apparently due to a coloring matter, which, according to Loewe, consists of quercitrin and quercitin, and exists in larger quantity in the American than in the Sicilian drug. Enormous quantities of a dark-red, semi-fluid, bitter, astringent extract are prepared in Virginia from sumach, and used both in America and in Europe. It is said to contain from 25 to 30 per cent. of tannin.

Recently the fruits of Rhus glabra have been replaced by those of the Stag Horn Sumac (Rhus typhina L.) This shrub is very abundant in the eastern United States. The fruits resemble those of rhus glabra both in form and size but are distinguished by being covered with needle-like crimson hairs which are frequently over 2 mm. long. For detailed description of the fruits of these two plants see Kraemer. (A. J. P., 1913, p. 398.)

Sumach berries are astringent and refrigerant. A strong decoction, or the fluidextract diluted, affords a very effective and pleasant gargle in angina, especially in combination with potassium chlorate. Fluidextractum Rhois Glabrae was official in the U. S. VIII, but then deleted. It was admitted to the National Formulary IV with a slight alteration in the menstruum. The fluidextract affords an excellent astringent in relaxing diarrhæas and other conditions where the tannin drugs are useful. The dose of the fluidextract is fifteen to thirty minims (1-2 mils).

**Rimu Resin.**—The resin of the Dacrydiumcupressinum Solander, the New Zealand red pine or rimu, a large coniferous tree of New Zealand, ia characterized by its rose color and its crystalline appearance. It is composed chiefly of a crystalline acid resin, rimuic acid. (Chem. News, Ixxxviii, 20.)
Robinia. Robinia Pseudo-Acacia L. Locust Tree False Acacia. Robinier, Fr. Falsche Akasie, G. (Fam. Leguminosae)—This well-known indigenous tree has a place in the materia medica of the eclectics. The bark of the root is the most active part, and is said to be tonic, and in large doses purgative and emetic. The root and inner bark are poisonous to cattle. The leaves, on the other hand, are said to offer a wholesome food for foraging animals. This would seem confirmed by the experiment of Paven, who failed to find in them any poisonous principles. (For an elaborate investigation of its histology, see P. J., 67, 153.) F. B. Power and J. Cambier (Ph. Rund., Feb., 1890) found an alkaloid identical with choline; also globulin and a phytalbumoae, which produces purging and vomiting. It is precipitated by alkaloidal reagents. The bark also contains a poisonous albuminoid or enzyme, robinalbin, which, according to Kobert (M. Bull., April, 1891), is similar to, but not identical with, ricin. Power (P. J., Aug. 17, 1901) summarizes the results of a more detailed investigation of this bark. He names the poisonous proteid robin and states that it belongs to the class of nucleo-proteids. He finds evidences of one or more alkaloids; by hydrolysis he obtained syringic acid, $C_9H_{10}O_5$, and a red amorphous substance, syringenin. These products indicate the glucoside syringin, $C_{17}H_{24}O_8$. He also considers that gluco-syringic acid, $C_{15}H_{20}O_{10}$, may pre-exist in the bark. Power subsequently reaffirmed the presence of the protein, robin, in robinia bark, and confirms its toxic properties and enzymic action. (A. J. P., 1913, 339.) Robin has emetic and purgative properties. Three cases of the poisoning of children by the root have been recorded. (Ann. Ther., 1860, 64.) Z. T. Emery (N. Y. M. J., Jan. 22, 1887) reports the poisoning of thirty-two boys from chewing the inner bark of the tree. The symptoms in the mildest cases were vomiting and flushed face, dryness of the throat and mouth, and dilated pupils. In the severest cases, to these were added epigastric pain, extremely feeble, intermittent heart action, and stupor.

Robinia Nicou Aubl., now known as Lonchocapus Rufescens Benth.—According to the researches of Geoffrey (Annal. del' Inst. botanico-geologique colon, de Marseille, 1895), this leguminous plant, which is used in Guiana for the purpose of stupefying fish, contains an active principle, nicoline ($C_3H_4O$), which crystallizes in oblique, rhomboidal tables. It has been found by E. Boinet (C. R. S. B., 1896, 10 s., iii) to produce in the lower animals a short primary stage of excitation, followed by one of stupor, great muscular relaxation, enfeeble-ment of sensibility, mydriasis, fall of temperature, cyanosis, and death through centric paralysis of the respiration, though there is also fall of arterial pressure. In the dog there was salivation and vomiting.

Rosa.—Of the genus rosa at least four species have been, and probably to some extent are still, in use in medicine—namely, Rosa canina L., Rosa centifolia L., Rosa damascena Mill., and Rosa gallica L.

Rosa canina.—The Dog Rose, Wild Brier, or Hip Tree, of Europe, is distinguished by its prickly stem and petioles, and ovate, smooth, rigid leaves. It has white or pale red flowers, having usually five obcordate fragrant petals. The fruit consists of a fleshy, hollow receptacle, bearing on its inner surface a number of hairy achenes. The ripe fruit, which is usually employed in the fresh condition, is ovoid, smooth, shiny and of a reddish color. The summit is crowned with 5-calyx teeth. Rose hips possess a pleasant, sweet, acidulous taste. It was formerly official in the British
Pharmacopoeia under the name of Rosae Caninae Fructus. It contains about 30 per cent. of sugar, combined with citric and malic acids, also salts of these acids, and a trace of tannin. It was used for the preparation of an acidulous confection. Vanillin has also been found present in the petals.

Rosa centifolia has prickly stems and the leaves consist of two or three pairs of leaflets, with an odd one at the summit, closely attached to the common footstalk, which is rough, but without spines. The leaflets are ovate, broad, serrate, pointed, and hairy on the under surface. The flowers are large, with many petals, generally of a pale red color, and supported upon peduncles beset with short bristly hairs. The varieties of R. centifolia, produced by its almost universal cultivation, are very numerous, but the plant is said to grow with single flowers in the eastern part of the Caucasus. It is very closely allied to R. gallica, some botanists maintaining that the species are really one. The petals, which were recognized by the U. S. P., 1890, as pale rose, are roundish-obovate and refuse, or obcordate, pink, fragrant, sweetish, slightly bitter, and faintly astringent. They contain volatile oil, malic and tartaric acids, tannin, fat, resin, sugar, and a coloring matter which seems to be identical with that of the red rose. They should be collected when the flower is fully expanded but has not begun to fall. Their fragrance is impaired but not lost by drying. They may be preserved for a considerable time by compressing them with alternate layers of common salt in a well-closed vessel, or beating them with twice their weight of that substance. A rose water is often prepared from them by distillation.

Rosa damascena is not known in the wild state, and is thought by some botanists to have been produced by cultivation by hybridizing R. gallica with R. canina. It is the rose which is cultivated in Turkey and yields the commercial otto of rose. (See Oleum Rosae, p. 870.) It is a tall shrub with semi-double, light red to white flowers of moderate size, having several on a branch, though not clustered. Its volatile oil is the base of rose water.

**ROSA GALLICA. U. S. (Br.)**

**RED ROSE Rosa Gall.**

"The dried petals of Rosa gallica Linne (Fam. Rosaceae), collected just before the expansion of the flower. Preserve Red Rose in tightly-closed containers, protected from the light." U. S. "Red-Rose Petals are the fresh or dried unexpanded petals of Rosa gallica, Linn.; obtained from cultivated plants." Br.

Rosae Galiicae Petala, Br., Red-rose Petals; Flores Rosarum Rubrarum; Rose rouge ou Rose de Provins, Fr. Cod.; Roses rouges, Fr.; Sammtrose, Zuckerrose, Französische Rose, Esaigrosenblatter, G.; Rosa rossa, It.; Rosa roja (Flore de), Rosa rubra, Sp.

At one time pale rose or Rosa centifolia was official in addition to red
rose or Rosa gallica. There is no uniformity on the subject in the several Pharmacopoeias. The Pharmacopoeia of the Netherlands and the French Codex still include both species. The German Pharmacopoeia, on the other hand, specifies only the petals of Rosa centifolia. The British and Austrian Pharmacopoeias are in unison with the U. S. Pharmacopoeia in restricting the drug to R. gallica.

Rosa gallica is smaller than R. centifolia L., but resembles it in the character of its foliage. The stem is beset with short bristly prickles. The flowers are very large, with obcordate widely spreading petals, which are of a rich crimson color, and less numerous than in the R. centifolia. The stamens on thread-like filaments, and the villose styles bearing papillary stigmas, are numerous. The fruit is oval, shining, and of a firm consistence. The red rose is a native of the south of Europe, and is cultivated in gardens throughout the United Scales.

The drug is officially described as "petals either separate or imbricated in small cones, broadly ovate, summit rounded and deeply notched, margin entire and somewhat recurved, base obtuse; externally of a purplish-red color except the light-brown claw; texture velvety; when dry, brittle; odor agreeable; taste astringent and slightly bitter. Under the microscope, transverse sections of the petals of Red Rose show the upper epidermal cells modified to conical papillae and containing a purplish-red cell sap; a loose mesophyll composed of from 2 to 10 rows of cells among which are the fibro-vascular bundles with spiral tracheae, and a lower epidermis of rectangular cells filled with a purple cell sap. Red Rose yields not more than 3.5 per cent. of ash." U. S.

"Usually in little cone-like masses, or sometimes separate and more or less crumpled. Petals velvety, deep purplish-red passing into brownish-yellow towards the base. Fragrant odor; taste slightly astringent." Br.

The petals should be gathered before the flower has blown, separated from their claws, dried in a warm sun or by the fire, and kept in a dry place. Their odor, which is less fragrant than that of R. centifolia, is improved by drying. They have a velvety appearance, a purplish-red color, and a pleasantly astringent and bitterish taste.

An illustrated article on the structural characteristics of rose petals, whole and powdered, has been published by Hans Kramer in B. P. G., 1907, xvii, p. 354.
Their constituents, according to Cartier, are tannin, gallic acid, coloring matter, a volatile oil, a fixed oil, albumen, soluble salts of potassium, insoluble salts of lime, silica, and ferric oxide. (J. P. C., vii, 531.) According to Filhol, the astringency of red roses is ascribable less to tannc acid, of which they contain but a trace, than to quercitrin, which he obtained in notable proportion, and with which their color is probably connected. Rochleder found that in red roses the g'allic acid is accompanied by querci-tannic acid. They also contain much uncrystal-
lizable sugar. (Repert de Pharm., Mai, 1863.) The sensible properties and medicinal virtues of the flowers are extracted by boiling water. Their coloring matter, according to Senior (Y. B. P., 1877, p. 63), is an acid, which appears to form crystallizable salts with potassium and sodium, and amorphous ones with the heavy metals. Senior gives as the formula of the insoluble lead compound Pb$_2$C$_{21}$H$_{29}$O$_{30}$. Their infusion is of a pale reddish color, becoming bright red on the addition of sulphuric acid. As their color is impaired by exposure to light and air, they should be kept in opaque well-closed bottles or canisters.

**Uses.**—Bed rose is slightly astringent and tonic, and it was formerly thought to possess peculiar virtues. It it at present chiefly employed as affording an elegant vehicle for tonic and astringent medicines.

**Off. Prep.**—Confectio Rosae Gallicae, Br.; Fluidextractum Rosae, U. S.; Infusum Rosae Acidum, Br. (N. F.); Confectio Rosae, N. F.; Syrupus Rosae (from Fluidextract), N. F., Br.

**Rosemary.** Rosmarinus. Folia Rosmarini, s. RorisMarini. Folia Anthos. Feuilles de Romarin, Fr. Cod. Rosmarin, Rosmarinblatter, G. Rosmarino, It. Romero, Sp.—"The leaves of Rosmarinus officinalis (Fam. Labiatae)." U. S., 1880. Rosemary is a small evergreen shrub, with an erect stem, divided into many long, slender, ash-colored branches. The leaves are numerous, sessile, opposite, about 2.5 cm. long, rigid, linear, entire, obtuse at the summit, folded backward at the edges, of a firm consistence, smooth and green on the upper surface, whitish, woolly, and glandular beneath. The flowers are axillary, pale blue or white. The plant grows spontaneously in the countries which border on the Mediterranean, and is cultivated in the gardens of Europe and this country. The leaves, which have already been described, have a strong balsamic odor, which ia possessed, but in a less degree, by all parts of the plant. Their taste is bitter and camphorous. These properties are imparted partially to water, completely to alcohol, and depend on the volatile oil. (See Oleum Rosmarini.) The tops lose a portion of their sensible properties by drying, and become inodorous by age. Rosemary is gently stimulant, and has been considered emmenagogue. In the practice of this country it is scarcely used; but in Europe, especially on the continent,
it enters into the composition of several syrups, tinctures, etc., to which it imparts its agreeable odor and excitant property. It is sometimes added to sternutatory powders, and is used externally in connection with other aromatics in the form of fomentation. In some countries it is employed as a condiment; and its flowers, which are much sought after by the bees, impart their peculiar flavor to the honey of the districts in which the plant abounds.

Rourea. Rourea oblongifolia Hook. and Am. (Fam. Connaraceae)—This Mexican creeper is affirmed to contain an alkaloid, and to act as a violent convulsant poison. (El Estudio, 1890.)

Rubia. Garance, Fr. Krappwurzel, Farberrothe, G. Robbia, It. Rubia detintoreros, Granza, Sp.—Under this name the U. S. P. formerly recognized madder, Rubia tinctorum L. (Fam. Rubiaceae). The root of dyer's madder is perennial, and consists of numerous long, succulent fibers, varying in thickness from the size of a quill to that of the little finger, and uniting at the top in a common head, from which also proceed side-roots that run near the surface of the ground, and send up many annual stems. The quadrangular stems are furnished with short prickles by which they adhere to neighboring plants, upon which they climb. The leaves are arranged in whorls at the joints of the stem. The flowers are small, yellow and terminal. The plant is a native of Southern Europe. The root, which is dug up the third summer, enters commerce either in the form of the whole root deprived of its cuticle, or in the form of a reddish-brown powder. Madder has a weak, peculiar odor, and a bitterish, astringent taste, and imparts these properties, as well as a red color, to water and alcohol. It contains as its most important constituent alizarin, C$_{14}$H$_{6}$(OH)$_{2}$O$_{2}$, and with it as coloring matter of secondary importance purpurin, C$_{14}$H$_{5}$(OH)$_{3}$O$_{2}$. Besides these two technically important constituents there have been recognized pseudopurpurin, an orange dye color, and a yellow one (xanthopurpurin). These coloring matters, however, are probably decomposition products from glucosides existing in the fresh plant. Thus, alizarin is known to result along with glucose from the treatment with dilute acids of rubianic or ruberythric acid, C$_{26}$H$_{28}$O$_{14}$, according to the reaction:

$$C_{26}H_{28}O_{14} + 2H_{2}O = C_{14}H_{8}O_{4} + 2C_{6}H_{12}O_{6}$$

The most interesting of the coloring substances is the alizarin, and this is now termed dihydroxy-anthraquinone, C$_{14}$H$_{8}$O$_{14}$. This occurs as orange-red crystals, almost insoluble in cold water, but readily soluble in alcohol, ether, the fixed oils, and alkaline solutions. The alcoholic and aqueous solutions are rose-colored; the ethereal, golden yellow; the alkaline, violet and blue when concentrated, but violet-red when sufficiently diluted. A beautiful rose-colored lake is produced by precipitating a mixture of the solutions of alizarin and alum. Alizarin was recognized by Graebe and Liebermann in 1868 as a derivative of anthracene, C$_{14}$H$_{10}$—a hydrocarbon contained in coal tar—and in the same year they elaborated a method for preparing it commercially from anthracene. Upon this arose rapidly a great chemical industry, and the cultivation of madder, has, of course, decreased correspondingly.
Madder is used in amenorrhea and dropsy, and when taken into the stomach imparts a red color to the milk and urine, and to the bones of animals, without sensibly affecting any other tissue. The effect is observable most quickly in the bones of young animals, and in those nearest the heart. Under the impression that it might effect some change in the osseous system, it has been prescribed in rachitis, but without favorable result. Dose, about half a drachm (2.0 Gm.), repeated three or four times a day.

Rubus. N. F. IV. Blackberry Bark. Bramble. Finger Berry, Ecorce de Ronce Noir, Fr. Brambeeren, Brombeerrinde, G.—"The dried bark of the rhizome of Rubus villosus Alton, Rubus nigrobaccus Bailey, or of Rubus cuneifolius Pursh (Fam. Rosaceae)." N. F. Of the genus Rubus a large number of species are indigenous in the United States, where they are called by the various names of blackberry, dewberry, cloudberry, etc. Most of them are shrubby or suffruticose briers, with astringent roots and edible berries; some have annual stems without prickles. They are naturally divided into the raspberries, in which the edible fruit is composed of pulpy, one-seeded, coherent little drupes, separate from the dry receptacle, and the blackberries, in which the receptacle is juicy and coheres with the drupes to form the fruit. The National Formulary recognizes as the source of rubus only three species, but it is probable that others contribute to the bark of the markets. In fact, the U. S. Pharmacopoeia of 1890 recognized officially R. canadensis L., and R. trivialis Michaux.

The blackberry root is branching, cylindrical from 0.5 to 2.5 cm. in thickness, and covered with a thin bark, which is externally of a light brownish or reddish-brown color, and in the dried root is wrinkled longitudinally. The dewberry root is usually smaller, without the longitudinal wrinkles, but with transverse fissures through the epidermis, and of a dark ash color, without any reddish tinge. Both are inodorous. The National Formulary IV describes blackberry bark as follows: "In elongated, tough, flexible quills or bands, from 3 to 6 mm. in diameter, the bark from 1 to 2 mm. in thickness; outer surface deep red-brown or dark gray-brown, occasionally blackish-brown, somewhat scaly; inner surface yellow or pale brown, strongly and coarsely long straight-striate; fracture tough-fibrous; readily splitting. Inodorous; taste strongly astringent and bitter. Rubus yields not more than 5 per cent. of ash." N. F.

Blackberry bark was official in the U. S. VIII, but it was deleted, and the National Formulary IV admitted it under the name of Rubus. Its virtues are extracted by boiling water and by diluted alcohol, and depend chiefly upon tannin, which is an abundant constituent. The woody part of the roots is inert.

Dewberry and blackberry roots have long been a favorite domestic astringent remedy in diarrheas. Given in decoction, they are usually acceptable to the stomach, without being offensive to the taste. The decoction may be prepared by boiling an ounce of the smaller roots, or of the bark of the larger, in a pint and a half of water down to a pint, of which from one to two fluidounces (30 to 60 mils) may be given to an adult three or four times, or more frequently, during the twenty-four hours.

A fluidextract and compound elixir of rubus are in the N. F.
The fruit is official in the N. F. under the English title **Blackberries**, N. F. IV. Rubi Fructus. It is described by the N. F. as "The fresh, ripe fruit of varieties of Rubus nigrobaccus Bailey or Rubus villosus Alton (Fam. Rosaceae). An aggregate fruit, ovate to oblong, rounded or slightly pointed, composed of numerous, shining black drupelets attached to an esculent receptacle; pericarp externally smooth or with only a few hairs (R. villosus), mesocarps fleshy, juice purple-red, endocarps hard, black, surfaces deeply wrinkled." N. F.

The fruit of Rubus Idaeus is official in the N. F. under the English title **Raspberries**, N. F. IV. Rubi Idaei Fructus. They are described as "The fresh, ripe fruit of varieties of Rubus Idaeus Linne or of Rubusstrigosus Michaux (Fam. Rosaceae). An aggregate fruit, globular or hemispherical with a concave depression at the base where separated from the receptacle, composed of twenty or more small, rounded-polygonal, succulent drupelets; pericarps externally red, haira numerous; mesocarps fleshy, juice red; endocarps small stones with wrinkled surfaces. Odor characteristic, aromatic; taste pleasant, sweet, acidulous. For pharmaceutical purposes, Black Raspberries, the fresh ripe fruit of varieties of Rubus occidentalis Linne (Fam. Rosaceae), may be substituted either in part or wholly for Red Raspberries." N. F. Rubus strigosus has yielded to cultivation certain superior raspberries, especially those which have been known commercially as the Cuthbert and Hansall raspberries. Rubus neglectus Peck, the purple wild raspberry, with a fruit which varies from dark red or purple to yellowish in cultivation, has also yielded a commercial raspberry.

Raspberries are employed for the production of the N. F. syrup.

The Rubus occidentalis L., black raspberry or thimbleberry of the Northern United States, which is also cultivated, is sometimes employed for the making of a raspberry syrup, but yields a very inferior product.

Rubus Chamoemorus L. Cloud Berry. Baked-Apple Berry. (Fam. Rosaceae.) —This plant, which inhabits the northern portions of both continents, is largely employed in Northern Russia, in the form of an infusion of the berries or leaves, as a diuretic in dropsy. The fruits are about 2 cm. in diameter, of an amber color, and very juicy when ripe.* Popoff found in it a crystallizable acid which is an essential diuretic, acting directly upon the renal secreting structures without affecting either cardiac action or arterial tension. (Vrach., iv, 1886.)

**Rumex.** N. F. IV. Yellow Dock. Curled Dock. Radix Lapathi.—Rumex was official in the U. S., 1890, and has been admitted to the N. F. IV and is defined as “The roots of Rumex crispus Linne, or of Rumex obtusifolius Linne (Fam. Polygonaceae), without the presence of more than 5 per cent. of stem bases." N. IV. The roots of rumex are officially described as "Usually split longitudinally or cut into transverse pieces about 2 cm. in length. The entire root, nearly simple, slightly tapering, with few if any rootlets, somewhat twisted, up to 30 cm. in length and 7 cm. in diameter, externally reddish-brown or grayish from adhering soil, finely annulate above, deeply wrinkled longitudinally, marked with small indented root scars which are often transversely
elongated and with occasional stem scars or remains of stem, the latter being hollow and finely striated; leaf buds few, obconical; fracture short and dusty, somewhat fibrous. The transverse section exhibits a yellowish or brownish cortex and a whitish or yellowish wood which is finely radiate in the outer portion. When examined under the microscope, it exhibits a thick cortex with several layers of cork, beneath which is an interrupted row of stone cells; a distinct cambium; and vascular bundles with few fibers. The powder, when examined under the microscope, shows calcium oxalate crystals in rosette aggregates from 0.025 mm. to 0.06 mm. in diameter; numerous starch grains ellipsoid or narrowly elongated, sometimes truncate, up to 0.025 mm. in length; stone cells from 0.04 mm. to 0.2 mm. in diameter, with walls somewhat lamellated, from 0.008 mm. to 0.025 mm. in thickness and with few simple pores; sclerenchymatous fibers few, thin-walled with simple pores; tracheae up to 0.1 mm. in width with scalariform or reticulate thickenings of the wall; cork cells light brown. Rumex yields not more than 10 per cent. of ash. "N. F. IV.

Several species of rumex have sour leaves, and are distinguished by the common name of sorrel from the others, which are called dock. Of the former, Rumex Acetosa L., or common English sorrel, formerly held a place in the London and Dublin Pharmacopoeias. R. Acetosella L. is the common sorrel of our fields, though supposed to have been originally introduced from Europe. The leaves of both these plants are agreeably sour to the taste, and owe their acidity to acid potassium oxalate with a little tartaric acid. They quite lose this taste in drying. They are refrigerant and diuretic, and may be used advantageously as an article of diet in scurvy. For this purpose they are prepared in the form of salad. The juice of the leaves forms with water an agreeable acidulous drink, sometimes used in fevers. Taken very largely, the leaves are said to have produced poisonous effects. R. Scutatus L., of Europe, Northern Africa, Asia Minor, and the Caucasus, also ranks among the sorrels (French sorrel).

Of the proper docks, the roots of R. silvestris Wallr., an European plant, and of R. Conglomeratus Murr., R. Aquaticus, R. Sanguineus L., and R. Patientia L., belonging both to Europe and to the United States, may be employed indiscriminately with those of the R. Crispus L., which was formerly recognized by the U. S. Pharmacopoeia. R. Britannica L., and R. Obtusifolius L., were formerly official. R. Hydrolapathum Hudson, which is the R. Aquaticus of the old Dublin Pharmacopoeia, is thought to be the Herba Britannica of the ancients, celebrated for the alleged cure of scurvy and diseases of the skin. The docks are herbaceous plants with perennial roots, and especially distinguished by the sheathing petioles of the leaves. The flowers are small, mostly green, and occur in terminal or axillary panicles.

Dock root, from whatever species derived, has an astringent, bitter taste, with little or no odor. The leaves of most of the species are edible when young, and are occasionally used like spinach. They are somewhat laxative, and form an excellent diet in scurbutic cases. The roots are used to dye a yellow color. According to J. H. Salisbury (N. Y. Journ. Med., March, 1855), the petioles of the leaves contain nearly one per cent. of oxalic acid; the cortical part of the root, which is the most active, yielded, on analysis, starch, a little sugar, albuminous matter, gummy matter, bitter extractive, tannic acid of the kind which gives green precipitates with the salts of iron,
lignin, and various salts. The root yields its virtues to water and to alcohol, but is injured by long boiling.

Dock root is astringent, gently tonic, and has been supposed to have alterative properties, making it useful in skin diseases and even syphilis. From the root of R. Nepalensis Wall., which is largely used in Madras as an astringent for medicinal purposes and for dyeing, O. Hesse has separated three crystalline substances to which he gives the names of rumicin, nepalin, and nepodin. (P. J., lvi; also Proc. A. Ph. A., 1896, 551.) According to Tutin and Clewer (Trans. Chem. Soc., 1910, xcvi) the R. Eckolianus Meissner, a South African herb, contains chrysophanic acid, emodin, and allied products, and is mildly purgative. Tschirch and Well found small quantities of emodin and chrysophanic acid with lapathinic acid, C_{20}H_{18}O_{14}, in the root of R. obtusifolius. (A. de Pharm., 1912, No. 1, 20.) R. aquaticus and R. Britannica are the most astringent. The roots of some species unite a laxative with the tonic and astringent property, resembling rhubarb somewhat in their operation. Such are those of R. crispus and R. obtusifolius, and R. alpinus L., has in some parts of Europe the name of mountain rhubarb. This resemblance is not singular, as the two genera belong to the same natural family. A. Gilbert and P. Lereboullet have discovered a remarkable property of Rumex crispus. For the roots of this plant are said to possess the power of taking up the iron present in the soil, and fixing it in the form of organic compounds of iron. By watering the plants with a solution of iron carbonate, roots are said to be obtained which contain 1.5 per cent. of iron. Rumex is said to give good results in the treatment of chlorosis and anemia. The authors gave the dried and powdered root during meals in doses of fifteen to forty-five grains (1-3 Gm.), in view of their good results they regard it as a valuable iron medicine. Dock root is given in powder or in decoction. Two ounces (62 Gm.) of the fresh root bruised, or one ounce (31 Gm.) of the dried, may be boiled in a pint (480 mils) of water, of which two fluidounces (60 mils) may be given at a dose, and repeated as the stomach will bear it. George G. Flemmyg (L. L., i, 1896) reported the death of two sisters, aged respectively five and six and a half years, preceded by symptoms of oxalic acid poisoning as the result of the ingestion of sorrel leaves.

**Ruta.**—Under this name the U. S. Pharmacopoeia formerly recognized Ruta graveolens L.; Rue Rue odorante, Fr.; Garten-Raute, G.; Ruta, It.; Ruda, Sp., (Fam. Rutaceae). It is a low, shrubby plant, with several shrubby branching stems, which, near the base, are woody and covered with a rough, bark, but in their ultimate ramifications are smooth, green, and herbaceous. The leaves are fleshy, 2- to 3-pinnatifled, the ultimate lobes or divisions being obovate-cuneate. The flowers are yellow, and disposed in a terminal branched cyme. The plant is a native of the south of Europe, locally established in pastures in the United States and cultivated in our gardens. The whole herb is active, and yields its properties to water and alcohol. The leaves have a strong, disagreeable odor, especially when rubbed. Their taste is bitter, hot, and acrid. When recent, and in full vigor, they have so much acrimony as to inflame and even blister the skin, if much handled; but the acrimony is diminished by drying. Their virtues depend chiefly on a volatile oil, which is contained in glandular vesicles, apparent over the whole surface of the plant. They contain, also, according to Bornträger, a peculiar acid which he calls rutinic acid, C_{25}H_{32}O_{15} (or C_{27}H_{32}O_{16},...
Rutinic acid is the coloring principle of rue, and has been found in various other plants; though, like quercitrin, yielding quercetin and sugar, it has been shown to be distinct. (J. P. C., 1862, 165.)

Rue yields a very small proportion of a yellow or greenish volatile oil (Oleum Rutae, U.S.; 1880), which becomes brown with age. According to Zeller, the yield from the fresh herb is 0.28 per cent., that from the seeds about 1 per cent. The oil has the strong unpleasant odor of the plant, and an acrid taste. Kane gives its sp. gr. at 0.837, its boiling point at 230° C. (446° F.). "A neutral reaction. Sp. gr. about 0.880. It is soluble in an equal weight of alcohol." U. S., 1880. It consists mainly of an oxidized constituent, which Strecker proved to be methyl-nonyl-ketone, CH₃.CO.C₉H₁₉; that is, a ketone analogous to acetone, CH₃.CO.CH₃. This accounts for its yielding under treatment with oxidizing agents, pelargonic acid, C₉H₁₈O₂. The methyl-nonyl-ketone, when pure, is a colorless liquid, fluorescing blue, boiling at 225° 0. (437° F.), and crystallizing at about 15° C. (59° P.). Schimmel & Co. (Schim. Rep., 1892, 31) state that pure oil of rue consists of 90 per cent. of methyl-nonyl-ketone, and solidifies even at a moderate temperature to a solid, crystalline mass, and has the sp. gr. 0.837.

According to von Soden and Henie, Algerian oil of rue differs from the ordinary oil in that it is chiefly composed of methyl-heptyl-ketone, with but small quantities of methyl-nonyl-ketone. Its specific gravity at 15° C. (59° P.) is 0.842; and it does not solidify at -15° C. (5° P.). (Ph. Ztg., 46.) Frederick B. Power and Frederic H. Lees (Trans. Chem. Soc., 1902) have since published an elaborate investigation of a similar Algerian oil. They find 80 per cent. of the two ketones, methyl-heptyl-ketone and methyl-nonyl-ketone, 10 per cent. of the corresponding carbinols (alcohols), pinene, 1-limonene, cineol, methyl salicylate, ethyl valerate, and some free fatty acids.

Rue is said to have been used by the ancients as a condiment. In modern times it has been employed in hysteria, worms, colic, and astatic amenorrhea and menorrhagia. Its medicinal activity depends upon its volatile oil, which is a powerful local irritant, causing, when applied to the skin persistently, burning, redness, and vesication, and when taken internally in large doses, violent gastric pains and vomiting, great prostration, confusion of mind, convulsive twitching, and in pregnant women, abortion. It has been considerably used in Europe for the production of criminal abortion, in a number of cases with fatal results. In a case of fatal poisoning in a man, reported by G. F. Cooper, there were vomiting, violent tormenta and tenesmus, with bloody stools, great abdominal distention, with tenderness and severe strangury. (Med. Exam., N. S., ix, 720.) The dose of the oil is from two to five minims (0.12-0.3 mil) every two or three hours. The rue itself is sometimes given in the dose of from ten to thirty grains (0.65-2.0 Gm.).

Rye. Secale cereale L. (Fam. Gramineae) Roggen, G. Leigle, Fr. Centeno, Sp.—Rye is allied to wheat and barley. Its native country is somewhat doubtful, but is said to be found wild throughout the Mediterranean countries, extending to Central Asia. There are two prominent varieties known as "Winter" and "Spring" rye, the difference being due to cultivation mainly. Rye is now cultivated in all temperate latitudes. The average composition of rye as a cereal may be thus stated: fat, 1.43 per cent.; starch,
61.87 per cent.; sugar (as sucrose), 4.30 per cent.; albumen (insoluble in alcohol), 9.78 per cent.; nitrogenous matter (soluble in alcohol), 5.09 per cent.; cellulose, 3.23 per cent.; mineral matter, 1.85 per cent.; moisture, 12.45 per cent. (Sadtler, Industrial Organic Chemistry, 3d ed., p. 169.) Rye flour is used, in the dry state, as an external application to erysipelas or inflammatory and other eruptive affections, the burning and unpleasant tingling of which it tends to allay, while it absorbs the irritating secretions. In the form of mush it is an excellent laxative article of diet, and, mixed with molasses, it may be given with great advantage in hemorrhoids and prolapsus ani, connected with constipation. Rye carbonized by heat, with exclusion of the air, has been highly recommended as a tooth powder.
Sabadilla. Cevadilla.—The dried ripe seeds of Schoenocaulon officinale (Schlecht.) A. Gray [Asagroea officinalis (Chain. and Schlecht.) Lindl.], were recognized by the Br. Pharm. of 1885. At one time cevadilla was generally believed to be derived from Veratrum Sabadilla Schiede. The plant grows in the Andes of Mexico and in the mountains of Guatemala and Venezuela. It is also cultivated. The fruit is a capsule having three locules in each of which there are from three to four seeds. A resemblance, existing or supposed, between this fruit and that of barley is said to have given rise to the Spanish name cevadilla, which is a diminutive of barley. The seeds are elongated, pointed at each end, flat on one side and convex on the other, somewhat curved, 5 to 8 mm. long, wrinkled, slightly winged, black or dark brown on the outside, whitish within, hard, inodorous, and of an exceedingly acrid, burning, and durable taste.

Pellatier and Caventou first noted the presence of an alkaloid in cevadilla, which base they called veratrine; Meissner in the same year announced the presence of an alkaloid, sabadilline, C\textsubscript{34}H\textsubscript{53}O\textsubscript{8}N, and Courbe, Merck, and Weigelin all described what they considered as distinct bases; but its exact composition remained unsettled until Wright and Luff (J. Chem. S., 33, 338) found in it three bases: (1) cevadine, C\textsubscript{32}H\textsubscript{49}O\textsubscript{8}N, (agreeing with the base described by Merck as veratrine), crystallizing in needles or compact crystals, fusing at 205° C. (401° F.) (202° C. (395.6° F.), according to Merck), insoluble in water, easily soluble in alcohol and ether, and decomposed by hot alcoholic potash into cevine, C\textsubscript{27}H\textsubscript{43}O\textsubscript{8}N (C\textsubscript{27}H\textsubscript{45}O\textsubscript{9}N, Fluckiger), and methyl-crotonic acid (cevadic acid of Pelletier and Caventou), C\textsubscript{5}H\textsubscript{8}O\textsubscript{2}; (2) veratrine, C\textsubscript{37}H\textsubscript{53}O\textsubscript{11}N, obtained from the syrupy mother liquor from which the cevadine has crystallized; (3) cevadilline or sabadilline, C\textsubscript{34}H\textsubscript{53}O\textsubscript{8}N, obtained after the extraction of the veratrine with ether; it is insoluble in ether, slightly soluble in boiling benzene, and readily soluble in fusel oil, uncrystallizable, and appears to yield methyl-crotonic acid on treatment with alcoholic soda. For method of extracting the alkaloids, see U. S. D., 19th ed., p. 1636.

Merck has since (M. R., Jan., 1891, 3-9) isolated two new alkaloids from cevadilla, which he names sabadine and sabadinine respectively. The former has the formula C\textsubscript{29}H\textsubscript{51}N\textsubscript{8}O\textsubscript{8}, crystallizes from ether in short needles, and fuses at from 238° to 249° C. (460.4°-464° F.). It dissolves in concentrated sulphuric acid with a yellow color and
a green fluorescence, which gradually disappears, while the liquid assumes a blood-red and then violet color. The alkaloid is sternutatory, although in a much less degree than veratrine. The second alkaloid crystallizes from ether in filiform needles, which begin to sinter at 160° C. (320° F.), but show no fixed fusing point. Concentrated sulphuric acid causes a permanent blood-red color. The formula is given as C$_{27}$H$_{45}$NO$_8$. This alkaloid is not sternutatory. Cevadilla yields about 0.3 per cent. of veratrine.

Cevadilla is an acrid, drastic emeto-cathartic, operating occasionally with great violence, and in overdoses capable of producing fatal effects. Known in Europe as early as 1752, and formerly used to some extent as a tsericide, in doses of from five to twenty grains (0.32-1.3 Gm.), it was official solely as the source of veratrine. It is the principal ingredient of the pulviscapucino-rum, sometimes used in Europe for the destruction of vermin in the hair.

According to E. Falk, 0.001 Gm. of pure cevadine will paralyze the frog; 0.01 Gm. will cause death from cardiac paralysis in rabbits; 0.02 Gm. per kilogramme produces paralysis, interrupted by tetanic spasms. Cevine was found to be much less poisonous than cevadine, though producing similar symptoms.

**SABAL. U. S.**

**SABAL [Saw Palmetto Saw Palmetto Berries]**

"The partially dried, ripe fruit of Serenoa serrulata (Michaux) Hooker filius (Fam. Palmae). Preserve Sabal in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." U.S.

The Saw palmetto flourishes on the Atlantic coast from South Carolina to Florida, where it forms the so-called "palmetto scrub." According to Schneider it is also found in southern portions of California. (Pacific Pharm., ii, p. 466.) It was introduced into medicine in 1879. (Bull. Lloyd Library, 1911, No. 18, p. 71.) The stem of saw palmetto is from 6 to 10 feet high, has a crown of large leaves, long petioled, with a circular fan-shaped leaf blade split at the edge into from 15 to 30 divisions, which are slightly cleft at their apices. The fruit is a one-sided blackish-brown drupe, from half an inch to one inch long; ovoid-oblong in shape, with a somewhat wrinkled exterior, and a sweetish, not agreeable taste. It occurs in a large panicle which in, some cases may weigh as much as nine pounds.

**Properties.**—Sabal is officially described as follows: "Ellipsoidal or ovoid, occasionally compressed, from 1.5 to 3 cm. in length and from 1 to
1.5 cm. in diameter; externally brownish-black to bluish-black, smooth and somewhat oily, with a few large, more or less angular depressions due to the contraction of the inner layer on drying, summit marked by the scar of the style, and the base either with a short stalk or stem-scar; epicarp and sarcocarp together forming a thin coriaceous shell enclosing a hard but thin endocarp, which is externally reddish-brown and somewhat fibrous as is also the inner layer of the sarcocarp; inner layer of endocarp smooth, enclosing a hard, ellipsoidal or ovoid, somewhat flattened, reddish-brown seed; odor pronounced, aromatic; taste sweetish, aromatic, slightly acrid. The powder is yellowish-brown; when examined under the microscope it exhibits large, irregular fragments; parenchyma cells of sarcocarp containing a yellowish-brown or brownish-red, amorphous substance; whitish fragments of endosperm; the walls being considerably thickened and with large pores; stone cells occasional, nearly colorless, more or less tabular or irregular in shape, about 0.125 mm. in length, walls about 0.015 mm. in thickness, and with numerous simple or branching pores."

Kraemer gives an illustrated article on the pharmacognosy of the saw palmetto in the Practical Druggist, 1910, xxviii, p. 97. In it Coblentz (Proc. New Jersey Pharm. Assoc., 1895, 45) believes that he found, besides a volatile oil an alkaloid. In the studies of Sherman and Briggs (Ph. Archiv., vol. 2) no alkaloid could be detected. Sieker (Ph. Rev., 1897, 113) examined the fixed oil: the sp. gr. was 0.9138, and it was soluble in alcohol, ether, and petroleum benzin. By pressure the fruit yields about 1 1/2 per cent. of a brownish-yellow to dark red oil, soluble in alcohol, ether, chloroform and benzene, and partly soluble in dilute solution of potassium hydroxide. It contains, according to Sherman and Briggs (Ph. Archiv., 1899,101; see also Ph. Rev., 1900, 217), about 63 per cent. of free acids, and 37 per cent. of ethyl esters of these acids. The oil obtained exclusively from the nut was thick and of a greenish color, without fruity odor. It was a glyceride of fatty acids.

Yanderkleed and E'we (Proc. P. Ph. A., 1916, p. 284) contribute formulas for syrup of sabal and elixir of sabal with terpin hydrate. The latter is made as follows:

Dissolve 1.75 Gm. of terpin hydrate in 40 mils of fluidextract of sabal and 10 mils of alcohol. Add 1 mil of tincture of sweet orange peel, 0.2 mil of solution of saccharin, 40 mils of glycerin, and 100 mils of syrup. This preparation will contain 8 grains of terpin hydrate and 184 grains of
sabal in each fluidounce.

**Uses.**—The oil of saw palmetto is probably eliminated through the kidneys unchanged, although we know of no actual experiments to prove this, and appears to exert a stimulant alterative action upon the mucous membrane of the genito-urinary tract, similar to that of other alterative diuretics. Saw palmetto is milder and less stimulant than is cubeb or copaiba, or even the oil of sandal-wood. Like these drugs it also has the power of affecting the respiratory mucous membrane, so that it has been used not only in chronic and sub-acute cystitis, but also in chronic bronchitis, laryngitis, and the catarrhs which accompany asthma, phthisis, and other more serious diseases of the lungs. It has been affirmed that saw palmetto is capable of increasing the nutrition of the testicles and of the mammae in functional atony of these organs, but this is very doubtful. It has been especially recommended in cases of enlarged prostate of old men; it is not probable that it has a direct influence upon the prostatic gland itself but there is much clinical testimony as to its value and it probably acts by reducing the catarrhal irritation and the relaxed condition of the mucous membrane of the bladder and urethra, which are almost universally present in prostatic hypertrophy.

Dose, ten to twenty grains (0.65-1.3 Gm.).

**Off. Prep.**—Fluidextractum Sabal, U. S.; Tinctura Sabal et Santali, N. F.

**Sabbatia.** American Centaury. Centauree Americaine, Fr. Sabbatie, G.—The overground plant of Sabatia (Sabbatia) angularis (L.) Pursh. (Fam. Gentianaceae), an herb found in rich soil throughout the Eastern and Central United States and Ontario. The stems are much branched, distinctly 4-angled, and from 3 to 9 dm. high. The leaves are ovate, 5-nerved, having a heart-shaped clasping base. The flowers are rose-pink and on drying become pinkish-brown. The fruit is a 2-valved capsule, dark brown and covered with a resin. It is more or less used in popular medicine as a tonic and antiperiodic. It is a simple bitter of some activity, and may very well be substituted for the foreign remedies of its class. Rodney H. True found American centaury adulterated with Rhexia mariana, also known as deer grass or meadow beauty. (A. J. P., 1905, 213.) John F. Huneker found in sabbatia a small proportion of erythrocentaurin, C_{27}H_{24}O_{8}, previously discovered by Mehu, a French chemist, in Erythraea Centaurium Pers., of Europe.

In the Southeastern United States, the Sabbatia Elliottii Steud., or Quinineflower, and in the Southwestern United States the Sabbatia campestris Nutt. have been
employed like the S. angularis in the North. According to Merck the S. Elliottii contains a glucoside, sabbatin, as its active principle. Of the S. angularis and the S. campestris the whole plant is used, the dose being a drachm (3.9 Gm.), given in the form of fluid-extract or in decoction. Of the quinine flower, the root is employed; dose, of the fluid-extract, one fluidrachm (3.75 mils); in intermittent fever to be repeated at short intervals.

**Sabina.** U. S. VIII. Savin. SabinaeCacumina. Summitates (Herba) Sabinae. Savine Tops. Sabine, Fr. Cod. Sevenbaum. Sadebaums spitzen. Sevenkraut, G. Sabina, It., Sp.—"The tops of Juniperus Sabina Linne (Fam. Coniferae)." U. S. VIII. J uniperus Sabina is an evergreen shrub from three to fifteen feet high, with numerous erect, pliant branches. The leaves, which completely invest the younger brandies, are numerous, small, erect, firm, smooth, pointed, dark green, glandular in the middle, opposite, and imbricated in four rows. The fruit is a blackish-purple berry of an ovoid shape, and containing three seeds. The savin is a native of the south of Europe and the Levant, and grows wild in the neighborhood of the northwestern lakes of the United States.

The ends of the branches, and the leaves by which they are invested, are collected for medicinal use in the spring. When dried they are very much faded in color. They were officially described as "short, thin, subquadrangular branchlets bearing leaves which are rather dark green, in four rows, opposite, scale-like, ovate-lanceolate, more or less acute, appressed, imbricated, having on the back a shallow groove containing an oblong or roundish gland; odor peculiar, terebinthinate; taste disagreeable, resinous and bitter." U. S. They have a strong, heavy, disagreeable odor, and a bitter, acrid taste. These properties, which are less striking in the dried than in the recent leaves, are owing to a volatile oil. The leaves impart their virtues to alcohol and to water. C. H. Needles found in them volatile oil, gum, tannic or gallic acid, resin, chlorophyll, fixed oil, bitter extractive, lime, and salts of potassium. (A. J. P., xiii, 15.)

In America the tops of J uniperus virginiana L., or common red cedar, also commonly referred to as savin, are sometimes substituted in commerce for savin, which they resemble closely, but from which they can be distinguished by some of their leaves being obtuse or acutish and the fruits being smaller, purplish and containing fewer seeds. In Europe savin is said to be adulterated with the tops of J. phoenicea L., which contain volatile oil similar to that of J. communis. Such substitution is to be detected by the fact that in J. phoenicea the imbricated leaves occur in spirals of five, and the berries are large, shiny, and vary in color from yellow to reddish-yellow. In the mesophyll there occur large stone cells which are either single or in groups.

According to the more recent authorities, the proportion of volatile oil obtained from savin varies as much as from 1 to 2.5 per cent. The oil of savine (Oleum Sabinae, U. S. VIII) is "a colorless or yellowish liquid, having a peculiar terebinthinate odor, and a pungent, bitter, and cam-phoraceous taste. Specific gravity: 0.903 to 0.923 at 25° C. (77° F.). The Oil is dextrogyrate, the angle of rotation varying between +40° and +60° in a 100 Mm. tube, at a temperature of 25° C. (77° F.). Soluble in about one-half volume or more of 90 per cent. alcohol." U. S. According to Schimmel & Co. (Schim.
Rep., April, 1897), its specific gravity is from 0.91 to 0.925, optical rotation +45° to +60°, and it contains pinene, C\(_{10}\)H\(_{16}\), cadinene, C\(_{15}\)H\(_{24}\), and an alcohol, C\(_{10}\)H\(_{16}\)O, sabinol, which is present both in the free state and as acetic ester. With iodine it becomes heated, detonates, and gives off yellow and violet-red vapors. (Flaschoff.)

Savin is highly irritant, and is supposed to have a special direction to the uterus. It has been much used in amenorrhoea and atonic menorrhagia, and occasionally as a remedy for worms. Chapman strongly recommended it in chronic rheumatism, and it is employed in Germany, both internally and externally, in chronic gout. In overdoses it may produce dangerous gastro-intestinal inflammation, and it should therefore be used with caution. In no case should it be employed when much general or local excitement exists. In pregnancy it should always be given with great caution. As an external irritant, savin is useful, in the form of cerate, for maintaining a discharge from blistered surfaces; but as in this country savin ointment is often feeble, either from the age of the drug or from the substitution of red cedar, it has fallen into disrepute. In powder or infusion, savin is used in Europe as an application to warts, indolent or gangrenous ulcers, psora, and tinea capitis, and the expressed juice of the fresh leaves, diluted with water, is sometimes used for similar purposes. Powdered savin should not be used after it has lost the green color, characteristic of the fresh drug. The oil of savin is a powerful local irritant, producing, when persistently applied to the skin or the mucous membrane, violent inflammation. It has been much used for the purpose of producing criminal abortion, and in a number of such cases has caused death, the symptoms being violent abdominal pain, bloody vomiting and purging, diminution or suppression of urine, disordered respiration, unconsciousness, convulsions, and fatal collapse. Although Prochnow (A. I. P. T., 1911, xxii, p. 316) has found that small doses of savin have a slight stimulating effect upon the uterus it is manifest that any abortifacient results must be due to general disturbance of the health rather than to any local action. The fluidextract is rarely used internally but the stated dose is from five to ten minims (0.3-0.6 mil). The dose of the oil of savin is from one to three minims (0.06-0.2 mil).

**Fluidextract of Savin. Fluidextractum Sabinae U. S. VIII.**—The U. S. VIII gave the following directions for the preparation of the fluid-extract: "Savin, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]. Moisten the powder with two hundred and fifty mils [or 8 fluidounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the Savin is exhausted. Reserve the first nine hundred mils [or 30 fluid-ounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° G. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluidextract measure one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]." U. S. VIII

**Sagapenum.**—This gum-resin, formerly highly esteemed, but at present very rarely

**UNITED STATES DISPENSATORY - 1918 - Botanicals Only - S - Page 6**
The Southwest School of Botanical Medicine http://www.swsbm.com
met with even in Eastern commerce, is the concrete juice of a Persian plant, Ferula Persica Willd. (Fam. Umbelliferae), related to those that yield galbanum. It is in irregular masses, composed of agglutinated fragments, slightly translucent, of a brownish-yellow, olive, or reddish-yellow color externally, paler internally, brittle, of a consistence somewhat resembling that of wax, and often mixed with impurities, especially with seeds more or less entire. An inferior variety is soft, tough, and of uniform consistence. It has an alliaceous odor less disagreeable than that of asafetida, and a hot, nauseous, bitterish taste. It softens and becomes tenacious by the heat of the hand. The effect of time and exposure is to harden and render it darker. It is inflammable, burning with a white flame and much smoke, and leaving a light spongy charcoal. Pure alcohol and water dissolve it partially, diluted alcohol almost entirely. Distilled with water it affords a small quantity of volatile oil, and the water is strongly impregnated with its flavor. According to Tschirch (Harze und Harzbehalter, 229), it contains 23.3 per cent. of gum; 19.2 per cent. of essential oil, containing sulphur; and 57.5 per cent. of a resin which is free from sulphur and melts at 74° to 76° G. (165.2°-168.8° F.). The ether soluble resin of sagapenum can be separated by saponification into umbelliferone and sagaresitannol, \( C_{24}H_{27}O_4 \). This latter yields on oxidation oxypicric acid. The oil is pale yellow, very fluid, lighter than water, and of a disagreeable alliaceous odor. Sagapenum was formerly used in doses of from ten to thirty grains (0.65-2.0 Gm.) in amenorrhrea, hysteria, etc.; also externally in plasters as a discutient.

**Sage.** Salvia. U. S. VIII. Garden Sage. Meadow Sage. Save. Picked Sage. Sauge Officinale, Fr. Cod. Sauge Fr. Folia Salviae, P. G. Salbei, G.—"The dried leaves of Salvia officinalis Linne (Fam. Labiatae)." U. S. VIII. Salvia officinalis, or common gardensage, is a perennial plant, about two feet high, with a quadrangular, pubescent, branching, shrubby stem, furnished with opposite, petiolate, ovate-lanceolate, crenulate, wrinkled leaves, of a grayish-green color, sometimes tinged with red or purple. The flowers are blue, variegated with white and purple, and are disposed on long terminal spikes, in distant whorls, each composed of a few flowers, and provided with ovate, acute, deciduous bracts. The calyx is tubular and striated, with two lips, of which the upper has three acute teeth, the under two. The corolla is tubular, bilabiate, ringent, with the upper lip concave, and the lower divided into three rounded lobes, of which the middle is the largest. The filaments are supported upon short pedicels, to which they are affixed transversely at the middle.

Sage grows spontaneously in Southern Europe, and is cultivated abundantly in our gardens. There are several varieties, differing in the size and color of their flowers, but all possessing the same medicinal properties. The flowering period is in June, at which time the plant should be cut, and dried in a shady place. The leaves were officially described as "long and stoutly petiolate, the blade elliptical or ovate-oblong, 3 to 7 Cm. long, obtuse or subacute at the summit, rounded or subcordate at the base, finely crenulate, thick, grayish-green, very pubescent, especially on the under surface, conspicuously reticulate-veined; odor aromatic; taste aromatic, bitter, and somewhat astringent." U. S. VIII.

Both the leaves and the flowering summits have a strong, fragrant odor, and a warm,
bitterish, aromatic, somewhat astringent taste. They abound in a volatile oil, which may be obtained separate by distillation with water. Muir (J. Chem. S., 37, p. 678) found it to contain a terpene boiling at 156° C. (312.8° F.), another boiling at 171° C. (339.8° F.), thujone, C_{10}H_{16}O, a liquid boiling at from 197° to 203° C. (386.6°-397.4° F.), and ordinary camphor, C_{10}H_{16}O. In the fresh oil the first terpene predominates. On standing, the amount of thujone increases, and then the camphor. The oil from English leaves contains also a sesquiterpene, C_{15}H_{24}, of the boiling point 260° C. (500° F.). Wallach (Ann. Ch. Ph., 1889) states that the first portions contain pinene and cineol, but the greater portion consists of thujone, C_{10}H_{16}O (formerly called salviol). Ferrous sulphate strikes a black color with infusion of sage.

Sage unites slightly tonic, astringent, and aromatic properties. By the ancients it was highly esteemed; it is at present little used, except as a condiment, but has been given in dyspepsia, also for colliquative sweats. According to Cadeac and Meunier (Lyons Med., May, 1891), the volatile oil of sage is a violent epileptiform convulsant, resembling in its action the oil of absinthe, but less powerful.

The dose of the powdered leaves is from twenty to sixty grains (1.3-3.9 Gm.). Dose, of the infusion (one oz. in one pint of boiling water), two fluidounces (60 mils).

Although the Salvia officinalis was the only species of this genus which was recognized by the U. S. P. VIII, many other species share the feeble medicinal properties of sage. S. pratensis L., S. Æthiopis L., S. glutinosa L., and S. Sclarea L., or clarry, have been officially recognized in Europe, but are less agreeable than is S officinalis and are not much used; the leaves of S. Sclarea are said to be introduced into wine in order to impart to it a muscatel taste. The infusion of the Rocky Mountain sage, probably S. lanceolata Willd., is affirmed by A. Comstock (T. G., 1887, 660) to be valuable as a diaphoretic in malarial and rheumatic fevers, taken in the form of hot infusion, and when cold to be distinctly tonic and astringent. The dose of fluidextract is half a fluidrachm (1.8 mils).

The seeds of various sages contain enough farinaceous and mucilaginous material to make them useful as food. In the Western United States the ordinary sages of the plains are highly esteemed for fattening cattle, which eat their ripened tops freely (these sages must be distinguished from the so-called "sage brushes" of the West, which belong to the genus Artemisia). Chia, is the seeds of one or more species of salvia largely used in Mexico and Southern Arizona by the natives as food. It is affirmed that the variety known as Chia pinoli is yielded by S. columbaria (see Report U. S. Geogr. Surveys, 100th Merid., vol. vi, 48). S. Chia was described in the Farmacopea Mexicana as a new species, yielding chia, but Mariano Bascena affirms (La Naturaleza, 1881) that the common chia-yielding sage of Mexico is S. polystachya Ort., while Chia asul is yielded by S. patens Cav. Guibourt is probably in error in ascribing chia to S. hispanica L. The chia seeds are used not only when crushed as food and for the making of mucilaginous poultices, but also for the preparation of a mucilaginous drink, prepared by adding a teaspoonful of the seed to a tumblerful of cold water, allowing it to stand for half an hour, sweetening and flavoring to taste. Chia seeds are described as follows: "The seed is oblong-ovate, somewhat flatfish,
from 1 to 8 mm. in length, at one end there is a small, dark line, forming a slight projection, which is the microphyle of the seed, and this, when exposed to moisture, opens in a star-shaped or scalloped manner, emitting the growing embryo. The seed is smooth and glossy, and is surrounded by a transparent epithelium, swelling very largely when in water. The testa is darkish-gray, striated with dark brown lines, running diagonally, and dotted, forming a very beautiful variegated surface; when pressed or crushed under a spatula it bursts at the hilum, exposing the cotyledons and the oil cells, leaving an oily stain upon paper. Internally the testa is dark, grayish-brown, perfectly smooth, glossy, and devoid of the external variegations or striae. It contains the embryo, with the radical pointing towards the hilum, and a white, mucilaginous substance much resembling unrendered fat." (A. J. P., May, 1882, 227-229.) The European species, Salvia verticillata L., S. Verbenaca L., S. horminum L. and S. viridis L., all indigenous to Central or Southern Europe, are also noted for the mucilaginous character of their seeds, and have on this account been employed to remove foreign substances from the eye. S. Verbenaca is sparingly naturalized in waste places in the Middle and Southern States.

**Sago.** Sagou, Fr. Sago, G., It. Sagu, Sp.— Under this name the U. S. P. formerly recognized the starch obtained from the sago palms. Numerous trees, inhabiting the islands and coasts of the Indian Ocean, contain a farinaceous pith from which is extracted the starch in enormous quantities. In India and the East Indies it is obtained from several palms, viz.: Metroxylon Rumphii Mart. and M. laeve Mart."

The fruit of the Cycas circinalis, according to J. van Donjen, contains a poisonous glucoside, pakoeine (P. J., May, 1903.)

According to H. von Rosenberg (Proc. A. Ph. A., xxvii, 140), pith cells of these palms consist mostly of starch when the large leaves have fallen off and the flowers are just taking their place. At this time the tree is felled, and the trunk cut into billets six or seven feet long, which are split in order to facilitate the extraction of the pith. This is obtained in the state of a coarse powder, which is mixed with water in a trough having a sieve at the end. The water, loaded with farina, passes through the sieve, and is received in convenient vessels, where it is allowed to stand till the insoluble matter has subsided. It is then strained off, and the farina which is left may be dried into a kind of meal or molded into whatever shape may be desired. For the consumption of the natives it is usually formed into cakes of various sizes, which are dried, and extensively sold in the islands. The commercial "Pearl" sago is prepared by forming the meal into a paste with water, and rubbing it into grains. It is produced in the greatest abundance in the Moluccas, but of the finest quality on the eastern coast of Sumatra. The Chinese of Malacca refine it so as to give the grains a fine pearly luster. Malcolm states that it is also refined in large quantities at Singapore.

Pearl sago is that which is now generally used. It is in small grains, 'about the size of a pin head, hard, whitish, of a light brown color, in some instances translucent, inodorous, and with little taste. It may be rendered perfectly white by a solution of chlorinated lime. Common sago is in larger and browner grains, of more unequal size, of a duller aspect, and frequently mixed with more or less of a dirty looking powder.
An average palm about fifteen years old will yield from 300 to 400 kg of sago starch.

Sago meal is imported into England from the East Indies. It is in the form of a fine amylaceous powder, of a whitish color, with a yellowish or reddish tint, and of somewhat musty odor.

Sago starch grains are oval or ovate and often truncated. As the article of commerce is partially cooked the grains are more or less altered. The individual grains usually show a large central area around which are the narrow, distinct altered lamellae which are sometimes traversed by radiating fissures. The starch grains vary from 0.015 to 0.080 mm in length. When examined by polarized light the grains show a distinct cross. At one time sago flour showed considerable amounts of stone cells, hairs and calcium oxalate crystals, but as the product is more highly refined in recent years, these impurities have been eliminated.

Common sago is insoluble in cold water, but by long boiling unites with that liquid, becoming at first soft and transparent, and ultimately forming a gelatinous solution. Pearl sago is partially dissolved by cold water, probably owing to the heat used in its preparation. Chemically considered, it is a very pure natural starch, as the nitrogenous matter rarely amounts to more than one per cent, and the ash to one-half per cent., the remainder being starch and moisture.

Potato starch is sometimes prepared so as to resemble bleached pearl sago, for which it is sold. But, when examined under the microscope, it exhibits larger granules, which are also more regularly oval or ovate, smoother, less broken, and more distinctly marked with lamellae than are those of sago, and the hilum often cracks with two slightly diverging slits. Imitation sago is now made in the United States from various kinds of starch.

Sago is used exclusively as an easily digestible, non-irritating food. It is given in the liquid state, and in its preparation care should be taken to boil it long in water, and stir it diligently, in order that the grains may be thoroughly dissolved. Should any portion remain undissolved, it should be separated by straining. A tablespoon-ful to the pint of water is usually sufficient.

**Salep.** Tubera Salep, P. G. Salep, Fr., G.—This name is given to the dried tubers of numerous species of the genus Orchis, and other allied genera of the Orchidaceae. At present the salep of European commerce is prepared chiefly in the Levant, but to some extent in Germany and other parts of Europe. The German salep is said to be more translucent than the Levant.

Salep is in small, oval, irregular, ovoid or oblong tubers, rarely palmate, hard, horny, semi-transparent, of a yellowish color, a feeble odor, and a mild mucilaginous taste. It is sometimes kept in the state of powder. In composition and relation to water it is closely analogous to tragacanth, consisting of a substance insoluble but swelling up in cold water (bassorin), of another in much smaller proportion, soluble in cold water, and
of minute quantities of saline matters. It also occasionally contains a little starch. It is highly nutritive, and may be employed for the same purposes as tapioca, sago, etc. Its medieval and Oriental reputation as an aphrodisiac is unfounded. On account of its hardness, salep, in its ordinary state, is of difficult pulverization; but the difficulty is removed by macerating it in cold water until it becomes soft, and then rapidly drying it. Royal salep, said to be much used as a food in Afghanistan, has been identified by J. E. T. Aitchison as the product of Allium Madæanii Baker. (Fam. Liliaceæ) (P. J., Sept., 1889.)

E. Reeb stated that salep possesses, like diastase, the property of coagulating milk, which it attributes to erythrodextrin, but finds that this body, in distinction from diastase, will retain its coagulating property even after heating it to 100° C. (212° F.). (Journ. der Pharm. v. Elsass-Loth-lingen, 1912, No. 8.).

**Salix.** U. S. 1880.—Willow-bark. Weidewinde, G. Ecorce de Saule, Fr. Most of the species of the large genus Salix are possessed of similar medicinal properties. (For elaborate study of various willow barks see Wellcome Chemical Research Laboratory Report, No. 39.) S. fragilis L. or Crack Willow, which has been introduced into this country from Europe, is said by Sir James Smith to be the most valuable species. S. purpurea L., a European species, is stated by Lindley to be the most bitter, and S. pentandra L. is preferred by Nees von Esenbeck. Many native species are in all probability equally active with the foreign.

Salix alba L., the species formerly recognized by the U. S. Pharmacopoeia, is the common European or white willow. It has sparingly escaped from cultivation, growing from New Brunswick and Ontario southward to Pennsylvania. It is a large tree with a rough grayish bark, the twigs being brittle at the base, and in this respect somewhat resembling S. fragilis. The leaves are pubescent on both surfaces and finely serrulate. It hybridizes with other species of Salix. It flowers in April and May, and the bark is easily separable throughout the summer. That obtained from the branches rolls up when dried into the form of a quill, from 0.5 to 1 mm. thick, has a brown, more or less finely warty periderm, is flexible, fibrous, and of difficult pulverization. The inner surface is brownish-white, and smooth, separating in thin layers. Willow bark has a feebly aromatic odor and a peculiar bitter astringent taste. It yields its active properties to water, with which it forms a reddish-brown decoction. Pelletier and Caventou found among its ingredients, tannin, resin, a bitter yellow coloring matter, a green fatty matter, gum, wax, lignin, and an organic acid combined with magnesia. The proportion of tannin is so considerable that the bark has been used for tanning leather. The characteristic constituent of all species of willow, however, is salicin. Robert W. Beck (A. J. P., 1891, 581) has determined the relative percentages of salicin and tannin as follows:

<table>
<thead>
<tr>
<th>Salicin.</th>
<th>Tannin.</th>

</tbody>
</table>

Jowett and Potter made an examination of thirty-three samples of willow and poplar,
and found in but one (Salix discolor Muhl.) the related glucoside salinigrin, which Jowett had previously discovered in an unknown sample of willow bark. This compound has the formula $C_{13}H_{16}O_7$, and on hydrolysis yields glucose and meta-hydroxyben-zaldehyde. (Welcome Chem. Research Laboratory Report, No. 28.) The bark of the willow is feebly tonic, but it is at present never employed in regular medicine.

Salix nigra Marsh. Black Willow.—This is a tree with a dark brown bark, and is noted for its rapid distribution along streams into which its brittle twigs fall, which strike root, forming new plants. It hybridizes with Salix alba. The younger Michaux states that this is a strong bitter, and according to various eclectic practitioners its green aments or floral buds are a very active sexual depressant, useful in spermatorrhæa, in all forms of sexual excitement, and in the nervous disturbances of the menstrual period. From twenty to thirty minims (1.3-1.8 mils) of the fluidextract are to be given four times a day.

The Pussy Willow (Salix discolor Muhl.) is a shrub growing in swamps and on moist hillsides of the northern United States. It is well known because of its silky downy catkins which appear in early spring before the leaves.

Samandera Bark.—This is the inner baric of Samandera indica Gartn., a tree belonging to the family of Simarubaceae, growing in Ceylon and the East Indies. It is intensely bitter, and probably contains quassin. For further particulars, see P. J., 1872, 541.

Sandal Wood. Santalum Album, White Sandal Wood.—" The heart wood of Santalum, album, Linne (Fam. Santalaceae)." N. F. IV.

White sandal wood was introduced into the N. F. IV to serve as an ingredient in tincture of saw palmetto and santal of the National Formulary. It is described as follows:

"In billets, pieces or chips of varying shapes and sizes, heavy, hard but splitting easily, color light yellow; transverse sections yellow to light reddish-brown, with alternating light and dark concentric zones nearly equal in diameter, with numerous pores and traversed by many very narrow medullary rays.

"When examined under the microscope, sections show the medullary rays from two to four rows wide, the cells thick-walled and radially marked; the wood wedges consisting largely of wood fibers with pointed ends, large parenchyma and thick-walled secretion vessels and cells containing single crystals of calcium oxalate; the oil in globules adhering to the walls of the ducts and parenchyma cells and especially rich in the medullary cells. Odor characteristic, aromatic, persistent; taste peculiar, strongly aromatic.

"Sandal Wood yields not more than 8 per cent. of ash." N. F. IV. For further information on sandalwood see Oleum Santali. It owes its therapeutic virtue entirely
to the volatile oil it contains.

**Sandarac.** Sandaraca. Gum Juniper. Sandaraque, Fr. Sandarak, G.—A resinous substance obtained from the Callitris quadrivalvis Vent. (Thuja articulata, Vahl), an evergreen tree (fam. Pinaceae) growing in the mountains of northwestern Africa.

Sandarac is a resinous exudation which occurs as a natural secretion in schizolysigenous reservoirs in the bark. It exudes naturally, but an increase in yield is obtained by cutting through the bark. The exuding resin hardens and is collected. It is sent by the natives to Mogador, Casablanca and Nazagan. From these points it is shipped to London, Trieste, Marseilles and Hamburg. It occurs in small, irregular, roundish oblong grains or tears, of a pale yellow color, sometimes inclining to brown, more or less transparent, dry and brittle, breaking into powder under the teeth, of a faint, agreeable odor increased by warmth, and of a resinous, slightly acrid taste. It melts with heat, diffusing a strong balsamic odor, and easily inflames. It is almost entirely soluble in ordinary alcohol, and entirely so in that liquid when anhydrous, and in ether. Heated oil of turpentine also dissolves the greater part of it, but very slowly. According to Unverdorben, it consists of three resins, varying in their relations to alcohol, ether, and oil of turpentine. The sandaracin of Geise, which remains after sandarac has been exposed to the action of ordinary alcohol, is a mixture of two of these resins. Tschirch (Harze und Harzbehalter, p. 276) has isolated and described an acid, sandaracolic acid, $C_{44}H_{64}O_4(OH)COOH$, making up 85 per cent. of the natural resin and callitrolic acid, $C_{64}H_{82}O_5(OH)COOH$, of which 10 per cent, is present. In Australia and Tasmania Callitris trees grow in vast numbers, and produce a sandarac which is almost colorless, having highly refractive power, and a pleasant aromatic odor, becoming dark by age, and sometimes assuming a superficial mealiness. This Australian sandarac softens easily, but does not melt in boiling water, is gritty to the touch, and can scarcely be distinguished from the African drug. (P. J., Jan., 1890.) For an elaborate description of Australian sandarach, see also A. J. P., 1896, 215. Sandarach was formerly given internally, and entered into the composition of various ointments and plasters. At present it is used chiefly as a varnish and as incense; its powder, termed pounce, is rubbed upon paper to prevent ink from spreading after letters have been scratched out. It is sometimes adulterated with mastic, rosin and dammar. A false sandarach has been described by R. Haneke. It resembled the real article, being lemon-yellow in color, transparent, and the tears elongated and rounded at the tips. When chewed it broke into fine powder and stuck to the teeth, while it softened on the water bath and flowed together into a resinous mass. Examination showed it to consist largely of colophony. (O. Z., liv.)

**SANGUINARIA.** U. S.

**SANGUINARIA** Sanguin. [Bloodroot]

The dried rhizome and roots of Sanguinaria canadensis Linne (Fam. Papaveraceae). U. S.
puccoon, Pauson, Snakebite, Sweet-slumber, Tumeric, Red Puccoon, Tetterwort, Red
Indian Paint; Sanguinaire, Fr.; Blut wurzel, G;

Bloodroot (Sanguinaria canadensis), or, as it is sometimes called, 
puccoon, is an herbaceous or perennial plant. The rhizome is horizontal, 
abrupt, often contorted, about as thick as the finger, two or three inches 
long, fleshy, of a reddish-brown color on the outside, and brighter red 
within. It is furnished with numerous slender roots, and makes offsets 
from the sides, which succeed the old plant. From the end of the rhizome 
arise the scape and leaf-stalks, surrounded by the large sheaths of the 
bud. These spring up together, the folded leaf enveloping the flower-
bud, and rolling back as the latter expands. The leaf, which stands 
upon a long channelled petiole, is reniform, somewhat heart-shaped, 
deeply lobed, smooth, yellowish green on the upper surface, paler or 
glaucous on the under, and strongly marked by orange-colored veins. 
The scape is erect, round, and smooth, rising from a few inches to a foot, 
and terminating in a single flower. The calyx is two-leaved and 
deciduous. The petals, varying from seven to fourteen, but usually 
about eight in number, are spreading, ovate, obtuse, concave, mostly 
white, but sometimes slightly tinged with rose or purple. The stamens 
are numerous, with yellow filaments shorter than the corolla, and 
orange oblong anthers. The ovary is oblong and compressed, with a 
sessile, persistent stigma. The capsule is oblong, acute at both ends, one-
celled, two-valved, and contains numerous oval, reddish-brown seeds. 
The whole plant is pervaded by an orange-colored sap, which flows from 
every part when broken, but is of the deepest color in the rhizome. The 
bloodroot is one of the earliest and most beautiful spring flowers of the 
Northern United States, growing abundantly in loose, rich soils and 
shady situations. After the fall of the flower the leaves continue to grow, 
and by the middle of summer have become so large as to give the plant 
an entirely different aspect. Except the seeds, all parts of the plant are 
active.

Properties.—The following is the official description of sanguinaria: " 
Of horizontal growth, occasionally branching, more or less cylindrical, 
somewhat flattened, from 2 to 7 cm. in length, and from 5 to 15 mm. in 
diameter; externally dark brown, slightly annulate, with a few stem-
scars on the upper surface and numerous more or less broken filiform 
roots and root-scars on the lower surface; fracture short and somewhat 
waxy, brownish-red, occasionally yellowish-white, with numerous, 
small, circular, yellowish fibro-vascular bundles within about 1 mm. of
the epidermis, pith very large; odor slight; taste persistently acrid and bitter. Under the microscope, transverse sections of the rhizome of Sanguinaria show an outer layer of a single row of thin-walled epidermal cells; a cortex of from 10 to 15 rows of thin-walled parenchyma cells containing numerous starch grains, or a small amount of fixed oil; a zone of cambium, most of which is inter-fascicular; a narrow circular zone of small collateral fibro-vascular bundles, separated from each other by parenchyma; pith large, consisting of starch-bearing parenchyma cells; latex cells containing a red or orange colored secretion, either isolated or connected into irregular chains and distributed among the parenchymatous cells of the middle bark and pith; sections treated with glycerin show in the secretion cells, after twenty-four hours, spheroidal aggregates of crystals which strongly polarize light. The powder is brownish-red, sternutatory; when examined under the microscope it exhibits numerous starch grains, from 0.003 to 0.02 mm. in diameter, being mostly single, seldom 2- to 3-compound, the individual grains nearly spherical or ovoid, sometimes more or less plano-convex, somewhat resembling those of wheat starch in outline but polarizing light more strongly: numerous fragments of short latex cells with reddish-brown resinous masses; tracheal fragments few, having numerous slit-like pores. U. S.

For an interesting microscopical description of the rhizome by E. S. Bastin, see Pharm., 1885, p. 201. Sanguinaria has a faint odor, and a bitterish very acrid taste, the pungency of which remains long in the mouth and fauces. Lloyd states that sanguinaria is both a contamination and an adulterant of hydrastis. (Pharm. Rev., 1905, xxiii, p. 332.) It yields its virtues to water and alcohol.

Dana of New York, obtained from it an alkaloid, denominated by him sanguinarine. (Ann. Lyc. of Nat. Hist., New lark, ii, 250.) It may also be conveniently procured by a process similar to that employed by Probst for obtaining chelerythrine from celandine. (Chem. Gaz., i, 145.)

G. Konig (A. J. P., 1891, p. 457) found chelerythrine, which is present in greatest quantity, sanguinarine, β- and γ-homochelidonine, and protopine. Chelerythrine crystallizes with a molecule of alcohol which is not separated at 150° C. (302° F.). Its formula is C_{21}H_{17}O_{4}N, and it is identical with the alkaloid extracted from Chelidonium majus. The salts are lemon-yellow. Sanguinarine has the formula C_{20}H_{15}O_{4}N (Schmidt,
C₉₁H₁₅O₄N), and is very similar to chelerythrine in its properties. It crystallizes with one-half molecule of H₂O, and melts at 211° C. (411.8° F.). Its salts are red. The base named γ-homochelidonine is probably identical with that separated by Selle from Chelidonium majus, and its formula is C₂₂H₂₁O₅N. The fourth alkaloid, protopine, has been prepared from Chelidonium majus, from Sanguinaria canadensis, and from opium, all three of the specimens being identical. Its formula is C₂₀H₁₇O₅N, and it melts at 204° C. (399.2° F.). The virtues of the root are said to be rapidly deteriorated by time. Thos M. Newbold extracted from sanguinaria a non-volatile liquid acid (sanguinarinic acid) (A. J. P., 1866, p. 496), which L. C. Hopp has shown to be a solution of impure citric and malic acids. Schlotterbeck (Ph. Rev., 1900, 358) examined sanguinarine nitrate of commerce and found it to consist mainly of chelerythrine, with some sanguinarine and traces of protopine and homo-chelidonine; he believes that chelerythrine should be called sanguinarine. For methods of assay of sanguinaria see A. J. P., 1896, 305; M. K., 1900, 451; Proc. A. Ph. A., 1903, 284; A. J. P., 1913, p. 395.

Uses.—Sanguinaria is an active local irritant, in large doses producing nausea and vomiting. When snuffed up the nostrils it excites much irritation and sneezing. According to the investigations of Meyer (A. E. P. P., 1892, xxix, p. 397) sanguinarine is an active stimulant to the spinal cord producing in frogs strychnine-like convulsions followed, after very large doses, by complete paralysis. It also stimulates the respiratory center, increasing both the depth and rate of the breathing. By virtue of a stimulant action upon the vasomotor center it causes a rise in blood pressure which, with toxic doses, is followed by a fall in the blood pressure, due to weakening of the heart action. It also excites the flow of saliva and increases intestinal peristalsis. In toxic doses it acts as a poison to the voluntary muscles. When locally applied it causes at first pain, followed by a local anesthesia. Chelerythrine, although present in larger amounts in sanguinaria, is a much less poisonous alkaloid than sanguinarine and it is probable that it plays a role of relatively small importance in the action of the whole drug. It differs widely in its action from sanguinarine, acting chiefly as a paralyzant of the nerve centers, including the spinal cord, the respiratory and the vasomotor centers. It is also a poison to the voluntary muscles. It is locally irritant but has neither anesthetic nor narcotic properties. Beta-homochelidonine, the third most important alkaloid, has a feeble narcotic effect, produces cerebral convulsions, but does not increase reflex activity. It is an active
local anesthetic without the irritant effect of sanguinarine.

Sanguinaria is used chiefly as an expectorant, especially in the treatment of subacute or chronic bronchitis. Whether it possesses any beneficial action for this purpose except that which may be attributed to its nauseating effect, seems doubtful. It has also been recommended by Graber (J. A. M. A., 1907, xlix, p. 705) as a local application in chronic eczema, especially when secondary to varicose ulcers.

In toxic quantities sanguinaria produces burning in the epigastrium with vomiting, tormenting thirst, faintness, vertigo, dimness of vision, and alarming prostration. Twenty grains (1.3 Gm.) are said to usually act as a violent emetic. (For fatal cases, see Am. J. M. S., n.s., ii, p. 506.)

The alkaloid sanguinarine has been used in doses of from one-twelfth to one-sixth of a grain (0.005-0.01 Gm.). Sanguinaria is rarely given in substance.

Dose, U. S. P., two grains (0.13 Gm.).

**Sanicula.** Sanicula marylandica L. Sanicale Fr. Sanikel, G.—The root of this indigenous umbellifer is popularly known in some parts of the country by the name of black snake-root. It is fibrous and of an aromatic taste, and, according to C. I. Houck (A. J. P., vol. xiv, 463), contains a volatile oil and a resin. It has been used in intermittent fever, and also in chorea by Zabriskie. Dose of powder to children eight years old, half a drachm (2.0 Gm.) three times a day. (Am. J. M. S., n. s., xii, 374.)

**SANTALUM RUBRUM. U. S. (Br.)**

**RED SAUNDERS Santal. Rub.**

"The heart-wood of Pterocarpus santalinus Linne filius (Fam. Leguminosae)." U. S. "Red Sanders Wood is the heart-wood of Pterocarpus santalinus, Linn. f." Br.

**Pterocarpi Lignum,** Br., Red Sanders Wood; Lignum Santalimum Rubrum, Rasura Santalum Ligni; Red Sandal Wood; Red Santal Wood; Ruby Wood; Santal rouge, Fr.
Pterocarpus santalinus is a large tree, with alternate branches, and petiolate ternate leaves, each leaflet being ovate, blunt, somewhat notched at the apex, entire, veined, smooth on the upper surface, and hoary beneath. The flowers are yellow in axillary spikes, and have a papilionaceous corolla, of which the vexillum is obcordate, erect, somewhat reflexed at the sides, toothed and waved, the alee spreading with their edges apparently toothed, and the carina oblong, short, and somewhat inflated. The tree is a native of India, attaining the highest perfection in mountainous districts, and inhabiting especially the mountains of Coromandel and Ceylon. It is cultivated also in Southern India and in the Philippine Islands. Its wood is the official red saunders, though there is reason to believe that the products of other trees are also sold by the same name.

Properties.—The wood comes in heavy, irregular, roundish or angular billets of various size and thickness, externally brown from exposure, internally of a deep blood-red color, on transverse section variegated with zones of a lighter red. The structure is heavy, compact, and fibrous. In the pharmacies red saunders is usually kept in the shape of small chips, or raspings, or coarse powder, of a deep reddish-brown color, slightly astringent in taste, and when rubbed of a faint peculiar odor. It has little odor or taste. Red saunders is officially described as follows: "Usually in the form of a coarse powder, of a brownish-red or dark saffron color and nearly odorless and tasteless. Under the microscope, Red Saunders shows numerous wood-fibers which are mostly irregular in outline, with sharply pointed and occasionally forked ends, the individual fibers from 0.3 to 0.75 mm. in length, the walls being very thick, porous, yellowish, unevenly thickened, and strongly lignified, and the lumina being filled with a fine, granular, protoplasmic content; occasional trachea) with simple or bordered pores and filled with light lemon-yellow, resinous masses; occasionally fragments showing medullary rays in narrow elliptical groups 1 cell wide and 3 to 6 cells deep; also occasional groups of crystal fibers with calcium oxalate in the form of monoclinic prisms, from 0.01 to 0.02 mm. in diameter. Mounts in hydrated chloral T.S. are of a deep, rich red color. Add 0.5 Gm. of Red Saunders to 10 mils of alcohol; the solution becomes distinctly red. Add 0.5 Gm. of Red Saunders to 10 mils of ether, the solution assumes an orange-yellow color and when held in a bright light shows a distinct, greenish fluorescence. Add 0.005 Gm. of Red Saunders to 10 mils of
water; the liquid remains clear and colorless. Red Saunders yields not more than 3 per cent. of ash." U. S.

"Imported in irregular logs or billets, freed from the pale sapwood; reddish-brown or blackish-brown externally, deep blood-red internally; hard, but easily split longitudinally. In transverse section, narrow, closely approximated, reddish medullary rays traversing a nearly black wood with scattered, large, isolated vessels. Coloring matter readily soluble in alcohol (90 per cent.), but almost insoluble in water. Odor of the warmed Wood faintly aromatic; taste very slightly astringent." Br.

It imparts a red color to alcohol, ether, and alkaline solutions, but not to water, and a test is thus afforded by which it may be distinguished from some other coloring woods. The alcoholic tincture produces a deep violet precipitate with ferrous sulphate, a scarlet with mercuric chloride, and a violet with the soluble salts of lead. The coloring principle, which was separated by Pelletier and called by him santalin, is of a resinous character, scarcely soluble in cold water, more so in boiling water, very soluble in alcohol, ether, acetic acid, and alkaline solutions, but slightly in the fixed and volatile oils, with the exception of those of lavender and rosemary, which readily dissolve it. It is precipitated when acids are added to the infusion of the wood, prepared with an alkaline solution. Weyermann and Haeffely have found it to possess acid properties, and give it the formula \(C_{15}H_{14}O_5\). (Ann. Ch. Ph., 74, p. 226.) Weidel (Wien. Akad. Ber., lx, p. 388), by extracting the red saunders with potassium hydroxide, precipitating with hydrochloric acid, and again extracting from the purified precipitate with ether, obtained a colorless crystalline principle, which he calls santal, \(C_8H_6O_3 + \frac{1}{2}H_2O\).

Cazeneuve and Hugonneng (C. R. A. S; 104, 1722, 1725) have described two crystalline principles which they have extracted from red saunders, pterocarpin, \(C_{20}H_{16}O_6\) and homo-pterocarpin, \(C_{24}H_{24}O_6\), of which the former fuses at 152° C. (305.6° F.) and the latter at from 82° to 86° C. (179.6°-186.8° F.). The wood has no medicinal virtues, and is employed solely for the purpose of imparting color.

**Santolina.**—A composite plant, commonly called Holy herb, Heiligenpflanssen, Cypress herb, Cypressenkraut (Santolina Chamaeyparissus L.), is stated to have long been used popularly against the round worm in Scotland. It has been analyzed by T.
Maben (P. J., xvi, 301), who finds in it a volatile oil and a considerable percentage of resin, with a bitter principle, which he believes to be an alkaloid and the active principle of the drug. The decoction of the plant may be made by boiling half an ounce in a pint of water for half an hour, straining and making up to a pint. It is given in doses of five fluidounces (150 mils) to adults and half that quantity to children, repeated for four mornings, and then followed by a brisk cathartic.

**Santonica.** U. S. VIII. Levant Wormseed. Turkestan, Aleppo, Alexandria, or European Wormseed. Santonic Semen. Semen cinae. Flores Artemisiae. Semen Sanctum. Semen contra Dalep. Semecinium ou Barbotine, Fr. Cod. Flores Cinae, P. G. Wurmsamen, Zitwersamen, G. Santonico, It., Sp.—The dried unexpanded flowers of the Artemisia Cina Berg. (A. pauciflora (Ledebour) Weber) (Fam. Compositae). This plant is a small, semi-shrubby perennial, from whose oblique, knotted rootstalks arise numerous leafy shoots and flowering stems. The glabrous and woody stems bear on their many branches numerous small (one inch long) bi- to multi-pinnatifid leaves, while the leaves of the flowering stems are very minute, the upper ones simple. The flower heads are small, numerous, one-tenth of an inch long, with from twelve to eighteen involucral scales, and from three to five flowers; The plant varies very greatly, and several species have been made out of its varieties. The plant grows in Persia and Turkestan and the flower-buds are collected in July and August. The Levant wormseed was officially described as "heads 2 to 4 Mm. long, oblong-ovoid, slightly flattened, obtuse, consisting of an involucre of about 12 to 18 closely imbricated, glandular scales with broad midribs, enclosing 4 to 5 rudimentary florets. Santonica has the appearance of a granular, yellowish-green or greenish-brown, somewhat glossy powder; odor strong, peculiar, somewhat camphoraceous; taste aromatic and bitter." U. S. VIII. Astolfi (Ph. Ztg., 1893, 333) gives the following test for recognizing adulteration of santonica. 1 Gm. of the suspected drug is finely pulverized and then agitated with 10 mils of absolute alcohol; the whole is heated to boiling, filtered, a piece of potassium hydroxide is added to the filtrate, which is then heated. If the drug is pure, the liquid will acquire a pronounced red color; if falsified, the color will be yellow; and if no santonica be present, the liquid will be colored but faintly, if at all.

Most of the wormseed of commerce comes from the steppes of the northern portion of Turkestan to the great Nizhni-Novgorod fair, whence it finds its way to Moscow and Western Europe. The export from this region has largely declined, because of the erection in Orenburg and Tschimkent of factories for the manufacture of santonin, which is now sent from there into commerce. The yearly consumption of santonin throughout the world is estimated at about twenty-five tons, and of this at least twelve tons are produced in the factories just spoken of. The santonin in the plants is said to reach its maximum proportion in July and August, and to disappear immediately after the flowering.

Attention was called by C. H. LaWall (J. A. Ph. A., 1813, p. 596) to a variety of santonica that has appeared upon the market, which seems to be devoid of santonin or to contain not more than traces. He proposes a simple test which may be applied directly to the drug as a preliminary procedure and thus avoid the necessity of going
through the long assay process if the sample is valueless: Place 5 Gm. of santonica (whole or ground) in a test tube, add 5 mils of spirit of nitrous ether and boil gently. No more color should be developed or not more than a slight greenish yellow color due to the solvent action of the spirit on the resins of the drug. Now add 10 drops of alcoholic solution of potassium hydroxide. In an active drug a rose red color is developed in direct proportion to the amount of santonin present.

Wormseed contains a volatile oil, but it owes its efficiency to santonin. According to Merck, the mother liquors in the manufacture of santonin from the seeds of Artemisia maritima yield a crystalline principle, C_{15}H_{18}O_{4}, which has been named artemisin. It is freed from santonin by recrystallization from chloroform. It melts at 200° C. (392° F.), gradually turns yellow in the air, and is more readily soluble in water and in dilute alcohol than is santonin. It gives a fugitive carmine red color when heated with aqueous or alcoholic sodium hydroxide, and is apparently a hydroxy-santonin. (P. J., 1896, 484.) Dose, of artemisin, one-six hundred and forty of a grain (0.0001 Gm.).

The oil of santonica, according to Wallach (Ann. Ch. Ph., ccxxv, 314; and ccxxvii, 277), consists chiefly of cineol, C_{10}H_{18}O, which is isomeric with borneol, and seems to be identical with the cajuputol of cajuput oil, together with some dipentene. Wormseed is rarely used in this country in substance. It is stated that artemisin is a powerful stimulant to the mucous membrane and muscles of the alimentary canal and that its addition to the simple bitters greatly increases their activity. Dose, of santonica, ten to thirty grains (0.65-2.0 Gm.). For a method of valuing santonica, by Dragendorff, see Proc. A. Ph. A., xxvi, 229. For Ehling's Process for Valuing Santonica, see U. S. D., 19th ed., page. 1085.

**Sapindus**.—Various tropical plants belonging to this genus of the Sapindaceae contain saponin, and are largely used for cleaning purposes. The berries are commonly used, being called "Soap berries" Thus, in India are employed the pulp of the fruit of Sapindus Mukorossi Gaertn., the capsules of S. trifoliatus L., and in South America the oil and seed vessels of S. Saponaria L. (P. J., 1871. 585.) For the properties of saponin, see Saponaria officinalis, below. The fruits of S. rarak DC., according to O. May, contain saponin and a fixed oil. (A. Pharm., 1906, 25.)

**Sapium.** Sapium sebiferum (L.) Roxb. Chinese Tallow Tree, Tankawang Fat.—This is a species of the family Euphorbiaceae, cultivated in the Chinese provinces of Kiangse, Kiang-sou, and Chih-kiang for the sake of the fixed oil which covers the seeds and is extracted by methods detailed in A. J. P., 1872, 264. (See P. J., June, 1872.) The "tallow" occurs in hard, brittle, opaque, white masses of about eighty pounds' weight. It consists chiefly of palmitin with a little stearin and is said to be nearly pure stearin. The oil is largely used for lighting purposes. The remnants of the nut are employed as fuel and as manure. (See also P. J., 1883, 401, and 1887, 901.)

**Saponaria.** Saponaria officinalis L. Soapwort. Bouncing Bet. Fuller's Herb. Sheep Weed. Saponaire. Savonniere, Fr. Seifenwurzel, G. (Fam. Caryophyllaceae.)—A perennial, herbaceous plant, having large rose-colored flowers, which are commonly double. It is common along roadsides and waste places in the United States. The rhizome and roots are employed. The rhizomes are cylindrical, from 5 to 12 cm. long.
and 5 to 12 mm. thick, outer surface being reddish-brown. The fracture is short and even. They are inodorous, and of a taste at first bitterish and slightly sweetish, afterwards somewhat pungent, continuing long, and leaving a slight sense of numbness on the tongue. They impart to water the property of forming a lather when agitated, like a solution of soap, whence the name of the plant was derived. This property, as well as the medicinal virtues of the plant, resides in saponin, C_{32}H_{54}O_{18}. This principle constitutes, according to Bucholz, its discoverer, 34 per cent. of the dried root which contains also a considerable quantity of gum and a little bassorin, resin, and altered extractive, besides lignin and water. For description of saponin, see Quillaja. Saponin has been found in many other plants, among them some species of Silene, Dianthus, and Lychnis, in Vaccariavulgaris Host., and in Agrostemma Githago L., all belonging to the fam. Caryophyllaceae (J. P. C., 3e ser., x, 339; also P. J., 1871, 585; Australian Journ. Pharm., 1887.) Serious poisonings by the mixture of the seeds of Agrostemma Githago with wheat have been reported. (D. M. W., 1903.) According to Augustine Henry, there are at least eleven species of trees whose products are used in China for washing purposes and probably contain saponin, which is also found to the extent of 10 per cent. in the seeds of the Chinese tea oil tree, and is left in such large proportion in the refuse after the extraction of the oil that the "tea seed cake" is used as a fish poison. (Am. Drug., 1896.) In California the Indian Soap Root, Chlorogallum pomeridianum (Ker.) Kunth., is much used for washing clothes; it probably contains saponin. The fruits of various species of Sapindus are also rich in saponin and are used as detergents accordingly.

SAPPAN. Br.

SAPPAN

"Sappan is the heart-wood of Caesalpinia Sappan, Linn." Br.

Sappan wood, Sampfen wood, Bakam, Tairi, Patang, Teri, Verzino, It.; False Sandalwood, Indian Redwood, Samfen.

Caesalpinia Sappan is a small thorny tree indigenous to the Eastern and Western Asiatic Peninsulas, Pegu and Tenasserim, and is also cultivated in Central India. The leaves are large and abruptly bipinnate; the flowers being yellow and in axillary racemes; and the pods are oblong, flattened, nearly smooth and dehiscent or indehiscent. The wood yields a valuable red dye which is also prepared from the pods and from the bark. The commercial samples vary considerably. There are two commercial varieties, viz., (1) Singapore or Dhansari, and (2) Ceylon sappan, the former being preferred. According to Dymock, the freshly cut wood is whitish, but becomes red on exposure to the air. He also states that the addition of alkalies increases the yield of coloring matter, turning it a reddish-violet. According to the British Pharmacopoeia, it
occurs in "hard, heavy pieces of variable size, or in orange-red chips. In transverse section, well-marked concentric rings, numerous narrow medullary rays, and large vessels. No odor; taste slightly astringent. It communicates to alcohol (90 per cent.) and to water a red color, which becomes carmine-red, but not purple, upon the addition of solution of sodium hydroxide (distinction from Logwood)." Br.

According to the investigations of Bolley, sappan wood contains brasilin, C$_{16}$H$_{14}$O$_{5}$, identical with that of Brazil wood.

Sappan, or samfen, as it is sometimes called, has been an article of commerce for at least five hundred years. It is employed in the arts as a substitute for logwood in dyeing. Medicinally it is used as an astringent in the treatment of diarrhea. It may be given in the form of a decoction.

Dose, from fifteen to forty-five grains (1-3 Gm.).

**Off. Prep.**—Decoctum Sappan, Br.

**Sarcocolla.** Sarcocolle, Fr. Fleischleimgummi, Fischleimgummi, G.—A peculiar vegetable product, exuding spontaneously from Penoea Sarcocolla L. (now P. fulcata L.), and P. mucronata L. (Fam. Peneaeææ), small shrubs, growing at the Cape of Good Hope, in Ethiopia, Arabia, etc. Sarcocolla occurs in the form of small, roundish, irregular grains, somewhat spongy, sometimes agglutinated in masses, at times admixed with fine hairs, friable, opaque or semi-transparent, of a yellowish or brownish-red color, inodorous unless heated, when they have an agreeable odor, and of a peculiar, bitter, sweetish, and acrid taste. Sarcocolla, according to Pelletier, consists of 65.3 per cent. of a peculiar substance, considered by Thomson as holding an intermediate place between gum and sugar, and called sarcocollin, C$_{13}$H$_{23}$O$_{6}$, 4.6 of gum, 3.3 of a gelatinous matter having some analogy with bassorin, and 26.8 of lignin, etc. It is said to be purgative, but at the same time to produce serious inconvenience by its acrid properties. The Arabian physicians used it internally, and by the ancients it was employed as an external application to wounds and ulcers, under the idea that it possessed the property of agglutinating the flesh, whence its name.

**Sarracenia.** Side-saddlePlant. FlyTrap. Pitcher Plant. Huntsman's Cup. Water Cup. Sarracenie, Fr., G.—According to E. P. Porcher, the roots of Sarracenia flava L., and S. variolaris Michx., have long been used in the Southern United States in dyspepsia, and are tonic, laxative, and diuretic. Sheppard found them to contain lignin, coloring matter, resin, an acid salt of lime, and probably an alkaloid. Stan. Martin asserts that he has found in the root—(1) an alkaloid which he proposes to name sarracenine; (2) a resin; (3) a yellow coloring principle (probably identical with Schmidt's sarracenic acid); (4) extractive; (5) substances which constitute the framework of plants. Sarracenine is white, soluble in alcohol and ether, combines with acids to form salts,
and with sulphuric acid forms handsome needles, which are bitter, and communicate
this taste to its menstrua. (Ann. Ther., 1866, 73.) E. Schmidt, however, found no
alkaloid but discovered sarracenic acid. (A. J. P., 1872, 213.) Dose, of tincture (two
ounces in one pint), a fluidrachm (3.75 mils); of fluidextract, from ten to twenty
minims (0.6-1.3 mils).

SARSAPARILLA. U. S.

SARSAPARILLA Sarsap.

"The dried root of Smilax medica Chamisso and Schlechtendal, known
in commerce as Mexican Sarsaparilla; or Smilax officinalis Kunth, or
an undetermined species of Smilax, known in commerce as Hondurassarsaparilla; or Smilax ornata Hooker filius, known in commerce as
Jamaica Sarsaparilla (Fam. Liliaceæ)." U. S. "The dried root of Smilax
ornata, Hook. f. Imported from Costa Rica and commonly known as
Jamaica sarsaparilla" Br. 1898.

Sarsae Radix, Br. 1898; Jamaica Sarsaparilla; Salsepareille, Fr. Cod.; Radix
Sarsaparillae, P. G.; Sarsaparille, Sarsaparilla, G; Salsapariglia, It.; Zarzaparrilla
(Raiz de), Sp.

The medicinal species of smilax grow in Mexico, Guatemala, and the
warm latitudes of South America. The roots are very long and slender,
and originate in great numbers from a common head or rhizome, from
which the stems of the plant rise. The whole root with the rhizome is
usually dug up, and as brought into market exhibits not unfrequently
portions of the stems attached, sometimes several inches in length. The
commercial sarsaparillas are conveniently divided into the mealy and
non-mealy sarsaparillas. The first class comprises especially the
Honduras, Guatemala, and Brazilian varieties; the second the Jamaicaisa,
Mexican and Guayaquil sarsaparillas. A very convenient key for
distinguishing the commercial sarsaparillas by certain anatomical
characters has been devised by Luerssen in his Handbuch der Medicin-
pharm. Botanik, ii, 404.

All the species of Smilax are climbing or trailing plants, with prickly
stems—a character expressed in the name of the medicine, which is
derived from two Spanish words (zarsa parilla), signifying a small
thorny vine.
The official species of smilax are as follows:

S. medica, has an angular stem, armed with straight prickles at the joints, and a few hooked ones in the intervals. The leaves are smooth, bright green on both sides, shortly acuminate, five-nerved, with the veins prominent beneath. They vary much in form, the lower being cordate\^ auriculate-hastate, the upper cordate-ovate. In the old leaves the petiole and midrib are armed with straight subulate prickles. The inflorescence is an umbel of from eight to twelve flowers, with a smooth axillary peduncle and pedicels about three lines long.

The Mexican or Vera Cruz sarsaparilla is derived from this species. Although sometimes in bundles, it commonly comes in large, rather loose bales, weighing about two hundred pounds, bound with cords or leather thongs, and usually containing the roots folded upon themselves, and separately packed. These, as in the Honduras sarsaparilla, consist of a head or caudex with numerous long radicles, which, however, are somewhat smaller than in that variety, and have a thinner bark. They are often also much coiled with earth. It contains but little starch and has quadrangular endodermal cells, with thickened walls, and more or less oval lumen. It was formerly little esteemed; but, from the acrid taste which it possesses, it is probably of equal value to the other kinds.

S. officinalis.—In this species the stem is twining, angular, smooth, and prickly; the young shoots are unarmed; the leaves ovate-oblong, acute, cordiform, five- or seven-nerved, coriaceous, smooth, twelve inches long and four or five broad, with footstalks an inch long, smooth, and furnished with tendrils. The young leaves are lanceolate-oblong, acuminate, and three-nerved. Large quantities of the root are said to be sent down the Magdalena River to Mompos and Carthagena.

It is the source of Honduras Sarsaparilla. It is brought from the bay of Honduras and comes in bundles two or three feet long, composed of several roots folded lengthwise, and secured in a compact form by a few circular turns. These are packed in bales imperfectly covered with skins, each bale containing one hundred pounds or more. The roots are usually connected at one extremity in large numbers in a common head, to which portions of the stems are also attached. In some bundles are many small fibers, either lying loose or still adhering to the roots. The roots externally are a dirty grayish or reddish-brown; the cortical
portion beneath the epidermis often appears amylaceous when broken.

*S. ornata* Hook.—This plant was recognized by both Fliickiger and Hanbury, and by Bentley and Trimen as *S. officinalis*, and was described by Lemaire with a query to it to express his doubtfulness of its specific distinctness. The species is, however, now generally accepted. The plant has large seven-nerved leaves resembling *S. officinalis*. It is especially distinguished by the young leaves being mottled with white. (See Botanical Magazine, 1889, cxv, 7054.)

This species yields Jamaica or red sarsaparilla of foreign writers, although but little known by the latter name in the United States. It is collected in Central America, especially in Costa Rica, and it owes its name to the fact that it has been largely exported to Europe through the island of Jamaica. As found in commerce it is in rolls from twelve to eighteen inches long by four or five in thickness, composed exclusively of long slender many-radicled roots very loosely held together by a few turns. Sometimes it is pressed into large bales. It is further to be distinguished from Honduras sarsaparilla by its dark color, the greater abundance of coarse rootlets, the less quantity of starch, its relatively thick cortex, and its less sharp taste. Externally it is also redder than is commonly the case with Honduras sarsaparilla. Kobert (P. J., 1912, Ixxxviii, p. 779), has found that the ornata has only one-eighth of the hemolytic power of the Vera Cruz sarsaparilla, which he takes as a test of its saponin content. He believes the plant is unfit for medical use.

Cultivated Jamaica Sarsaparilla (Roja Inglesa) occurs in thick short rolls and is especially characterized by its yellow-brown or orange color. According to W. B. Hemsley, Hooker’s I. P. pl. 2589, it is the product of *S. utilis* Hemsley, a species related to *S. ornata*, from which it differs by its long pediculated simple umbels.

An investigation by Power and Salway (Chem. News, 1914, p. 56) showed the presence of the following constituents in Jamaica sarsaparilla: a glucoside, sarsaponin, C_{44}H_{76}O_{20}7H_{2}O, which upon hydrolysis yields sarsapogenin, C_{26}H_{42}O_{3}, and dextrose; sitosterol-d-glucoside, C_{27}H_{46}O; sitosterol, C_{27}H_{46}O; stigmasterol, C_{30}H_{50}O; sarsapid acid (a new dicarboxylic acid), C_{6}H_{4}O_{6}, and a mixture of fatty acids, including palmitic, stearic, behenic, oleic and linolic acids. The alcoholic extract contained acetyl-d-glucoside and potassium nitrate was
also found.

Another variety is the Caracas sarsaparilla, brought in large quantities from La Guayra. It is in oblong packages, of about one hundred pounds, surrounded with broad strips of hide, which are connected laterally with thongs of the same material, leaving much of the root exposed. The roots, as in the last variety, are separately packed, but more closely and carefully. The radicles are often very amylaceous internally, in this respect resembling the following variety.

S. papyracea is said to have foliage like S. officinalis, with a multiangular stem, with squamiform thorns on the angles, and petioles which are vaginate for one-fourth their length. It is thought to be the source of Para sarsaparilla which is no longer found in commerce.

The Brazilian, or, as it is called in Europe, the Lisbon or Para sarsaparilla, is not very plentiful in commerce. It comes from the ports of Para and Maranham, in cylindrical bundles from three to five feet in length by about a foot in thickness, bound about by close circular turns of a very flexible stem, and consisting of unfolded roots, destitute of caudex (rhizome) and stems, and having a few radical fibers. It was also shown in the Brazilian exhibit in the Centennial Exhibition, neatly cut and tied into bundles about a foot long and eight inches in diameter. It is the variety of which Hancock speaks as celebrated throughout South America by the name of Sarsa of the Rio Negro, and was considered one of the most valuable varieties of the drug. It is distinguished by the thinness of its cortex, the large amount of starch that it contains and its large, radially elongated endodermal cells. It was said by Martius to be derived from Smilax syphilitica; but Hancock considers that portion of it which comes from the Rio Negro, and is shipped at Para, as the product of an undescribed species, certainly not S. syphilitica. As determined by Richard, it is the product of the S. papyracea of Poiret.

The variety described by Bentley under the name of Guatemala sarsaparilla was collected in the province of Sacatapeques, about ninety miles from the sea. It is in cylindrical bundles about two feet eight inches long by four inches in diameter, composed of separate roots, arranged in parallel order, without rootstalk, and bound together by a few turns of the flexible stem of a monocotyledonous plant. The bundles resemble the Brazilian in arrangement, but are much less compact. It is amylaceous, has considerable acridity, and is probably one of the most
efficient varieties. Bentley ascribes it to *S. papyracea*. For a particular description of the root, see P. J., xii, 472.

Guayaquil sarsaparilla, according to Spruce, grows in valleys on the western slopes of the equatorial Andes. It is usually not in bundles, but carelessly packed in bales. "The rhizome and a portion of the stem are often present, the latter being round and prickly. The root is dark, large, and coarse-looking, with a good deal of fiber. The bark is furrowed, rather thick, and not mealy in the slenderer portions of the root, which is near the rootstalk; but, as the root becomes stout, so its bark becomes smoother, thicker, and amylaceous, exhibiting when cut a fawn-colored or pale yellow interior."

The root (rhizome) of Smilax China, a native of China and Japan, has been employed under the name of China Root for similar purposes with the official sarsaparilla. As it occurs in commerce, it is in pieces from three to eight inches long and an inch or two thick, usually somewhat flattened, more or less knotty, often branched, of a brownish or grayish-brown color externally, whitish or of a light flesh-color internally, without odor, and of a taste flat at first, but afterwards very slightly bitterish and somewhat acrid, like that of sarsaparilla. The root of *Smilax aspera* is said to be employed in the south of Europe as a substitute for sarsaparilla; but it has little reputation. The East India sarsaparilla, which was at one time referred to this species of smilax, is the product of *Hemidesmus indicus*. (See *Hemidesmus*.)

Under the name of Raiz de china de Mexico, the Mexican Pharmacopoeia recognizes the root of *S. rotundifolia* as diaphoretic and depurative, but, according to Maisch, this reference is incorrect. (See A. J. P., 1879.)

**Properties.**—The several varieties of sarsaparilla are officially described as follows:

"MEXICAN SARSAPARILLA.—In loose bundles, or pressed into bales, single bundles attaining a length of 60 cm. and composed of from 20 to 35 folded roots attached to a crown with one or more stout stems; roots from 3.6 to 6 mm. in diameter; externally grayish-brown to dark brown, minutely hairy, longitudinally furrowed, the furrows containing more or less of a blackish earth; fracture tough, fibrous; internally light brown with a more or less shrunken, mealy or sometimes horny cortex.
surrounding the porous central cylinder, pith distinct; nearly inodorous; taste mucilaginous, somewhat sweetish and acrid. Remove the woody, knotty crown with portions of the overground stems.

“HONDURAS SARSAPARILLA.—In more or less compact, cylindrical bundles, attaining a length of 55 cm. and a diameter from 8 to 15 cm., consisting of the long, folded roots bound together by roots of the same plant; roots from 2 to 6 mm. in diameter; externally dark- or reddish-brown, longitudinally fun-owed, the furrows usually free from soil; fracture fibrous; internally consisting of a grayish-white or dark brown cortex, a light yellow and porous central cylinder and a whitish pith; taste mucilaginous and slightly acrid.

“JAMAICA SARSAPARILLA.—In more or less compact and somewhat flattened bundles, from 30 to 45 cm. in length and from 10 to 15 cm. in width, consisting of the folded roots loosely bound with roots of the same plant; roots from 2 to 5 mm. in diameter; externally grayish-brown to reddish-brown, longitudinally wrinkled, more or less furrowed and bearing numerous coarse fibrous rootlets; taste somewhat sweet and slightly bitter.

“Under the microscope, transverse sections of all of the commercial varieties of Sarsaparilla show an epidermal layer with basal portions of root hairs; a hypodermis composed of several layers of strongly lignified cells, the walls being uniformly thickened, except in Mexican Sarsaparilla in which the inner walls are only slightly thickened; a cortex composed of numerous parenchyma cells mostly containing starch, some containing resin or raphides of calcium oxalate; an endodermis of a single layer of strongly lignified cells, the walls being uniformly thickened except in Mexican Sarsaparilla in which the outer walls are only slightly thickened; a central cylinder composed of radial bundles connected with sclerenchymatous fibers, the tracheas being large and oval and the phloem in small groups at the periphery of the bundle; and a pith composed of starch-bearing parenchyma cells. Powdered Sarsaparilla is light grayish-brown to dark grayish-brown; when examined under the microscope it exhibits numerous starch grains, from 0.003 to 0.023 mm. in diameter, spherical, or biconvex or spherical-tetrahedral, single to 2- to 4-compound, and frequently with a central-elliptical cleft; calcium oxalate in raphides, from 0.006 to 0.035 mm. in diameter, occurring singly or in groups; cells of the hypodermis and endodermis with lemon-yellow or reddish-yellow porous walls and,
in the case of Mexican Sarsaparilla, showing an uneven or irregular thickening, the individual cells from 0.08 to 0.5 mm in length; fragments of trachea) with simple and bordered pores or scalariform or reticulate thickenings associated with sclerenchymatous fibers having rather thin, very slightly lignified and porous walls. Sarsaparilla yields not more than 10 per cent. of ash."

U. S.

According to Tunmann (Apoth. Zeit., xxv, p. 475), the consumption of sarsaparilla in Europe has decreased materially, and the chief market for this drug at the present time appears to be the United States. While the U. S. Pharmacopoeia recognizes three commercial varieties, most of the drug which is used is the Mexican variety, a relatively small quantity of Honduras sarsaparilla being imported. The red Jamaica, Orange or Native Jamaica varieties are used chiefly in England. Hartwich has recently pointed out that the varieties of sarsaparilla on the market are more numerous than are generally supposed. He also states that the greatest emphasis should be placed on the structural characteristics in order to distinguish the several varieties, rather than the form of packing and the supposed botanical origin. He is the best authority on this subject and all of his articles, some of which are enumerated, should be consulted (S. W. P., 1897, No. 44 and 45; 1898, No. 37, and 1909, p. 126; Arch. d. Pharm., 1894, p. 37, and 1902, p. 325; Ber. d. D. Pharm. Ges., 1907, p. 250). A recent article on the pharmacognosy of the several commercial sarsaparillas is by Fleury in Bull. des Sc. Pharmacol., xii, p. 190. Rusby reports finding lots of Mexican sarsaparilla which consisted entirely of "butts" or rhizomes. (Proc. A. Ph. A., 1908, lvi, p. 773.) Kraemer reports finding nineteen ounces of dirt in a bundle of Mexican sarsaparilla weighing four and a half pounds. (Proc. A. Ph. A., 1906, liv, p. 345.) Rusby has reported the presence of a thick, blackish, woody and decidedly astringent root in several shipments of Vera Cruz sarsaparilla. (Jour. A. Ph. A., 1913, p. 1104.)

Sarsaparilla is efficient in proportion as it is acrid to the taste, which is said by some authors to be confined to the cortical portion, while the ligneous fiber and medullary matter are insipid and inert. Hancock avers that all parts are equally acrid and efficacious. The truth is probably between the two extremes, and, as in most medicinal roots, it must be admitted that the bark is more powerful than the interior portions, while these are not wholly inactive. The virtues of the root are communicated to water, cold or hot, but are impaired by long boiling.
They are extracted also by diluted alcohol. According to Hancock, the whole of the active matter is not extracted by water. In South America it is the custom to prepare sarsaparilla by digestion in wine or spirit, or by infusion in water with additions which may produce the vinous fermentation and thus add alcohol to the menstruum. The same result, as to the superior efficacy of alcohol as a solvent of the acrid principle of sarsaparilla, has been obtained by the French experimentalists. It has been suggested that sarsaparilla, the virtues of which are admitted to be impaired by long boiling, might also be injured by the degree of heat applied in the water or steam bath. But the contrary appears to have been proved by J. F. Judge of Cincinnati. (Proc. A. Ph. A., 1873, p. 595.)

Parillin. (Smilacin. Pariglin. Salseparin. Parallinic acid.)—The crystalline principle to which any activity of sarsaparilla is due is now called parillin. It was first discovered by Palotta, who described it in 1824 under the name of pariglin. Subsequently, Folchi supposed that he had found another principle, which he called smilacin. Fluckiger recommends the preparation of parillin by exhausting the crushed root with warm alcohol and distilling the tincture until the residue weighs one-sixth of the root. It is then gradually mixed with one and a half times its weight of water, and after several days the liquid is decanted from the light yellow precipitate, which is then mixed with about half its volume of alcohol, transferred to a filter, and washed with alcohol of 20 or 30 per cent. because parillin is less soluble in weak alcohol than in strong alcohol. The yield was 0.18 and 0.19 per cent. It is whiter inodorous, almost tasteless in the solid state, but bitter, acrid, and nauseous when dissolved in alcohol or water. It is very slightly soluble in cold water, but more readily in boiling water, without crystallizing on cooling. It is very soluble in alcohol, especially at the boiling temperature. Ether and the volatile oils also dissolve it. Its aqueous solution has the property of frothing very much on agitation. According to Fluckiger, concentrated sulphuric acid yields a yellow solution, which, on absorbing moisture, gradually turns cherry-red; warm diluted sulphuric acid colors parillin greenish, then red, and finally brown; phosphoric acid has a similar reaction, but the color is more greenish-yellow. The aqueous solution is precipitated by alcoholic solution of lead acetate, by lead subacetate, and by tannin, and when warmed reduces alkaline copper tartrate, but does not react with other tests for sugar until after it has been boiled with a dilute acid, when the solution acquires a green fluorescence. This is best observed if a trace of parillin is dissolved in warm concentrated sulphuric acid, and disappears on
dilution with water or on neutralizing with ammonia. Parillin is not
certimately; its acid taste is best observed in alcoholic solution. (See A.
J. P., xii, 245.) The solutions of parillin are without acid or alkaline
reaction. By treatment with dilute mineral acids, it is resolved into
parigenin and sugar. Poggiale found parillin both in the cortical and in
the medullary part of the root, but most largely in the former. W. von
Schulz (P. J., 1892, 6) has shown that Dragendorff's smilacin, smila-
saponin, or sarsaparill-saponin, $C_{20}H_{32}O_{10}$, sarsa-saponin, $C_{22}H_{36}O_{10}$,
discovered by himself, and Fluckiger's parillin, $C_{26}H_{44}O_{10}$; are three
homologous compounds all belonging to the same series, having the
general formula $C_{n}H_{2n-8}O_{10}$. These three all split up into sar-
sasapogenin (parigenin of Fluckiger) and one or more molecules of
 glucose on boiling with dilute acids. Robert (A. J. P., 1892, 465) comes to
practically the same results, stating the constituents to be parillin
($C_{26}H_{44}O_{10} + 2\frac{1}{2}H_{2}O$), insoluble in water; saponin (sarsapurill-
saponin), $5(C_{20}H_{32}O_{10} + 2\frac{1}{2}H_{2}O)$, soluble in water; and sarsa-saponin,
$12 (C_{22}H_{36}O_{10} + 2H_{2}O)$, easily soluble in water, and the most active of
the constituents.

The sarsaparilla of commerce is apt to be nearly if not quite inert, either
from age, or from having been obtained from inferior species of Smilax.
This inequality of the medicine, with the improper modes of preparing it
long in vogue, has probably contributed to its variable reputation. The
only criterion of good sarsaparilla to be relied on is the taste. If it leave a
decidedly acrid impression in the mouth after having been chewed for a
short time, it may be considered efficient; if otherwise, it is probably
inert. Various false sarsaparillas have been sent into commerce from
South America. For description by C. Hartwich see A. Pharm., July,
1902.

Uses.—The use of sarsaparilla in medicine is an interesting example of
the power of superstition to survive the attacks of truth and reason. It
was introduced into Europe about the middle of the 16th century as a
remedy for syphilis, but soon fell into disrepute until revived by Fordyce
in 1757. Subsequently it came to be used as an alterative in various
other chronic diseases, especially chronic rheumatism and scrofula.
There is, however, no reason to believe that it possesses any virtues
except as a mild gastric irritant through its saponin content. Its most
popular employment is in the form of its compound syrup which is used
as a vehicle especially for mercury and potassium iodide.

Sarsaparilla may be administered in the form of infusion, compound decoction, compound syrup, or fluidextract. A beer made by fermenting an infusion of the drug with molasses is said to be a popular remedy in South America. The smoke of sarsaparilla has been highly recommended in asthma, (J. P. C., xviii, 221.)

Dose, thirty, to sixty grains (2-3.9 Gm.).

**Off. Prep.**—Fluidextractum Sarsaparillae, U. S. (Br.); Fluidextractum Sarsaparillae Compositum, U. S.; Syrupus Sarsaparillae Compositus, U. S. (from fluidextract); Decoctum Sarsaparillae Compositum, N. F.

**SASSAFRAS. U. S.**

**SASSAFRAS Sassafras.**

"The bark of the root of Sassafras variifolium (Salisbury) O. Kuntze (Fam. Lauraceae), without the presence or admixture of more than 2 per cent. of adhering wood, collected in the early spring or autumn, deprived of the outer corky layer and dried." U. S.

Sassafras Radix, Br.; Sassafras Bark, Sassafrax; Sassafras, Fr. Cod., G.; Sasafrasso, It.; Sasafras (Leño de), Sp.

Sassafras is an indigenous tree, of medium size, rising in favorable situations to a height of 35 feet. The bark of the stem and large branches is rough, deeply furrowed, and grayish: that of the extreme branches or twigs is smooth and beautifully green. The leaves, which are alternate, petiolate, and downy when young, vary much in their form and size even upon the same tree. Some are oval and entire, others have a lobe on one side, but the greater number are three-lobed. The flowers, which appear before the leaves, are small, of a pale greenish-yellow color, and disposed in racemes which arise from the branches below the leaves and have linear bracts at their base. The fruit is an oval drupe, about as large as a pea, of a deep blue color when ripe, and supported on a red pedicel, enlarged at the extremity into a cup for its reception. For the microscopical character of the root and bark, see E. S. Bastin, A. J. P., June, 1895. See also Ph. Rev., 1899, 450.
The sassafras is common throughout the eastern United States, and extends into Mexico. The fresh flowers have a slightly fragrant odor, and almost all parts of the plant are more or less aromatic. The best time for collecting the pith is after the occurrence of frost in autumn, and the same is the case also with the bark of the root.

Bark of Sassafras Root.—As found in commerce, this is usually in small irregular fragments, sometimes invested with a brownish cork, sometimes partially or wholly freed from it, of a reddish or rusty cinnamon hue, very brittle, and presenting when freshly broken a lighter color than that of the exposed surfaces. The living bark is nearly white, but becomes colored, on exposure, immediately after collection. It is officially described as “in irregularly transversely curved or quilled pieces, from 1 to 15 cm. in length and from 1 to 4 mm. in thickness; outer surface orange-brown, nearly smooth and marked with more or less irregular ridges; inner surface light to dark reddish-brown, obscurely short- striate; fracture short with a thin reddish-brown corky layer and a yellowish-white inner bark; odor aromatic; taste slightly mucilaginous, astringent, aromatic and somewhat pungent. The powder is light reddish-brown; when examined under the microscope it exhibits numerous starch grains and prominent, characteristic bast-fibers; starch grains either single or 2- to 4-compound, the individual grains being more or less spherical or polygonal and frequently with a distinct cleft, from 0.003 to 0.02 mm. in diameter, some of the swollen or altered grains attaining a diameter of 0.03 mm.; bast-fibers spindle-shaped, occasionally very irregular in outline, with sharply pointed ends, from 0.15 to 0.4 mm. in length, about 0.025 mm. in diameter, and with very thick, strongly lignified walls, the lumina being frequently nearly obliterated; parenchyma cells containing either starch grains or irregular yellowish-red masses of tannin and becoming bluish-black upon the addition of ferric chloride T.S.; fragments of wood few, with large, thin-walled trachea? marked by simple pores and associated with rather thin-walled wood-fibers. Sassafras yields not more than 30 per cent. of ash.” U. S.

According to Reinsch, the bark contains a heavy and light volatile oil, camphorous matter, fatty matter, resin, wax, a peculiar decomposition product of tannic acid called sassafrid, tannic acid, gum, albumen, starch, lignin, and salts. (See Oleum Sassafras) The sassafrid bears some analogy to cinchonic red, and, like it, appears to be a derivative of
the tannin, which exists in much larger proportion in the fresh bark than in that long kept. (Procter, A. J. P., 1866, p. 490.) Owing to its volatile oil and tannic acid, the bark of sassafras root is an aromatic stimulant and astringent. It is used almost exclusively as an adjuvant to other more efficient medicines, the flavor of which it improves, while it renders them more acceptable to the stomach. The volatile oil may be used as an aromatic. In overdoses it is capable of producing marked narcotic poisoning, and it is said to act upon the lower animals as a narcotic. John Bartlett has reported several cases in which its use apparently caused abortion.

Sassafras Pith (Sassafras medulla) was recognized by the U. S. VIII, and is at present included in the N. F. IV. It occurs in "sub-cylindrical, often curved or coiled pieces, from 2 to 10 cm. in length and from 2 to 5 mm. in diameter; very light in weight; externally whitish, occasionally with small fragments of adhering wood; fracture short. Odor slight; sassafras-like; taste mucilaginous. When examined under the microscope, transverse sections of Sassafras Pith, mounted in phloroglucinol T.S. and hydrochloric acid, show nearly isodiametric cells with large intercellular spaces, the walls being more or less lignified and provided with numerous simple pores; mounts made in water show the separation of a thin layer of mucilage from the inner walls of the cells, characterized by the gradual disappearance of the pores. Macerate 0.5 Gm. of Sassafras Pith with 25 mils of cold distilled water for several hours and filter it through purified cotton; a mucilaginous solution is obtained which does not give a precipitate upon the addition of an equal volume of alcohol." N. F.

It abounds in a gummy matter, which it readily imparts to water, forming a limpid mucilage, which is not precipitated by alcohol, but has much less tenacity than that of gum arable and will not answer as a substitute in the suspension of insoluble substances. This mucilage is much employed as a soothing application in inflammation of the eyes, and forms an agreeable and useful drink in dysenteric, catarrhal, and nephritic diseases. It may be prepared by adding a drachm of the pith to a pint of boiling water.

Dose, of sassafras bark, one to two drachms (3.9-7.7 Gm.).
Sassy Bark. Nkasa. Doom Bark. Casca Bark. Mancona Bark. Saucy Bark. Ecorce de Mangoine, Fr. Manconarinde, G.—This bark is interesting chiefly from its employment by the natives of Western Africa as an ordeal in their trials for witchcraft or sorcery. (For details, see P. J. lxv, 2.) This bark was first studied by C. A. Santos (A. J. P., 1849, xxii, 97), and subsequently by Procter (Ibid., xxiii, 301; xxiv, 195). It is obtained from Erythrophleum guineense Don, and is a large tree with spreading branches, doubly pinnated leaves, flowers in spike-like racemes, and leguminous fruit. The bark is in pieces more or less curved, with or without epidermis, in the former case somewhat fissured externally, of a dull red color diversified by whitish spots, brittle, presenting when cut transversely numerous fawn-colored spots surrounded by reddish-brown tissue, nearly inodorous, and of an astringent taste. A comprehensive description of sassy bark is given in the Commentar zur österrechischen Pharmacopoeia, 1890, by Vogi; and in the Resume de la Matiere Medicale et Toxicologique Coloniale, by Corre and Lejuanne, the plant, fruit, seeds, etc., are carefully illustrated. Gallois and Hardy obtained the poisonous principle erythrophleine by making an alcoholic extract of the bark, exhausting this with water, evaporating, rendering this extract alkaline with ammonia, and treating with acetic ether. The alkaloid is a colorless, crystalline solid, soluble in water, acetic ether, alcohol, and amyl alcohol, insoluble in chloroform, benzoin, and ether. In contact with sulphuric acid and black manganese oxide, a violet color (less intense than that produced with strychnine) is developed. Harnack and Zabrocki (A. E. P., xv, 404) also prepared erythrophleine, and by the action of hydrochloric acid upon it obtained an acid they call erythrophleic acid, and a volatile alkaloid they call manconine. The bark yields its virtues to water. Power and Salway examined sassy bark in 1912 and confirmed the presence of erythrophleine as described by Harnack. (A. J. P., 1912, 337.)

According to the observations of Savage, made in Africa (Charleston Med. Journ; 1859), sassy bark produces in the natives a feeling of constriction in the fauces, attended by prickling, and followed by numbness, with, after a toxic dose, stricture across the brow, severe pain in the head, coma, and death. The physiological action of erythrophleine has been studied by various observers, especially by E. Harnack and R. D. Zabrocki, Gallois and Hardy, and Lauder Brunton, with results which are fairly concordant. Erythrophleine exercises a digitalis-like action on the circulation causing a slow, strong pulse, with a rise in the arterial pressure. These changes are certainly in great part due to the direct action upon the heart, but are also seemingly in part produced by a stimulating influence upon the muscle fibers or nerves in the walls of the arterioles. Purging was also noted as the result of an increased peristalsis, thought to be due to the local action of the poison. Vomiting is believed by Lauder Brunton to be the result of an influence upon the nerve centers, because it occurs when the alkaloid is given hypodermically. In fatal poisoning in the lower animals, convulsions are pronounced, and the respiration is also markedly affected. In 1888 L. Lewin asserted erythrophleine to be a powerful local anesthetic, whose action is more pronounced than that of cocaine. His paper gave rise to an extraordinary controversy, the outcome of which appears to be that, although the alkaloid is possessed of not very active anesthetic powers, it is for various reasons practically not useful. (See 17th edition, U. S. D., p. 1739.) A solution of the strength of one-tenth of one per cent. is used as an application to the cornea.
Germain See asserts (Med. Mod., Dec., 1891) that, although sassy bark does not act well upon the heart, it gives great relief in dyspnea, the number of respirations being lessened and the inspirations being extraordinarily increased in depth. He gave of the alkaloid from one-fortieth to one-thirtieth of a grain (0.0016-0.002 Gm.); of the extract, from one-fourth to one-third of a grain (0.016-0.021 Gm.).

**Saururus.** Saururuscernuus L. Lizard's Tail. (Fam. Saururacea.)—D. L. Phares, of Newtonia, Miss., considers this indigenous swamp plant of the Eastern and Central United States "laxative, antispasmodic, sedative, and slightly astringent"; useful in irritation of the kidneys, bladder, prostate, and urinary passages generally. The dose of the strong infusion was, with the plant either fresh or dried, from one to four fluidounces (30-120 mils) every fifteen or thirty minutes, or three or four times a day. (A. J. P., 1867, 468.)

**Saxifraga.**—Garreau and Machelast have isolated from S. crassifolia L. and other species of this genus a crystallizable bitter substance, bergenin. It is obtained by boiling the stems of the plants with absolute alcohol, after the tannin has been removed by ether. It crystallizes in alcohol, has a bitter taste, melts at 140° C. (284° F.), and burns up completely at 300° C. (572° P.). It is soluble in 167 parts of 90 per cent. alcohol and in 830 parts of water, but is more soluble in these liquids at a boiling temperature; it is faintly acid to litmus, and is not changed by treatment with dilute sulphuric or hydrochloric acid, but by diluted nitric acid is converted into oxalic acid. Concentrated sulphuric acid decomposes it. Its formula is given as $C_6H_3O_3.H_2O$. Bergenin is asserted to be intermediate in its action between salicylic acid and quinine. (A. Pharm., 1881, 293.) The rhizome of Saxifraga ligulata Wall., which is used in India, in dysentery, has been found by David Hooper to contain about 16 per cent. of gallic and tannic acids, but no other active principles. (P. J., Aug., 1888.)

**SCAMMONIA RADIX. U. S., Br.**

**SCAMMONY ROOT Scam. Rad.**

"The dried root of Convolvulus Scammonia Linne (Fam. Convolvulaceæ), yielding not less than 8 per cent. of the total resins of Scammony Root." U. S. "Scammony Root is the dried root of Convolvulus Scammonia, Linn." Br.

As the resin of scammony is obtained in Oriental countries by a
somewhat tedious process, it has been very difficult to obtain sufficient quantities of the genuine article for use in medicine. The British Pharmacopoeia long ago solved the question by making official scammony root from which the resin is prepared. The U. S. P. IX following this precedent and for the same reason has introduced scammony root. There seems to be little doubt, however, that the natural exudation has properties which make it a more desirable medicine than the extracted resin. (C. D., lxix, p. 864.) On the other hand, the therapeutic committee of the British Medical Association states that the natural exudation possesses no advantages over the resin. (P. J., 1908, xxvii, p. 811.) Heuisler states that the extracted resin of true scammony root as well as the resin obtained from Mexican scammony (Ipomoea Orizabensis) are sold for "virgin" scammony. (Proc. Md. Ph. Assoc., 1908, p. 35.)

Scammony root is officially described as follows: "Cylindrical or somewhat tapering, from 10 to 25 cm. in length and from 1 to 4.5 cm. in thickness; externally grayish- to reddish-brown; usually distinctly twisted, deeply longitudinally furrowed, marked by distinct root-scars, otherwise nearly smooth except for the lenticels and abraded cork, the upper portion terminated usually by a number of short stem branches; hard and heavy; fracture tough, irregular with projecting wood-fibers; internally somewhat mottled, showing yellowish, porous wood-wedges separated by whitish parenchyma containing starch and resin, bark thin; odor slight, resembling that of jalap; taste very slightly sweet, becoming slightly acrid. Under the microscope, sections of Scammony Root show a corky layer consisting of from 2 to 10 rows of cells with thin, yellowish-brown lignified walls; an outer cortex with numerous stone cells occurring singly or in small groups, the walls being moderately thick, porous and not strongly lignified; parenchyma with numerous starch grains and mono-clinic prisms of calcium oxalate; fibro-vascular bundles numerous, circular or elliptical with a well developed wood consisting of large tracheae surrounded by slightly lignified wood-fibers; phloem or sieve prominent in which are included large resin ducts; the parenchyma, both in and surrounding the bundles, more or less collapsed and containing either starch or calcium oxalate crystals. The powder is light grayish-brown; when examined under the microscope it exhibits starch grains from 0.003 to 0.018 mm. in diameter, mostly single, occasionally 2- to 4-com-pound, the grains showing occasionally a central cleft; calcium oxalate crystals numerous, in monoclinic prisms from 0.01 to 0.045 mm. in length; fragments of
leptomes or sieve with accompanying yellowish-brown resin cells; tracheae mostly with reticulate thickenings and simple or bordered pores and associated with short wood-fibers having prominent oblique pores; stone cells of variable shape and varying from 0.04 to 0.11 mm. in length, the walls being from 0.006 to 0.012 mm. in thickness, slightly lignified and traversed with prominent, often branching pores; lignified cork cells relatively few.

"Assay.—Proceed as directed under Jalapa, using 10 G-m. of Scammony Root in No. 60 powder." U. S.

“Brownish-grey or yellowish-grey, tapering or nearly cylindrical, varying usually from two to eight centimetres, or more, in diameter. Frequently contorted and longitudinally furrowed; enlarged at the crown, and bearing the remains of slender aerial stems. Fracture very coarsely fibrous; internally light or dark grey. In transverse section, numerous rounded wood-bundles distributed throughout a paler ground-tissue in which dark resin cells can be distinguished with a lens; in the parenchymatous tissue abundant, characteristic starch grains. Characteristic odor; taste at first somewhat sweet, afterwards slightly acrid. Yields to alcohol (90 per cent.) a resin which has the properties described under (Scammoniae Resina).” Br.

The wood consists of compressed pale brown, coarsely porous, usually subdivided fibers in a parenchymatous tissue similar to the bark. For microscopic structure, see Dragendorff’s Jahresbericht, 1875.

The root of the male jalap (orizaba root, Mexican scammony, Purgo macho) has recently largely replaced in commerce the scammony root on account of its containing a much larger percentage of resin chemically indistinguishable from that of scammony. The Levant or true scammony root, it is said, averages a little under 9 per cent. of resin, while the Mexican root usually yields over 15 per cent. Male jalap occurs in transverse pieces one-half to an inch in thickness and two to four inches in diameter or in the case of the smaller roots in pieces three or four inches long sometimes obliquely cut, the transverse slices show concentric rings with protruding coarse fibers which at once distinguishes it from the true scammony in which the vascular bundles are scattered.

Large quantities of a false scammony root of unknown botanical origin
have appeared in the London market. The root is 2 to 3 inches in
diameter with a thin, brittle, blackish-brown bark, and on transverse
section six or seven rings of wood. It is odorless and tasteless. (See P. J.,
May, 1901, 596.)

Mexican Scammony Root.—Mexican scammony root has been identified
by E. M. Holmes as being undoubtedly the root of Ipomoea orizabensis,
and is described as follows: The appearance is quite characteristic and
quite different from that of scammony root. It occurs mostly in
transverse slices, showing concentric rings, from which coarse fibers
protrude on both of the transverse surfaces. The sections are mostly
those of the larger portion of the root, and vary from two to three inches
or more in diameter, but are only about one-half to three-quarter inch
in thickness. The smaller roots are about one inch or so in diameter, but
are frequently three or four inches long— a few pieces are obliquely cut.
The concentric arrangement of the vascular bundles at once
distinguishes it from the root of Convolvulus Scammonia, in which they
are scattered and somewhat rounded, forming isolated strands, in the
softer tissue. It appears that during 1903 there was an importation of
over 3000 bags, which sold readily to the German makers of scammony
resin. Analyses made showed from 6.4 to 22.2 per cent. of resin, but most
of it yielded about 17 per cent. While chemically there appears to be no
difference between scammony resin and the resin of Ipomoea
orizabensis, it remains to be ascertained if they are identical in their
physiological action. At the request of Holmes, Harold Dean determined
the amount of resin in a specimen and, in a separate paper, gives the
method employed and the results, as follows: The drug was powdered,
exhausted by percolation with alcohol (90 per cent.), the greater part of
the alcohol distilled off, and the resulting strong tincture poured into
three times its volume of water. The resin separated as a mass of honey-
like consistence. It was well washed with boiling water until the
washings were free from sugar and from color, and then dried on a
water bath until the weight was constant. The yield of resin amounted
to 18.5 Gm. from 100 Gm. of the powdered drug; this is the highest
percentage yet recorded from this source. The dried resin was pale
brown, and almost entirely soluble in ether, the insoluble portion from
18.5 Gm. weighing less than 0.25 Gm. It had the general characteristics
of scammony resin. The powdered drug, dried at 100° C. (212° F.),
yielded 9.89 per cent. of ash. (P. J., March 5, 1904, 226, 327.)

**Uses.**—Scammony root in substance is not used medicinally, but solely
for making resin of scammony.

Schinus Schinusmolle L. (Fam. Anacardiaceae)—The peppertree of South America yields a berry the size of a pea, having a flavor similar to a mixture of pepper and fennel. It has been introduced as a shade tree in Southern California. (A. J. P., 1896, 215.) The leaves contain a volatile oil which is readily discharged, as after a rain when the air is filled with fragrance. Schimmel & Co. examined the volatile oil distilled from the berries; it had the sp. gr. 0.850, the odor of phellandrene, and was soluble in alcohol. (Ph. Rev., 1897, 114.) It has been used successfully in gonorrhea as a substitute for cubeb. The leaves, bark, and gum resin have been employed medicinally. (See A. J. P., 1866, 1885, 1890; also P. J., 1887.)

SCILLA. U. S., Br.

SQUILL Scill.

"The fleshy, inner scales of the bulb of the white variety of Urginea maritima (Linne) Baker (Fam. Liliaceae), cut into pieces and carefully dried. Preserve Squill in tightly-closed containers, in a dry place. If made into the official tincture and assayed biologically, the minimum lethal dose should not be greater than 0.006 mil of tincture, or the equivalent in tincture of 0.0000005 Gm. of ouabain, for each gramme of body-weight of frog." U. S. "Squill is the bulb of Urginea Scilla, Steinh., divested of its dry membranous outer scales, cut into slices, and dried. When powdered should be kept quite dry over quicklimes." Br.

Squills; Scille, Fr. Cod.; Bulbus Scillae, P. G.; Meerzwiebel, G.; Scilla, It.; Escila (Bulbo de), Cebolla albarrana, Sp.

Urginea maritima (Urginea Scilia Steinh.) is a perennial plant, with fibrous roots proceeding from the bottom of a large bulb, which sends forth several long, lanceolate, pointed, somewhat undulated, shining, deep-green leaves. From the midst of the leaves a round, smooth, succulent flower-stem rises, from one to three feet high, terminating in a long, close spike of whitish flowers. These are destitute of calyx, and stand on purplish pedundes, at the base of each of which is a linear, twisted, deciduous floral leaf. The squill grows on the sea coast of Spain,
France, Italy, Greece, and the other countries bordering on the Mediterranean. The bulb is the official portion. It is generally dried for use, but is sometimes imported in the recent state packed in sand.

**Properties.**—The fresh bulb is pear-shaped, from 15 to 30 cm. in diameter, weighing as much as 5 or 6 pounds, and consists of fleshy scales attenuated at their edges, closely applied over each other, and invested by exterior scales so thin and dry as to appear to constitute a membranous coat. There are two varieties, distinguished as the red and the white squill. In the former the exterior coating is of a deep reddish-brown color, and the inner scales have a whitish rosy or very light pink epidermis, with a yellowish-white parenchyma; in the latter the whole bulb is white. They do not differ in medicinal virtue. The bulb abounds in a viscid, very acrid juice, which causes it to inflame and even excoriate the skin when much handled. By drying, this acrimony is very much diminished, with little loss of medicinal power. The bulb loses about four-fifths of its weight in the process. Vogel found 100 parts of fresh squill to be reduced to 18 by desiccation. The process is somewhat difficult, in consequence of the mucilaginous character of the juice. The bulb is cut into thin transverse slices, and the pieces dried separately by artificial or solar heat. The outer and central scales are rejected, the former being dry and destitute of activity, the latter too fleshy and mucilaginous.

Dried squill, as found in commerce, is "in irregular, more or less curved, somewhat flattened pieces, from 0.5 to 5 cm. in length, yellowish-white, somewhat translucent, nearly smooth and lustrous with slight projections of fibro-vascular bundles; brittle when dry and somewhat flexible when damp; odor slight; taste bitter and acrid. Under the microscope, sections of the scales of Squill show on the upper and lower surface a thin-walled epidermal layer, a mesophyll of nearly isodiametric or slightly elongated thin-walled cells and occasionally show in alcoholic or glycerin mounts spheroidal aggregates of a carbohydrate; numerous more or less rectangular cells containing mucilage and bundles of raphides of calcium oxalate, the latter from 0.075 to 1.0 mm. in length; fibro-vascular bundles few and isolated, with spiral or reticulate tracheae. Occasionally some of the parenchyma cells contain a few somewhat spherical starch grains. The powder is light yellow, with a tendency to cake in moist atmosphere and consisting of very irregular fragments; when examined under the microscope it exhibits numerous single crystals and bundles of long raphides of
calcium oxalate; fragments of thin-walled, colorless parenchyma, frequently with dark intercellular spaces due to the inclusion of air; fragments with spiral or reticulate tracheae are occasionally found. Squill yields not more than 8 per cent. of ash.

Examined by the microscope, the bulb is seen to be pervaded by innumerable minute acicular crystals of calcium oxalate. According to Hartwich, the mucilage occurs either in the form of large drops, filling the parenchymatous cells, or as masses enclosing the raphides. For an elaborate microscopic study, with plates, see A. Pharm., July, 1889. Water distilled from it had neither taste nor odor, and was drunk by Vogel to the amount of six ounces without effect. When kept in a dry place, squill retains its virtues for a long time; but if exposed to moisture it soon becomes mouldy.

"Assay. In curved, yellowish-white, somewhat translucent strips, from about two and a half to five centimetres long, frequently tapering towards both ends; tough and slightly flexible while moist, but brittle and easily pulverisable when dry. Almost inodorous; taste disagreeably bitter. Ash not more than 5 per cent." Br.

The virtues of squill are extracted by alcohol, but apparently only in part by water. It has been analyzed by Vogel, J. H. Marais, Lebour-dais, Tilloy, Merck, and by Schmiedeberg (Zeit. Physiol. Chem., 111, 112) with varying results. The bitter principle, not yet obtained pure, is scillitin. Merck, however, obtained three compounds of this class—scillipicrin, scillitoxin, and scillin. Jarmersted (A. E. P. P., 11, 22) obtained a glucoside which he called scillain, but which seems to be identical with scillitoxin.

Ewins (J. P. and Ex. T., 1912, ii, p. 155) separated from the squill two active principles, although neither of them in crystallizable form. The first is water soluble glucoside, which is fatal to the frog in doses of 0.03 Gm. for a 25 gramme frog. The second is a resinous body, very slightly soluble in water, but readily so in alcohol. Fatal dose for a frog is 0.06. Besides these they found a trace of caffeine. These authors state and it is generally acknowledged that the so-called active principles of squill which are found upon the market are not true principles but are impure bodies.

Schmiedeberg found a peculiar mucilage, analogous to dextrin, which
he calls sinistrin, \((C_6H_{10}O_5)\). It is white, easily soluble in water, insoluble in alcohol, laevo-rotatory; on boiling with dilute sulphuric acid it yields levulose and an inactive sugar of reducing properties. The mucilage is not affected by saliva or diastase. This last statement, however, was contradicted by F. Kurtz (A. J. P., 1894, 246), who says that diastase acts upon it, producing a reducing sugar. Kurtz also obtained a reducing sugar (probably dextrose) along with the gum direct by extracting the bulb with hot alcohol. S. Wanizewski (A. J. P., 1893, 498) found scillinine, soluble in alcohol, but insoluble in water and in chloroform; scillapicrine, soluble in both water and alcohol, and scillamarine, soluble in both chloroform and alcohol. The bulbs of Scilla maritima also yield a slightly colored liquid oil of unpleasant odor when distilled in a current of steam. (Husemann's Pflanzenstoffe, 2d ed., p. 406.)

**Uses.**—Squill belongs to that series of drugs, commonly known as the digitalis group, which have for their characteristic properties the power of slowing and strengthening the pulse, of contracting the blood vessels, and in toxic doses causing systolic spasm of the frog's heart. While it in many regards closely resembles digitalis in its physiological action, it is notable for the strong degree of vasomotor action and for its local irritant effect. Probably by virtue of its effects on the circulation, but also largely because of its local irritant action upon the renal epithelium, squill is one of the most active diuretics among this group of drugs. Indeed it is so stimulating to the kidney that in overdose it is capable of causing an acute inflammation of this organ. When given in large dose, partly because of the central emetic effect which is characteristic of the digitalis group, but largely because of its local irritant influence upon the stomach, it produces severe nausea and even vomiting. In overdoses it has been known to cause hypercatharsis, strangury, bloody urine, and fatal inflammation of the stomach and bowels.

While squill is capable of exercising all the beneficial effects of digitalis in chronic heart disease, because of its action upon the alimentary canal it is rarely employed for this condition unless associated with dropsy. Because of its stimulant action upon the kidney as well as upon the heart, it is peculiarly useful for the evacuation of edematous infusions due to weakness of the heart, and is also sometimes of service in the ascites of hepatic cirrhosis. When, however, there is active inflammation of the kidney it must be used with great caution if at all. Like other emetic drugs, if given in sufficient doses to nauseate it tends to increase
in the bronchial secretions and is occasionally used as an expectorant in bronchitis and spasmodic croup. Because of its potent action upon the circulation its use for this purpose, however, is not to be encouraged.

Neither water nor dilute acetic acid entirely extract the activity of squill. The only liquid preparations, therefore, which thoroughly represent the drug are those made with alcohol, of which the tincture is probably the better.

When given in substance it is most conveniently administered in the form of pill.

Dose, of squill, from one to two grains (0.065-0.13 Gm.).

**SCOPARII CACUMINA. Br.**

**BROOM TOPS**

"Broom Tops are the fresh and the dried tops of Cytisus scoparius, Link.". Br. "The dried top of Cytisus Scoparius (Linne) Link (Fam. Leguminosae)." N. F.

**Scoparius, N. F.;** Herba Scoparii, Spartium; Irish or Scotch Broom, Besom, Genet & balais, Fr.; Gemeine Besenginster, Besenginster, Besenkraut, Priemenkraut, G.

Cytisus scoparius is a common European shrub, cultivated as a sand-binder and locally naturalized on the Atlantic Coast from Nantucket to Virginia. It is a low, densely branched shrub, from three to eight feet high, with numerous straight, pentangular, bright green, very flexible branches, and small, oblong, glabrous leaves, usually ternate, but on the upper part of the plant sometimes simple. The flowers are numerous, papilionaceous, large, showy, of a golden-yellow color, and solitary upon
short axillary peduncles. The seeds are contained in a compressed legume, which is hairy at the sutures. It is essential that true broom be carefully distinguished from Spanish broom (Spartium Junceum), since a number of cases of poisoning have occurred from the substitution of the dried flowers of Spartium for those of broom.

The whole plant has a bitter, nauseous taste, and, when bruised, a strong, peculiar odor. The tops of the branches are used in medicine. They are in thin, flexible, branched twigs, from 2 to 3 mm. in thickness, five-angled; externally dark green, nearly glabrous, with numerous reddish-brown cork patches; internally yellowish, fracture short-fibrous, that of thicker pieces tough and splintery, upper leaves sessile, with often only one obovate leaflet present in small amount or absent. Odor slight, on bruising more distinct and peculiar; taste disagreeable, bitter. Scoparius yields not more than 5 per cent. of ash." N. F. IV.

"Stem dark green, with long, straight, slender, alternate branches; the latter, like the upper part of the stem, winged, tough, flexible, and glabrous. Leaves, when present, small, sessile, and simple above, stalked and trifoliate below. Odor of the fresh tops, especially when bruised, characteristic; the dry tops almost inodorous." Br.

The seeds are reported to be used sometimes, and to be as active as the tops. Water and alcohol extract their active properties. According to Cadet de Gassicourt, the flowers contain volatile oil, fatty matter, wax, chlorophyll, yellow coloring matter, tannin, a sweet substance, mucilage, albumen, and lignin. Stenhouse has separated from them two principles, scoparin, \(\text{C}_{21}\text{H}_{22}\text{O}_{10}\) (Goldschmidt and Himmelmayer (Ap. Ztq., 1893, 566) give the following formula of scoparin: \(\text{C}_{10}\text{H}_{16}\text{O}_8(\text{OH})(\text{OCH}_3)\)), and an alkaloid, sparteine, \(\text{C}_{15}\text{H}_{26}\text{N}_2\). The former is in stellate crystals, easily dissolved by boiling water and alcohol, and is obtained by purifying a yellow gelatinous substance deposited upon the evaporation of the decoction. It is only slightly soluble in cold water, more readily in hot water with greenish light yellow color, easily soluble in aqueous ammonia and caustic and carbonated alkalies. It is decomposed by heat. When fused with potassium hydroxide it yields, according to Hlasiwetz, phloroglucin and protocatechuic acid. Sparteine was obtained by distillation from the mother waters of the scoparin. It is a colorless liquid, having a peculiar bitter taste, and all the properties of a volatile alkaloid. It is heavier than water, and boils at 288° C. (550.4° F.) if distilled in a current of
hydrogen gas. It dissolves only slightly in water, but takes up some water itself. In contact with water it becomes opalescent. It turns yellowish on distillation in air, but can be distilled colorless in an atmosphere of carbon dioxide. It is colorless, but becomes brown by exposure to light; it has at first an odor of aniline, but this is altered by rectification. It readily neutralizes acids and forms crystallizable salts, which are extremely bitter. Its sulphate occurs in colorless crystals, and is freely soluble in water. (See P. J., June 28, 1879; also Sparteinae Sulphas.) By the action of potassium dichromate and sulphuric acid, oxysparteine, $C_{15}H_{24}N_2O$, is formed, and by the action of hydrogen dioxide upon this, a deliquescent trioxysparteine, $C_{15}H_{24}N_2O_3$, is obtained; if the hydrogen dioxide acts upon sparteine itself, dioxysparteine, $C_{15}H_{24}N_2O_2$, is formed as a solid, crystallizing in prisms melting at 128.5° C. (263.3° F.). Zinc and hydrochloric acid reduce sparteine to hydrosparteine, $C_{15}H_{28}N_2$, a thick liquid boiling at from 281° to 284° C. (537.8°-543.2° F.). (Schmidt, Pharmaceutische Chemie, 3te Auf., Bd. ii, 1276.)

**Uses.**—Scoparius is diuretic and cathartic, and in large doses emetic, and has been employed with advantage in dropsy. Cullen prescribed it in the form of decoction, made by boiling half an ounce of the fresh tops in a pint of water down to half a pint, of which he gave a fluidounce (30 mils) every hour until it operated by stool or urine. The seeds may be given in powder, in the dose of from ten to fifteen grains (0.65-1.0 Gm.). A fluidextract is official in the N. F. IV.

Scoparin probably represents the diuretic and purgative influences of scoparius, although its physiological and therapeutic properties have not as yet been sufficiently investigated. For description of the effects of sparteine, see Sparteinae Sulphas.

**Oxysparteine, $C_{15}H_{24}N_2O$.**—This is an alkaloidal oxidation product of sparteine, originally described by F. Ahrens (Ber. d. Chem. Ges., 1891). It occurs in white, somewhat hygroscopic needles, melting at about 84° C. (183.2° F.), soluble in water, alcohol, ether, and chloroform. It has been found by Hurthle (A. E. P. P., 1892) to be a cardiac stimulant, decreasing the pulse rate, but markedly increasing the arterial pressure and heart work. The hydrochloride, which occurs in large needles (often consolidated together) and is very soluble in water, has been used hypodermically by von Oefele in cases of heart failure. The dose is half a
grain (0.032 Gm.), rapidly increased to one and a half grains (0.096 Gm.). The system is said soon to become accustomed to it.

Dose, of scoparius, ten to fifteen grains (0.65-1.0 Gm.).

**Off. Prep.**—Infusum Scoparii, Br.; Succus Scoparii, Br.

**Scolopendrium.** Scolopendrium Scolopendrium (L.) Karst. Asplenium Scolopendrium L. Phyllitis Scolopendrium (L.) Newman. Hart's Tongue.—The fronds of this fern, which is indigenous both in Europe and America, have a sweetish, mucilaginous, and slightly astringent taste, and, when rubbed, a disagreeable oily odor. They were used as a deobstruent in visceral affections, as an astringent in hemorrhages and fluxes, and as a demulcent in pectoral complaints.

**Scopola.** Scopolia. Belladonna Scopola. Scopola Belladonna. Japanese Belladonna, (incorrectly).—"The dried rhizome of Scopola Carniolica Jacquin (Fam. Solanaceae), yielding, when assayed as directed below, not less than 0.5 per cent. of its alkaloids." U. S. VIII. The genus Scopola is the connecting link between Atropa and Hyoscyamus, resembling Atropa in leaf and flower and in the microscopical character of its rhizome, but differing in that its fruit is not a berry but is a pyxis resembling that of Hyoscyamus. For description of drug and its histological study, see Kraemer, A. J. P., 1908, p. 459. The Japanese plant, S. japonica, is so closely allied to S. carniolica that its specific distinction is very doubtful; it has been separated upon the characters of the style being curved, the calyx-teeth unequal and the leaves less obovate and having much longer petioles than S. Carnioliaca; but Holmes has shown that the curved style occurs in S. Carniolica. S. Carniolica is a common plant in Bavaria, Austro-Hungary, and Southwestern Russia, usually in the hilly districts, where it grows in damp, stony places. Its general appearance is that of the belladonna, but it is much shorter, rarely growing above a foot in height, has thinner leaves, and is especially distinguished by its fruit being a transversely dehiscent capsule and by the presence of a distinct rhizome.

The rhizome was officially described as "of horizontal growth, more or less curved and shortly and sharply flexuous, cylindraceous and somewhat flattened vertically, occurring mostly in pieces from 2.5 to 7.5 Cm. long and 0.8 to 1.6 Cm. broad, often split before drying; upper surface marked with closely set, large, cup-shaped stem scars, margins irregularly contracted; externally varying from yellowish-brown to dark brownish-gray, finely and irregularly wrinkled longitudinally, obscurely annulate and more or less nodular-roughened; fracture short and sharp, exhibiting a yellowish-white bark, its corky layer dark brown, or pale brown, wood indistinctly radiate, and central pith rather horny; nearly inodorous; taste sweetish, afterwards bitterish and strongly acrid." U. S. VIII.

The Japanese rhizome is from 5 to 15 cm. long, about 1 cm. in diameter, rarely branched, cylindrical or slightly compressed, knotty, bent, with circular disk-like
scars, of a pale brown color, not whitish when abraded, with a slightly mousy, narcotic odor, and a taste nearly free from bitterness. According to Thos. Greenish, the microscopical characteristics of the rhizome of *S. Carniolica* are very similar to those of belladonna root, the chief differences being that the bark is less thick, the dark line under the epidermis narrower, the vascular bundles neither so large nor so numerous, and the bundles of raphides less pronounced; the starch grains are also smaller and their shape less distinct. The structure of the rhizome of *S. japonica* was found to be the same as that of the European species. Kraemer (loc. cit.) has since shown that acopola possesses only reticulate tracheae while in belladonna root the tracheae possess both simple and bordered pores.

The alkaloid scopolamine (or *scopoline*), C$_{17}$H$_{21}$O$_4$N, has been found to be the characteristic constituent of the root. (See p. 985.) Inactive scopolamine, C$_{17}$H$_{21}$O$_4$N, also known as atroscine, is present. It melts at 82° C. (179.6° F.), and yields by hydrolysis tropic acid and scopoline. Seward W. Williams states, as the result of the assay of many tons of the root of Atropa belladonna and of the rhizome of scopola, each of the best qualities occurring in the American market, that while the belladonna root yields on an average 0.50 per cent. of alkaloid, the scopola yields 0.58 per cent. See also *Proc. A. Ph. A.*, 1899, 285.

**Fluidextract of Scopola, U. S. VIII,** was made as follows: "Scopola, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity, to make about one thousand mils [or 33 fluidounces, 61/2 fluidrachms] Mix eight hundred mils [or 27 fluidounces, 24 minims] of Alcohol with two hundred mils [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with three hundred and fifty mils [or 11 fluidounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Scopola is exhausted. Reserve the first eight hundred mils [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and mix thoroughly. Assay ten mils of this liquid as directed below; from the result thus obtained, ascertain by calculation the amount of mydriatic alkaloids in the remainder of the liquid, and add to this enough menstruum to make each one hundred mils of the finished Fluidextract contain 0.5 Gm. of the mydriatic alkaloids from Scopola." U. S. VIII.

**Extract of Scopola, U. S. VIII,** was made by evaporating the fluidextract and assaying it so that it contains 2 per cent. of mydriatic alkaloids. Dose, one-eighth to one-fourth of a grain (0.0016 Gm.).

The physiological and medicinal properties of scopola are very similar to those of belladonna, but the crude drug has been scarcely used at all in internal medicine. It has been largely employed in America in the manufacture of belladonna plaster and
much of the hyoscine of commerce in the last decade has been obtained from it. Its alkaloid Scopolamine hydrobromide is recognized in the United States Pharmacopoeia. Dose, of the drug, one to two grains (0.65-0.13 Gm.); of the fluid extract, one-half to three minims (0.03-0.2 mil).

**Scrophularia.** Scrophularia marilandica L. (S. nodosa L.). Figwort. Scrofula Plant. Scrofulaire, Fr. Kropfwurz. Kontenwurz, G. (Fam. Scrophulariaceae)—This rather tall herb, having a square stem, opposite leaves and slender panicles of small, greenish-purple flowers, grows in rich open woods from New York to North Carolina and west to Kansas. Its leaves have when fresh a rank fetid odor, and a bitter, somewhat acrid taste; but these properties are diminished by drying. Water extracts their virtues, forming a reddish infusion, which is blackened by ferric sulphate. For histological study of root, see P. J., 1896. Walz has obtained from it two proximate principles, which he names respectively scrophularin and scrophularosmin. (Mayer, A. J. P., 1863, p. 295.) Figwort leaves were formerly considered. tonic, diuretic, diaphoretic, discutient, anthelmintic, etc.; useful in scrofula and as a local application in hemorrhoids. Van de Moer (P. J., 1896) affirms that the seeds are toxic, belonging to the digitalis group.

**Scutellaria.** N. F. IV. Skullcap. Scullcap. Hoodwort. Madweed. Mad-dog or Sideflowering Scullcap. Blue Pimpernel. Hooded Willow-herb. Scutellaire, Fr. Helmkraut, Schildkraut, G.—"The dried plant of Scutellaria lateriflora Linne (Fam. Labiatae)." N. F. Scutellaria was official in the U. S. P. VIII, but was introduced into the N. F. IV.

Several species of scutellaria have attracted attention. Scutellaria galericulata L., which grows in wet places from Newfoundland to North Carolina and west to Nebraska, has a feeble, somewhat alliaceous odor, and a bitterish taste. It has been employed in intermittents, and externally in old ulcers. S. integrifolia L. is intensely bitter, and might probably be found useful as a tonic.

Scutellaria lateriflora is an indigenous, perennial herb, with a stem erect, much branched, quadrangular, smooth, and one or two feet high. The leaves are ovate, acute, dentate, subcordate upon the stem, opposite, and supported upon long petioles. The flowers are small, of a pale blue color, and disposed in long, lateral, 1-sided, leafy racemes. The plant grows in wet shaded places in the United States and Canada.

The dried tops are described as "about 50 cm. in length, smooth; stem quadrangular, branched; leaves opposite, petiolate, about 5 cm. in length, ovate-lanceolate or ovate-oblong, serrate; flowers about 6 mm. in length, in axillary one-sided racemes, with a pale blue corolla and bilabiate calyx, closed in fruit, the upper lip helmet-shaped. Odor slight; taste slightly bitter. Scutellaria yields not more than 12 per cent. of ash." N. F. H. Molisch and G. Goldschmidt (Ph. Ztg. Dec. 4, 1901, 965) obtained from scutellaria and a number of other labiates an identical body, to which they gave the name scutellarin. It is present in all of the different scutellarias, being most abundant in the upper epidermis of the leaf, but found also in the roots, stems and flowers of the plant. It was further obtained from the leaves of Galeopis Tetrahit L., and of Teucrium.
Chamaedrys L. In Scutellaria altissima L., the presence of cinnamic and fumaric acids were also established. Scutellarin is obtained by boiling freshly gathered leaves for fifteen minutes in ten times their weight of water, filtering the decoction and adding from 1 to 2 per cent. of hydrochloric acid, which causes an abundant precipitate of scutellarin. If precipitation is effected from the hot solution, the scutellarin separates in the form of light yellow crystals. The formula $C_{10}H_8O_3$ has been assigned to scutellarin. Its alcoholic solution gives a red precipitate with lead acetate and an intense green color with ferric chloride, changing on heating to a red color if the reagent is not present in great excess; alcoholic potassium or sodium hydroxides, as also alkali acetates, produce reddish-yellow precipitates, which change to green on exposure to the air. Solution of barium hydroxide has the same effect. The green color is produced immediately if an oxidizing agent, such as chlorine or bromine water, is added.

Scullcap is as destitute of medicinal properties as a plant may well be, not even being aromatic. When taken internally, it produces no very obvious effects, and probably is of no remedial value, although at one time it was esteemed as a remedy in hydrophobia. It has also been used in neuralgia and convulsive affections, chorea, delirium tremens, and nervous exhaustion from fatigue or over-excitement. (A. J. P., xxiii, 370; N. J. M. R., v; M. S. Rep., 1870.) Dose, thirty to ninety grains (2.0-5.8 Gm.)

**Sedum.** Sedum acre L. Biting Stonecrop. Wall Pepper. Small Houseleek. Mossy Stonecrop. Joubarbe acre, Poivre des Murailles, Fr. Mauerpfeffer, Steinkraut, G. (Fam. Crassulaceae)—This European plant has escaped to some extent from the gardens and grows wild in New England. It is spreading moss-like, possesses small, very thick leaves and yellow flowers. It causes vomiting and purging, and applied to the skin produces inflammation and vesication. The fresh herb and the expressed juice have been used as an antiscorbutic, emetic, cathartic, and diuretic, and have been applied locally to old ulcers, warts, and other excrescences. Other species are less acrid, and are even eaten as salad in some parts of Europe. Such are Sedum rupestre L., and S. album L. Telephium L. was formerly employed externally to cicatrize wounds, and internally as an astringent in dysentery and hemoptysis, and is still esteemed by the common people in France as a vulnerary. Ernst Mylius found in 100 parts of Sedum acre 2.2 parts of a soft, not acid resin, 12.80 parts of uncrystallizable sugar, and 12.40 parts of a soft acid resin, besides an alkaloid and inert substance. (J. P. C., 4e ser., xvii, 81.)

**Semecarpus.** Semecarpus venosa (Fam. Anacardiaceae), the TschongottTree.—The highly poisonous nature of the bark of this tree, which is a native of the Caroline Islands, is, according to Thorns and Mannich [Ph. Ztg., 1902), due to the presence of cardol (anacardic acid).

**Sempervivum.** Sempervivum tectorum L. Common Houseleek. Hen-and-Chickens. Grandej oubarbe, Fr. Hauswurz, Hauslauch, Dachwurss, G. (Fam. Crassulaceae)—A succulent, perennial plant with imbricated leaves and cymes of rose-purple flowers. It is extensively cultivated. In Europe the bruised recent leaves of this plant are...
employed as a cooling application to burns and other external inflammations. The juice is said to cure warts.

**Senecio.** N. F. IV. Life Root.—Senecio was introduced into the N. F. IV. It is defined as follows: "The dried overground portions of Senecio aureus Linne (Fam. Compositae), gathered when flowering." N. F. Various species of this composite genus have been domestically used in the treatment of amenorrhea both in Europe and America, and their value has been confirmed by various practitioners. (See P. J., Dec., 1897.) The species specially used have been Senecio vulgaris L., Common Groundsel, Senecon, Fr., Kreutzkraut, Jacobskraut, G.; an annual European plant introduced into this country and growing quite commonly in waste grounds, and the North American species, S. aureus L., commonly called golden ragwort or liferoot and growing in wet meadows in the Northern United States. It is described as follows: "Stems from 3 to 6 dm. in length, if entire bearing a basal rosette of leaves; sparingly clothed with successively smaller leaves and bearing at the summit several yellow heads in a loose corymb, white floccose when young, but mostly glabrous when expanded, radical leaves on long, slender petioles, mostly of rounded form from 5 to 7 cm. in breadth, the base often cordate, the summit rounded, the margin crenate-dentate; stem-leaves gradually changing from the shape of the radical leaves to lyrately-pinnate, then pinnatifid and sessile, and at length clasping, oblong, and incised; heads slender peduncled, from 12 to 25 mm. in breadth, the lance-linear involucral scales in about two series, closely appressed, rays about ten, bright-yellow, disk flowers very numerous, small, bearing a glabrous akene and a white pappus. Odor characteristically aromatic; taste bitter, slightly astringent and distinctly acid and pungent. Senecio yields not more than 10 per cent. of ash." N. F. IV. The fluidextract is official in the N. F. IV and made from a menstruum of two volumes of alcohol and one volume of water. It is used in the dose of one fluidrachm (3.75 mils) three times a day.

In S. vulgaris, and in lesser amount also in S. Jacoboea L., Grandval and Lajoux (Union Medicale du Nord-est, xix, 1895) have found two alkaloids, senecionine, 

\[ C_{18}H_{26}NO_6 \]

which is slightly, and senecine, which is readily, soluble in ether. According to Wiet, senecionine is a paralyzant of the peripheral motor and sensory nerves, while Bunch has found that the alcoholic extract of Senecio Jacoboea is capable of producing a rise of the arterial pressure due to contraction of the arteries, followed, if the dose has been large enough, by arterial dilatation with fall of pressure. (B. M. J., 1900, ii, 212.) Senecin of the eclectic practitioners is made by precipitating the tincture with water and is not therefore a pure active principle.

The rhizomes of the Mexican species, Senecio grayanus Hemsl. and S. cervariaefolius Sell., constitute maturin, the plants being known as matarique, maturin, or guerena. They produce rise of temperature, dilatation of the pupil, and violent tetanic spasms. Henckel states that they contain a glucoside resembling digitalin. (A. J. P., Jan., 1891; also Nouv. Rem., 1888, and P. J., March, 1889.) Several species of senecio, especially the S. Jacoboea, have been accused of causing poisoning in cattle which have eaten them. Cushny has found in the S. Gladifolium Watt two alkaloids, senecifoline and senecifolidine, which are actively poisonous, causing symptoms
similar to those which have occurred in animals after eating the compound. The most characteristic pathological lesion was cirrhosis of the liver. The fluidextract of *S. vulgaris* has been recommended by Dalche and others in dysmenorrhea and amenorrhea. (Bull. Med., 1904.)

**SENEGA. U. S. (Br.)**

**SENEGA Seneg. [Senega Snakeroot, Seneca Snakeroot]**

"The dried roots of *Polygala Senega* Linne (Fam. Polygalaceae), without the presence or admixture of more than 5 per cent. of stems and other foreign matter." U. S. "Senega Root is the dried root of *Polygala Senega*, Linn." Br.

*Senega Root*, *Polygala Senega*, *Br. Senegae Radix*, *Rattlesnake Root*, *Mountain Flax*, *Senega or Seneca Root*, *Polygala de Virginie*, *Fr.*

Besides *P. Senega*, two other species have attracted some attention in Europe—*P. amara* and *P. vulgaris*—as remedies in chronic pectoral affections; but, as they are not natives of this country, and are never used by practitioners here, they do not merit particular notice.

A senega which was first used in Japan, and which has been referred by some writers to *P. japonica*, by others to *P. tenuifolia*, has been examined by Renter, who finds in it 0.8 per cent. of resin, traces of methyl salicylate, and 8.8 per cent. of an oil which has somewhat the odor of patchouli. For description of other species see *Polygala*.

*Polygala Senega* has a perennial branching root, from which several erect, simple, smooth, round, leafy stems annually rise, from nine inches to a foot in height. The stems are occasionally tinged with red or purple below, but are green near the top. The leaves are alternate or scattered, lanceolate, pointed, smooth, bright green on the upper surface, paler beneath, and sessile or short petiolate. The flowers are small and white, and form a close spike at the summit of the stem. The calyx is their most conspicuous part. It consists of five sepals, two of which are wing-shaped, white, and larger than the others. The corolla is small and closed. The capsules are small, much compressed, obcordate, two-valved and two-locular, with two oblong-ovate, blackish, hairy seeds, slightly longer than the lobes of the caruncle. In *P. alba* Nutt, the seeds are silky.
and about twice the length of the caruncle lobes.

Polygala Senega extends over most of the United States and Southern Canada, east of the Rocky Mountains. At one time it was largely collected in Canada and the Northeastern Atlantic states; when this supply was exhausted, Kentucky and the States West and Southwest of it we're invaded; then Wisconsin and the Northwestern States, from which with Western Canada the commerce at present derives its chief supply. There are two varieties of the plant, the typical P. Senega, the form found in the Northeastern United States, and the variety latifolia (T. and G.) which extends from Maryland and Pennsylvania to Michigan and Tennessee. This variety is distinguished by its height (from ten to twenty inches) and its very large, ovate or ovate-lanceolate leaves, which taper towards each end and attain a length of four inches. The root of commerce seems to be obtained from both varieties. It is brought into market in bales weighing from fifty to four hundred pounds. See True (Ph. Era, 1913, xlvi, p. 68).

Owing to the extensive use of senega considerable interest is manifested in the cultivation of the plant. Hood reports to have demonstrated that it can be successfully cultivated. (Vermont Sta. Rept., 1907, p. 371.) It has also been grown by the Bureau of Plant Industry, U. S. Dept. of Agriculture.

Properties.—Senega is officially described as "usually in broken pieces; when entire slenderly conical, more or less tortuous, somewhat branched, from 3 to 15 cm. in length and from 2 to 10 mm. in thickness and bearing a few rootlets; crown knotty with numerous buds and short stem-bases; externally brownish-yellow, the crown rose-tinted, longitudinally wrinkled, frequently marked by a keel; fracture short, wood pale yellow, usually eccentrically developed; odor peculiar, penetrating; taste sweetish, afterwards acrid. Under the microscope, transverse sections of Senega usually show a characteristic eccentric development of wood, the central cylinder varying in outline from elliptical or ovate to irregularly fan-shaped, and being surrounded by an unevenly developed cortex which is thickest next to the broadest strands of wood and where the wood-wedges are narrow and the medullary rays very broad, the cortical parenchyma occupies a very narrow zone of the cross-section; in older roots a corky layer of from 4 to 5 rows of tangentially elongated, light yellowish or yellowish-brown cells; outer bark of about 20 rows of cells on one side of the root and only
10 or less on the other, the cells having slightly thickened walls and containing a colorless or pale yellow, amorphous substance, which is liberated in the form of large globules on the addition of a drop of potassium hydroxide T.S.; inner bark, the cells in radial rows, consisting of parenchyma, small groups of sieve tissue and medullary rays, the latter from 1 to 3 cells wide; all the cells in this zone show a collenchymatous thickening of the walls and contain an amorphous substance similar to that found in cells of the outer bark; woody layer of tracheas with bordered pores, wood-fibers with oblique simple pores, tracheids, and medullary rays, the latter being rather indistinct and resembling the wood-fibers; tissues of the central layer of wood colored yellowish-or reddish-brown on the addition of a drop of potassium hydroxide T.S. The powder is yellowish-gray to light yellowish-brown, odor penetrating, slightly sternutatory; when examined under the microscope it exhibits a mixture of fragments of parenchyma containing oily globules and wood-fibers with tracheae; wood-fibers, non-lignified and with oblique simple pores, from 0.175 to 0.25 mm. in length; trachea? with simple and bordered pores and about 0.175 mm. in length; medullary ray cells somewhat lignified and with large simple pores. Extract 10 Gm. of powdered Senega by means of a Soxhlet apparatus, using 50 mils of ether containing 2 drops of hydrochloric acid. Continue the extraction during four or five hours and then add sufficient ether to make the liquid measure 50 mils. Take 25 mils of this solution and evaporate it on a water bath to dryness; the residue weighs not less than 0.3 Gm., and upon dissolving it in 10 mils of chloroform, transferring the solution to a test tube and adding 5 mils of sulphuric acid to form an underlying layer, a reddish-brown color is produced at the zone of contact, and the sulphuric acid shows a slightly green fluorescence after the mixture has stood for twenty-four hours. Pour 10 mils of the original ethereal solution into a beaker containing 10 mils of water and warm the mixture on a water bath until the ether has evaporated; the aqueous solution, upon filtering and adding a few drops of ferric chloride T.S., becomes a bright pinkish purple. Senega yields not more than 5 per cent. of ash." U. S.

"Greyish or brownish-yellow, slender, usually from five to ten centimetres long, with a knotty crown bearing the bases of numerous, slender, aerial stems; frequently curved or contorted, sparingly branched, keeled, sometimes transversely wrinkled. Fracture short. In transverse section, a horny translucent cortex free from starch grains and a white, often irregularly developed, wood. Characteristic odor;
taste at first sweet, afterwards acrid." Br.

Holm describes the pharmacognosy of senega root and the morphology of the plant in M. R., 1907, xvi, p. 155. Hartwich has made a very interesting observation in that he has found starch occasionally present in official senega. (Apoth.-Ztg., xxvi, p. 84.) Hartwich has also described two false senegas. (S. W. P., xlvi, pp. 537 and 749.) The pharmacognosy of the drug has been well elaborated by Tunmann in Ph. Zentralh., xlxi, p. 61. Muller describes and figures senega and a number of the drugs that have been used as adulterants of this drug or as occasional contaminations. (Pharm. Praxis., vii, p. 309.)

Senega root varies somewhat in appearance according to the locality from which it is derived, and local varieties are recognized in commerce. In Southern senega the roots are very small, while in Manitoba senega they are large and thick, dark in color, and often have purple markings about the crown. The official senega is often known in commerce as Southern senega, or small senega, the roots seldom attaining the size of an ordinary lead-pencil, and four to five hundred of the dried roots being required to make a pound.

Since 1870 the so-called Northern, White, False, or Large senega has been sent into the American market from Wisconsin, Minnesota, and further west. It is much larger than true senega, probably eighty to one hundred to the pound. The knot at the top of the root is from one to three inches in diameter; below it the root abruptly contracts to from half an inch to an inch in diameter; it is usually from eight to ten inches long, more fleshy and much less contorted than true senega, nearly free from small rootlets, but breaking-up below into from four to eight descending branches; very light-colored, with the ligneous portion thick and regular, and in the circular outlines of the section, with the keel rudimental or not rarely altogether absent. The taste is similar to that of true senega, but somewhat more mucilaginous and less rapidly acrid. In structure, false senega root is very -similar to the true root; it has, indeed, been asserted that there are anatomical differences between the two senegas, but O. Linde (P. J., xvi, 724) has been unable to make out any such differences. According to L. E. Sayre (A. J. P., Sept., 1897), it is not possible to distinguish the two drugs when powdered. For description of the roots of a number of species of Polygala see Flora, Jan., 1886, and D. C., 1901, 26. False Senega was thought to be the product of Polygala Boykinii Nuttall, or of P. alba Nuttall, whose
habitat extends from the mountains of Texas to western British America, but Farwell (M. R., 1907, xvi, 221) believes it is from the P. Senega, as it has the characteristic keel-like ridge of the official drug. The properties of senega as well as the medicinal virtues of the root, are extracted by boiling water and by alcohol. Diluted alcohol is an excellent solvent.

Senega root was analyzed by Gehlen, Peschier of Geneva, Feneulle of Cambray, Dulon d'Astafort, Folchi, and Trommsdorff, and subsequently by Quevenne. The virtues of senega appear to reside chiefly, if not exclusively, in the acid principles called senegin, $C_{17}H_{26}C_{10}$, and polygalic acid, $C_{19}H_{30}C_{10}$. These principles resemble saponin very closely and are recognized as distinct. Quevenne obtained polygalic acid by the following process: Powdered senega is exhausted by alcohol of 33°, and so much of the alcohol is distilled off as to bring the resulting tincture to the consistence of syrup. The residue is treated with ether in order to remove the fatty matter. The liquid upon standing deposits a precipitate, which is separated by filtration and is then mixed with water. To the turbid solution thus formed alcohol is added, which facilitates the production of a white precipitate, consisting chiefly of polygalic acid. The liquid is allowed to stand for several days, that the precipitate may be fully formed. The supernatant liquid being decanted, the precipitate is drained upon a filter, and, being removed while yet moist, is dissolved by the aid of heat in alcohol of 36°. The solution is boiled with purified animal charcoal, and filtered while hot. Upon cooling, it deposits the principle in question in a state of purity. Thus obtained, polygalic acid is a white powder, inodorous, and of a taste at first slight, but soon becoming pungent and acrid, and producing a very painful sensation in the throat. It is fixed, unalterable in the air, inflammable, soluble in water slowly when cold and rapidly with the aid of heat, soluble in all proportions in boiling absolute alcohol, which deposits most of it on cooling, quite insoluble in ether and in the fixed and volatile oils, and possessed of the properties of reddening litmus and neutralizing the alkalies. Quevenne found it, when given to dogs, to occasion vomiting, and much embarrassment in respiration, and in large quantities to destroy life. Dissection exhibited evidences of inflammation of the lungs, and frothy mucus was found in the stomach, esophagus, and superior portion of the trachea, showing the tendency of this substance to increase the mucous secretion, and explaining in part the beneficial influence of senega in croup. (J. P. C., xxii, 449, and xxiii, 227.) Bolley showed that this active principle was resolvable by
hydrochloric acid into glucose and a peculiar substance called sapogenin. Rochleder (Chem. Cb., 1867, p. 925) confirmed this view of the identity of polygalic acid and saponin.

Christophson (J. P. C., 1874) and Schneider (A. Pharm., [3], 7, 394) have thoroughly established the existence of saponin in senega root. According to the researches of Trommsdorff and Schneider, saponin is contained solely in the bark, the woody tissues being inert. (See Quillaja.) L. Renter (A. Pharm., 1889, 309 and 452) finds that the constituents of senega root are fixed oil and resin, traces of volatile oil (a mixture of valeric ether and methyl salicylate), sugar (7 per cent.), which seems to develop to a greater extent upon standing, senegin or saponin (from 2 to 5 per cent.), yellow coloring matter, and malates. The quantity of methyl salicylate varied in different samples from 0.25 to 0.33 per cent. See also Schroeder’s analysis. (A. J. P., 1896, 178.) Methyl salicylate occurs in very many, if not all, of the species of the genus Polygala. (See paper by Kremers and James, Ph. Rev., xvi.) Kain (Ph. Ztg., 1898, 562) states that he has discovered a laevorotatory glucoside distinguished from saponin by its mild taste, solubility in absolute alcohol, and in its not giving a precipitate with barium hydroxide.

Senega yields its virtues to water, cold or hot, and to boiling alcohol, and the extracts obtained by means of these liquids have the sensible properties of the root. But under the influence of heat a portion of the acrid principle unites with the coloring matter and coagulated albumen, and thus becomes insoluble in water. In forming an aqueous extract, the infusion should be prepared by percolation, as it is thus most concentrated, and consequently requires less heat in its evaporation. In preparing the infusion, the temperature of the water should not exceed 40° C. (104° F.). Experience has thoroughly proved the value of the use of an alkali in small proportion in making galenical preparations of senega, it prevents gelatinization and combines with the active principles. (See Fluidextractum Senega)

The roots of Panax quinquifolius L., or ginseng, were at one period frequently mixed with those of senega, but are easily distinguishable by their shape and taste. The roots of Gillenia trifoliata (L.), Moench., and Asclepias Vincetoxicum L. (P. J., ix, 411), and of Triosteum perfoliatum L., are noted as occurring in commercial senega; they are readily detected by the absence of the keel-like line.
Uses.—Senega owes what therapeutic virtues it possesses to its saponins. (See Quillaia.) These by their local irritant action upon the mucous membrane of the stomach tend to cause nausea, thereby increasing the secretions of the sweat glands and especially of the bronchial glands. For this reason the drug has been used as an expectorant in various forms of bronchitis and in asthma. In overdose it is capable of acting as an irritant poison producing violent vomiting and purging. Polygalic acid may be employed in doses of from one-fourth to one grain (0.016-0.065 Gm.), administered in the form of either pill or capsule.

For a formula for its preparation, see also A. J. P., 1860, 150.

Dose, from fifteen to twenty grains (1.0-1.3 Gm.).

SENNA. U. S. (Br.)

SENNA Senn.

"The dried leaflets of Cassia acutifolia Delile, known in commerce as Alexandria Senna, or of Cassia angustifolia Vahl, known in commerce as India Senna (Fam. Leguminosae), without the presence or admixture of more than 10 per cent. of stem tissues, pods, seeds and other impurities." U. S. " Senna Leaves are the dried leaflets of Cassia acutifolia, Delile, and of Cassia angustifolia, Vahl. Known in commerce as Alexandria senna, and Tinnevelly senna." Br.

Sennae Folia, Br.; Senna Leaves; Sene, Fr. Cod.; Feuillea de Sene, Fr.; Folia Senna; P. G.; Sennesblatter, G.; Sena, It.; Sen, Sp.

The plants which yield senna belong to the genus Cassia, of which several species contribute to furnish the drug. These were confounded by Linneaus and comprised in a single species, which he named Cassia Senna. Since his time the subject has been more thoroughly investigated, especially by Delile, who accompanied the French
expedition to Egypt and had an opportunity of examining the plant in its native country. Besides the official species, it is probable that C. lanceolata of Forskhal and C. aethiopica of Guibourt contribute towards commercial senna. The leaves of a number of species of Cassia are utilized like senna leaves in the respective countries in which they grow, among which may be mentioned C. marilandica L.; C. cathartica Mart.; C. rugosa Don.; C. splendida Vog.; C. laevigata Willd.; C. multijuja Rich.; C. Chamaecrista L.; and C. montana Hayne. Farwell asserts that Cassia marilandica and other American species of Cassia have been offered in large lots and sold as senna. (M. R., xvii, p. 35.)

Cassia acutifolia is a small undershrub, two or three feet high, with a straight, woody, branching, whitish stem; but, according to Landerer, the senna plant attains the height of eight or ten feet in the African deserts. The leaves are alternate and pinnate, with glandless petioles, and two small narrow pointed stipules at the base. The leaflets, of which from four to six pairs belong to each leaf, are almost sessile, oval-lanceolate, acute, oblique at their base, nerved, from half an inch to an inch long, and of a yellowish-green color. The flowers are yellow, and in axillary spikes. The fruit is a flat, elliptical, obtuse, membranous, smooth, grayish-brown, bivalvular legume, about an inch long and half an inch broad, scarcely if at all curved, and divided into six or seven cells, each containing a hard, heart-shaped, ash-colored seed. C. acutifolia grows wild in great abundance in Upper Egypt, Nubia, Sennaar, and other parts of Africa. This species furnishes the greater part of the variety known in commerce by the name of Alexandria senna.

Cassia angustifolia, as usually grown is annual, but with care it may be made to live through the year, and then assumes the character of an undershrub. It has an erect, smooth stem, and pinnate leaves, with from four to eight pairs of leaflets. These are nearly sessile, lancedolate, obscurely mucronate, oblique at the base, smooth above and somewhat downy beneath, with the veins turned inward so as to form a wavy line immediately within the edge of the leaflet. The most striking character of the leaflet is its length, which varies from 2 to 5 cm. The petioles are without glands; the stipules minute, spreading and semi-hastate. The flowers are bright yellow, and arranged in axillary and terminal racemes rather longer than the leaves. The legume is oblong, membranous, tapering abruptly at the base, rounded at the summit, and 4 to 5 cm. long by about 1.5 cm. broad. This plant is found in Southern Arabia and on the coast of East Africa from Mozambique to
the Somali land. It has been said to grow in the interior of India, and is cultivated at Tinnevelly for medicinal use.

Cassia obovata Colladon, possesses a rather shorter stem than that of C. acutifolia, rising to the height of only a foot and a half. The leaves have from five to seven pairs of leaflets, which are obovate, very obtuse, sometimes mucronate. The flowers are in axillary spikes, of which the peduncles are longer than the leaves of the plant. The legumes are very much compressed, curved almost into the kidney form, of a greenish-brown color, and covered with a very short down, which is perceptible only by the aid of a magnifying glass. They contain from eight to ten seeds. This species grows wild in Syria, Egypt, Senegambia, and Jamaica. (P. J., Sept., 1867.) It has been cultivated successfully in Italy, Spain, and the West Indies. It is said to be no longer gathered for senna, although its leaflets and pods have been found in Alexandria senna.

C. lanceolata of Forskhal, found by that author growing in the deserts of Arabia, is admitted by Lindley and others as a distinct species. Some difference of opinion, however, exists upon this point. De Candolle considered it a variety of the C. acutifolia of Delile, from which it differs chiefly in having leaflets with glandular petioles, and, as Forskhal’s description preceded that of Delile, he designated the species by the name of C. lanceolata. Forskhal’s plant has been supposed by some to be the source of the India or Mocha senna, but the leaflets in this variety are much longer than those of C. lanceolata, from which the plant differs also in having no gland on the petiole. Niebuhr informs us that he found the Alexandria senna growing in the Arabian territory of Abu-Arisch, whence it is taken by the Arabs to Mecca and Jedda. This is probably the C. lanceolata of Forskhal. It is highly probable that this species is the source of a variety of senna which has been brought to this market under the name of Mecca senna.

Cassia aethiopica of Guibourt (C. ovata of Merat), formerly confounded with C. acutifolia, is considered by Lindley to be a distinct species. It grows in Nubia, Fezzan, to the south of Tripoli, and probably, according to Guibourt, throughout Ethiopia. It is from this plant that the Tripoli senna of commerce is derived.

Several varieties of this valuable drug are known in commerce. Of these, four have been received in America—the Alexandria, the Tripoli,
the India, and the Mecca senna—but only two are recognized by the Pharmacopoeia, which are officially described as follows:

"Alexandria Senna.—Usually unbroken, occasionally in fragments, leaflets inequilaterally lanceolate or lance-ovate, from 2 to 3.5 cm. in length and from 6 to 10 mm. in breadth, having extremely short, stout petiolules; acutely cuspidate, entire, subcoriaceous, brittle, pale green or grayish-green, sparsely and obscurely hairy, especially beneath, the hairs appressed; odor characteristic, taste somewhat mucilaginous and bitter. Pods few, broadly elliptical, somewhat rent-form, dark green, thin and membranous.

"India Senna.—Leaflets usually unbroken, from 2 to 5 cm. in length and from 6 to 14 mm. in breadth, usually more abruptly pointed than those of Alexandria Senna, yellowish-green and smooth above, paler beneath; in odor and taste closely resembling Alexandria Senna. Pods few, elliptical, more or less reniform and from 4 to 5 cm. in length. Powdered Alexandria Senna is light green; when examined under the microscope it exhibits non-glandular hairs, 1-celled, conical, often curved, from 0.1 to 0.35 mm. in length, walls thick and papillose; calcium oxalate in rosette aggregates, from 0.009 to 0.01 mm. in diameter, and in 4- to 6-sided prisms, about 0.015 mm. in length, usually in crystal fibers; stomata broadly elliptical, about 0.02 mm. in long diameter. In India Senna the powder is slightly darker green than that of Alexandria Senna and the hairs are similar but relatively fewer. Mix 0.5 Gm. of powdered Senna with 10 mils of an alcoholic solution of potassium hydroxide (1 in 10), boil the mixture for about two minutes, dilute it with 10 mils of water and filter. Now acidify the nitrate with hydrochloric acid, shake it with ether; remove the ethereal layer and shake it with 5 mils of ammonia water; the latter is colored pinkish-red or bluish-red. Senna yields not more than 12 per cent. of ash, The yield of ash insoluble in hydrochloric acid is not more than 3 per cent. of the Senna taken." U. S.

"Pale greyish-green or yellowish-green, thin, brittle; usually from two to four centimetres long, the leaflets of Alexandrian senna being usually smaller than those of Tinnevelly senna; lanceolate, or oval-lanceolate, acute, entire, and unequal at the base. Surface finely pubescent or nearly glabrous, veins on the under surface distinct. Epidermis of both surfaces consisting of polygonal cells and bearing one-celled, thick-walled, warty hairs together with stomata, each stoma being enclosed
between two cells with their long axes parallel to the ostiole. The powdered Leaves greenish-yellow, exhibiting, in addition to the characteristic epidermis, stomata, and hairs, elongated palisade cells and grouped sclerenchymatous fibres accompanied by prismatic crystals of calcium oxalate. Ash not more than 12 per cent."

1. ALEXANDRIA SENNA.—This variety of senna is gathered in extreme Upper Egypt and the Soudan, and thence sent to Assouan at the First Cataract of the Nile, whence it finds its way into commerce through Cairo, Suakim, Suez and Alexandria. Two crops are produced annually, one in the spring and one in the autumn. The plants are first cut, then dried, and then the stripped-off leaves and pods are packed in crude bales, in which several species of senna are represented in varying proportion, the predominating species being C. acutifolia. Formerly there was an intentional mixture of the product of Cassia acutifolia with the leaflets of C. obovata, brought from other parts of Egypt, and even from Syria, with the leaves of Cynanchum oleaefolium (C. Argel of Delile, Solenastemma Argel Hayne), known commonly by the name of argel or arguel, and sometimes with those of Tephrosia apollinea of De Candolle, a leguminous plant growing in Egypt and Nubia. According to M. Royer, the proportions in which the three chief constituents of this mixture were added together were five parts of C. acutifolia, three of C. obovata, and two of Cynanchum. Thus prepared, the senna was again packed in bales, and transmitted to Alexandria. But at present there is much more uniformity in the constitution of Alexandria senna. This variety of senna is often called in French pharmaceutical works sene de la palthe, a name derived from an impost formerly laid upon it by the Ottoman Porte. A parcel of Alexandria senna, as it was formerly brought to market, consisted of the following ingredients: (1) the leaflets of C. acutifolia, characterized by their acute form, and their length, almost always less than an inch; (2) the leaflets of C. obovata, known by their rounded very obtuse summit, which is sometimes furnished with a small projecting point, and by their gradual diminution in breadth towards their base; (3) the pods, broken leafstalks, flowers, and fine fragments of other parts of one or both of these species; (4) the leaves of Cynanchum oleaefolium, which are distinguishable by their length, almost always more than an inch, their greater thickness and firmness, the absence of any visible lateral nerves on their under surface, their somewhat lighter color, and the regularity of their base. In this last character they strikingly differ from the genuine senna leaflets, which, from whatever species derived, are
always marked by obliquity at their base, one side being inserted in the petiole at a point somewhat lower than the other, and at a different angle. Discrimination between this and the other ingredients is of some importance, as the Cynanchum must be considered an adulteration. It is said by the French writers to produce hypercatharsis and much irritation of the bowels, but was found by Christison and Mayer to occasion griping and protracted nausea, with little purgation. The flowers and fruit of the Cynanchum were also often present, the former white and in small corymbs, the latter an ovoid follicle rather larger than an orange-seed. Besides the above constituents of Alexandria senna, it occasionally contained leaflets of genuine senna, much longer than those of the acutifolia or obovata, equalling in this respect the Cynanchum, which they also somewhat resembled in form. They were distinguishable, however, by their greater thinness, the distinctness of their lateral nerves, and the irregularity of their bases. The leaflets and fruit of Tephrosia apollinea, which have been an occasional impurity in this variety of senna, may be distinguished, the former by their downy surface, their obovate-oblong, emarginate shape, their parallel un-branched lateral nerves, and by being usually folded longitudinally; the latter, by its dimensions, being from an inch to an inch and a half long, and only two lines broad. In Europe, Alexandria senna was formerly adulterated with the leaflets of Colutea arborescens L., or bladder senna, and the leaves of Coriaria myrtifolia L., a poisonous plant of Southern Europe.

The leaflets of the Coriaria are ovate-lanceolate, grayish-green with a bluish tint, and are readily known, when not too much broken up, by their strongly-marked mydrib and two lateral nerves running from the base nearly to the summit. They are free from hairs and do not contain crystals of calcium oxalate. Another addition to Alexandria senna has been detected by Lacroix of Macon, France, in the leaves of the Globularia Turbith (Globularia Alypum Linn.), which seem to have taken the place of the Colutea arborescens, because more closely resembling the senna leaflet. The leaves of the Globularia are spatulate, much enlarged towards the upper end, rounded at the extremity, but always terminating in a short sharp point. Besides, they are brown, thick, firm, and hard to the touch, while those of the Colutea are green, very thin, and soft. They have an acrid, very bitter taste, but are without nauseous odor. They are asserted to be cathartic, but milder than senna, and capable of being substituted for it in twice the dose. (J. P. C., 4e ser., i, 413.)
The so-called Aden senna which Holmes states to be active, is composed of small, broad, not very acute, hairy leaves, and is believed to be obtained from C. holosericea Fres. A false senna from Madras has been identified by E. M. Holmes as the product of Cassia montana Hayne. The leaflets are about the size of the Tinnevelly senna, but are distinguishable by obtuse or rounded ends which are with distinct mucronate, the tip is, however, often broken off and absent from individual leaflets; by the obtuse angles of the lateral veins and by the presence of a well marked network of veins of the under surface; further, the color of the upper surface is distinctly browner than of the Tinnevelly leaflet. The whole leaves of Cassia montana have from 10 to 15 pairs of leaflets, while the Tinnevelly senna has only from 6 to 8 pairs. In the drug this character can usually be made out by noticing the number of scars on the rachis. For a microscopic description of powder, see H. G.- Greenish, P. J., lvi, 694. In detecting the adulteration of senna, the apothecary may avail himself not only of the general physical characteristics of the leaves, but also of the fact that while the senna leaf, containing no tannic acid, does not precipitate ferric chloride, most leaves used in adulteration do alter the ferric solution. The microscopic characteristics of the false leaves, though varying greatly, are almost always very different from those of senna. In the senna leaflets the epidermis from the upper and under surface is very similar. The stomata are numerous; the epidermal hairs are unicellular and deciduous, leaving, when detached, a base which has the appearance of an annular pad, around which the neighboring cells seem to radiate. The parenchyma of the cell has a thick epidermis, and is divided into three layers, the uppermost and lowest of which consist of palisade tissue, and are separated by a zone of very small, rounded, parenchymatous cells. Rosette aggregate crystals of calcium oxalate are scattered throughout the parenchyma, and prismatic crystals, one in each cell, occur (clustered around the bast tissue of the principal veins.

For a microscopical description of Alexandria senna, see Proc. A. Ph. A., 1882, p. 238.

2. INDIA SENNA.—This variety is in Europe sometimes called Mocha senna, probably because obtained originally from that port. It derives its name of India senna from the route by which it reaches us. Though produced in Arabia, it is brought to this country and Europe from Calcutta, Bombay, and possibly other ports of Hindostan. It consists of
the leaflets of Cassia elongata, with some of the leafstalks and pods intermixed. The eye is at once struck by the great length (about two inches) and comparative narrowness of the leaflets, so that the variety may be readily distinguished. The pike-like shape of the leaflet has given rise to the French name of sene de la pique. Many of the leaflets have a yellowish, dark-brown, or blackish color, probably from exposure after collection, and the variety has commonly in mass a characteristic dull tawny hue. It is generally considered inferior in purgative power. Leaflets of a senna resembling the Indian were brought by Livingstone from Southern Africa, where the plant grows abundantly. (P. J., xvii, 499.)

A variety of India senna has reached this country which is a product of Hindostan, being cultivated at Tinnevelly, and probably other places in the south of the Peninsula. The plant was originally raised from seeds obtained, from the Red Sea, and is the same as that from which the common Indian senna is derived. The drug is exported from Madras to England, where it is known by the name of Tinnevelly senna. It is a fine unmixed variety, consisting of unbroken leaflets, from one to two or more inches long, and sometimes half an inch in their greatest breadth, thin, flexible, and of a fine green color. T. B. Groves, however, states as the result of his experiments that Tinnevelly senna contains only two-thirds as much of the active principle as does the Alexandrian. (P. J., Oct., 1868, p. 292.)

Much study has been given to the question of distinguishing the powder of Alexandria and India senna by means of the microscope. (See papers by Sayre, A. J. P., 1896, 1897; Schneider, Am. Drug., 1897; Denniston, Ph. Rev., vol. xvi.) As a result of these studies it is asserted that it is possible to take advantage of the greater hairiness of the Alexandria senna as a practical distinction, it being alleged that a fragment of the epidermis of Alexandria leaf contains twice as many hairs as does a similar sized shred of epidermis from the India senna. It is especially proposed to count the number of epidermal cells between two hairs or their scars, the average distance of the hairs from one another being in the Alexandria senna three epidermal cells, and in the India six cells. Advantage may also be taken of the difference in the neighboring cells of the stomata; in the majority of stomata, in each case, there are two of the neighbor-cells, but in India senna the proportion is one having three neighbor-cells to seven having two, and in the Alexandria the proportion is one having three to two having two.
3. TRIPOLI SENNA.—Genuine Tripoli senna consists in general exclusively of the leaflets of one species of Cassia, formerly considered to be a variety of *C. acutifolia*, but now admitted to be distinct, and named *C. aethiopica*. The leaflets, however, are much broken up, and it is probably on this account that the variety is usually less esteemed than the Alexandrian. The aspect given to it by this state of comminution, and by the uniformity of its constitution, enables the eye at once to distinguish it from the other varieties of senna. The leaflets, moreover, are shorter, less acute, thinner, and more fragile than those of *C. acutifolia* or Alexandria senna, and their nerves are much less distinct. The general opinion at one time was that it was brought from Sennaar and Nubia to Tripoli in caravans; but, it is reasonably asked by Fee, how could it be afforded at a cheaper price than the Alexandrian, if thus brought on the backs of camels a distance of eight hundred leagues through the desert. It is probably collected at Fezzan, immediately south of Tripoli.

4. MECCA SENNA is still imported under the name of Arabian or Bombay Senna, and is obtained from both wild and cultivated plants of *Cassia angustifolia*. The best drug is obtained from British India, great care being taken in its garbling. Much of the commercial article is of a dark brown color. The leaflets are oblong-lanceolate, on the average longer and narrower than those of *C. acutifolia*, and shorter than those of *C. elongata*. The variety in mass sometimes has a yellowish or tawny hue, more like that of India than like that of Alexandria senna and may be the product of the *C. lanceolata* of Forskhal. Landerer speaks of a valuable variety of senna, characterized by the large size of the leaflets, and sold under the name of Mecca senna, which he says comes from the interior of Africa.

Commercial senna is prepared for use by garbling, or picking out the leaflets, and rejecting the leafstalks, the impurities, and the leaves of other plants. The pods are also rejected by some apothecaries. (See *Senna Fructus*.)

The market for senna is gradually changing. For years the drug used in the United States was imported from London or European ports. At the present time, the importations into the United States are largely direct from Egypt. The amount of senna annually exported is about 8000 bales of each of the varieties. Owing to the failure of the crops at certain
seasons, the price of senna is very high, and what is known as "broken" senna is found upon the market and sold for the genuine article. This is done with the sanction of the government. In addition, what is known as "senna settings," which contain large amounts of sand and other foreign matter, have been offered, and these have caused the government inspectors a large amount of trouble. There is considerable difference in the actual constituents of the two sennas, and it would seem advisable for the Pharmacopoeia to restrict the drug to one species or else to include them under two separate titles. This principle has been followed by the German Pharmacopoeia, as well as the Swiss Pharmacopoeia, which restrict the official drug to the Indian senna, or that derived from Cassia angustifolia. Indian senna is known commercially as Tinnevelly senna, and this name should probably have been used in the Pharmacopoeia. Alexandria senna is occasionally admixed with the leaflets of C. obovata Coll. (Bull. Soc. roy. d. pharm. Brux., liii, p. 169). In addition to admixture of senna with the leaflets of Cassia marilandica it is stated that the leaves of Ailanthus glandulosa have been found admixed. A very interesting and characteristic test for genuine senna depends upon the sublimation of its oxymethylanthraquinone, which is always a constituent, and this may be further confirmed by testing the sublimed material with a drop of one of the solutions of the alkalies which will show a red-colored test. (Pharm. Prax., v, p. 435.)

**Constituents.**—The odor of senna is faint and sickly; the taste slightly bitter, sweetish, and nauseous. Water and diluted alcohol extract its active principles. Pure alcohol extracts them but imperfectly. (Bley and Diesel, Ph. Cb., Feb., 1849, p. 126.) The leaves are said to yield about one-third of their weight to boiling water. The infusion is of a deep reddish-brown color, and has the odor and taste of the leaves. When exposed to the air for a short time, it deposits a yellowish insoluble precipitate, supposed to result from the union of extractive matter with oxygen. The nature of this precipitate, however, is not well understood. Decoction also produces some change in the principles of senna, by which its medicinal virtues have been supposed to be impaired, but some experiments of B. Heerlein would seem to show that this opinion is incorrect. An extract prepared by boiling down an infusion, redissolving the residue, and again boiling down to a solid consistence, was found to operate actively in a dose equivalent to a drachm of the leaves. (Ph. Cb., 1851, p. 909.) To diluted alcohol it imparts the same reddish-brown color as to water, but rectified alcohol and ether, digested upon the powdered
Lassaigne and Feneulle first isolated a substance to which they gave the name of cathartin, but it proved to be a mixture; Bley and Diesel (Ph. Cb., 1849, p. 126) isolated a yellow coloring matter, which they called chrysoretin, but which Martins identified as chrysophan; Ludwig (A. Pharm. (2), cix, p. 42, and cxc, p. 69) obtained two bitter principles, sennapicrin and sennacroli, the first insoluble, the second soluble in ether; but the active purgative principle was first discovered in 1866 by Dragendorff and Kubly (Viertelj. f. Prakt. Pharm., 16, pp. 96 and 337), who found it to be a glucoside of weak acid character, and named it cathartactic acid. Thos. B. Groves, in 1868 (P. J., 1869, p. 196), unaware of Dragendorff and Kubly's discovery, isolated the same principle, and found for it the same reactions. For a method of preparing cathartic acid, by Ralph Stockman, see P. J., 1885, p. 740. Its formula is given as C$_{180}$H$_{96}$N$_2$SO$_{82}$, and by boiling its alcoholic solution with acids it yields cathartogenic acid and sugar. Gensz (A. J. P., 1893, 334), who prepared it later by the method of Kubly and Stockman, gave the formula C$_{30}$H$_{36}$NO$_{15}$. It is amorphous, difficultly soluble in cold water, readily soluble in boiling water. The best solvent is a 30 to 40 per cent. alcohol; ether, benzene, chloroform, and petroleum ether are without solvent action. Alkalis with heat decompose it. It is prepared by partially precipitating with alcohol infusion of senna, concentrating to a syrupy consistence in vacua, filtering, treating the filtrate with a large proportion of absolute alcohol, and repeatedly dissolving in water, and precipitating by alcohol the precipitate thus obtained. It is purified by submitting it (dissolved in moderately strong hydrochloric acid) to dialysis on a diaphragm of parchment paper, cathartic acid having strong colloidal properties. Groves found that ammonium cathartate purged moderately in the dose of three and three-quarters grains, with considerable griping, and that of certain mixed cathartates seven and a half grains purged violently, with much griping and sickness, and continued to act through most of a day. He considers four grains a fair dose. It should be given in connection with an aromatic and a saline cathartic. Magnesium cathartate is soluble. The salts of this acid in aqueous solution are decomposed and rendered inert by long exposure to heat in contact with the air. (Groves, P. J., Oct., 1868, 200-1.) Dragendorff and Kubly also found chrysophanic acid in small proportions, the two substances, sennacroli and sennapicrin, previously mentioned, and a peculiar non-fermentable saccharine principle, with
the formula $C_{21}H_{44}O_{19}$, which they named catharto-mannite. (J. P. C., 4e ser., v.) A. Seidel proposes the name of sennit for catharto-mannite, and gives a process for its preparation in A. J. P., 1885. In 1900 Tschirch and Hiepe made a comprehensive investigation of the chemical constituents of senna in which they found that the active principles belonged to the oxymethylan-thraquinone group of glucosides, yielding emo-din upon decomposition. From the aqueous percolate they extracted, besides cathartic acid, a crystalline body, giving the same reactions as sennanigrin and having the composition $C_{14}H_{10}O_{5}$. From the weak ammoniacal percolate they obtained anthraglucosennin, which, however, is composed of several distinct substances, for on treating it with ether, a portion enters solution and another remains undissolved; then the ether-soluble portion, if boiled with toluene and the solution poured on petroleum benzin, precipitates sennaemodin, while sennachrysophanic acid remains in solution and may be obtained on evaporation; the portion insoluble in toluene is a body which the authors have named glucosennin. Its composition agrees with the formula $C_{22}H_{18}O_{8}$, and it is possibly an emodin glucoside. From the portion of anthraglucosennin insoluble in ether, sennaisoemodin is obtained by treatment with acetone and shaking the resultant solution with petroleum benzin. The acetone solution retains a substance which the authors have named sennarhamnetin. Finally, the portion of anthraglucosennin remaining undissolved after treatment with ether and acetone is a black body which resembles in this and other respects aloe-nigrin. Sennanigrin, however, yields on treatment with alcoholic potassium hydroxide, sennaemodin and sennachrysophanic acid. (A. Pharm., Aug. 31, 1900, 427, 448.)

Some results of experiments on the properties of senna which more particularly concern the pharmacist are noted in a paper contained in the J. P. C. (Janv., 1874, p. 80), and require to be mentioned here, because they tend to fix certain points which are left undetermined in the above statement. An extract made by evaporating in the air an aqueous infusion of senna possesses but partially the purgative properties of the leaves. If the extract be redissolved in a large quantity of water, and the solution be again evaporated, the extract now obtained will be quite inert. It follows that a prolonged decoction of senna destroys its cathartic powers. The presence of an alkali in the decoction increases the rapidity of the destruction. An infusion of senna in lime water, heated to the boiling point, and then deprived of lime by
a stream of carbon dioxide, becomes inert. An infusion of senna, made to boil after the addition of potassium hydroxide, and then neutralized by an acid, is also inert. The mineral acids destroy the purgative powers of senna, but less energetically than the alkalies; the vegetable acids exercise the same power but feebly. Concentrated alcohol does not dissolve the active principle, which is soluble in cold water. It was Heerlein who first determined the complete want of purgative power in the pure alcoholic extract of senna. Nevertheless, this extract possesses in a high degree the odor and taste of senna, and, taken internally, without purging, imparts a deep-yellow color to the urine, which the alkalies change to red. The leaves exhausted by alcohol have all their purgative effect, but lose the power of affecting the urine so that an alkaline solution shall color it red. These facts prove that chrysophanic acid is not the purgative principle of senna. The fact that alcohol removes the odor and taste of senna without affecting its purgative action may sometimes be advantageously applied in cases in which the taste of senna is extremely offensive. L. Siebold, after experimenting with senna leaves washed with alcohol, arrived at the following conclusions: (1) Strong spirit does not remove any of the active principle from senna leaves; (2) the therapeutic action of cathartic acid is assisted by one or more of the constituents yielded by senna to strong alcohol, though these constituents produce no purgative effect when taken alone; (3) senna exhausted by alcohol is a reliable and pleasant purgative, but somewhat weaker in its action than the unexhausted leaves. Tutin reports the analysis of the water soluble portion of an alcoholic extract of Tinnevelly senna as containing (1) salicylic acid, (2) rhein (C₁₅H₈O₆), (3) kaempferol (1:3:4 trihydroxyflavonol), (4) aloe-emodin (C₁₅H₁₀O₅), (5) kaempferin (C₂₃H₃₀O₆), a glucoside of kaempferol, (6) glucosides of rhein and aloe-emodin, (7) a magnesium salt of an unidentified organic acid, (8) a sugar. The water insoluble portion contained (1) myricyi alcohol, (2) a phytosterol (C₂₇H₄₆O), (3) a phytosterolin (C₃₃H₅₆O₆), (4) palmitic and stearic acids, besides a small amount of essential oil.

**Incompatibles.**—Many substances produce precipitates with the infusion of senna, but it does not follow that they are all medicinally incompatible, as they may remove only inert ingredients. Cathartic acid is precipitated by infusion of galls and solution of lead sub acetate. Lead acetate and tartar emetic which disturb the infusion, have no effect upon the solution of this substance.
Uses.—Senna was first used as a medicine by the Arabians. It was noticed in their writings as early as the ninth century, and the name itself is Arabic. Like the other cathartics of the anthraquinone series, its action is chiefly upon the lower bowel, and is therefore especially suitable in habitual costiveness. It increases the peristaltic movements of the colon by its local action upon the intestinal wall. The tendency to grippe may be obviated by combining it with aromatics or with a saline laxative. The coloring matter of senna is absorbable, and twenty or thirty minutes after the ingestion of the drug it appears in the urine and may be recognized by a red color on the addition of ammonia. It is asserted also that the milk of nursing women acquires purgative properties after the administration of senna. Under the name of cathartin there is upon the market a mixture of the salts of cathartic acid which may be used in doses of from three to six grains (0.2-0.4 Gm.). Sennax is the name applied to the water-soluble glucoside of senna, and is marketed in tablets each one of which contains 0.075 Gm.

Dose, of senna, one-half to two drachms (2.0-7.7 Gm.).

SENNAE FRUCTUS. Br.

SENNÆ PODS

"Senna Pods are the dried ripe fruits of Cassia acutifolia, Delile, and of Cassia angustifolia, Vahl." Br.

Senna pods, while regarded as an adulterant in the U. S. P. IX in that the quantity is restricted, are official in the Br. Pharm. They are described as follows: "About five centimetres long, and from two to two
and a half centimetres wide; broadly oblong or somewhat rent-form; pale green; brownish in the centre above the seeds; very flat; rounded at the base, slightly mucronate at the apex. Pericarp papery. Seeds obovate-cuneate, flattened. Odor and taste slight. "Br.

Uses.—They were preferred by the Arabian and mediasval physicians of Europe to the leaves, while Pereira states that they are much milder in their operation than the leaflets. This has been explained by the researches of E. F. Salmon, who has found that they contain about 25 per cent. more cathartic acid and emodin than the leaves, but no resinous principle or volatile oil. (P. J., Oct., 1889.) The griping of senna being largely due to the resin, it is a priori to be expected that the pods would act more kindly than the leaves. A. W. Macfarlane has found this to be actually the case. From six to twelve pods for the adult, or from three to six for the young or very aged, infused in a claret-glass of cold water, in his experience, act very mildly but very thoroughly upon the whole intestine.

Dose, from one-half to one drachm (2.0-3.9 Gm.).

SERPENTARIA. U. S. (Br.)

SERPENTARIA Serpent.
[Virginia Snakeroot, Texas Snakeroot]

"The dried rhizome and roots of Aristolochia Serpentina Linne, known in commerce as Virginia Snakeroot, or of Aristolochia reticulata Nuttall, known in commerce as Texas Snakeroot (Fam. Aristolochiaceae), without the presence or admixture of more than 10 per cent. of the stems or other foreign matter." U. S. "Serpentary Rhizome is the dried rhizome and roots of Aristolochia Serpentina, Linn., and of Aristolochia reticulata, Nutt." Br.

Serpentaria Rhizoma. Br., Serpentine Rhizome; Virginia Serpentina, Virginia Snakeroot, Snakeweeds, Pelican-flower, Snagrel, Sangrel, Radix Colubrina, Radix Viperina; Serpentine, Sangree; Serpentine de Virginie, Fr. Cod.; Couleuvree de Virginie, Fr.; Virginische Schlangenwurzel, G.

Many species of Aristolochia have been employed in medicine. Their supposed possession of emmenagogue properties has given origin to the name of the genus.
Aristolochia Serpentaria is an herbaceous plant, with a short rhizome and numerous slender roots. Several stems often rise from the same rhizome. They are about eight or ten inches in height, slender, round, flexuose, jointed at irregular distances, and frequently reddish or purple at the base. The leaves are oblong-cordate, acuminate, entire, of a pale yellowish-green color, and supported on short petioles. The flowers proceed from the joints near the root, and stand singly on long, slender, round, jointed peduncles, which are sometimes furnished with one or two small scales, and bend downward so as nearly to bury the flower in the earth or decayed leaves. The tube of the calyx is curved like the letter S, enlarged at the base (ovary) and at its throat, the short limb being obtusely three-lobed. The anthers—six or twelve in number—are sessile, attached to the under part of the stigma, which is fleshy and from three to six-lobed. The fruit is an hexangular, six-celled capsule, containing several small flat seeds. The plant grows in rich shady woods from Connecticut west to Michigan and Missouri and south to Florida and Louisiana, abounding in the valley of the Ohio and in the mountainous regions of our interior. It flowers in May and June. The root is collected in Western Pennsylvania, West Virginia, Ohio, Indiana, and Kentucky. It is usually in bales containing about one hundred pounds, and is often mixed with the leaves and stems of the plant, and with adhering dirt. For an account of A. hirsuta, see 18th ed., U. S. D., p. 1222. On account of the rather large use of Serpentaria the drug is becoming scarcer and some attempts at cultivation have been made. (See Proc. A. Ph. A., 1905, liii, p. 275, and West. Drug., xxvii, p. 775.)

A. hastata (Nuttall.) Duchartre.—This is now considered to be nothing more than a variety of A. Serpentaria, from which it differs in having hastate, acute, somewhat cordate leaves, and the lip of the corolla ovate. It flourishes on the banks of the Mississippi, in the Carolinas, and elsewhere. Its root scarcely differs from that of the official plant, and is frequently mixed with it, as is proved by the presence of the characteristic hastate leaves in the parcels brought into market.

A. reticulata was probably first observed by Nuttall, as a specimen labelled "A. reticulata, Red River," in the handwriting of that botanist, is contained in the Herbarium of the Academy of Natural Sciences of Philadelphia. From a root similar to that of A. Serpentaria numerous short, slender, round, flexuose, jointed stems arise, usually simple, but sometimes branched near the root. The older stems are slightly villous. the young densely pubescent. The leaves, which stand on very short
villous petioles, are round or oblong-cordate, obtuse, reticulate, very
prominently veined, and villous on both sides, especially upon the veins.
From the lower joints of the stem four or five hairy, jointed peduncles
proceed, which bear small leafy villous bracts at the joints, and several
flowers on short pedicels. The flowers are small, purplish, and densely
pubescent, especially at the base and on the ovary. The hexagonal
capsule is deeply sulcate. This species grows from Virginia to Louisiana,
Texas, Arkansas, and Oklahoma.

Properties.—Serpentaria is officially described as follows: "Rhizome in
both commercial varieties oblique, subcylindrical, more or less curved,
from 10 to 30 mm. in length and from 1 to 2 mm. in diameter; externally
dark brown, upper portion with short stem-bases and from lower and
lateral portions arise numerous, long, thin, nearly straight, yellowish-
brown roots; fracture short; internally yellowish-white, wood with
broad, excentric wedges; odor terebinthinate; taste bitter, aromatic.
Under the microscope, transverse sections of the rhizome of both
commercial varieties of Serpentaria show an outer layer of epidermal
cells; a cortex of from 10 to 15 rows of parenchyma; inner bark
sometimes showing strongly lignified bast-fibers, either single or
distributed in a more or less interrupted circle; a xylem of broad wood-
wedges separated by broad medullary rays about 8 cells wide, the walls
being strongly lignified and with numerous simple pores; pith excentric,
composed of polygonal cells, the walls being lignified and porous. Starch
in the cells of cortical parenchyma, medullary rays and pith. The root in
transverse section shows a compact, 4- to 6-rayed stele, and a large
starch-bearing cortical area. The stem in transverse section shows an
interrupted circle of from 6 to 10 fibro-vascular bundles, a cortex with a
prominent continuous ring of strongly lignified cells, and a few non-
glandular hairs. The powder is grayish-brown; when examined under
the microscope it exhibits numerous starch grains, single and 2- to 4-
com-pound, the individual grains being more or less spherical or plano-
convex and frequently with a central cleft, from 0.003 to 0.014 mm. in
diameter; lignified elements numerous, consisting of tracheae, wood-
fibers, medullary ray cells and pith cells; a few non-glandular hairs of
the stem are occasionally present." U. S.

"Rhizome of Aristolochia Serpentaria tortuous and slender, about two
centimetres long and three millimetres thick; on the upper surface the
remains of slender, aerial stems, and on the under surface numerous
wiry interlacing roots, often about seven centimetres long. Both rhizome
and roots dull yellowish-brown. Characteristic odor; taste strong, camphoraceous, bitter. Ash not more than 10 per cent. Rhizome and roots of Aristolochia reticulata resemble the foregoing, but are longer and thicker, and the roots are straighter."

Holm has published an illustrated article on the pharmacognosy of serpentaria, including the morphology of the stems and leaves. (M. R., xvi, p. 276.)

Texas Serpentaria contains a larger percentage of volatile oil than does the other variety of the drug. The color of serpentaria, which in the recent root is yellowish, becomes brown on keeping.

The roots of Spigelia marilandica are sometimes found associated with serpentaria. They may be distinguished by the absence of the bitter taste, and, when the stem and foliage are attached, by the peculiar character of these parts. (See Spigelia.) We have seen the young roots of Polygala Senega mixed with serpentaria. Independently of their difference in odor and taste, they may be distinguished by being simple, and by a projecting line running from one end to the other of the root. Another adulteration was detected by P. S. Milleman of Chicago, who found in a parcel a large quantity of "golden seal" (Hydrastis canadensis). The rhizomes, with rootlets attached, were from a quarter of an inch to an inch in length, and about one-eighth of an inch in diameter, but at the present time (1917) on account of the high price of senega and hydrastis neither admixture is likely to occur.

The root yields all its virtues to water and alcohol, producing with the former a yellowish-brown infusion, with the latter a bright greenish tincture, rendered turbid by the addition of water. Chevallier found in the root a volatile oil, a yellow bitter principle, soluble in water and alcohol, resin, gum, starch, albumen, lignin, and various salts. Bucholz obtained from 1000 parts, 5 of a green fragrant volatile oil, 28.5 of a yellowish-green resin, 17 of extractive matter, 181 of gummy extract, 624 of lignin, and 144.5 of water. The active ingredients are probably the volatile oil and the yellow bitter principle of Chevallier, which that chemist considers analogous to the bitter principle of quassia; alkaline solution of cupric tartrate shows, moreover, the presence of a glucose sugar. The volatile oil passes over with water in distillation, rendering the liquid milky, and impregnating it with the odor of the root. The volatile oil has been carefully investigated by J. C. Peacock (A. J. P.,
1891, 257). He found it to contain a terpene, $C_{10}H_{16}$, boiling at 157° C. (314.6° F.), of sp. gr. 0.865 (probably pinene); a compound ester boiling at 211° C. (411.8° F.), sp. gr. 0.9849, which on saponification yielded borneol, $C_{10}H_{18}O$, and a crystalline acid; a fraction boiling at from 239° to 240° C. (462.2°-464° F.), sp. gr. 0.9888, and of the composition $C_{18}H_{20}O$; and some green or bluish-green fluorescent oil in small quantity, which decomposes even when distilled under reduced pressure. The borneol ester constitutes about 60 per cent. of the oil. A principle called aristolochine, obtained from A. Clematitis and the roots of A. rotunda and A. longa, was investigated by Jul. Pohl. (A. E. P. P., xxix.) He obtained it as a yellow crystalline mass, soluble in chloroform, ether, acetone, acetic anhydride, and alcohol, insoluble in petroleum benzin, benzene, and carbon disul-phide, almost insoluble in cold water, slightly soluble in hot water. An ultimate analysis gave for its composition $C_{32}H_{22}O_{13}N$. O. Hesse obtained from the root of Aristolochia argentina an alkaloid to which he gives the name aristolochine, but has furnished no formula; a principle, aristolin, $C_{15}H_{28}O_3$; physoserin palmitate, in white scales, fusing at 82° C. (179.6° F.); and a mixture of acids to which he gives the names aristic acid, $C_{18}H_{13}NO_7$, aristidic acid, $C_{17}H_{10}(CH_3)NO_7$, and aristolic acid, $C_{15}H_{13}NO_7$.

The resinous aristinic acid has been obtained from a number of species of the genus Aristolochia, notably by Walz from A. Clematis, by Chevallier from A. Serpentaria, by Dymock and Warden from A. indica, by Hesse from A. argentina, by Hooper from A. bracteata. Hooper has also obtained a closely allied, if not identical, resinous acid from the aristolochiaceous plant Bragantia Wallichii, besides an alkaloid, which, under the name of Alpam, has long been used in Western India as an antidote to snake venom. The allied species, Bragantia tomentosa of Blume, is said to be employed in Java as an emmenagogue.

**Uses.**—Serpentaria is a feeble stimulant tonic. Too largely taken, it occasions nausea, griping pains in the bowels, sometimes vomiting and dysenteric tenesmus. It has been recommended in intermittent fevers, and may be serviceable as an adjunct to quinine. It is sometimes given in dyspepsia. The dose of fluid-extract is from twenty minims to half a flui-drachm (1.3 to 1.8 mils). According to Pohl, aristolochine in sufficient dose produces in the higher animals violent irritation of the
gastro-intestinal tract and of the kidneys, with death in coma from respiratory paralysis.

Dose, fifteen to thirty grains (1 to 2 Gm.).

**Sesamum.** Sesamum indicum L. (Fam. Pedaliaceae)—The benne plant of our Southern States is annual, with a branching stem four or five feet high, and bearing opposite, petiolate leaves, varying considerably in their shape. The flowers are reddish-white, and stand solitarily upon short peduncles in the axils of the leaves. The fruit is an oblong capsule, with small, oval, yellowish seeds.

There are some ten or twelve species referred to the genus Sesamum, the majority of which are natives of Africa. In India one or two species occur wild, one of these, Sesamum indicum L. (S. orientate L.), has been cultivated from time immemorial in various parts of Asia and Africa. From the latter continent it is supposed that seeds were brought by the negroes to the United States, where, as well as in the West Indies, it is now cultivated to a considerable extent. The plant above described will grow as far north as Philadelphia. The seeds are employed as food by the negroes, who parch them over the fire, boil them in broths, make them into puddings, and prepare them in various other modes. By expression they yield a fixed oil, which was introduced into the Pharmacopoeia at the revision of 1880 and is official in U. S. IX. Berjot obtained from the seeds 53 per cent. of oil by means of carbon disulphide. Rautenberg reported a series of severe poisonings from the intestinal injection of sesame oil. (J. A. M. A., xlvii, p. 1962.) These accidents, he believes, are due to adulteration of the oil.

**Benne Leaves.**—These abound in a gummy matter, which they readily impart to water, forming a rich, bland mucilage, much used in the Southern States as a drink in various complaints to which demulcents are applicable, as in cholera infantum, diarrhoea, dysentery, catarrh, acute cystitis, strangury, etc. The remedy has attracted attention also in the North, and has been employed with favorable results in Philadelphia. One or two fresh leaves of full size, stirred about in half a pint of cool water, will soon render it sufficiently viscid. With dried leaves hot water is used. The leaves also serve for the preparation of emollient cataplasms.

**Sethia.** Sethia acuminata Arn. (now Erythroxylon lucidum H. B. K.) (Fam. Erythroxylaceae)—The juice of this Ceylon plant or the powdered leaves—dose, fifteen grains (1.0 Gm.)—are affirmed to be an efficient vermifuge. (P. J., April 7, 1883.)

**Sida.** Mesbe. Sida rhombifolia L.—Queensland hemp (Fam. Malvaceae), jelly leaf, is largely used in Australia as a demulcent. It contains a large quantity of mucilage. The fluidextract has been asserted to possess expectorant properties and to be especially
valuable in the treatment of pulmonary tuberculosis. Zink (M. M. W., 1912), however, was unable to obtain evidence of any specific action in tuberculosis. Sida paniculata L. (S. floribunda H. B. K.), of Peru, which also contains a large quantity of mucilage, is said by Martinet to be a very active vermifuge, owing its powers, probably, to the extremely minute but very resisting spines which cover its leaves, the part used.

**Siegesbeckia.** *Siegesbeckia orientalis* L. (Fam. Compositae).—This plant is used in the Mauritius Islands in syphilis, leprosy, and various skin diseases. A white, crystalline principle, darutine, has been discovered in it by M. L. Auffray. (P. J., vol. xvi, 1047; also B. M. J., June 25, 1887.)

**Silene.** *Silene virginica* L. (Fam. Caryophyllaceae). Catchfly, Wild Pink.—The wild pink, growing from Western New York to Minnesota and southward, was considered by the Indians poisonous and by Barton an anthelmintic. It is a slender herb having thin-spatulate or oblong-lanceolate leaves and deep crimson or scarlet flowers in a loose raceme.

**Silphium.** *Silphium laciniatum* L. (Fam. Compositae).—The rosin weed, or compass plant, of Ohio, yields an oleoresin, which is said to be used in making chewing gum. (A. J. P., 1881, 487.)

**Simaruba.**—Under this name the U. S. P. formerly recognized the bark of the root of *S. amara* Aublet (S. officinalis DC.) Ecorce de simarouba, Fr. Simarubarinde, Ruhrrinde, G. Cortecia di Simaruba, It. Cortesa de Simaruba, Sp. (Fam. Simarubaceae) This is a tree of considerable height, having alternate branches, with a bark which in the old tree is black and somewhat furrowed, in the young is smooth, gray, and marked here and there with broad yellow spots.

Simaruba bark is in long pieces, from 4 to 12 cm. wide and 2 to 5 mm. thick, folded lengthwise, light, flexible, tenacious, very fibrous, externally of a light brownish-yellow color, rough, warty, and marked with transverse ridges, internally of a pale yellow. It is without odor, and of a bitter taste. It readily imparts its virtues, at ordinary temperatures, to water and alcohol. The infusion is at least equally bitter with the decoction, which becomes turbid as it cools. Its constituents, according to Morin, are a bitter principle identical with quassin, $C_{10}H_{12}O_3$, to which Gilling (P. J., 1908, lxxxi) ascribes the formula, $C_{22}H_{30}PO_9$, a resinous matter, a volatile oil having the odor of benzoin, malic acid, gallic acid in very minute proportion, an ammoniacal salt, calcium malate and oxalate, some mineral salts, ferric oxide, silica, ulmin, and lignin.

It is a native of French Guiana and the Islands of Dominica, Martinique, St. Lucia, St. Vincent and Barbadoes, in the West Indies. A closely related species, having, however, dioecious instead of monoeccious flowers, nourishes in Jamaica, San Domingo, Bahama Islands, Panama and Guatemala, extending even to Florida; it is called in Jamaica mountain damson, and is known as *S. glauca* DC. (S. officinalis Macf., not DC.) The two species have probably identical medicinal properties. The bark of the root is the part employed, the wood being nearly tasteless and inert. The middle bark contains much resin. A decoction of the bark and leaves of *S. versicolor*
St.-Hil. (Cortex Paraibae), is employed in Brazil as an antidote for snakebites and in the treatment of syphilis and tapeworm; the powder is used against vermin.

Simaruba possesses the same tonic properties as other simple bitters. In large doses it is said to purge and vomit. On account of its difficult pulverization, it is seldom given in substance. The best mode of administration is by infusion. The dose is from twenty grains to a drachm (1.3-3.9 Gm.).

Simulo.—The dried fruit of Capparis coriacea Burch., one of the Capparidaceae, has been recommended as a palliative in epilepsy; also in chorea. (See T. G., 1888, 1889; and Th. M., Aug., 1888.)

**SINAPIS ALBA. U.S.**

**WHITE MUSTARD**

Sinap. Alb. [Yellow Mustard]

"The ripe seeds of Sinapis alba, Linne (Fam. Cruciferae), without the presence or admixture of more than 5 per cent. of other seeds or other foreign matter. Preserve powdered White Mustard in tightly-closed containers." U. S.

Sinapis Albae Semina, Br. 1898; White Mustard Seeds; Yellow Mustard Seed; Moutarde blanche, Fr. Cod.; Semen Erucae, P. G.; Weisser Senfsamen, Weisser Senf; G.; Senape bianca, It.; Mostaza blanca, Sp.

Neither black nor white mustard is any longer official in the British Pharmacopoeia.

Yellow or white mustard is a native of Europe and is extensively cultivated, being occasionally spontaneous, in the United States. The commercial supplies are obtained from England, Holland, Germany and California.

**Properties.**—The official description of white mustard is as follows: "Sub-globular, from 1.5 to 2.5 mm. in diameter; testa yellowish, nearly smooth; embryo yellowish, oily, with two large cotyledons; inodorous, taste mildly pungent, acrid. The powder is light yellowish or pale brownish-yellow, developing a slight odor when moistened; when examined under the microscope it exhibits numerous tissues of the embryo containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S.; fragments of seed-coat comparatively few, nearly colorless, with small,
characteristic stone cells and large epidermal cells, the outer walls being mucilaginous. The powder contains few or no starch grains. White Mustard does not yield allyl isothiocyanate upon distillation with steam (distinction from Black Mustard). White Mustard yields not more than 9 per cent. of ash."

For an illustrated monograph on the pharmacognosy of white mustard, see Winton and Moeller, "Microscopy of Vegetable Foods." The only adulterant of white mustard are the seeds of the white Indian colza, obtained from Brassica campestris Sarson (L.) Prain. They are distinguished in having a more pronounced ridge over the radicle. Under the microscope the seeds have an indistinct epidermis, the collenchymatous subepidermal layer is wanting, and the palisade cells are quite large compared with white mustard. For further information see Sinapis. Nigra.

**SINAPIS NIGRA. U. S.**

**BLACK MUSTARD**

*Sinap. Nig. [Brown Mustard]*

"The ripe seeds of Brassica nigra (Linne) Koeh (Fam. Cruciferae), without the presence or admixture of more than 5 per cent. of other seeds or other foreign matter. Preserve powdered Black Mustard in tightly-closed containers." U. S.

*Sinapis Nigrae Semina* Br. 1898; Black Mustard Seeds; Semina Brassicae; Moutardenoire, Fr. Cod.; Moutarde, Fr.; Semen Sinapis, P. G.; Senisamen, Schwarzer Senf.; Senape nera, It.; Mostaza (Semilla de), Sp.

Linnaeus described two genera, Brassica and Sinapis, and subsequent botanists have greatly disagreed as to whether they should be considered identical or not. The revisers of the U. S. P. have adopted the opinion of Engler and Pranti and of Britton and Brown, that the two genera are distinct. The genus Sinapis differs from Brassica in that the pods of the former are terminated by a long, flat, sword-like beak, whereas in Brassica the beak is cylindrical or conical.

Common or black mustard (Brassica nigra), is an annual plant, with a stem three or four feet in height, divided and subdivided into numerous spreading branches. The leaves are petiolate and variously shaped. Those near the root are large, rough, lyrate-pinnate, and unequally
toothed, those higher on the stem are smooth, and less lobed, and the uppermost are entire and narrow. The flowers are small, yellow, and stand closely together upon peduncles at the upper part of the branches. The pods are smooth, erect, nearly parallel with the branches, quadrangular, and furnished with a slender beak; seeds numerous, dark brown.

The white mustard is also annual. It is rather smaller than the preceding species. The lower leaves are deeply pinnatifid, the upper subly-rate, and all irregularly toothed, rugged, with stiff hairs on both sides, and pale green. The flowers are in racemes, with yellow petals, and linear, green calycine leaflets. The pods are spreading, bristly, rugged, roundish, swelling in the position of the seeds, ribbed, and provided with a very long ensiform beak.

Both Sinapis alba and Brassica nigra are natives of Europe and cultivated in our gardens, and B. nigra has become naturalized in some parts of this country. Their flowers appear in June. The seeds are kept in the pharmacies, both whole and in the state of very fine powder as prepared by the manufacturers for the table. The latter is sometimes mixed with spices and ground into a smooth paste with water in a mill resembling a paint mill, and then is known as French mustard.

The seeds of Brassica ibertifolia, according to O. Harz, are sometimes sold as true white mustard seed. He examined some obtained from Bavaria, which had been returned by customers to the dealers on account of their bitter and disagreeable taste. He furnishes characteristic microscopical tests for distinguishing the false from the true mustard seed. His statement, however, that powdered white mustard seed when mixed with water is odorless, and that the false gives off a strong odor of essential oil of mustard, would seem to be a good reason, if correct, for preferring the false seed. (P. J., 1887, 478.)

The Brassica juncea (L.) Coss. (Sinapis juncea L.), is extensively grown in India, and its seeds are largely exported to Europe. The same plant is also cultivated in Southern Russia. The seeds afford a very fine yellow mustard flour, and, according to Paul Birkenwald, yield 1.67 parts per hundred of volatile oil, against 1.89 parts per hundred by the true black mustard seed. (S. W. P., 1888.)

Black mustard seeds are officially described as "ellipsoidal or irregularly
spheroidal, from 1 to 1.6 mm. in diameter; testa deep reddish-brown, sometimes yellowish-brown and with a grayish tinge, minutely pitted or reticulate; embryo greenish-yellow or dark yellow, oily, with two large cotyledons; odor when dry, slight, on moistening very irritating; taste strongly pungent and acrid. The powder is light brown or greenish-brown; on moistening developing a strongly pungent, irritating, characteristic odor; when examined under the microscope it exhibits numerous tissues of the embryo, the cells containing small aleurone grains and a fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S.; fragments of seed-coat conspicuous, with large, polyhedral, dark yellow areas, enclosing small, yellowish stone cells, each of the latter with a dark lumen. The powder contains few or no starch grains. Black Mustard, upon distillation with steam, yields allyl isothiocyanate (distinction from White Mustard). Black Mustard yields not more than 9 per cent. of ash." U. S.

Both white and black mustard afford a powder, which has a somewhat unctuous appearance, and cakes when compressed. This is commonly called flour of mustard, or simply mustard, and is prepared by crushing and pounding the seeds and then sifting them, the purest flour being obtained by a second sifting. Both the black and the white seeds are used in its preparation. Formerly it was adulterated with wheat flour colored by turmeric, to which cayenne pepper was added to render the mixture sufficiently hot. Pure mustard powder contains very few starch granules, but was formerly adulterated with farinaceous powders; the U. S. P. VIII required that White or Black Mustard should conform to the following test: "If 1 Gm. of powdered White (or Black) Mustard be exhausted by slow percolation with alcohol, and the marc mixed with 200 Cc. of water and heated to boiling", and if, after cooling, sufficient cold water be added to make the mixture measure 1000 Cc., the addition of 4 Cc. of tenth-normal iodine V.S. should not produce a dark blue color (limit of starch); U. S. VIII.

The epidermis of white mustard seeds contains a mucilaginous substance which is extracted by boiling water. An excellent basic monograph on the pharmacognosy of black mustard is that given by Winton and Moeller in "The Microscopy of Vegetable Foods." Tschirsch and Oliva have made a comparative study of the seeds of the Cruciferae, with special reference to the variations found in the seed-coat of the several species of mustard. (S. W. P., xliii, p. 614.) Spaeth gives the results of chemical and microscopical study of the mustards
and some of their adulterants in Ph. Zentralh., xlix, p. 698. Carles has also contributed a valuable article on the pharmacognosy of the different mustard seeds and the commercial varieties of mustard flour in J. P. C., 1913, pp. 438 and 535. The most common adulteration of black mustard is charlock, which is the seeds of Brassica arvensis (L.) Ktze. This plant is especially abundant in the Northwestern part of the United States and the Dakota mustard contains varying mixtures of brown mustard and charlock. The presence of charlock is very easily determined by the use of a solution of chloral hydrate which changes the color of the palisade cells to a crimson red.

When bruised or powdered, both kinds of mustard impart their active properties wholly to water, but in a very slight degree to alcohol.

They yield upon pressure a fixed oil, called oil of mustard, of a greenish-yellow color, little odor, and a mild not unpleasant taste; and the portion which remains is even more pungent than the unpressed seeds. The fixed oil of mustard consists of the glycerin compounds of stearic, oleic, and erucic or brassic acid, \( C_{22}H_{42}O_2 \), a homologue of oleic acid. Small quantities of behenic acid, \( C_{22}H_{44}O_2 \), also occur in oil of black mustard. This fixed oil is a yellow non-drying oil of from 0.915 to 0.920 sp. gr. at 15° C. (59° F.), solidifying at from -12° to —16° C. (10.4-3.2° F.). It has been long known that black mustard seeds yield by distillation with water a very pungent volatile oil, containing sulphur. Guibourt conjectured, and Robiquet and Boutron proved, that this oil does not pre-exist in the seeds, but is produced by the action of water. Hence the absence or very slight degree of odor in the seeds when bruised in a dry state, and their pungency when water is added. It seemed reasonable to suppose that the reaction in this case was similar to that exercised by water upon bitter almonds (see Amygdala Amara), and this has been proved to be the fact by the experiments of Simon, Bussy, Boutron, and Fremy. The composition and peculiar decompositions of the volatile oil of black mustard have already been described. (See Oleum Sinapis Volatile.)

A principle was extracted by Will from white mustard seed, with the aid of alcohol. It has been named sinalbin, and has the formula \( C_{30}H_{44}N_2S_2O_{16} \). It is decomposed, after the analogy of sinigrin (potassium myronate), into acrinyl sulphocyanate, \( C_7H_7OCNS \), sinapine bisulphate, \( C_{16}H_{25}NSO_9 \), and sugar, \( C_6H_{12}O_6 \), an albuminoid
substance being formed at the same time. "The acrínyl sulphocyanate (C\textsubscript{7}H\textsubscript{7}OCNS) is a very active principle, oily, insoluble in water, not volatile. It may be obtained by causing ether to act on the product of the decomposition of sinalbin. Treated by an alkali and then neutralized by an acid, it colors ferric chloride red." (J. P. C., Avril, 1872, 327.)

The analyses of mustard seeds and mustard flour given in the table below, are by Piesse and Stansell. (Analyst, 1880, p. 161.)

According to F. W. Widmayer (D. C., 1904, 8), the oil from yellow seed is of a greenish-yellow color, that of the brown seed a much darker shade. Both have but little odor and a mild, not unpleasant taste. Mustard seed oil is a semi-drying oil. The analytical data showing maximum and minimum results by M. L. Tolman and L. S. Munson on five samples are as follows: Specific gravity at 15.5° C. (59.9° F.), 0.9147 to 0.9193; Butyrophoractometer reading (15.5° C. (59.9° F.)), 74.5 to 76.5; Index of refraction at 15.5° C. (59.9° F.), 1.4750 to 1.4762; Maumene number 61.4 to 79.4; Specific temperature reaction 130.9 to 190.3; Hubl number, 98.4 to 113.0; Saponification value, 173 to 182.8; Melting point of fatty acids, 20.8 to 21.5° C. 69.4 - 70.7° F.); Free fatty acids oleic, 0.13 to 1.13 per cent.; Solidification from -8° to -18° C. (17.6° to -0.4° F.). One remarkable feature of this oil is its penetrating or diffusing power. Barrels that will hold olive, cotton seed, or petroleum, oil or even new oil or alcohol barrels invariably leak on being filled with it, and it is said by one who has had extensive experience in the mustard business that it has been known to come through a tank which had stood a pressure of 80 pounds of steam. (D. C., 1904, 8.)

J. U. Lloyd has proposed standards for black and white mustard seed, mainly directed towards limiting the proportion of starch; the latter is not a constituent of ripe mustard seed, but commercial mustard nearly
always contains starch, due to starch-bearing seeds accidentally present in the mustard seed, or to fraudulent admixture. (A. J. P., 1898, 433.) Dieterich (Ph. Ztg., Oct. 3, 1900, 767) proposed an assay for mustard seed, mustard oil and mustard paper.

**Uses.**—Mustard seeds swallowed whole operate as a laxative, and have acquired some reputation as a remedy in dyspepsia, and in other affections attended with torpid bowels and deficient excitement. The white seeds are preferred, and are taken in the dose of a tablespoonful (15.5 Gm.) once or twice a day, mixed with molasses, or previously softened and rendered mucilaginous by immersion in hot water. They probably act in some measure by mechanically stimulating the bowels. The powder, commonly called simply mustard, in the quantity of from one to two teaspoonfuls (3.9-7.7 Gm.), is an efficient and prompt—although unpleasant—stimulant emetic, especially valuable in narcotic poisoning. As a condiment mustard acts as a stimulant to the gastric mucous membrane, increasing according to Gottlieb (A. E. P. P., 1894, xxxiii, 261), also the pancreatic secretion. By virtue of this stimulant action it will sometimes relieve obstinate hiccough.

But mustard is most valuable as a rubefacient. Mixed with water in the form of a cataplasm, and applied to the skin, it very soon produces redness with burning pain, which in less than an hour usually becomes insupportable. When a speedy impression is not desired, especially when the sinapism is applied to the extremities, the powder should be diluted with an equal, or double, portion of wheat flour. Care should be taken not to allow the application to continue too long, as vesication with obstinate ulceration, and even sphacelus, may result. This caution is particularly necessary when the patient is insensible and the degree of pain can afford no criterion of the sufficiency of the action. In making a mustard plaster the admixture of alcohol, vinegar, or other fluid than water, should be avoided as hindering the development of the volatile oil. The volatile oil is powerfully rubefacient, and capable of producing speedy vesication, but certainly is less controllable than is the mustard poultice. For external application as a rubefacient, 10 to 20 drops of the oil may be dissolved in a fluidounce of alcohol, or 6 or 8 drops in a fluidrachm of almond or olive oil. (See Linimentum Sinapis Compositum, N. F.) To form a sinapism it has been recommended to mix 20 drops of the volatile oil with a gelatinous mass made by heating together 3.5 drachms of glycerin and 5 drachms of starch. Lebaigue
proposes applying to one sheet of paper a concentrated solution of potassium myronate, and to a second a concentrated solution of myrosin, and drying them. When used, the leaves are to be moistened and placed to the surface, one over the other. Volatile oil of mustard is formed by the reaction of the two principles, and a sinapism is obtained. (J. P. C., Aout, 1868, p. 118.) The volatile oil of mustard has been given internally in colic, two drops being incorporated with a six-ounce mixture, and half a fluidounce (15 mils) given for a dose. In overdoses it is highly poisonous, producing gastro-enteric inflammation, and probably perverting the vital processes by pervading the whole system. Its odor is perceptible in the blood, and is said to impart the smell of horse-radish to the urine. A spirit of mustard may be prepared by macerating, for two hours, 250 parts of powdered black mustard with 500 parts of cold water, then adding 120 parts of alcohol of 86 per cent., and distilling over 120 parts of spirit.

Dose, of mustard aeed, one to two drachms (3.9-7.7 Gm.).

Off. Prep.—Emplastrum Sinapis, U. S.

Sisymbrium. Sisymbrium officinale (L.) Scop. HedgeMustard. Herbeaux chantres, Tortelle, Fr. Wildersenf, Hederich, G. (Fam. Cruciferae)—This annual, growing in Europe and in waste grounds in the United States, is said to be diuretic and expectorant, and has been recommended in chronic coughs, hoarseness, and ulceration of the mouth and fauces. The juice of the plant may be used mixed with honey or sugar, or the seeds may be taken in substance. Sisymbrium Sophia L., or the flax weed, a plant which grows sparingly in waste places in the United States, was formerly official. It is of a pungent odor when rubbed, and of an acrid, biting taste. W. Zopf attributes its poisonous qualities to a volatile alkaloid. (Zeit. f. Nat. Pharm. Central., 1894, 494.) The herb has been used externally in indolent ulcers and the seeds internally in worms, calculous complaints, etc. Diplotaxis muralis DC., (S. MuraleL.), a plant growing about Atlantic ports, has been used in France in scurvy, scrofula, and other cachetic affections, especially associated, in the form of a syrup, with potassium iodide. (Ann Ther., 1863, 126.) Grazing sheep are said to be killed in Southern France by feeding on Diplotaxis tenuifolia DC., and human poisoning has occurred. This species is also sparingly localized like D. muralis. George Heyl has separated a toxic and apparently uncrystallizable alkaloid. (Ap. Ztg., May 30, 1900.)

Sium.—Sium cicutaefolium Schrank (fam. Umbelliferae), which grows in British America and the United States, particularly along the water courses of the valleys of the Pacific slope, and is the hemlock water parsnip of this country, is positively asserted to be poisonous. A. R. Porter and N. Rogers (A. J. P., 1876, 348, 483) found in it an active resinous body, toxic to animals. Oil of Sium cicutaefolium is stated by Rabak to be found in the plant in the proportion of 0.5 per cent. It is yellow and has
an odor resembling that of caraway. (Mid. Druggist, 1905, 5.) S. Sisarum L., or skirret, a plant of Chinese origin, cultivated in Europe, has a sweetish, somewhat aromatic root. The latter is used in much the same manner as the oyster plant and parsnip. It is supposed to be a useful diet in chest complaints.

**Skimmia.** Skimmia japonica Thumb. Miramashikimi. (Fam. Rutaceae)—From this dwarf-growing holly-like shrub, which is cultivated on account of its dark, shining, evergreen leaves and clusters of bright-red berries, Eykman separated a glucoside, skimmin, and a decomposition product, skimmetin. (Abhandl. d. Tokyo Diagaku., No. 10, Tokyo, 1883.) J. Honda (A. E. P. P., Oct., 1904), however, finds that the activity of the plant depends upon the presence of the crystalline alkaloid, skimmianine. It is a muscle poison, producing no primary excitement in the muscle, but an increasing paralysis, the influence of the alkaloid extending to involuntary muscles, such as the heart, so that in mammals arterial pressure is progressively decreased.

**Soja.** Glycine hispida Maxim. (Soja hispida Moench.) Soy Bean. Soja or Sahuca Bean. Miso. (Fam. Leguminosae)—Soja is an important food plant and forage crop. It is an annual having hairy, trifoliate leaves, inconspicuous, violet-colored flowers, and forma broad legumes containing 2 to 5 seeds. The latter are compressed, spherical and vary from brownish-green to brownish-black. Meissel and Bocker (A. J. P., 1885, 108) give the composition of soja bean as follows: water, 10 per cent.; soluble casein, 30; albumen, 0.5; insoluble casein, 7; fat, 18; cholesterin, etc., 2; dextrin, 10; starch, 5; cellulose, 5; ash, 5; traces of sugar and an amido compound. Stingi and Morawski (Monatsschrift fur Chemie, April, 1886) have determined the presence in this bean of a ferment said to be one of the most powerful known in its action upon starch, two-thirds of which it converts into sugar and one-third into dextrin. Soja bean has been suggested as a diabetic food, but it contains upwards of 25 per cent. of carbohydrates.

**Solanum.**—The genus Solanum contains a number of species which are possessed of active physiological properties and some of which have been used to a considerable extent in medicine.

*S. carolinense* L. Horse Nettle. Sand Brier. Poisonous Potato. Apple of Sodom.—Under the name of Solanum the N. F. IV has made the berries of *S. carolinense* official and has introduced fluid-extract of solanum made with a menstruum of two volumes of alcohol and one volume of water.

"The air-dried ripe fruit of Solanum, carolinense Linne (fam. Solanaceae)." N. F. IV.

"Globose, slightly depressed, somewhat shriveled and wrinkled in drying, from 0.8 to 2 cm. in diameter, orange-yellow, glabrous, fleshy, two-celled, many-seeded, calyx and pedicel usually persistent; calyx stellate pubescent, deeply five-lobed, the lobes ovate or ovate-lanceolate, acuminate and enclosing half or more of the berry; seeds orbicular, flat, yellow, smooth, shining. Odor pepper-like; taste bitter and acrid.

"Solanum yields not more than 6 per cent. of ash." N. F. IV.
This is a coarse perennial weed growing in waste sandy ground in the United States as far west as Iowa and as far south as Florida, and yields an orange-yellow berry which is said to be the most active part of the plant. For study of microscopic structure, see A. J. P., vol. lxix. It has been examined by G. A. Krauss (A. J. P., 1890, 601, and 1891, 65 and 216) and Harry Kahn (A. J. P., 1891, 126). Krauss found two active principles corresponding probably to solanine, C\(_{42}\)H\(_{75}\)N\(_{15}\), and solanidine, C\(_{41}\)H\(_{71}\)NO\(_2\), together with a characteristic organic acid to which he gives the name solanic acid. J. U. Lloyd believes that the alkaloid in this plant is not identical with solanine, and proposes to call it solnine (A. J. P., 1894, 61, and 1897, 76, 89, 108.) E. Q. Thornton (T. G; xii, 1896) finds that in frogs this solanum produces stupor with tetanic spasms, not prevented by section of the cord. It is said to have long been used by the negroes of the South in the treatment of the so-called falling sickness, and in 1889 it was recommended by J. L. Napier as of value in epilepsy. H. C. Wood has found that, although when given by itself its usefulness is very limited, as an adjuvant to the bromides it lessens the size of the doses necessary to keep the convulsions in check. Not less than a fluidrachm (3.75 mils) of the fluidextract should be given three times a day. No unpleasant effects have been produced by it. The N. F. recognizes a fluidextract.

S. aculeatissimum Jacq., known as Apple of Sodom, is indigenous to Brazil; the fruit yields traces of solanine.

S. bacciferum ?), of Jamaica, yields the so-called Susumber berries, which are habitually used as fruit by the natives, but Manners has recorded in the Ed. M. J., 1867, fatal poisoning by these berries, death being preceded by dilated pupils and collapse. It is probable, however, that the berries were not true susumber berries but were the product of some other species of solanum.

S. Chenopodium, F. Muell.—In this plant, which is a native of Queensland, C. E. Sage has found the alkaloid solanine. According to E. B. Ormerod the plant is useful in the treatment of dysentery. (P. J., lxviii, 1902.)

Under the English title Bittersweet the N. F. IV recognizes "The dried stems and branches of Solanum Dulcamara Linne (Fam. Solanaceae)." N. F. The Latin title is Dulcamara, the synonyms Stipites Dulcamarae, Tiges de Douceamere (de Morelle grimpante), Douceamere, Fr. Bittersuss, Bittersuss-Stengel, Alpranken, G. Dulcamara. Dulcamara is a climbing shrub with a woody branching stem and purplish, cymose flowers, with lemon-yellow anthers. The bright scarlet berries remain after the falling of the leaves. The plant grows in wet places and around dwellings and is common to Europe and North America, and in the United States grows from New England to Ohio. All portions of the plant are very active. Fatal results from the eating of the berries by a child have been recorded. (P. J., 1861.) For medicinal purposes the plant should be gathered in the autumn after the fall of the leaf, and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

It is described in the N. F. as "In short sections about 5 mm. or less in thickness, cylindraceous, somewhat angular, longitudinally striate, more or less warty, usually
hollow in the center; bark thin, externally pale greenish, or light greenish-brown, glabrous, marked with alternate leaf scars, internally green, the greenish or yellowish wood occurring in one or two concentric rings. Odor slight; taste bitter, afterwards sweet.

"The powder is greenish-yellow and, when examined under the microscope, exhibits tracheae up to 0.05 mm. in diameter and with bordered pores; lignified wood fibers with few pores; non-lignified bast fibers with walls up to 0.02 mm. in thickness; fragments of cork cells; few, simple, unicellular hairs up to 0.8 mm. in length, and with the lumina distinct in the lower portions only; few starch grains, spheroidal, up to 0.012 mm. in diameter; sphenoidal crystals of calcium oxalate numerous, up to 0.007 mm. in length.

"Bittersweet yields not more than 6 per cent. of ash." y. F. IV.

The dried twigs are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous odor. Their taste, which is at first bitter and afterwards sweetish, have given origin to the name of the plant.

Boiling water extracts all their virtues. These are supposed to depend, at least in part, upon the alkaloid solanine. Wittstein (1852) supposed another alkaloid, dulcamarine, to be present, but Geissler (1875) showed that this substance was a glucoside, and not an alkaloid, yielding on decomposition with dilute acids dulcamaretin and sugar. He assigned the formula C_{22}H_{34}O_{10} to dulcamarine, and C_{16}H_{26}O_{6} to dulcamaretin. (Fluckiger, Pharmacographia, 2d ed., p. 451.) Besides solanine, the stalks of S. Dulcamara contain, according to Pfaff, a peculiar principle to which he gave the name of picroglycion, indicative of the taste, at once bitter and sweet, which it is said to possess. This was obtained by Blitz, in the following manner: The aqueous extract was treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with lead subacetate, the excess of this salt-decomposed by hydrogen sulphide, the liquor then evaporated to dryness, and the residue treated with acetic ether, which yielded the principle in small isolated crystals by spontaneous evaporation. Frederick Davis (Y. B. P., 1902) found the two alkaloids, solanine and solanidine, the glucoside solanein, and the bitter principle dulcamarin, in fresh specimens of the plant.

Dulcamara possesses feeble narcotic properties, with the power of increasing the secretions, particularly those of the kidneys and skin. George B. Wood observed, when the system was under its influence, a dark purplish color of the face and hands, and at the same time considerable languor of the circulation. In overdoses it produces nausea, vomiting, faintness, vertigo, and convulsive muscular movements. (London Med. Gaz., 1850.)

Anaphrodisiac properties have been attributed to dulcamara, and it has also been employed with alleged benefit in chronic rheumatism. But its chief use has been in the treatment of scaly cutaneous eruptions, such as lepra, psoriasis, and pityriasis. A fluidextract is official in the N. F. Dulcamara may be given in doses of from thirty
grains to a drachm. (2-3.9 Gm.).

D. Freire has obtained from the fruit of S. grandiflorum, or wolf fruit, of Brazil, a toxic alkaloid, grandiflorine. (C. R. A. S., cv.)

S. J. acquinii Willd. is used in India as a diaphoretic and expectorant.

S. Lycopersicum L. Tomato Plant (formerly termed the Love Apple).—The tomato is believed by many practitioners to be an injurious article of diet to gouty persons on account of the great acidity of the juice, an acidity which T. D. McElhenie has demonstrated to be due at least in part to citric, malic, and oxalic acids. (A. J. P., 1872.) Solanine is said not to be present in the juice but has been found by George W. Kennedy (P. J., 1873) in the herbaceous part of the plant. It probably also exists in the seeds. (A. J. P., xxxiv.)

S. nigrum L. Black, or Garden, or Common Nightshade. Duscle. Hound's Berry. Morelle.—Tills is a simple leaved annual plant, growing widely in shaded and rich open ground throughout the United States. The leaves have been used in medicine in the treatment of scrophulous dyscrasias, and are said to produce diaphoresis when in overdose; also nausea, purging, and nervous disturbance. The poisonous properties commonly attributed to this plant are, however, to be doubted, since Dunal of Montpellier, states, as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon and in the Hawaiian Islands by the natives as food, having been previously boiled in water. In the latter case the active principle of the plant may have been extracted by decoction. Introduced by importers under the name of juruteba, this plant was examined by Kobert and found to be inert. According to Peckoldt, however (Ph. Rund., 1889), true jurubeba is Solanum insidiosum Mart., from which the results would have been more favorable. It is used in Brazil in gonorrhcea and syphilis.

S. Pseudocapsicum L., or Jerusalem or Winter Cherry, a plant cultivated for greenhouse or house decoration when covered with its bright colored berries, yields a fruit whose resemblance to the common cherry is said to have led to its being eaten by children with fatal results.

S. rostratum Dunal. Sand Bur. Buffalo Bur. Beaked Nightshade. Bull Nettle.—This very prickly plant, which grows on the prairies from Nebraska to Mexico, and is noteworthy as having been the original food of the Colorado beetle or potato bug, has yielded to W. S. Amos an alkaloid. (Notes on N. R., iv.)

Narcotic properties have been attributed to the leaves, stalks and unripe berries of S. tuberosum L., or common white potato, and the extract has been used in various diseases. Worsham, of Philadelphia, found the extract, in the quantity of nearly one hundred grains, to cause no sensible effect. (Phila. Journ. of the Med. and Phys. Sciences, vi, 22.)

A case is recorded of death in a girl of fourteen, from eating the unripe fruit of the
potato. (B. M. J., Sept. 3, 1859.) The prominent symptoms were partial stupor, speechlessness, jactitation, hurried breathing, lividity of the skin, cold sweats, very frequent and feeble pulse, and a constant spitting through the closed teeth of viscid frothy phlegm.

It is probable that the properties of the plant vary with the stage of growth, or with the place and circumstances of culture. C. Haaf found solanine in old potatoes which had begun to germinate, in the proportion of 0.16 in 500 parts, and in very young potatoes, deprived of their coating, precisely the same quantity. Fully ripe potatoes, which had not begun to sprout, gave a negative result. (N. R. Pharm., 1864, p. 559.) Solanine has also been found in the germs of potatoes by Schmiedeberg. (A. E. P. P., 1899, xxxvi, 361.)

**Solidago.** Goldenrod. Verge d'Or, Fr. Gold-ruthe, G.—There are very numerous species of this composite genus in the United States. Of these S. odora Ait., or the Sweet Golden-rod, was formerly official. S. Virgaurea L. [now S. Raudii (Porter) Britton], which occurs on dry or granitic soil in the northern United States and Europe, was formerly directed by the Dublin College. It is aromatic, astringent, in hot infusion diaphoretic, and is asserted to be diuretic. (Rev. Gen. de Clin. et de Therap., 1889.) For a study of the flowers of S. bicolor L., by Adam Conrath, see A. J. P., 1873, 253. For an analysis of S. rugosa Mill., see A. J. P., 1893, 122.

**Sonchus.** Sonchusoleraceus L. Common Sow Thistle (Fam. Compositae)—A coarse weed, having runcinate-pinnatifid leaves clasping by a heart-shaped base and producing corymbs of pale yellow flowers in summer and autumn. This European plant is commonly found in waste places around, dwellings in the United States. The brownish gum left after the evaporation of the juice of this plant is said to be a powerful hydragogue cathartic, in doses of from two to four grains (0.13-0.26Gm.). Combined with aromatics or belladonna, it may be used instead of elaterium in dropsy. (Med. Bull., July, 1888.) It has also been used as a so-called cure for the opium habit. (Pac. Pharm., 1908, 113.)

**Sophora.** S. speciosa Benth. Coral Bean,—From the poisonous seeds of this leguminous Texan tree, H. C. Wood obtained a. volatile liquid alkaloid (sophorine) whose chloride is crystalline (see A. J. P., 1878), and which, according to P. O. Plugge, is identical with cytisine. This same alkaloid probably exists in many species of the genus, as Parsons found a liquid alkaloid in S. sericea Nutt., crazy-weed, which grows in Colorado and Mexico (Rep. Commissioner of Agricult; 1879, and N. R., 1881, 67; see also Kalteyer and Neill, A. J. P., 1866, 465), and Greshoff (P. J., xxii). The latter found a poisonous alkaloid in the leaves of S. tomentosa L., the seeds and roots of which are used in Ceylon and Java as a remedy for cholera. Plugge, however (A. Pharm., 1895), affirms that matrine, the alkaloid discovered by Nagai in S. angustifolia, is distinct from cytisine.

Its fruit contains a peculiar kind of sugar called sorbinose, \( C_6H_{12}O_6 \), isomeric with levulose. It reduces Fehling's solution, but is not fermentable with yeast. Hofmann has also discovered two new acids, which he designates as sorbic and parasorbic acids, \( C_6H_8O_2 \). Sorbic acid forms colorless needle-like crystals fusing at 134.5° C. (274° F.), while parasorbic acid ia a laotone-like body, which, on heating with concentrated acids or solid alkali, changes into sorbic acid. M. J. Boussingault has found in it a crystalline saccharine principle, sorbitol, isomeric with mannitol, melting, when anhydrous, at from 110° to 111° C. (230°-231.8° F.), when hydrated, at 102° C. (215.6° F.). Its formula is \( C_6H_{14}O_6 \). It does not undergo the vinous fermentation. (P. J., 1872, 28.) The seeds of the fruit contain 22 per cent. of fixed oil. The fruit has been used in scurvy, and in infusion, as a remedy in hemorrhoids and strangury. All parts of the tree are astringent, and may be employed in tanning and dyeing black. S. americana Marsh, (now Pyrus americana (Marsh.) DC.), or American Mountain Ash, probably has similar virtues to the European species. Edwin Johanson found the fruit to yield from 4.92 to 6.6 per cent. of malic acid. (Ph. Z. R., i, 1882.)

**Sorghum.**—A cane-like plant resembling Indian corn, from which it is distinguished by producing large heads of small grains. There are a number of varieties and these are usually distinguished as "saccharine" sorghums and "non-saccharine" sorghums. The former contain a sugary sap and are referred to Andropogonarundinaceus var. saccharatus. The latter are commonly known as broom corn or Kaffir corn and are varieties of A. arundinaceus var. Durrha. The saccharine sorghums are cultivated in the United States to some extent as a forage crop. They are not used in the manufacture of sugar, owing to the difficulty of effecting its crystallization. Broom corn has been cultivated in the United States since 1798 and is especially adapted to the manufacturer of brooms and brushes. In some of the semi-arid districts of the West it is reported that cattle have been poisoned from eating of the green sorghum, usually of a second growth. This is apparently due to the production of hydrocyanic acid in the leaves.

**Spartium.** Spartium junceum L. Spanish Broom. (Fam. Leguminosae) —A small shrub, indigenous in the south of Europe, and cultivated in our gardens as an ornamental plant. The flowers are large, yellow, and of an agreeable odor. Spanish broom, in its medicinal properties closely resembles Scoparius, but appears to be from five to six times more active, 6 Gm. of the dried plant, given in infusion, having produced very violent poisoning; serious results have been produced by the substitution of the Spanish for the true broom. The dried flowers are readily differentiated, those of the true broom having a small, bell-shaped calyx with two unequal lobes, the upper of which is bidentate, the lower minutely tridentate, and the style always rolled, while in Spartium junceum the calyx is deeply cleft to the base on one side only, and the style is deeply rolled.

The symptoms produced by overdoses are vomiting and purging, with renal irritation. The seeds have been used to a considerable extent in dropsy in doses of from ten to fifteen grains (0.65-1.0 Gm.) three times a day in the form of tincture.

**Sphaeranthus.** Sphaeranthus indicus L. (Fam. Compositae)—An herbaceous plant
having winged stems and widely distributed in Africa, Asia and Australia. It is used as a
general tonic, deobstruent, alterative, and aphrodisiac, under the names of Mundi
Gorakhmuni, Murmuria, and Kottakkarandai. Dymock has found it in a deep cherry-
colored essential oil.

**SPIGELIA. U. S.**

**SPIGELIA [Pinkroot]**

"The dried rhizome and roots of Spigelia marilandica Linne (Fam.
Loganiaceae), without the presence or admixture of more than 10 per-
cent. of stems or other foreign matter." U. S.

Maryland, Carolina or Indian Pink, Worm-grass, Worm-weed, American worm-root.
Star-bloom; Spigelie du Maryland, Fr.; Marylandiache Spigelie, Spigelie, G.; Spigelia, It.

Two species of spigelia have attracted attention as anthelmintics—S.
Anthelmia L., of South America and the West Indies, and S.
marilandica L. of this country. Spigelia Anthelmia L., of South America
is an annual plant, from one or two feet in height, with thin, shortly
petioled leaves, those of the lower stem being lanceolate, those above
varying from very broadly lanceolate to ovate, with a distinct tendency
to a rhomboidal outline and attaining a length of over four inches. It is
much used as an anthelmintic in its native country, and its rhizome is
said to have appeared in the European markets. The only specimens
which we have seen, however, have been the whole dried plant, of
which the attached rhizomes are much smaller and the rootlets much
finer than in the North American species. It is affirmed that in
overdoses this rhizome is a powerful poison, which has caused death not
only in the domestic animal but also in man.

The Carolina pink (Spigelia marilandica) is an herbaceous perennial
plant. The stems, several of which rise from the same rhizome, are
simple, erect, four-sided, nearly smooth, and from twelve to twenty
inches high. The leaves are opposite, sessile, ovate-lanceolate,
acuminate, entire, and smooth, with the veins and margins slightly
pubescent. Each stem terminates in a one-sided spike, and supports
from four to twelve flowers with very short peduncles. The calyx is
persistent, with five long, subulate, slightly serrate leaves, reflexed in
the ripe fruit. The corolla is funnel-shaped, and much longer than the
calyx, with the tube inflated in the middle, and the border divided into
five acute, spreading segments. It is of a rich carmine color externally, paler at the base, and orange-yellow within. The edges of the segments are slightly tinged with green. The stamens, though apparently very short, and inserted into the upper part of the tube between the segments, may be traced down its internal surface to the base. The anthers are oblong, heart-shaped; the ovary superior, ovate; the style about the length of the corolla, and terminating in a linear fringed stigma projecting considerably beyond it. The capsule is double, consisting of two cohering, globular, one-celled portions, with many seeds.

The plant is a native of our Southern and Southwestern States, being seldom found north of the Potomac. It grows in rich soils on the borders of woods, and flowers from May to July. The rhizome and roots are the only portions recognized in the Pharmacopoeias. The drug was formerly collected in Georgia and the neighboring States by the Creek and Cherokee Indians, who disposed of it to the white traders. After the emigration of the Indians, the supply of spigelia from this source very much diminished, and at one time it nearly if not quite ceased. But a new source of supply was opened from the Western and Southwestern States, and it is now again obtainable. The commercial supplies being so restricted, some attention has been given to the cultivation of the plant. The Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., has grown spigelia under shade, and Miss Henkel states that it is readily cultivated in Georgia. (D. C., lvi, p. 132.)

No drug has had a commercial history like spigelia. For twenty years or more it was largely substituted by Ruellia ciliosa Pursh. Sanders reported examining 57 samples of pink-root which were obtained from various sections of the country and none were genuine. (Jour. A. Ph. A., 1912, p. 502.) To Prof. Greenish (A. J. P., 1891, p. 226) belongs the credit for the first pharmacognostic description of this common substitute, although he incorrectly attributed it to Phlox Carolina L. (P. ovata L.). He pointed out that it was distinguished by the fact that it contained stone cells and cystoliths of calcium carbonate. Greenish's work was confirmed by Holm (A. J. P., 1906, p. 553) and by Stockberger (Ph. Rev., 1907, p. 2). His false identification continued in literature for several years, probably owing to the statements of the large drug houses which make a specialty of collecting American drugs. (Proc. A. Ph. A., 1909, p. 1171.) The presence of Phlox ovata L. in commercial lots of spigelia has not been confirmed, and Kraemer illustrates the
pharmacognosy of the rhizome and roots of this drug in A. J. P., 1910, p. 470. Moser, however, affirms that Phlox ovata and P. glaberrima L. are frequently collected and sold as spigelia. (A. J. P., 1909, p. 576.) Among some of the adulterants which have been identified are the rhizomes of goldenseal and caulophyllum, although a large variety of rhizomes are no doubt more or less intermixed.

**Properties.**—Pinkroot is officially described as "rhizome horizontal or slightly oblique, more or less flexuous, somewhat branched, from 1.5 to 5 cm. in length and from 2 to 5 mm. in diameter; externally dark brown, slightly annulate, with scars of bud scales, the upper surface knotty from approximate stem-bases, bearing cup-shaped scars; from the lower and lateral portions arise numerous, long, rather coarse, sparingly branched, brittle roots; fracture short, internally differentiated into three nearly equal zones of pith, wood and bark; odor slightly aromatic; taste bitter, pungent. Few if any of the roots exhibit thin, terminal portions with the bark stripped from the slender strands of wood. Stems usually attached to the upper portion of the rhizome, nearly cylindrical, attaining a length of 6 cm. and a diameter of 3 mm., light grayish-brown to purplish-brown, nodes annulate, marked by opposite leaf-scars. Under the microscope, transverse sections of the rhizome of Spigelia show a dark brown, more or less exfoliated epidermal layer; a cortex composed of from 10 to 15 rows of starch-bearing parenchyma; a distinct zone of sieve tissue from 0.075 to 0.15 mm. in width; a compact woody area composed of tracheae and tracheids which are hardly distinguishable from each other, both kinds of vessels being marked with bordered pores; an internal sieve closely resembling the sieve in the bark; and a pith composed of fairly uniform, nearly polygonal, thin-walled cells, more or less filled with small starch grains. Transverse sections of the root show a large cortex, the cells of which are more or less filled with small starch grains and a central stele of 6 or 8 radial fibro-vascular bundles, which in the older roots are united by a strong development of lignified cells. The stem in transverse section is distinguished from the rhizome by a narrower woody zone, the tracheae having spiral thickenings, and by a nearly uninterrupted circle of non-lignified bast-fibers in the bark. The powder is grayish-brown; when examined under the microscope it exhibits starch grains generally numerous, at times, however, few, spherical or slightly angular, from 0.002 to 0.006 mm. in diameter; fragments of lignified tracheae and tracheids conspicuous; fragments of tracheae with spiral thickening relatively few; bast-fibers few, very long, non-lignified; occasional
fragments of the reddish-brown epidermal cells. Spigelia yields not more than 10 per cent. of ash." U. S.

The virtues of spig'elia are extracted by boiling water. The root, analyzed by Feneulle, yielded a fixed and volatile oil, a small quantity of resin, a bitter substance supposed to be the active principle, a mucilaginous saccharine matter, albumen, gallic acid, the malates of potassium and calcium, etc., and woody fiber. The principle upon which the virtues of the root are thought to depend is brown, of a bitter nauseous taste, like that of the purgative matter of the leguminous plants, and when taken internally produces vertigo and a kind of intoxication. An analysis of the root by R. H. Stabler yielded as results a bitter uncrystallizable principle upon which the virtues of the medicine are supposed to depend, a little volatile oil, tannic acid, inert extractive, wax, resin, lignin, and salts of sodium, potassium, and calcium.

The active principle is a volatile alkaloid discovered by W. L. Dudley (Am. Chem., vol. i, p. 150), who, on the contrary, found that the active principle of spigelia is a volatile alkaloid. He made it by distilling the ground root with milk of lime over a paraffin bath, and collecting the distillate in hydrochloric acid. After evaporation to dryness, the residue is taken up with alcohol and crystallized out of solution. He compared the reactions of this alkaloid, which he called spigeline, with those of nicotine, coniine, and lobeline. Spigeline yields a brownish-red precipitate with a solution of iodine in potassium iodide, a white crystalline precipitate with potassio-mercuric iodide, and a white floc-culent precipitate with meta-tungstic acid. Boorsma (P. J., 1898, 89) found 0.0005 Gm. of spigeline to be lethal to guinea pigs.

Uses.—The activity of spigelia is somewhat diminished by time. Spigelia is generally considered among the most powerful anthelmintics, especially esteemed against the round-worm. In the ordinary dose it usually produces little sensible effect on the system; more largely given it acts as a cathartic, though unequal and uncertain in its operation; in overdoses it is said to cause vertigo, dimness of vision, dilated pupils, spasms of the facial muscles and of the eye-lids, and even general convulsions. The death of two children who expired in convulsions was attributed to it by Chalmers. H. A. Hare (Med. News, March, 1887) has found that in the lower animals it produces symptoms similar to those just described, namely, dilatation of the pupil, exophthalmia, strabismus, progressive muscular weakness of spinal origin, cardiac
depression, and death from failure of respiration. The narcotic effects are said to be less likely to occur when the medicine purges, and to be altogether obviated by combining it with cathartics. The danger from its employment cannot be great, as it is in very general use in the United States, in both regular and domestic practice, and we never hear at present of serious consequences. Its effects upon the nervous system have been erroneously conjectured to depend on other roots sometimes mixed with the genuine. The vermifuge properties of spigelia, first learned from the Cherokee Indians, were made known to the medical profession by Lining, Garden, and Chalmers, of South Carolina.

It may be given in substance or infusion, or as the fluidextract. The infusion may be made by macerating half a troyounce of the root in a pint of boiling water. It is usually combined with senna or some other cathartic, to insure its action on the bowels. A preparation much sold under the name of worm tea consists of spigelia, senna, manna, and savin, mixed together, in various proportions, to suit the views of different individuals.

Dose, of the powdered root, for an adult, one or two drachms (3.9-7.7 Gm.), to be repeated morning and evening for several days successively, and then followed by a brisk cathartic.

**Off. Prep.**—Fluidextractum Spigeliae, U. S.

**Spilanthes.** Spilanthes Acmella Murr. (S. oleracea L.) Para Cress. Cresson de Para, Fr. Parakresse, G. (Fam. Compositae)—A plant of India, used as a masticatory for toothache; when chewed it produces a copious salivation. (A. J. P., xlv, 323.)

**Spiraea.**—Many if not all of the species of this genus contain a colorless volatile oil, very similar to the oil of gaultheria, but composed mainly of salicylic aldehyde, with only smaller amounts of methyl salicylate. The species which have been submitted to actual analysis are the Spiraea Ulmaria L. (Filipendula Ulmaria (L.) Maxim.), commonly known as Queen of the Meadow, or Meadow-sweet—a European plant which has been introduced into this country; also the European species S. lobata Jacq. and the species S. Filipendula L. (Filipendula vulgaris Moench.), which grows in Southern Europe and Northern Africa. A yellow, crystalline powder of a bitter taste, insoluble in water, slightly so in alcohol, readily soluble in ether, and having an acid reaction. Spiraeaic acid (now recognized as salicylic acid) (J. Pr. Chem., xix) was separated from the flowers of S. Ulmaria by Lowig and Weidmann, and has been found by Rochebrune in the flowers of S. Filipendula L.

The roots of probably most of the species contain tannic acid, gallic acid, and when fresh some of the volatile oils. (A. J. P., 1887.) The root of Spiraea tomentosa L.
(Hardback, Steeplebush, or Whitecap), was formerly recognized in the U. S.
Pharmacopoeia. It is an indigenous shrub growing in low grounds from New
Brunswick and Nova Scotia to the mountains of Georgia and westward. The stems
and lower surfaces of the ovate-lanceolate, serrate leaves are whitish and tomentose.
The rose-colored flowers are disposed in terminal, compound, crowded spikes or
racemes.

The flowers of Spiraea, possess to a very feeble extent the medicinal virtues of
salicylic acid, and have been used as diuretic and tonic in the form of decoction. The
roots are astringent, and have been used in the treatment of diarrhea in doses of from
five to twenty grains (0.32-1.3 Gm.) of the aqueous extract repeated pro renata.

SPIRITUS

SPIRITS

Alcoolats, Fr.; Geiste, G.; Spirito, It.

Spirits, as the term is here used, are alcoholic solutions of volatile
principles formerly in general procured by distillation, but now
frequently prepared by simply dissolving the volatile principle in alcohol
or diluted alcohol. The distilled spirits are prepared chiefly from aromatic
vegetable substances, the essential oils of which rise with the vapor of
alcohol and condense with it in the receiver. Some of the oils, however,
will not rise at the temperature of boiling alcohol, but may be distilled
with water. In this case it is necessary to employ diluted alcohol or proof
spirit, with the water of which the oil comes over in the latter part of the
process. As the proof spirit of commerce is often impregnated with
foreign matters, which give it an unpleasant flavor, it is better to use
alcohol which has been carefully rectified, and to dilute it with the due
proportion of water, as directed by the U. S. Pharmacopoeia. In
preparing the spirits, care should be taken to avoid the color and
empyreumatic flavor arising from the decomposition of the vegetable
matter by heat. Sufficient water must, therefore, be added to cover the
vegetable matter after the alcohol shall have been distilled, and, as a
rule, the heat should be applied by means of a water bath, or of steam.
The aromatic should be macerated for some days with the alcohol before
being submitted to distillation, as the oil, being thus dissolved, rises
more readily with the spirituous vapor than when confined in the tissue.

The aromatic spirits are used chiefly to impart a pleasant odor and taste
to mixtures, and to correct the nauseating and griping effects of other
medicines. They serve also as carminatives in flatulent colic, and as
agreeable stimulants in debility of the stomach.

SPIRITUS AMYGDALÆ AMARÆ. U. S.

SPIRIT OF BITTER ALMOND
Sp. Amygd. Amar. [Essence of Bitter Almond]

Alcoole d'essence amande amere, Fr.; Bittermandelgeist, G.

"Oil of Bitter Almond, ten mils [or 162 minims]; Alcohol, eight 'hundred mils [or 27 fluidounces, 24 minims]; Distilled Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Dissolve the oil in the alcohol, and add enough distilled water to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Note: This Spirit is intended for medicinal use; it must not be used for flavoring foods." U. S.

Although the U. S. P. states that "this spirit is intended for medicinal use; it must not be used for flavoring foods" U. S., it has little medicinal virtue except for its flavor. Because of the hydrocyanic acid in the oil of bitter almond this preparation will contain approximately 0.03 per cent. of that acid and hence cannot be used incautiously. It would have been better to have replaced this spirit with a solution of benzaldehyde.

Dose, from two to eight minims (0.12-0.5 mil).

Off. Prep.—Elixir Anisi, N. F.

SPIRITUS ANISI. U. S., Br.

SPIRIT OF ANISE Sp. Anisi

Essence of Anise; Teinture d'essence d'anis vert, Fr. Cod.; Anisgeist. G.

Oil of Anise, one hundred mils [or 3 fluid-ounces, 183 minims]; Alcohol, a sufficient quantity to make one thousand mils [or 33 fluid-ounces 6½ fluidrachms]. Mix the oil with sufficient alcohol to make the product measure one thousand mils [or 33 fluidounces. 6½ fluidrachms].” U. S.

"Oil of Anise, 100 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered
talc and filter." Br.

Dose, as a stomachic and carminative, from twenty to sixty minims (1.3-3.75 mils), properly diluted.

**SPIRITUS ARMORACIÆ COMPOSITUS. Br.**

**COMPOUND SPIRIT OF HORSERADISH**

Esprit (alcoolat) de Raifort composee, Alcoolat antiscorbutique, Fr.; Zusammengesetzter Meerrettiggeist, G.

"Horseradish Root, scraped, 125 grammes; Dried Bitter-Orange Peel, bruised, 125 grammes; Nutmeg, bruised, 3 grammes; Alcohol (90 per cent.), 625 millilitres; Distilled Water, 750 millilitres. Macerate the Horseradish Root in the Distilled Water for one hour, add the other ingredients, and distil one thousand millilitres. Specific gravity 0.917 to 0.927." Br.

This may be used advantageously as an addition to diuretic remedies, in dropsy attended with debility, especially in the case of drunkards.

Dose, from one to four fluidrachms (3.75-15 mils).

**SPIRITUS AURANTII COMPOSITUS. U. S.**

**COMPOUND SPIRIT OF ORANGE Sp. Aur. Co.**

Teinture d'essence d'orange, Fr. Cod.; Esprit d'orange composee, FT.; Zusammengesetzter Orangegeist, G.

*"Oil of Orange, two hundred mils [or 6 fluidounces, 366 minims]; Oil of Lemon, fifty mils [or 1 fluidounce, 331 minims]; Oil of Coriander, twenty mils [or 325 minims]; Oil of Anise, five mils [or 81 minims]; Alcohol, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Mix them. Keep the product in completely filled, well-stoppered bottles, in a cool and dark place." U. S.

This compound spirit has been introduced for the purpose of producing the orange flavor in making the official aromatic elixir, and in various N. F. elixir's. It will be found by physicians to be a useful and fragrant
addition to prescriptions.

**Off. Prep.**—Elixir Aromaticum, U. S.

**SPIRITUS CAJUPUTI. Br.**

**SPIRIT OF CAJUPUT**

Teinture (alcoole) d'essence de Cajeput, Alcoole d'essence de Cajeput, Fr.; Cajeputgeist, G.

"Oil of Cajuput, 100 millilitres; Alcohol (90 per cent.) sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered talc and filter." Br.

For an account of the medicinal properties and uses of oil of cajuput, of which this is simply an alcoholic solution, see Oleum Cajuputi.

Dose, from five to twenty minims (0.3-1.3 mils), properly diluted.

**SPIRITUS CINNAMOMI. U. S., Br.**

**SPIRIT OF CINNAMON** Sp. Cinnam.

Teinture (alcoole) d'essence de Cannelle, Esprit de Cannelle, Fr.; Zimmtspiritus, G.; Spirito di cannella, It.

"Oil of Cinnamon, one hundred mils [or 3 fluidounces, 183 minims]; Alcohol, a sufficient quantity to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Mix the oil with sufficient alcohol to make the product measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]." U.S.

"Oil of Cinnamon, 100 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered talc and niter." Br.

The spirit of cinnamon is an agreeable aromatic cordial.

Dose, from ten to thirty minims (0.6-1.8 mils) in water.
SPIRITUS JUNIPERI. U. S., Br.

Teinture d'essence de Genievre, Fr, Cod.; Spiritus Juniperi, P. G.; Wacholderspiritus, G.

"Oil of Juniper, fifty mils [or 1 fluidounce, 331 minims]; Alcohol, a sufficient quantity to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Mix the oil with sufficient alcohol to make the product measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]." U. S.

"Oil of Juniper, 100 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a tittle powdered talc and filter. This Spirit is of twice the strength of the corresponding preparation of the British Pharmacopoeia, 1898." Br.

This spirit is used chiefly as an addition to diuretic infusions. It is about 33 per cent. stronger than the spirit official before 1890.

Dose, from thirty to sixty minims (1.8-3.75 mils).

SPIRITUS JUNIPERI COMPOSITUS. U. S.

Teinture (alcoole) d'essence de Genievre compoaeae, Fr.; Zusammengesetzter Wachholderspiritus, G.

"Oil of Juniper, eight mils [or 130 minims]; Oil of Caraway, one mil [or 16 minims]; Oil of Fennel, one mil [or 16 minims]; Alcohol, fourteen hundred mils [or 47 fluidounces, 162 minims]; Water, a sufficient quantity, to make two thousand mils [or 67 fluidounces, 301 minims]. Dissolve the oils in the alcohol, and gradually add enough water to make the product measure two thousand mils [or 67 fluidounces, 301 minims]." U. S.

This spirit is a useful addition to diuretic infusions and mixtures in debilitated cases of dropsy. It corresponds very closely to Holland gin.

Dose, from two to four fluidrachms (7.5-15 mils).
SPIRITUS LAVANDULÆ. U. S., Br.

SPIRIT OF LAVENDER Sp. Lavand.

Teinture (alcoole) d'essence de Lavande, Fr.; Spiritus Lav-andulse, P. G.; Lavandelapiritus, G.

"Oil of Lavender, fifty mils [or 1 fluidounce, 331 minims]; Alcohol, a sufficient quantity to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix the oil with sufficient alcohol to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Oil of Lavender, 100 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered talc and filter." Br.

Spirit of lavender is used widely as a perfume, and as an ingredient in other preparations. The perfume usually sold under the name of lavender water is not a distilled spirit, but an alcoholic solution of the oil, with the addition of other odorous substances. The following is given by Brande as one of the most approved recipes for preparing it. "Take of rectified spirit five gallons, essential oil of lavender twenty ounces, essential oil of bergamot five ounces, essence of ambergris [made by digesting one drachm of ambergris and eight grains of musk in half a pint of alcohol] half an ounce. Mix." The Br. spirit is double the strength of the U. S. preparation. It is a grateful stimulant and carminative when administered in sweetened water.

Dose, of the U. S. Spirit, from ten to thirty minims (0.6-1.8 mils); of the Br. Spirit, five to twenty minims (0.3-1.3 mils).

Off. Prep.—Mistura Ferri Composita, N. F.

SPIRITUS MENTHÆ PIPERITÆ. U. S., Br.

SPIRIT OF PEPPERMINT Sp.Menth.Pip. [Essence of Peppermint]

Teinture d'essence de Menthe, Fr. Cod.; Spiritus Menthae Piperitae, P. G.; Pfefferminzspiritus, Englische Pfefferminz-essenz, G.; Alcohol de
"Oil of Peppermint, one hundred mils [or 3 fluidounces, 183 minims]; Peppermint, bruised, ten grammes [or 154 grains]; Alcohol, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Macerate the peppermint leaves, freed as much as possible from stems, during one hour in five hundred mils [or 16 fluidounces, 435 minims] of water and then strongly express them. Mix eight hundred mils [or 27 fluidounces, 24 minims] of alcohol with the oil, add the macerated leaves and enough alcohol to make one thousand mils [or 33 fluidounces, 6½ fluidrachms], macerate the mixture during six hours, with frequent agitation, and then filter it. Preserve the product in amber-colored bottles." U. S.

"Oil of Peppermint, 100 millilitres; Alcohol (90 per cent.) sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered talc and filter." Br.

The distilled spirit has no advantage over a simple solution of the oil in alcohol; and this mode of preparing it has been adopted both in the U. S. and British Pharmacopoeias. The American spirit is green in color, but the British is almost colorless. P. H. Utech suggests the maceration of the peppermint in water for two hours, washing and draining, before adding to the solution of the oil; water soluble matter is removed and a more permanent green color produced. He recommends the same treatment for the spearmint in making spirit of spearmint, and the U. S. P. IX adopted this plan. It has long been popularly used under the name of essence of peppermint. The spirit of peppermint affords a convenient method of administering a dose of the volatile oil, being of such a strength that when dropped on loaf-sugar it may be taken without inconvenience.

Dose, ten to thirty minims (0.6-1.8 mils), given as just mentioned, or mixed with sweetened water.

**SPIRITUS MENTHÆ VIRIDIS. U. S.**

**SPIRIT OF SPEARMINT Sp. Menth. Vir.**

Tinctura Olei Menthæ Viridis, U. S. 1850; Essence of Spearmint; Grune Minzessenz, G.
"Oil of Spearmint, one hundred mils [or 3 fluidounces, 183 minims]; Spearmint, bruised, ten grammes [or 154 grains]; Alcohol, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Macerate the spearmint leaves, freed as much as possible from stems, during one hour in five hundred mils [or 16 fluidounces, 435 minims] of water and then strongly express them. Mix eight hundred mils [or 27 fluidounces, 24 minims] of alcohol with the oil, add the macerated leaves and enough alcohol to make one thousand mils [or 33 fluid-ounces, 6½ fluidrachms], macerate the mixture during six hours, with frequent agitation, and then filter it. Preserve the product in amber-colored bottles." U. S.

The remarks made on the Spirit of Peppermint are equally applicable here.

Dose, ten to thirty minims (0.6-1.8 mils).

**SPIRITUS MYRISTICÆ. Br.**

**SPIRIT OF NUTMEG [Essence of Nutmeg]**

Teinture (alcoole) d'essence de Muscade, Fr.; Muskat-spiritus, G.

"Oil of Nutmeg, 100 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered talc and filter." Br.

It is used chiefly for its flavor. Spirit of nutmeg was not retained in the U. S. P. IX. It was made in the U. S. P., 1890, by dissolving 50 mils of nutmeg in 950 mils of alcohol. (See Oleum Myristicae.)

Dose, from five to twenty minims (0.3-1.3 mils).

**SPIRITUS ROSMARINI. Br.**

**SPIRIT OF ROSEMARY**

Spiritus Anthos; Teinture d'essence de Romarin, Fr. Cod.; Rosmarinspiritus, G; Alcohol de romero, Sp.
"Oil of Rosemary, 100 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Dissolve. When not clear, shake with a little powdered talc and filter." Br.

This spirit is not official in the United States Pharmacopoeia IX. It is a grateful perfume, and is used chiefly as an odorous ingredient in lotions and liniments.

**Sponge** Spongia. Spongia officinalis. Eponge, Fr. Schwamm. Badeschwamin, G.—The sponge is "a flexible, fixed, torpid, polymorphous animal, composed either of reticular fibers or masses of small spires interwoven together, and clothed with a gelatinous flesh, full of small mouths on its surface, by which it absorbs and ejects water." Until recently sponges were classified as colonial Protozoa, the lowest group of animals, but they are now brought under a separate phylum known as Porifera (or Spongiaria) a name applied to them because of their abundance of water pores. The latter are of two kinds, both opening into the digestive canals and ramifying passages of the sponge. Some of these are large, but most of them are small, being in the nature of inhalant pores or inlets for admitting the water. The current through these pores is a constant one which is induced by countless flagella which occur in definite enlargements on the canals and known as ciliated chambers. This current contains the minute organisms which are carried to the digestive cavities and upon which the animal feeds. Through these canals oxygen is distributed, the waste matters eliminated and fertilization of the eggs is effected. Sponges inhabit the bottom of the sea, where they are fixed to rocks or other solid bodies, and are most abundant within the tropics. They are collected chiefly in the Mediterranean and Red Seas, the West Indies and the coast of Florida and Central America. In the Grecian Archipelago, Crete, Cyprus, on the coast of Asia Minor, Syria, Barbary and the Bahama Islands, sponge fisheries constitute a very important industry. Formerly most of the sponges used in the United States were brought from the Mediterranean waters, but since 1852 the Bahamas and the coast of Florida have furnished much of the commercial supply. When collected they are enveloped in a gelatinous coating, which forms part of the animal. For details of fishery and preparation, see P. J., xx. Large quantities of the coarser kinds are imported from the Bahamas, but the finest and most esteemed are brought from the Mediterranean, especially from the coast of Syria. Recently the cultivation of sponges has been undertaken on an extensive scale. Small fragments are cut under water from the live sponge, and fixed upon a sandy bottom by means of skewers. In three years they will have grown sufficiently to be marketable.

Sponge, as found in commerce, is in yellowish-brown masses of various shapes and sizes, light, porous, elastic, and composed of fine, flexible, tenacious fibers, interwoven in the form of cells and meshes. It usually contains numerous minute fragments of coral or stone, or small shells, from which it must be freed before it can be used for ordinary purposes. Sponge is prepared by macerating it for several days in cold water, beating it in order to break up the concretions which it contains, and dissolving what cannot thus be separated of the calcareous matter by hydrochloric acid diluted with...
thirty parts of water. By this process it is rendered perfectly soft, and fit for surgical use. It may be bleached by steeping it in water impregnated with sulphurous acid, or by exposure in a moist state to the action of chlorine. It is stated that sponges which have been soaked in pus and infectious matters will recover their primitive condition by soaking in a 4 per cent. solution of potassium permanganate, then in a 25 per cent. solution of official sulphurous acid, and finally thorough washing in an abundance of water. (A. J. P., xliv, 355.) When intended for surgical purposes, the softest, finest, and most elastic sponges should be selected; for forming burnt sponge the coarser will answer equally well. According to Hatchett, the chemical constituents of sponge are gelatin, coagulated albumin, common salt, and calcium carbonate. Magnesia, silica, iron, sulphur, and phosphorus have been detected in it, as also iodine and bromine, combined with sodium and potassium. From the experiments of Croockewit, it would appear that sponge is closely analogous to, if not identical with, the fibroin and sericin of silk, differing from it only in containing iodine, sulphur, and phosphorus. (Ann. Ch. Ph., xlviii, 43.) Schlossberger, however, has shown that it is distinct, in its very slight solubility in ammoniacal solution of copper hydroxide and in its yielding leucine and glycocoll when treated with diluted sulphuric acid, while sericin yields under similar treatment tyrosine and serin. He names the principle spongin.

Sponges are used for mechanical purposes only. Sponge tent is employed for dilating sinuses. This is prepared by dipping sponge into melted wax, compressing it between two flat surfaces till the wax hardens, and then cutting it into pieces of a proper form and size. By the heat of the body the wax becomes soft, and the sponge, expanding by the imbibition of moisture, gradually dilates the wound or sinus in which it may be placed. When a conical sponge tent of uniform caliber is required, as for dilating the uterine cavity, a better plan is to cut the sponge into a conical shape while fresh and compress when moist, by winding it carefully with a fine tightly drawn cord, removing the cord when perfectly dry, and dipping the tent into melted wax, so as to get a thick coating. For other modes of preparing sponge tent, as well as of saturating the sponge at the same time with substances calculated to make a, remedial impression, as phenol, alum, lead acetate, etc., see A. J. P., 1868, 410; 1869, 446.

**Spongia Usta,** Burnt Sponge, was formerly official (Spongia Usta, U. S. 1850), but is no longer used in medicine. For method of preparation, analysis, and therapeutic properties, see 16th edition, U. S. D.

**STAPHISAGRIA. U. S. (Br.)**

**STAPHISAGRIA Staphisag. [Stavesacre]**

"The ripe seeds of Delphinium Staphisagria Linne (Fam. Eanunculaceae), without the presence or admixture of more than 2 per cent. of foreign vegetable matter." U. S. "Stavesacre Seeds are the dried ripe seeds of Delphinium Staphisagria, Linn." Br.

**Staphisagrias Semina,** Br.; Semen Staphisagiae, Staphidiagriae or Pedicularis;
Delphinium Staphisagria L., or stavesacre, is a handsome, annual or biennial plant, one or two feet high, with a simple, erect, downy stem, and palmate, five- or seven-lobed leaves, supported on hairy petioles. The flowers are bluish or purple, in terminal racemes, with pedicels twice as long as the flower, and bracteoles inserted at the base of the pedicel. The sepals are five in number, irregular, petal-like, the upper one being spurred at the base. The petals are four, irregular, the two upper having long spurs which are inclosed in the spur of the calyx, the two lower having short claws. The pistils form a many seeded pod or capsule in fruit.

The plant is a native of the south of Europe. E. M. Holmes calls attention to the remarkable fact that the plant in the English botanic gardens hitherto considered to be Delphinium Staphisagria is in reality another species, i.e., Delphinium pictum Willd. The author accounts for the absence of the true plant in botanic gardens partly by the fact that it is only half-hardy in Great Britain, while D. pictum is hardy, and partly by the reason that the illustrations in several works on medicinal plants—even in Bent-ley and Trimen's "Medicinal Plants"—are incorrect or unreliable. The two species are distinguished as follows: D. Staphisagria has very hairy stems, glandular hairs being mixed with the long spreading soft hairs; flowers that when well-developed have an ultramarine blue tint; a calyx with very short or almost obsolete spur; carpels containing only four or five seeds. D. pictum Willd., has shorter soft hairs, but no glandular hairs on the stems; the flowers are of a pale lilac color; the spur is as long as the calyx segments; each carpel contains ten or twelve seeds, and these are only half the size of those of D. Staphisagria. The true D. Staphisagria extends from Teneriffe around both the northern and southern coasts of the Mediterranean to Asia Minor. It is quite possible, therefore, that varieties having blossoms of different tints may occur. The evidence obtainable, however, goes to show that the form of the plant from which the seed of commerce is obtained has clear blue flowers. (Y. B. P., 1899, 390.) For description of other species of this genus, see Delphinium.

Properties.—The seeds of stavesacre are officially described as "irregularly triangular, flattened, or somewhat tetrahedral, one side being-convex, from 4 to 7 mm. in length and from 3 to 6 mm. in breadth;
externally dark brown, becoming lighter with age, and coarsely reticulate; easily cut, showing a somewhat light brown, oily endosperm, enclosing a small embryo at the pointed end; odor slight, disagreeable; taste intensely bitter and acrid. Under the microscope, transverse sections of Staphisagria show an outer layer of nearly tabular, thick-walled, non-lignified cells, some being extended centrifugally, and forming the reticulations of the seed-coat; 2 or 3 rows of parenchyma cells with more or less irregular thin walls; a thin layer of very small, thick-walled cells with numerous, lattice-like or reticulate pores; endosperm large, composed of polygonal cells enclosing small aleurone grains and fixed oil, the latter forming in large globules on the addition of hydrated chloral T.S."

"Irregularly triangular or obscurely quadrangular, arched, blackish-brown when fresh, but becoming dull greyish-brown on keeping. Surface wrinkled and deeply pitted; kernel soft, whitish, oily. No marked odor; taste nauseous, bitter and acrid." Br.

The seeds of the field larkspur (D. Consolida L.) and of D. Ajacis L. are being largely used in place of the official staphisagria; in fact, they are recognized in the National Formulary. These are readily distinguished, being about 2 mm. in length and of a black or blackish-brown color.

The virtues of staphisagria are extracted by water and alcohol. Analyzed by Lassaigne and Feneulle it yielded a brown and a yellow bitter principle, a volatile oil, about 30 per cent. of a fixed oil, albumen, a nitrogenous substance, a mucilaginous saccharine matter, mineral salts, and a peculiar alkaloid called delphinine, which exists in the seeds combined with an excess of malic acid. Marquis, in Dragendorff's laboratory in 1877, isolated the following four alkaloids: delphinine, C_{22}H_{35}O_5N, a crystallizable alkaloid, of bitter taste, weak alkaline reaction, soluble in alcohol, ether, and chloroform; delphinoidine, C_{42}H_{68}O_7N_2, amorphous, soluble in ether, alcohol, chloroform, reaction strongly alkaline, fusing point from 110° to 120° C. (230°-248° F.); delphisine, C_{27}H_{46}O_4N_2, crystallizing in warty aggregations, soluble in ether, alcohol, and chloroform; staphisagrine, C_{22}H_{33}O_5N, only obtained amorphous, difficultly soluble in water and ether, easily soluble in alcohol and chloroform, of bitter taste, fusing point 90° C. (194° F.), of alkaline reaction in alcoholic solution. If delphinine be rubbed up with an equal quantity of malic acid, and some drops of concentrated
sulphuric acid added, there will be produced an orange-red color passing into rose, growing deeper after some hours, and finally changing from the edges to violet, and at last becoming cobalt blue. (Tattersall, Chem. News, 41.) It is stated that no other alkaloid and no other organic acid, except malic, affords this reaction. (Pflanzenstoffe, 2d ed., 1884, 617.) The total amount of alkaloids is about 1 per cent. According to Charalampi Kara-Stojanow (In. Dis., Dorpat, 1890), delphinine and delphisine have the same composition, $C_{31}H_{49}O_7N$, crystallize from their solutions in ether and petroleum benzin in identical forms, and have their melting points at 189° and 191° C. (372.2° and 375.8° F.), while delphinoidine has the formula $C_{25}H_{12}O_4N$. Ahrens (Ap. Ztg., 1899, 361) obtained from the residue of the seeds of $D$. staphisagria, from which delphinine, delphinoidine, delphisine and staphisagrine had been extracted, the alkaloid staphisagroine (Ber. d. Chem. Ges., 1899, 1581). For Katz's process for extracting delphinine, see Ph. Ztg., 1900, 735.

Uses.—The seeds were formerly used as an emetic and cathartic, but have been abandoned in consequence of their violence. A strong tincture has been employed as an embrocation in rheumatism. The ointment is used to destroy lice and the itch-mite. Staphisagria should never be used internally, and when it is applied externally, care should be exercised not to put it on an abraded surface, but only upon the unbroken epidermis. In some countries the seeds are used like Cocculus Indicus to intoxicate fish.

When given in poisonous doses to the lower animals, delphinine produces excessive salivation, followed by violent and repeated vomiting, great disturbance of respiration, failure of heart action, gradual enfeeblement of voluntary motion and of sensation, and a peculiar fibrillary spasm of the muscles of the abdomen, which is said to be characteristic of the poisoning. Elevation of temperature and glycosuria have both been noticed; death is said to occur always from failure of respiration, though the heart is greatly enfeebled and finally ceases in diastole. According to Gauthier, the period of depression of the heart and of sensibility is preceded by one of excitement. The pupils are dilated and the motor nerve finally paralyzed. (L. M. R., Oct., 1887.) Turnbull, in his work On the Medical Properties of the Ranunculaceae states that pure delphinine may be given to the extent of three or four grains a day, in doses of half a grain each, without exciting vomiting,
and without producing much intestinal irritation, though it sometimes
purges. In most instances it proves diuretic, and gives rise to sensations
of heat and tingling in various parts of the body. Externally, it acts like
veratrine, but, according to Turnbull, produces more redness and
burning and less tingling than that substance. He has employed it in
neuralgia, rheumatism and paralysis. It may be applied by friction, in
the form of ointment or alcoholic solution, in proportions varying from
ten to thirty grains of the alkaloid to an ounce of the vehicle, and the
friction should be continued till a pungent sensation is produced.
Turnbull probably had an impure alkaloid; the doses just mentioned
would not be safe with a pure delphinine.

Staphisagrine is said to act like delphinine, except that it does not
depress the heart so much or produce fibrillary contractions. Although
cases of human poisoning's have occurred with staphisag'ria, we know
of none in which the result has been fatal. The symptoms are similar to
those produced in the lower animals. Robert states that the alkaloids of
staphisagria all resemble aconitine in their action, but that dei-
phinoidine has some narcotic action.

**Off. Prep.**—Fluidextractum Staphisagriss, U. S.; Unguentum
Staphisagriae, Br.

**Statice.** StaticeLimoniouon (L.) Gray. [Now Limonium carolinianum (Walt.) . Brittt.]
Strandnêeke, G. (Fam. Plumbaginaceae)—It is an indigenous maritime plant with a
perennial, very astringent, root, sending up annually tufts of leaves, which are
obovate or cuneiform, entire, obtuse mucronate, smooth, and on long foot-stalks.

Marsh rosemary grows in the salt marshes along the sea coast from Labrador to
Texas, and flowers from July to September. The root, which was formerly in the
Secondary List of the U. S. Pharmacopoeia, is large, spindle-shaped, or branched,
fleshy, compact, rough, and of a purplish-brown color. It is bitter and extremely
astringent, but odorless. It contains tannic acid (12.4 per cent.), volatile oil, resin, and
other substances. (A. J. P., xiv, 116.) Statice is powerfully astringent, and in some
parts of the United States, particularly in New England, is much employed, especially
as a local application, in decoction, to aphthous and ulcerative affections of the mouth
and fauces.

In Brazil and Buenos Ayres the roots of S. brasiliensis Boiss. are employed under the
name of Buaycura or Guayoura. (P. J., 1878, ix, 466.) For a description of the physical
and chemical characteristics of the root, see P. J., vol. xv, 86. In Russia and Spain the
very large roots of S. latifolia Sm. are used for tanning, and in Morocco the roots of S.
mucronata L. are stated to be employed, under the name of safrifa, as a nervine.
Sticta. Lungmoss. Lungwort.—The lichen Sticta pulmonaceae, a native of Europe, used largely by the natives in the treatment of pulmonary complaints. It owes its activity chiefly to stictic acid, which is bitter and possesses a powerful astringent action.

STILLINGIA. U. S.

STILLINGIA Stilling. [Queen's Root]

"The dried roots of Stillenia sylvatica Linne (Fam. Euphorbiaceae). Preserve Stillenia in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." U. S.

Silver Leaf, Queen's Delight, Yaw Root; Stillingie, Fr., G.

Stillenia sylvatica is an indigenous perennial plant* commonly called Queen's delight, with herbaceous stems, two or three feet high, and alternate, sessile, oblong or lanceolate-oblong, obtuse serrulate leaves, tapering at the base, and accompanied with stipules. The staminate and pistillate flowers are distinct upon the same plant. They are yellow, and arranged in the form of a spike, of which the upper part is occupied by the male, the lower by the female flowers. The staminate florets are scarcely longer than the bracteal scales. The plant grows in pine barrens from Maryland to Florida and west to Kansas and Texas, flowering in May and June. When wounded it emits a milky juice.

Properties.—The root, which is the part used, is large, thick, and woody. It is officially described as " entire, terete, unequally tapering, rarely branched, usually in pieces attaining a length of 40 cm. and from 0.5 to 3 cm. in diameter, externally reddish-brown, longitudinally wrinkled; fracture very fibrous; internally the bark is light reddish-brown, thick, spongy, finely fibrous, with numerous resin cells and easily separable from the porous, radiate wood; odor distinct; taste bitter, acrid and pungent. The powder is pinkish-brown or light reddish-brown; when examined under the microscope it exhibits numerous starch grains from 0.005 to 0.035 mm. in diameter, mostly single, very variable in shape, and usually with a central cleft; numerous fragments, with more or less tabular secretion cells, containing a reddish-brown, amorphous, resinous substance; fragments of tracheae mostly with simple pores and associated with wood-fibers, the walls...
being very thin, lignified and possessing numerous, transverse, slit-like simple pores; bast-fibers long, narrow, the walls thick and slightly lignified; fragments of reddish-brown cork cells; occasionally crystals of calcium oxalate in rosette aggregates about 0.035 mm. in diameter. Stilllingia yields not more than 5 per cent. of ash." U. S.

The odor is slight, peculiar, and somewhat oleaginous, but in the recent root. is said to be strong and acrimonious. The taste is bitterish and pungent, leaving an impression of disagreeable acrimony in the mouth and fauces. Holm gives an excellent illustrated article on the pharmacognosy of stilllingia in Merck's Rep., xx, p. 412. W. Saunders has obtained from the root a volatile oil, which he found to possess the odor, taste, and peculiar acrimony of the root in a high degree. He procured six and a quarter ounces from five pounds of the dried root. It had a thick consistence, and required the addition of alcohol to render it fit for manipulation. Wm. Bichy (A. J. P., 1885, p. 529) found an alkaloid which he named stilllingine. It was obtained as an amorphous powder, volatilizable on heating, forming a sulphate in fine scale-like crystals.

**Uses.**—In large doses Stilllingia is emetic and cathartic, but is rarely used for these purposes. Smaller quantities have been supposed to exercise an alterative effect upon the system and are used in syphilitic and scrofulous conditions. The drug is probably, however, without any real value.

Dose, half a drachm to a drachm (2.0-3.9 Gm.).

**Off. Prep.**—Fluidextractum Stilllingiae, U. S.;

Elixir Corydalis Compositum (from Fluidextract), N. F.; Fluidextractum Stilllingiae Compositum, N. F.; Syrupus Stilllingiae Compositus, N. F.

**Stipa.**—According to Gillespie (B. M. J., Oct., 1898), a number of species of this genus of grasses are actively poisonous, and have caused death in horses and other domestic animals. Of such character especially are Stipa viridula Trin., Stipa inebrrians Hance, and Stipa sibirica Lam., of the Russian steppes. A few experiments made with Stipa viridula Trin., a plant growing in the prairies and meadows from western Minnesota to the Dakotas and southernward, indicated that it acts powerfully upon the brain and spinal cord.

Stipa. Vaseyi Scribner.—According to Vernon Bailey this grass, which grows on the mountains of California, is a very active narcotic, producing in animals, which graze upon it, sleep lasting for a week or longer. (See Farwell, Merck's Rep., 1911, p. 271.)
STRAMONIUM. U. S. (Br.)

STRAMONIUM Stramon. [Jamestown Weed, Jimson Weed]

"The dried leaves of Datura Stramonium Linne, or of Datura Tatula Linne (Fam. Solan-aces), without the presence or admixture of more than 10 per cent. of stems or other foreign matter, and yielding not less than 0.25 per cent. of the total alkaloids of Stramonium." U. S.

"Stramonium Leaves are the dried leaves of Datura Stramonium, Linn." Br.

Stramonii Folia, Br., U. S. 1890—Stramonium Leaves; Herba Stramonii; Thornapple Leaves; Thorn, Devil's or Mad Apple, Apple of Peru, Stink-weed, Jamestown (Jimson) Lily, Devil's Trumpet, Deropty; Stramoine ou Pomme-epineuse, Fr. Cod.; Feuilles de Stramoine, Fr.; Folia, Stramonii, P. G.; Stechapfelblatter, G.; Stramonio, It.; Estramonio (Hojade), Sp.

The thornapple (Datura Stramonium) is an annual plant, of rank and vigorous growth, usually about three feet high, but in a rich soil attains a height of six feet or more. The root is large, whitish, and furnished with numerous rootlets. The stem is erect, round, smooth, somewhat shining, simple below, dichotomous above, with numerous spreading branches. The leaves are petiolate, five or six inches long, of an ovate-triangular form, irregularly sinuated and toothed at the edges, unequal at the base, dark green on the upper surface, and pale beneath. The flowers are large, axillary, solitary, and ped-uncled, having a tubular, pentangular, five-toothed calyx, and a funnel-shaped corolla with a long tube, and a wavy plaited border, terminating in five acuminate teeth. The upper portion of the calyx falls with the deciduous parts of the flower, leaving its base, which becomes reflexed and remains attached to the fruit. This is a large, fleshy, roundish-ovate, four-valved, four-locular capsule, thickly covered with sharp spines, and containing numerous seeds, attached to a longitudinal placenta in the center of each locule. It opens at the summit. There are two varieties of this species of Datura, one with a green stem and white flowers, the other with a dark reddish stem minutely dotted with green, and purplish flowers striped with deep purple on the inside. The latter is now considered as a distinct species, being the D. Tatula of Linnaeus. The properties of both are the same.

It is doubtful to what country this plant originally belonged. Many
European botanists refer it to North America, while we in return trace it to the old continent. Nuttall considers it as having originated in South America or Asia, and it is probable that its native country is to be found in some part of the East. It is said to grow wild, abundantly in Southern Russia, from the borders of the Black Sea eastward to Siberia. Its seeds, being retentive of life, are taken in the earth put on shipboard for ballast from one country to another, not infrequently springing up upon the passage, and thus propagating the plant in all regions which have any commercial connection. In the United States it is found everywhere in the vicinity of cultivation frequenting dung heaps, the road sides and commons, and other places where a rank soil is created by the deposited refuse of towns and villages. Its flowers appear from May to July or August, according to the latitude. Where the plant grows abundantly, its vicinity may be detected by the rank odor which it diffuses to some distance around. Notwithstanding the abundance of the plant, it is being cultivated in order to obtain a drug which shall be of uniform quality. The Bureau of Plant Industry, U. S. Department of Agriculture, has conducted experiments on a large scale. Several hundred pounds of leaf were grown, cured by artificial heat in a tobacco barn, and marketed at a price in advance of the highest quoted figure. Miltacher has reported his observations on the cultivation of stramonium in Zeit. Oest. Apoth., 1, p. 391. Miller has conducted comparative experiments on D. Stramonium and D. Tatula. (A. J. P., Ixxiv, p. 446.)

All parts of it are medicinal. The leaves, seeds, and root were formerly recognized by the U. S. P., the leaves and seed in the U. S. P., 1890, but in the U. S. P. VIII and IX the seeds were not included and the leaves alone are official under the title Stramonium. The leaves may be gathered at any time from the appearance of the flowers till the autumnal frost. In this country the plant is generally known by the name of Jamestown (vulgo, Jimson) weed, derived probably from its having been first observed in the neighborhood of that old settlement in Virginia. In India Datura alba, D. ferox, and D. fatuosa are employed as poisons. The last has been admitted to the Br. (See Daturae Folia.) Under the names of Man t'o lo fa, Wan t'o lo hua, and Nau yeung fa, the Chinese use as a medicine the flowers of the Datura alba; according to Frank Browne, they contain 0.485 per cent. of hyoscine, free from other alkaloids. El Bethene, a Datura of the Sahara Desert, is capable of causing delirium, coma, and death, and it is probable that all the species of the genus are
poisonous. A. R. L. Dohme (Proc. A. Ph. A., 1894, 231) examined
stramonium to determine the value in alkaloid of the various parts of
the plant; he found that, in general, the fresh parts yielded more than
the dried parts; the stems contained the most alkaloid, the seeds next,
then the leaves, and the roots the least of all.

The fresh leaves when bruised emit a fetid narcotic odor, which they lose
upon drying. Their taste is bitter and nauseous. These properties,
together with their medicinal virtues, are imparted to water and alcohol.
Water distilled from them, though possessed of their odor in a slight
degree, is destitute of their active properties. They contain, according to
Promnitz, 0.58 per cent. of gum, 0.6 of extractive, 0.64 of green starch,
0.15 of albumen, 0.12 of resin, 0.23 of saline matters, 5.15 of lignin, and
91.25 of water. The leaves, if carefully dried, retain their bitter taste. They are officially described as "usually much wrinkled and either loose
or more or less matted together; laminas when entire from 2 to 30 cm. in
length, having petioles from 0.5 to 8 cm. in length; inequilaterally ovate,
summits acute or acuminate, bases unequal, one side extending from 3
to 12 mm. below the other, margins sinuate, toothed or angled, the teeth
being few, acute or acuminate and with rounded sinuses; frequently
with numerous circular perforations which may have become filled with
cork; upper surfaces dark green, sparsely hairy, especially upon the
veins, lower surfaces light green; odor distinct, heavy and narcotic; taste
unpleasant, nauseous. Stems cylindrical, usually flattened, attaining a
length of 30 cm. and a diameter of 7 mm.; longitudinally wrinkled,
ocasionally with 1 or more deep furrows, light greenish-brown to
purplish-brown. The powder is brownish-green; upon clearing the
fragments with hydrated chloral T.S. and examining under the
microscope, it shows numerous elliptical stomata, about 0.025 mm. in
length, and surrounded usually with 3 neighboring cells; cells of the
mesophyll containing numerous small chloroplastids; calcium oxalate
either in rosette aggregates, from 0.01 to 0.02 mm. in diameter, or in
rod-like crystals, or in the form of sphenoidal micro-crystals; non-
glandular hairs few, characteristic, 2- to 4-celled, attaining a length of
0.5 mm., the basal cell about 0.04 mm. in width, some of the cells more or
less collapsed, the outer walls with numerous, slight, centrifugal
projections; glandular hairs few, with 1-to 2-celled stalks and usually 2-
to 4-celled, glandular heads; tracheae annular or spiral, fragments of
the tracheal wall frequently detached. Stem fragments show large
annular or spiral tracheae which occasionally are thickened, with simple
or bordered pores and associated with wood parenchyma; fragments
with long, narrow unequally thickened collenchymatous cells; parenchyma with sphenoidal micro-crystals; wood-fibers occasional; bast-fibers absent. Stramonium yields not more than 20 per cent. of ash."

J. S. Ward has found commercial stramonium leaves freely adulterated with those of Cardamus helenioides and Xanthium Strumarium. (P. J., lxvi, 326.) For a paper on the structure of the leaves of D. Stramonium, Atropa Beladonna, and Hyoscyamus niger by Schlotterbeck and van Zwaluwenburg, see Proc. A. Ph. A., 1897, 202. Holm has published an illustrated article on the morphology of stramonium. (M. R., xxii, p. 162.) Rosenthaler has subjected the leaves of stramonium to pyro-analysis and obtained a distinctive and characteristic sublimate. (B. P. G., xxi, p. 530.)

The following are some of the more common synonyms used to designate stramonium seeds: Stramonii Seminar, Stramonium Seed, Semen Stramonii, P. G.; Semences (Graines) de Stramoine, Fr.; Stechapfelsamen, G., which were formerly official. The seeds are small, kidney-shaped, pitted and wrinkled, flattened on the sides, of a dark-brown almost black color, inodorous unless bruised, and of the bitter, nauseous taste of the leaves, with some degree of acrimony. The testa is dull brownish-black, hard, and encloses a cylindrical curved embryo, which is embedded in a whitish oily albumen. They are much more energetic in their action on the system than are the leaves. Hirtz and Hopp inferred from their experiments that one part of an extract prepared from them was equal in strength to five parts of an extract prepared in precisely the same manner from the leaves. (Ann. Ther., 1862, p. 22.)

Geiger and Hesse succeeded in isolating an alkaloid, to which the name daturine was given, and which Trommsdorff has repeatedly procured by their process. Von Planta (A. J. P., 23, p. 38) found that daturine was identical with atropine, and this result has since been confirmed; but Ladenburg (Ber. d. Chem. Ges., 13, p. 909) found that Datura Stramonium contains two alkaloids, which he designated as heavy daturine and light daturine.

The more difficultly soluble heavy daturine fuses at 113.5° to 114° C. (236.3 °-237.2° F.), and must be considered as a mixture of atropine and hyoscyamine. It yields a gold salt fusing between 135° and 150° C. (275°
and 302° F.), out of which, by crystallization repeated six times and by rejection each time of the mother liquor, is obtained hyoscyamine gold-chloride fusing at 158° to 160° C. (316.4°-320° F.). From the mother liquors by evaporation is obtained nearly pure atropine gold chloride fusing at 135° to 140° C. (275°-284° F.). If the heavy daturine be repeatedly crystallized out of dilute alcohol, pure atropine can be isolated from it, fusing at 113.5° to 114.5° C. (236.3°-238.1° F.), and yielding a lusterless gold salt fusing at 135° to 139° C. (275°-282.2° F.). The light daturine is the alkaloid which Ladenburg and Meyer in a previous study had shown to be identical with hyoscyamine. Hence Datura Stramonium contains the two alkaloids atropine, C_{17}H_{23}O_{3}N, and hyoscyamine, isomeric with the other, which Atropa Belladonna also contains. (A. J. P., 1884, 440.) The mother liquors from which hyoscyamine is obtained yield a difficultly crystallizable base, first called hyoscine, but now known as scopolamine. Its gold salt is more difficultly soluble than the gold salts of atropine and hyoseyamine, and affords a means of separation. The base, when purified, can be crystallized out of ether in colorless crystals, melting at 59° C. (138.20 F.). Its formula is C_{17}H_{21}O_{4}N, and it is decomposed by boiling with baryta water into scopolin, C_{8}H_{13}NO_{2}, and atropic acid, C_{9}H_{8}O_{2}. (Schmidt, Pharm. Chemie, 3te Auf., ii, 1339.)

Gerard (see J. P. C., 1892, 8) studied daturic acid obtained from stramonium seed. D. Holde has, by means of benzene, extracted from stramonium seed 16.7 per cent. of a fixed oil. (P. J., lxx, p. 90.) This has been examined by J. M. Baird and F. E. Sleeper, see Proc. A. Ph. A., 1903, 324.

Uses.—Stramonium is so similar to belladonna in the symptoms produced by it in small or large doses, in its toxicity and its general physiological and therapeutic action, that the two drugs are practically identical. Furthermore, they are about the same strength in activity, so the preparations may be used in similar doses. Stramonium has been employed in all the conditions for which belladonna is more commonly used, but has acquired special repute in the treatment of asthma, this probably being due to the fact that the practice of smoking Datura ferox in that disease was introduced into Great Britain from the East Indies by General Gent, and that afterwards the English species was substituted for that employed in Hindostan. Formerly the roots were chiefly used, but at present the dried leaves are exclusively employed.
The beneficial effect is doubtless due to the presence of atropine which paralyzes the endings of the pulmonary branch of the vagus, thus relieving the bronchial spasm, for Gunther (W. K. W., 1911, p. 748) has shown that the smoke from a stramonium cigarette containing 1.25 Gm. of stramonium leaves contains as much as 0.5 Mgm. of atropine. The leaves may be made up into cigarettes or smoked in a pipe, either with or without a mixture of tobacco; more commonly, however, the coarsely ground leaves are mixed with equal parts of potassium nitrate, in order to increase combustion, and burned in a saucer.

Death is said to have been produced by the free use of the India Datura ferox, but it seems hardly possible that the species which is found in North America would produce such a result.

The seeds are more powerful than the leaves. The seeds were once officially recognized, but the presence of a large amount of fixed oil made it difficult to extract them or to make stable preparations from them and the leaves have taken their place. They may be given in the dose of one-half to one grain (0.032-0.065 Gm.) twice a day; an extract made by evaporating the decoction, in one-quarter or one-half the quantity. The inspissated juice of the fresh leaves was formerly very commonly prescribed; but the alcoholic extract is now almost exclusively used, the dose being half a grain (0.032 Gm.). (See Extractum Stramonii.)

Dose, of the leaves, one to three grains (0.065-0.2 Gm.).

**Strychnos Potatorium** L. Chilbinj. Cleaning Nuts. Indian Gum Nuts. (Fam. Loganiaceae)—The nuts of this species of Strychnos are very largely used in some parts of India for clearing muddy water, and are stated to have found their way into American commerce. (A. J. P., 1871.) The fruit is also employed by the native practitioners of Hindostan, under the name of nirmali, as an emetic and in dysentery. They do not contain strychnine. In clearing water, one of the dried nuts is rubbed hard for a short time around the inside of the earthen water pot; on settling, the water is left pure and tasteless. The seeds contain a large quantity of an albuminous principle, upon which their virtues probably depend. The tree, which grows to a very large size, produces a shining, black, one-seeded berry (that of the nux vomica being many-seeded). The seeds are described (P. J., 1871, 44) as broadly lenticular, about half an inch in diameter and a quarter of an inch in thickness, of a dirty whitish-gray color,
and covered with a thick coating of delicate appressed hairs. These are so small that
the seed to the naked eye looks mealy. Under the microscope the hairs are seen to be
agglutinated in groups of from three to six, and to consist each of a single pointed
cylindrical cell.

**Stylophorum.** *Stylophorum diphyllum* (Michx.) Nuttall. (Fam. Papaveraceae)—This
plant, commonly known as "Celandine Poppy," is found in damp woods from western
Pennsylvania to Wisconsin and Tennessee. In its foliage and flowers it resembles
*Chelidonium majus*. According to E. Schmidt, the root contains chelidonine, with a
second alkaloid closely related to, if not identical with, chelerythrine. (A. J. P., 1888.)

**Stylosanthes.** *Stylosanthes biflora* (L.) B. S. P. (Fam. Leguminosae)—This low,
branching perennial has wiry stems, 3-foliate leaves and small yellow flowers. It is
found in the pine barrens of the Eastern and Central United States and it is asserted
that it possesses the power of relieving abdominal uterine pains during the latter
months of gestation, and is also a uterine tonic during parturition. Dose, of the
fluidextract, from ten to twenty minims (0.6-1.3 mils) three times a day.

**STYRAX. U. S. (Br.)**

**STORAX [Liquid Storax]**

"A balsam obtained from the wood and inner bark of *Liquidambar orientalis* Miller (Fam. Hamamelidaceae)." U. S. "Prepared Storax is a
viscid balsam obtained from the wounded trunk of *Liquidambar orientalis*, Mill., purified by solution in alcohol, filtration, and
evaporation of the solvent." Br.

**Styrax Praeparatus,** Br.; Prepared Storax; Styrax Liquidus, Balsamum Storacis,
Balsamum Styracis, Balsamum Styrax Liquidua; Styrax liquide, Fr. Cod.; Styrax, P.
G.; Storax, Flussiger Storas, G.; Storage liquido, It.; Estoraque liquido, Sp.

All species of the genus *Liquidambar* as well as those of a related genus,
*Altingia*, yield storax. The product most valued, however, is that
obtained from *L. orientalis* Miller.

The oriental sweet-gum (*Liquidambar orientalis*) is a tree from twenty
to forty feet high. The palmate leaves have each of their divisions
obscurely three-lobed, and are serrate, perfectly smooth, bright green
and shining on the upper and pale on the under surface. The tree is a
native of Asia Minor, in the southwestern parts of which it forms large
forests. It yields the so-called liquid storax.
According to the researches of Moeller, storax is a pathological rather than a physiological product; when the young wood is injured secretion reservoirs are formed in which the storax is produced. (O. Z., 1.) In collecting the drug the outer bark is first heavily bruised, so as to injure the inner bark, and after a time the outer bark having been removed the inner bark is scraped off. According to Maltass, this inner bark is first pressed cold in horse-hair bag's, after which hot water is thrown over the bags and they are again pressed. Lieutenant Camp-bell states that the inner bark is first boiled with water, and, a portion of the balsam which rises having been skimmed off, is then pressed so as to extract the remainder. The residuary bark, after expression, is dried in the sun, and employed in various parts of Turkey for fumigation. It is the drug known in commerce as Storax bark or Cortex Thymbamatis. (Han-bury, P. J., 1857, xvi, 463.) The balsam is sent in casks to Constantinople, Smyrna, and other ports of the Levant.

Several kinds of storax have been described. The purest was the storax in grains, which was in whitish, yellowish-white, or reddish-yellow tears, about the size of a pea, opaque, soft, adhesive, and capable of uniting so as to form a mass. Another variety, formerly called styrax calamita, from the circumstance, it is supposed, that it was brought wrapped in the leaves of a kind of reed, consisted of dry and brittle masses, formed of yellowish agglutinated tears, in the interstices of which was a brown or reddish matter. The French call it storax amygdaloide. This and the preceding variety had a pleasant odor like that of vanilla. Neither of them, however, is now found in the markets. It is probable that one or both of these varieties may have been the product of Styrax officinale. A third variety, which was formerly seen in commerce, styrax calamita, was in brown or reddish-brown masses of various shapes, light, friable, yet possessing a certain degree of tenacity, and softening under the teeth. Upon exposure, it becomes covered upon the surface with a white efflorescence of styracin. It evidently consisted of sawdust, united with a portion of the balsam. As found in commerce, it was usually in the state of a coarse, soft, dark-colored powder, mingled with occasional light friable lumps of various sizes, and containing very little of the balsam. When good, it should yield, upon pressure between hot plates, a brown resinous fluid having the odor of storax. Hanbury states that some of this variety is prepared at Trieste, Venice, and Marseilles, by mixing the residue of the liquidambar bark remaining after expression, and reduced to coarse powder, with genuine liquid storax. (P. J., April, 1863.)
American Storax, Liquidambar styraciflua, or Sweet Gum of our Southern States.—Its geographical range reaches into Mexico, and it yields a storax-like product in an abundance proportionate to the heat of the climate. A specimen from Guatemala is described by Fliickiger and Hanbury as a yellow, opaque resin, of honey-like consistence, becoming transparent, amber-colored, and brittle by exposure to the air, and having a rather terebinthinous balsamic odor and but little taste. Sometimes it occurs as a thick golden-brown fluid. It contains cinnamic acid and stryacin. (A. J. P., 1874, p. 161.) It is soluble in alcohol, and has been gathered to a considerable extent in the United States for the preparation of chewing gum. The resins of Liquidambar formosana and L. altigiana are known in Eastern commerce. Malay storax is an aromatic resinous product obtained from the Altingia excelsa Noronha (L. altigiana Bl.) It is sometimes called rasamala resin and contains tannic acid besides a very minute amount of cinnamic and benzoic acids.

A fourth variety, which, under the name of liquid storax, is the one commonly used, is a semi-fluid, adhesive substance, brown or almost black upon the surface exposed to the air, but of a slightly greenish-gray color within, and of an odor somewhat like that of balsam of Peru, though less agreeable. It is kept in jars.

Properties.—The storax used by pharmacists should correspond to the following official description and tests: "Storax is a semi-liquid, grayish, sticky, opaque mass, depositing" on standing a heavy, dark brown stratum; transparent in thin layers, and having a characteristic odor and an acrid taste. It is heavier than water. It is insoluble in water, but completely soluble (with the exception of accidental impurities) in an equal weight of warm alcohol; almost completely soluble in ether, acetone, benzene, or carbon disulphide. When heated on a water-bath, Storax becomes more fluid, and if it is then agitated with warm, purified petroleum benzin, the supernatant liquid, on being decanted and allowed to cool, is not darker than pale yellow and deposits white crystals of cinnamic acid and cinnamic esters. The separated crystals evolve the odor of benzaldehyde when heated with diluted sulphuric acid and potassium permanganate. Incinerate about 0.5 Gm. of Storax; not more than 1 per cent. of ash remains. Dissolve about 10 Gm. of Storax, accurately weighed, in 20 mils of hot alcohol; the undissolved residue, after washing it on a filter with hot alcohol and drying at 100° C. (212° F.), does not exceed 2.5 per cent. The combined filtrate and
washings, after the evaporation of the alcohol at a temperature not exceeding 60° C. (140° F.) and drying the residue for one hour at 100° C. (212° F.), leave a brown, transparent, semi-liquid product representing not less than 60 per cent. of the weight of Storax taken; this product is soluble in ether, with the exception of a few flakes, but only partially soluble in purified petroleum benzin. Dissolve about 1 Gm. of Storax, purified as described above, and accurately weighed, in 50 mils of alcohol, add 0.5 mil of phenolphthalein T.S., and titrate with half-normal alcoholic potassium hydroxide V.S. The acid value so obtained is not less than 56 nor more than 85 (see Part III, Test No. 10). Mix about 1 Gm. of Storax, purified as described, and accurately weighed, in a 250 mil flask with 50 mils of purified petroleum benzin, add 25 mils of half-normal alcoholic potassium hydroxide V.S. and allow the mixture to stand twenty-four hours, with frequent shaking. Then add 0.5 mil of phenolphthalein T.S. and titrate with half-normal hydrochloric acid V.S. It shows a saponification value of not less than 170 nor more than 230 (see Part III, Test No. 9)." U. S.

As found in commerce, storax is usually so much adulterated as to require purification before it can be used, and in both Pharmacopoeias processes were formerly given. Whenever not originally pure enough for use, it should be dissolved in alcohol, the solution strained, and the alcohol distilled off to a certain extent, and then completely evaporated at a gentle heat. Among the substances used in the adulteration of storax is turpentine. To detect it Hager employed the following method. He liquefied the resin, in a tube, by means of a water bath, added half its volume of absolute alcohol, and hastened the solution by agitation; he then treated it with several volumes of benzin. This operation was repeated twice. The liquors obtained were then evaporated, in a tared vessel, and there was secured, for pure storax, a colorless residue (45 to 55 per cent.), with a light-blue opalescence; for that mixed with turpentine, a residue more considerable, yellowish, and having the terebinthinate odor. (J. P. C., Fev., 1876, p. 161.) The quality of storax at present on the market appears to be very much inferior to what it was a few years ago. It is stated (P. J., 1911, Ixxxvii, p. 86) that whereas in 1907 the commercial storax averaged about 19 per cent. of cinnamic acid with an acid number of 68.9, that upon the market in 1911 contained only about 2.5 per cent. of cinnamic acid, and had an acid number around 100. It is not improbable that this deterioration is due to the extraction of cinnamic acid before it is marketed.
Storax melts with a moderate heat, and, when the temperature is raised, takes fire and burns with a white flame, leaving a light, spongy, carbonaceous residue. It imparts its odor to water, which it renders yellow and milky. Its active constituents are dissolved by alcohol and ether. Neumann obtained from 480 grains of storax 120 of aqueous extract, and from an equal quantity 360 grains of alcoholic extract. Containing volatile oil and resin, and yielding ben-oic or cinnamic acid by distillation, it is entitled to rank as a balsam.

The most abundant constituent of storax is probably storesin, $C_{36}H_{55}(OH)_3$, discovered in 1877 by W. von Miller. This is present in two forms, designated respectively alpha and beta, both free and in the form of a cinnamic ester. Storesin is an amorphous substance, melting at 168° C. (334.4° F.), readily soluble in petroleum benzine. Cinnamic esters of phenylpropyl, cinnamic ester of ethyl, cinnamic ester of benzyl, and especially cinnamate of cinnamyl, $C_9H_7O_2.C_9H_9$, the so-called styracin of Bonastre, have also been observed. This last compound can be removed by ether, benzene, or alcohol after the separation from the resin of the cinnamic acid; it is insoluble in water, and volatile only in superheated steam. It crystallizes in tufts of long rectangular prisms, which melt at 38° C. (100.4° F.), but frequently do not solidify readily. By concentrated solution of potassium hydroxide, it is resolved into a cinnamate and cinnamic alcohol (styrone), $C_9H_{10}O$, which latter is not present in liquid storax. The yield of cinnamic acid varies from 6 to 12 per cent., or even, according to Lowe, as much as 23 per cent. of crystallized cinnamic acid can be obtained. The acid dissolves abundantly in ether, alcohol, or hot water, slightly in cold watery it is inodorous, but has an acrid taste. It fuses at 133° C. (271.4° F.), and boils at 290° C. (554° F.). Another minor constituent of storax is a fragrant substance melting at 65° C. (149° F.), and possessing the odor of vanillin, which Rump (Ber. d. Chem. Ges., 1878, 1034) identified. Miller also shows that water removes from the drug a little free benzoic acid. There is further found in liquid storax a hydrocarbon, $C_8H_8$, first prepared by Simon in 1839, which exists in the resin as a liquid, and also in a polymeric form as a solid. The former, called styrol, styrene, or cinnamene styrene, has a sp. gr. of 0.924, and a boiling point of 146° C. (294.8° F.). It is a colorless, mobile liquid, possessing the odor and burning taste of liquid storax. It has since been formed synthetically, and has been recognized as phenylethylene, $C_6H_5.CH=CH_2$. When
heated for a considerable time to 100° C. (212° F.), or for a shorter period to 200° C. (392° F.), it is converted without change of composition into the colorless, transparent solid metastyrol, which, unlike styrol, is not soluble in alcohol or in ether. Lastly, there has been found in liquid storax, by J. H. van t’Hoff (1876), about 0.4 per cent. of a pleasant-smelling laevo-rotatory oil of the formula C_{10}H_{16}O. (Pharmacographia, 2d ed., 274 and 275.) Tschirch and L. v. Itallie (A. Pharm., Sept., 1901, 506) state that styrax contains free cinnamic acid, vanillin, styrol, styracin, cinnamic acid-ethyl ester, cinnamic acid-phenyl-propyi ester and storesinol partly free and partly as cinnamic acid ester.

**Uses.**—Styrax is a stimulating expectorant and feeble antiseptic, which was at one time used in various pulmonic catarrhs, also in gonorrhea and leucorrhea, but at present is very seldom used except as a constituent of the compound tincture of benzoin. Externally, mixed with two or three parts of olive oil, liquid storax was found by H. Schultze, of Magdeburg, to be very effective as a local remedy in scabies.

Dose, ten to twenty grains (0.65-1.3 Gm.).

**SUCCI JUICES**

Sues vegetaux, Fr.; Pflanzensaft, G.

Though introduced to professional notice by Squire in the year 1835, and subsequently used by many practitioners, the juices were recognized but once by the U. S. Pharmacopoeia (1870). They consist of the expressed juices of fresh plants, preserved by the addition of one-third of their bulk of alcohol. Considering the great inequality in strength, and, of course, the uncertainty in operation, of fresh juices themselves, varying according to the soil, climate, mode of cultivation, season, and the age of the plant, it may be questioned whether they merit the prominence which has been given them in the past.
SUCCUS LIMONIS. Br.

LEMON JUICE

"Lemon Juice is the freshly expressed juice of the ripe fruit of Citrus Medica, Linn., var. β Limonum, Hook. f." Br.

Limonis Succus, U. S. P. VIII; Succus Citri; Sue de Citron (de Limon), Fr. Cod.; Citronensaft, Limonensaft, G.; Succo di limone, It.; Zumo de limon, Sp.

We are supplied with lemons and limes chiefly from the West Indies, the Mediterranean and California. Though the former of these fruits only is directed by the Br., lime juice is recognized by the N. F., and both kinds are employed indiscriminately for most medicinal purposes, and the lime affords a juice at least equal, in proportional quantity and acidity, to that obtained from the lemon.

The seed of the lime contains 58 per cent. of fixed oil, which is said to equal in flavor the best olive oil. Its tendency to resist rancidity is reputed to be very great. ((, 1894, 411.) Lime juice is official in the N. F. IV under the title of Succus Citri.

As lemons rapidly deteriorate on keeping, if exposed to the air, the suggestions of protecting them by dipping them in melted paraffin, or by using a varnish of shellac dissolved in alcohol, made by George Mee, of London, are not without value. Mee found that lemons thus covered with varnish continued sound for a period of many months. (See A. J. P., 1866, p. 474.)

The juice is the part for which the fruit is most esteemed. Jt is sharply acid, with a peculiar grateful flavor, and consists chiefly of water, citric acid (from 6 to 10 per cent.), gum and sugar (from 3 to 4 per cent.), and inorganic salts (2.28 per cent.). It sometimes has in it a little volatile oil, derived by pressure from the rind. It is "a slightly turbid, yellowish liquid. Taste sharply acid. Specific gravity 1.030 to 1.040. 20 millilitres require for neutralisation not less than 20 and not more than 25.7 millilitres of N/1 solution of sodium hydroxide, corresponding to a proportion of not less than 7 and not more than 9 grammes of citric acid in 100 millilitres. The residue obtained on evaporation, dried at 110° C. (230° F.), yields not more than 3 per cent. of ash. 100 millilitres of Lemon Juice are neutralised by about 11.4 grammes of Potassium
Bicarbonate, by about 9.5 grammes of Sodium Bicarbonate, and by about 16.5 grammes of Sodium Carbonate."

The U. S. P. IX does not recognize lemon juice, the U. S. P. VIII provided the following tests: "It reddens blue litmus paper and should contain from 7 to 9 per cent. of citric acid. If a few drops of barium chloride T.S. be added to filtered Lemon Juice, no turbidity or white precipitate should be produced (absence of sulphuric acid or sulphates). If an equal volume of sulphuric acid containing a few drops of alcohol be added to Lemon Juice, and the liquid heated, no odor of acetic ether should be developed (absence of acetic acid). Upon the addition of solution of potassium acetate (1 in 3) and alcohol in excess, no white crystalline precipitate should form after allowing the liquid to stand fifteen minutes (absence of tartaric acid). At least 10 mils of normal potassium hydroxide V.S. should be required to neutralize 10 mils of Lemon Juice, phenolphthalein T.S. being used as indicator." U. S. VIII.

As lemons cannot always be obtained, the juice is often kept in a separate state, but, from its liability to spontaneous decomposition, it speedily becomes unfit for medicinal use, and, though various means have been resorted to for its preservation, it can never be made to retain for any length of time its original flavor unaltered. One of the most effectual methods of preserving the juice is to allow it to stand for a short time after expression, until a coagulable matter separates, then to filter, and introduce it into glass bottles, with a stratum of almond oil or other sweet oil upon its surface. It will keep still better if the bottles containing the filtered juice be permitted, before being closed, to stand for fifteen minutes in a vessel of boiling water. Another mode is to add one-tenth of alcohol and to filter. The juice may also be preserved by concentrating it either by evaporation with a gentle heat, or by exposure to a freezing temperature, which congeals the aqueous portion and leaves the juice much stronger than before. When used, it may be diluted to the former strength, but though the acid properties are retained, bottled lemon juice is frequently found to be preserved with sulphur dioxide, which dissolves in it to form sulphurous acid. The presence of this preservative interferes with some of its pharmaceutical uses and such a product should not be employed for medicinal purposes. The flavor of the juice is found to have been deteriorated. Lemon syrup is another form in which the juice is preserved.

The proportion of citric acid in lemon juice varies greatly, ranging from
4.5 to nearly 9 per cent. Stoddart found the acidity to diminish rapidly with the advance of summer, with little change in the sp. gr. of the juice. (P. J., Oct., 1868.) H. H. Robins, after examining large consignments of lemons, states that the average yield of citric acid taken from a year's receipts was 35.23 grains in a fluidounce. (C. D., 1896, 742.) A solution of tartaric acid in water, with the addition of a little sulphuric acid, and flavored with the oil of lemon, has been fraudulently substituted for lemon juice, particularly as an antiscorbutic on long voyages, for which purpose it is quite useless. An application of the test for tartaric and sulphuric acids will at once detect the fraud.

The proportion of citric acid in lime juice is required by the N. F. IV to be not less than 5 Gm. nor more than 10 Qm. to each 100 mils. It is required to be free from sulphuric acid, but is permitted to contain 0.04 Gm. of 802 in each 100 mils. Other preservatives are prohibited as are also artificial colors.

**Uses.**—Lemon juice is refrigerant, and, properly diluted, forms a refreshing and agreeable beverage in febrile and inflammatory affections. It may be given with sweetened water in the shape of lemonade, or may be added to the mildly nutritive drinks, such as albumen water, barley water, etc., usually administered in fevers. It is also much employed in the formation of those diaphoretic preparations known by the names of neutral mixture and effervescing draught. One of the most beneficial applications of lemon juice is to the prevention and cure of scurvy, for which it may be considered almost a specific. For this purpose, ships destined for long voyages should always be provided with a supply of the preserved juice. In England every foreign-going ship is required by law to take such a supply of lemon or lime juice that every seaman shall have a daily allowance of an ounce after having been ten days at sea. Its antiscorbutic effects have been found to be due to the presence of one of a class of chemical activators called vitamines. It has been employed with advantage in acute rheumatism in doses of from one to four fluidounces (30-120 mils) from four to six times a day. Locally applied it acts as an astringent and has been used with benefit in pruritus of the scrotum, in uterine hemorrhage after delivery, in sunburn, and as a gargle in diphtheritic sore throat.

**Off. Prep..**—Syrupus Limonis, Br.; Trochiscus Acidi Carbolici, Br.
SUCCUS SCOPARII. Br.

J UICE OF BROOM

Sue de Genet a Balais, Fr.; Besenginstersaft, G.

"Bruise fresh Broom Tops; press out the juice; to every three volumes of juice add one volume of Alcohol (90 per cent.); set aside for seven days; filter." Br.

In large doses this juice is prone to disturb the stomach and bowels. It is more appropriately used as an adjuvant to other diuretics than alone.

Dose, as a diuretic, one to two fluidrachms (3.75-7.5 mils).

SUCCUS TARAXACI. Br.

J UICE OF TARAXACUM

Sue de Piasenlit, Fr.; Lowenzahnwurzelsaft, Lowenzahnsaft, G.

"Bruise Taraxacum Root; press out the juice; to every three volumes of juice add one volume of Alcohol (90 per cent.); set aside for seven days; filter." Br.

Dose, two fluidrachms to half a fluidounce (7.5-15.0 mils).

S UMBUL. U. S.

SUMBUL [Musk-root]

"The rhizome and roots of Ferula Sumbul (Kauffmann) Hooker filius (Fam. Umbelliferae)." U. S.

Sumbul Radix, Br.; Racine de Sumbul, Fr.; Sumbulwurzel, Moschuswurzel, G.

Under the name of sumbul or jatamansi, a root has long been used in India, Persia, and other parts of the East, as a perfume, an incense in religious ceremonies, and medicinally. It was the root of a then unknown plant, supposed to be umbelliferous, and, from the character of the root, to grow in low wet places. The plant is said to inhabit no part of British India, but the regions to the north and east of it, as Nepaul,
Bootan, Pucharia, etc. The root is taken northward to Russia, and reaches the rest of Europe through Petrograd. The physicians of Moscow and Petrograd were the first to employ it on the continent of Europe. Granville first introduced it to the notice of the profession in Great Britain and in this country. It has also been imported into England from India, whither it was brought from a great distance. The plant which is now recognized by the U. S. P. as the source of the sumbul is the Ferula Sumbul Hooker fil.

Ferula Sumbul was first discovered by the Russian Fedchenko in 1869, growing at an elevation of 3000 feet in the mountains which separate Russian Turkestan from Bucharia. In 1871 it was described by Kauffmann, who erected a new genus on characters dependent upon the enormous size of the vittse in the immature fruit. The plant has been cultivated in the Moscow botanical gardens, and, less successfully, at Kew, and it has been found that the vittas almost disappear in ripening, and do not afford a good generic character. The plant is a large umbellifer, reaching a height of eight feet, and having a solid, cylindrical, slender stem, which in the upper part gives origin to about twelve slender divericate branches. The root-leaves are two and a half feet long, with short, channelled, broadly dilated, completely clasping petioles. They are triangular in outline, tripin-nate, with the alternate divisions fine. The stem-leaves rapidly decrease in size until they become mere sheathing bracts. The flowers are polygamous, the fruit from three-eighths to one-half inch long by one-fourth inch wide; the mericarps oblong-oval, dorsally much compressed, thin, with three faint, thread-like, dorsal ridges; no dorsal vittse, and commissural ones collapsed. J. E. Aitchison states (Tr. Linn. Soc., ser. 2, Bot., 69) that the root of Ferula suaveolens, which has only a faint musky odor, is one of the kinds exported from Persia to Bombay by the Persian Gulf.

Properties.—Sumbul is officially described as "in transverse segments, attaining a length of 10 cm. and a diameter of 7 cm.; externally light brown to dark brown, longitudinally wrinkled and showing in the upper portions a smooth, grayish, epidermal layer, occasionally with the short stem-bases attached; fracture short, fibrous, spongy; internally light yellow or brownish-yellow, arrangement of wood irregular and with yellowish-brown or blackish resinous patches frequently extending over the entire ends of the segments; odor peculiar, musk-like; taste bitter and somewhat aromatic. The powder is grayish-brown; when examined under the microscope it exhibits numerous, irregular, brownish-black
fragments and well-defined isolated tracheae, the latter with distinct end-walls, and, mostly with reticulate thickenings and from 0.03 to 0.1 mm. in width; occasional fragments of polygonal epidermal cells with yellowish-brown walls; numerous, nearly colorless, yellowish-brown and reddish-brown fragments consisting of a granular substance in which the cellular structure is not well defined; long, narrow fragments consisting of more or less collapsed leptome or sieve tissue; occasional fragments of well-defined parenchyma with a few, nearly spherical starch grains, from 0.003 to 0.012 mm. in diameter."

The root has been analyzed by Reinsch and other German chemists, and found to contain volatile oil, two balsamic resins, one soluble in alcohol, the other in ether; wax, gum, starch, a bitter substance soluble in water and alcohol, and an acid which was named sambolic acid, but which Riecker and Reinsch showed to be angelic acid, C\(_5\)H\(_8\)O\(_2\), accompanied by a little valeric acid, C\(_5\)H\(_{10}\)O\(_2\). Solution of potassium hydroxide is said to convert the resin into the potassium salt of an acid called szim-bulamic, but which has not been sufficiently investigated. The musk-like odor seems to be connected with the balsamic resins, and probably depends on some principle associated with them not yet isolated. The volatile oil, of which 0.33 per cent. is yielded by distillation, has a taste like that of peppermint. On dry distillation it yields a bluish oil which contains umbelliferone. Philip H. Utech (A. J. P., 1893, p. 465) has extracted and purified the resin soluble in alcohol. He obtained it as a soft, whitish, translucent resin which, on drying at 110° C. (230° F.), yielded a clear, transparent, amber-colored product having a bitter taste and the aromatic odor of the root. It constituted 6.1 per cent. of the drug. J. H. Hahn (Proc. Penna. Ph. Assoc., 1896, 75) found 17.25 per cent. of fixed oil in sumbul.

A proximate analysis reported by Hcyi and Hart (A. J. P., Dec., 1916, p. 546, shows the following results: Moisture, 10.17 per cent.; starch, 7.70 per cent.; pentrosans, 10.60 per cent.; crude fiber, 17.15 per cent.; protein, 5.50 per cent.; dextrin, 1.40 per cent.; ash, 6.50 per cent.; sucrose, 1.64 per cent.; reducing sugar, 0.51 per cent., volatile oil, 1.10 per cent.; resins, 17.1 per cent. Alkaloids were not detected. The volatile oil did not show the presence of sulphur. Umbelliferone was detected, as was also betaine. Vanillic acid (C\(_8\)H\(_8\)O\(_4\)) was identified in the resinous portion and a phytosterol was also recognized as being present. Acetic, butyric, angelic and tiglic acids were among the volatile acids, while
among the non-volatile acids were oleic, linoleic, tiglic, cerotic, palmitic and stearic.

Uses.—Sumbul is supposed to have a quieting influence on the nervous system and is used in the treatment of various hysterical conditions. By many it is believed to have an especial relation to the pelvic organs and it is widely employed in dysmenorrhea and allied disorders. It has also been used as a stimulant to mucous membranes not only in chronic dysenteries and diarrheas, but in chronic bronchitis, especially with asthmatic tendency, and even in pneumonia.

Murawieff, of Russia, prepares the resin, which he considers to be the active principle, by macerating the root first in water, and then in a solution of sodium carbonate, washing it well, with cold water, drying it, treating it with alcohol, filtering the tincture, adding a little lime and again filtering, separating the lime by sulphuric acid, agitation with animal charcoal, again filtering, distilling off nearly all the alcohol, mixing the residuum with water, driving off the remaining alcohol, and, finally, washing the precipitate with water, driving off cold water, and drying it.

Half an ounce of a tincture produced narcotic symptoms, such as confusion of the head, a tendency to snore, even when awake, feelings of tingling, etc., with a strong odor of the medicine from the breath and skin, which continued for a day or two and gradually passed off. (N. R; Oct., 1874, p. 309.)

Dose, one-half drachm to two drachms (2.0-7.7 Gm.).

Sweet Pellitory.—The root of Tanacetum umbelliferum Boiss. (Fam. Compositae), of India, according to David Hooper, contains pyrethrine in minute proportions with fat and wax, an organic acid which is a pigment, glucose, and inulin. (P. J., xxi, 1890.)

Swietenia. Swietenia febrifuga Roxb. (Soymida febrifuga J. ugs.) Rohan Bark. (Fam. Meliaceae)—The bark of this East Indian tree contains a bitter principle and is said to be much used as an antiperiodic in half drachm (2 Gm.) doses. The extract is used in dysentery like kino.

Swietenia Mahogoni Jacq., or mahogany tree, which grows in the West Indies and other parts of tropical America, has also a bitter, astringent bark, containing catechin. (Bull. Soc. Chim. Paris, xxiv, 118.) The oil of the seeds is said to be used as a
purgative in the West Indies. The bark of *S. senegalensis* Desv. (Khayasenegalensis A. Juss.), Juribali bark, is used on the coast of Africa in the cure of intermittents, and Cavehtou extracted an alkaloid from it. (Am. J. M. S., N. S., xx, 168.)

**Symphytum.** Symphytum officinale L. Comfrey. Blackwort. Briussewort. Radix Symphiti. Radix Consolidae Majoris. Consoude, Fr. Schwarzwurz, Beinwurz, G.—A perennial, European plant often cultivated. Its root is spindle-shaped, branched, often more than 2.5 cm. thick and 3 dm. long, externally smooth and blackish, internally white, fleshy, and juicy. By drying it becomes wrinkled, of a firm, horny consistency, and of a dark color within. It is almost inodorous, and has a mucilaginous, feebly astringent taste. Titherley and Coppin in 1912 found 0.8 per cent. of allantoin, C₄H₆N₄O₃, in the rhizome. It contains mucilage in great abundance (according to Lewis, more than althsea, root), and a little tannin. It was formerly highly esteemed as a vulnerary. According to Maenalister (B. M. J., Jan. 6, 1912), allantoin, in aqueous solution in strengths of 0.3 per cent. has a powerful action in hastening epithelial formation, and is a valuable remedy not only in external ulceration, but also in ulcers of the stomach and duodenum. Comfrey is a demulcent, and is used domestically in chronic catarrhs, consumption, and other lung diseases.

**Symphocos.** Symphocos racemosa Roxb. (Fam. Styraceae.)—The bark of this East Indian tree is said to be a mild astringent, and especially useful in menorrhagia. (P. J., Sept. 24, 1881.)

**Syringa.** Syringa vulgaris L. Common Lilac. (Fam. Oleaceae)—The leaves and fruit of this common garden plant have a bitter and somewhat acrid taste, and have been used as tonics and antiperiodics. Petroz and Robinet found in the fruit a sweet and a bitter principle. The latter was afterwards obtained pure by Meillet, who gave it the name of lilacin, and by Bernays, who called it syringin. It has been investigated by Kromayer (A. Pharm. (2), cxxiii, 19), who established its glucosidal character, gave it the formula C₁₇H₂₄O₉ + H₂O, and showed it identity with the ligustrin of Polex. It forms long, white, stellate needles, which are tasteless, easily soluble in hot water and alcohol, insoluble in ether. The crystals become anhydrous at 115° C. (239° F.), and fuse at 212° C. (413.6° F.). As an antipyretic and anti-periodic drug it is said to be very valuable, especially when administered in the relapsing fever of malaria. On heating with dilute acids its breaks up into syringenin, C₁₁H₁₄O₄, and a fermentable glucose. The syringenin (which has been recognized as oxy methyl coniferin) is a light, rose-red amorphous mass, soluble in alcohol, insoluble in water and ether.

**SYRUPS.**

**Syrups**

Syrups are concentrated solutions of sugar in aqueous fluids, either
with or without medicinal impregnation. When the solution is made with pure water, it is named syrup or simple syrup; when made with water charged with one or more medicinal agents, it is called in general terms a medicated syrup, and receives its special designation from the substance or substances added.

Medicated syrups are prepared by dissolving sugar in infusions, vinegars, decoctions, expressed juices, fermented liquors, or simple aqueous solutions, or by adding a medicating substance, like a tincture or a fluidextract, to simple syrup. When the active matter of the vegetable is not readily soluble in water, is associated with soluble matter which it is desirable to avoid, or is volatilized or decomposed by a heat of 100° C. (212° F.), it is sometimes extracted by diluted alcohol, the spirituous ingredient of which is subsequently driven off.

The process of percolation has been applied for the solution of the sugar and is offered as an alternative process in a number of official preparations. This process offers several advantages over the older methods. The amount of labor attending the operation is greatly reduced, no heat is employed so that volatile constituents are not injured, and the finished syrup is filtered and protected from the usual contaminations attending straining, etc.

The quality and quantity of the sugar employed are points of importance. Official granulated sugar should be employed and although the commercial grades are usually of good quality it is possible to secure a sugar of better grade, known as "druggists' dry granular" or "crystal A," which is obtained from the first runnings from the bone-black filters. In this sugar the crystals are large and the syrup is unusually free from yellowish tint, even in a heavy strata. The syrup made from this sugar is often sold as "Rock Candy Syrup."

In relation to the quantity of sugar, if in too small proportion, fermentation is apt to occur; if too abundant, crystallization. The Pharmacopoeial formula calls for 850 Gm. of sugar to make 1000 mils of syrup, the amount of water required being about 465 mils. A somewhat smaller quantity will answer where an acid, such as lemon juice or vinegar, is used.

As it is desirable, in many instances, that the active matters should be in as concentrated a state as possible in the syrup, it is often necessary
to evaporate a large proportion of the aqueous fluid in which they are dissolved. This may be done either before the addition of the sugar or afterwards. In either case care is requisite not to apply a heat too great or too long continued, lest the active principles should be injured. The use of concentrated pharmaceutical preparations, such as tinctures and fluidextracts, as the source of medication, has largely replaced other methods. The proper point of concentration for syrups which are prepared on a large scale by boiling is best ascertained by the use of that variety of Baume's hydrometer called a saccharometer. This should stand at 30° in boiling syrup—30.5° in hot weather and at 35° in the syrup when it is cool. Another very accurate, though less ready, method is to ascertain the sp. gr. by weighing a portion of the liquid. Syrup, when boiling, should have a sp. gr. of about 1.261; at 25° C. (77° F.) about 1.313; this is the specific gravity of the official syrup. A third method of ascertaining the proper point of concentration is by the thermometer, which, in boiling syrup of the proper consistence, stands at 105° C. (221° F.). This indication is founded on the fact that the boiling point of syrup rises with the increase of its density.

When carefully prepared with the best refined sugar, syrups made by the hot process or by agitation in the cold usually require no other clarification than to remove any scum which may rise to their surface upon standing, and to pour them off from any dregs which may subside. But, as the sugar employed is seldom free from impurities, it may be best, as a rule, to remove the scum as it rises during the heating process, and to strain the syrup while hot through muslin or flannel. The percolation process avoids this necessity. Should syrups at any time lack the due degree of transparency, they may be filtered through paper if a hot water funnel is used, or, when likely to be injured by this treatment, may be clarified by other mechanical means, as mentioned under the head of Syrups. The vicious habit practised not long ago by sugar refiners of "blueing" sugars by the use of ultramarine and other coloring agents cannot be too strongly deprecated, and it is a great benefit to pharmacy that this practice has been discontinued by most sugar refiners. (See A. J. P., 1901, 119.)

The medicated syrups are liable to undergo various alterations, according to their nature and mode of preparation. The acid syrups, when too much boiled, often show a copious white deposit, which is invert sugar produced by the action of the acid upon the sugar. Even at ordinary temperatures, acids slowly convert common sugar into invert
sugar, which, being less soluble than the former, is often deposited in the form of crystalline grains. Excessive acidity soon causes a darkening of the syrup, due to caramelization of the sugar. Syrups containing too little sugar are subject to fermentation, in consequence of the presence of yeast cells. Those which contain too much, deposit a portion in the crystalline state, and the crystals, attracting the sugar remaining in solution, gradually weaken the syrup, and render it liable to the same change as when originally made with too little sugar. The want of due proportion of saccharine matter frequently also gives rise to mouldiness, when air has access to the syrup. It is said that syrups enclosed, while they are still hot, in bottles which are not full are apt to ferment, but if in well filled bottles they will generally keep better. When syrups undergo the vinous fermentation, they become covered at the surface with froth, produced by the disengagement of carbon dioxide, and acquire a vinous odor from the presence of alcohol, while their consistence is diminished by the loss of a portion of the sugar, which has been converted into that liquid. When the quantity of alcohol has increased to a certain point, the fermentation ceases, or goes on more slowly, owing to the preservative influence of the alcohol. Such syrups should never be used for pharmaceutical purposes, as no amount of rebelling can render them fit for use.

The percolation method for preparing syrups has come into general use. For some syrups it is to be preferred to the usual method of heating, and all syrups which contain a volatile principle, or one likely to be injured by heat, are preferably made by percolation. L. Orynski (D. C., March, 1871) first drew attention to the subject. The details of the official method are given below. It was first recommended that a small piece of sponge should be used to close the lower orifice of the percolator, but this has advantageously been replaced by purified cotton. Some experience is necessary in adjusting the cotton, but the proper degree of pressure is soon learned.

To be successful in using the process, care in several particulars must be exercised. (1) The percolator should be cylindrical or semi-cylindrical, and cone-shaped as it nears the lower orifice. (2) The sugar must be coarse, else it will form into a compact mass, which the liquid cannot permeate. (3) The sponge or pledget must be introduced with care. If pressed too tightly in, it will effectually stop the process; if inserted too loosely, the liquid will pass too rapidly, and will, in consequence, be weak and turbid (not properly filtered). See also a practical paper on

Syrups may be made (without heat) rapidly by putting the ingredients in a churn and agitating briskly.

“Rock Candy Syrup,” the evaporated mother liquor left after crystallizing sugar in the form of large crystals, called "rock candy," has come largely into use in America. It varies much in quality as made by various manufacturers, and often contains added glucose. It should never be used indiscriminately or for making the official syrups, and it should always be carefully tested before being used for any purpose. (See analyses by L. F. Kebler, in A. J. P., 1895, 143.)

At best, syrups are apt to change, and various measures have been proposed for their preservation, but the best plan is to make small quantities of syrups at a time, and to keep them, unless when wanted for immediate use, in bottles quite full and well stoppered, which should be put in the cellar or other cool place. Glycerin is often used to aid in the preservation of syrups; in special cases this may be advantageous, but the solvent properties of glycerin must be remembered, and the finished preparation may possess properties (due to the glycerin) which are not found in syrups made without glycerin, and which may therefore be injurious in prescriptions. (See West. Drug., 1898, 444.)

SYRUPUS. U.S., Br.

SYRUP [Sirup, Simple Syrup]

Syrupus Simplex; Syrupus Sacchari s. Albus; Sirop de Sucre, Fr. Cod.; Sirop simple, Fr.; Sirupus simplex, P. G.; Weisser Sirup, G.; Sciroppo semplice. It.; Jarabe simple, Sp.

"Sugar, in dry crystalline granules, eight hundred and fifty grammes [or 29 ounces av., 430 grains]; Distilled Water, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Place at the bottom of a glass percolator of suitable size, a layer of purified cotton about one-half inch in thickness, well fitted to the sides of the percolator, and moisten it with a little distilled water. Introduce the sugar into the percolator, make its surface level without shaking or
jarring, then carefully pour upon it four hundred and fifty mils [or 15 fluidounces, 104 minims] of distilled water and regulate the flow of the liquid, if necessary, so that it passes out in rapid drops. Return the first portion of the percolate until it runs through clear and, when all of the liquid has passed, follow it by distilled water, added in portions, so that all of the sugar may be dissolved and the product measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Mix thoroughly. Syrup may also be prepared in the following manner: Dissolve the sugar with the aid of heat in four hundred and fifty mils [or 15 fluidounces, 104 minims] of distilled water, raise the temperature to the boiling point, strain the liquid, and pass enough distilled water through the strainer to make the product, when cold, measure one thousand mils [or 33 fluid-ounces, 6 1/2 fluidrachms]. Mix thoroughly. Syrup thus prepared has a specific gravity of about 1.313 at 25° C. (77° F.)." U. S.

" Refined Sugar, 1000 grammes; Distilled Water, sufficient to produce 1500 grammes. Heat together until dissolved; add sufficient Distilled Water to produce the required weight. Specific gravity 1.330. Optical rotation +56° to +58° Br.

This syrup, when properly prepared, is inodorous, of a sweet taste without peculiar flavor, thick, viscid, nearly colorless, and perfectly transparent. It sometimes requires straining through muslin or it may be filtered through a pledget of cotton or often through paper.

From the observations of Maumene, it appears that a solution of pure cane sugar, when long kept, undergoes a molecular change analogous to that produced by the reaction of weak acids, the saccharine liquid becoming brown when boiled with potassium hydroxide. But, as this phenomenon is exhibited alike by uncrystallizable sugar and by glucose, the experiment does not determine which of those forms of saccharine matter has been produced. (C. R. A. S., xxxix, 914.) Procter observed a similar change in simple syrup which had been kept in his cabinet for six years. (A. J. P., xxvii, 430.) Schaeuffele, having noticed, on one occasion, in the preparation of simple syrup, that the foam exhibited a singular blue color, while a part of the cane sugar was rapidly transformed into the unerystallizable variety, made investigations as to the cause, and was led to the conclusion that it was the presence of indigo in the loaves of sugar, introduced with the view of giving brilliancy and whiteness, but this conclusion was erroneous, as
it is well known that ultramarine, and not indigo, was formerly used for this purpose. The presence of a blue coloring matter in sugar was frequently noticed in this country; syrup made from such sugar was not colorless, and in a short time deposited a dark-colored sediment. Colorless "rock candy" forms' an excellent source for pure syrup (the broken crystals can be procured cheaply from the manufacturers), and syrup entirely free from impurities is required in making such preparations as syrup of hydriodie acid, syrup of ferrous iodide, etc. Joseph L. Mayer (J. A. P. A., 1916, p. 712) shows that it is unfair to assume that commercial glucose is present as an adulterant of syrup, simply because it contains reducing sugar, for in a series of experiments conducted by him, working with both cold process and hot process syrups, the amount of invert sugar found after standing for one year, ranged from about 8 per cent. to over 40 per cent., depending entirely on the length of time of standing. The grade of granulated sugar known as "crystal A" or as "Druggists' Dry Granular," is used with success in some parts of the country where it can be readily obtained. It is crystallized from the first runnings from the bone-black filters.

Syrup is very useful in the formation of pills and mixtures, and in various other pharmaceutical operations in which sugar in solution is required.

The U. S. syrup is practically identical with that formerly official, being a trifle stronger, the sp. gr. being given as 1.313 at 25° C. (77° F.). That of the Br. syrup is 1.330 at 15.5° C. (60° F.), probably adapted to the climate of Great Britain, which is not so cold in winter as is ours, at least in the Northern and Middle States.

SYRUPUS ACACIÆ. U. S.

SYRUP OF ACACIA Syr. Acac.

"Acacia, in selected pieces, one hundred grammes [or 3 ounces av., 231 grains]; Sugar, eight hundred grammes [or 28 ounces av., 96 grains]; Distilled Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Place the acacia in an enameled or
porcelain dish, and add four hundred and thirty mils [or 14 fluidounces, 259 minims] of distilled water, and stir occasionally until the acacia is dissolved; then, having added the sugar, place the dish on a water bath and apply heat, gradually increasing the temperature until the water in the water bath boils. Maintain this temperature for fifteen minutes, and stir the syrup from time to time until the sugar is dissolved. Strain the syrup while hot, add sufficient distilled water, recently boiled, to make the product measure one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms], and transfer it, while yet hot, into small bottles which have been rinsed with boiling water and heated in an oven at 160° C. (320° F.) for from fifteen to thirty minutes. Close the bottles tightly with rubber stoppers which have been just previously boiled in water for thirty minutes and cap them with paper." U. S.

In the 18th edition of this work the process of the U. S. P., 1890, was condemned because of the tendency of the mucilage of acacia to spoil and thus make an unreliable syrup; the U. S. P. (9th Rev.) provides for a practically permanent preparation by the sterilization of the syrup, the containers, and the stoppers. This syrup is useful in the preparation of mixtures, pills, and troches, and is a good demulcent; but, unfortunately, the proportion of the gum to the sugar is too small to meet all the indications calling for the conjoint use of these substances. To avoid fermentation, C. B. Mann commends the use of one fluidounce of glycerin and seven fluidounces of water as the solvent. If the mucilage of acacia be made with chloroform water or a trace of chloroform be added to syrup of acacia, fermentation is measurably retarded, but the present official method is satisfactory for the purpose.

**Off. Prep.**—Syrupus Morphines et Acacise, N. F.

**SYRUPUS AROMATICUS. Br.**

**AROMATIC SYRUP**

Sirop Aromatique, Fr.; Aromatischer Sirup, G.

"Tincture of Orange, 250 millilitres; Cinnamon Water, 250 millilitres; Syrup, 500 millilitres. Mix the Tincture of Orange and Cinnamon Water; shake the mixture with a little powdered talc; filter; add the Syrup." Br. 

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - S - Page 141
The Southwest School of Botanical Medicine http://www.swsbm.com
This preparation of the Br. Ph., 1898, is practically a simple elixir (see Elixir Aromaticum); it has been introduced mainly as a vehicle or adjuvant.

SYRUPUS AURANTII. U. S., Br.

SYRUP OF ORANGE Syr. Aurant

Syrup of Orange Peel; Sirop d'Ecorce d'Orange amere, Fr. Cod.; Sirupus Aurantii Corticifs, P. G.; Pomerantenschalen-Sirup, Orangenschalen-syrup, G.; Sciroppo di arancio amaro, It.; Jarabe de corteza de naranja amarga, Sp.

"Tincture of Sweet Orange Peel, fifty mils [or 1 fluidounce, 331 minims]; Citric Acid, five grammes [or 77 grains]; Purified Talc, fifteen grammes [or 231 grains]; Sugar, eight hundred and twenty grammes [or 28 ounces av., 405 grains]; Distilled Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Triturate the Purified Talc in a mortar with the tincture; add gradually four hundred mils [or 13 fluidounces, 252 minims] of distilled water, filter, and add sufficient distilled water through the filter to obtain four hundred and fifty mils [or 15 fluidounces, 104 minims] of filtrate; in this filtrate dissolve the citric acid and sugar by agitation without heat, and -add sufficient distilled water to make the product measure one thousand mils' [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." U. S.

"Tincture of Orange, 125 millilitres; Syrup, sufficient to produce 1000 millilitres. Mix." Br.

The U. S. P. IX process is an improvement over all preceding formulas as the flavor is derived from the tincture of fresh orange peel and the alkaline magnesium carbonate of the U. S. P. VIII, which modified the flavor, has been replaced by inert talc, the latter being used as a distributing and filtering medium. The British preparation, which is a mere mixture of the tincture with syrup, is inferior. The syrup has an agreeable, slightly acid flavor, for which it is alone employed. For a process by E. E. Williams, using powdered pumice to disintegrate the orange peel, see D. C., 1898, 125.
SYRUPUS AURANTII FLORUM. U. S. (Br.)

"Sugar, eight hundred and fifty grammes [or 29 ounces av., 430 grains]; Orange Flower Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidraehms]. Dissolve the sugar in four hundred and fifty mils [or 15 fluidounce's, 104 minims] of orange flower water by agitation, without heat, add enough orange flower water to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidraehms], mix thoroughly and strain. Syrup of orange flowers may also be made in the following manner: Prepare a percolator in the manner described under Syrupus. Pour four hundred and fifty mils [or 15 fluidounces, 104 minims] of orange flower water upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it by orange flower water, until the sugar is all dissolved and the product measures one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Mix thoroughly." U.S.

"Orange-flower water of commerce, undiluted, 150 millilitres; Refined Sugar, 300 grammes; Syrup, sufficient to produce 1000 millilitres. Mix the orange-flower water with the Refined Sugar in a closed vessel; stand in a moderately warm place, shaking occasionally till dissolved; then add sufficient Syrup to produce the required volume." Br.

The second U. S. process, by percolation, will be preferable here. This syrup is used chiefly for flavoring mixtures.

SYRUPUS CASCARÆ AROMATICUS. Br.

AROMATIC SYRUP OF CASCARA

Sirop aromatique de Cascara Sagrada, Fr.; Aromatischer Amerikanisch-Faulbaumrindensirup, G.

"Liquid Extract of Cascara Sagrada, 400 millilitres; Tincture of Orange, 100 millilitres; Alcohol (90 per cent.), 50 millilitres; Cinnamon Water, 150 millilitres; Syrup, sufficient to produce 1000 millilitres. Mix." Br.
This was a new syrup in the Br. Pharm., 1898. It forms a convenient means of administering cascara, the alcohol being added to aid its preservation.

Dose, from one-half to two fluidrachms (1.8-7.5 mils).

**SYRUPUS IPECACUANHÆ.**

**U.S. SYRUP OF IPECAC Syr. Ipecac.**

"Fluidextract of Ipecac, seventy mils [or 2 fluidounces, 176 minims]; Acetic Acid, ten mils [or 162 minims]; Glycerin, one hundred mils [or 3 fluidounces, 183 minims]; Sugar, seven hundred grammes [or 24 ounces av., 303 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Dilute the fluidextract of ipecac with three hundred mils [or 10 fluidounces, 69 minims] of water to which the acetic acid has previously been added, and mix them thoroughly by shaking, and set the liquid aside in a cool place for twenty-four hours. Then filter, and pass enough water through the filter to make the filtrate measure four hundred and fifty mils [or 15 fluidounces, 104 minims]. To this filtrate add the glycerin, dissolve the sugar in the mixed liquids, and add enough water to make the product measure one thousand mils [or 33 fluid-ounces, 6¹/₂ fluidraehms]. Mix thoroughly, and strain, if necessary. Syrup of Ipecac may also be made in the following manner: Prepare a percolator in the manner described under Syrupus. Mix the filtrate obtained as directed in the preceding formula with the glycerin, pour the mixture upon the sugar, return the first portions of the percolate, until it runs through clear, and, when all the liquid has passed, follow it with water, until the sugar is all dissolved and the product measures one thousand mils [or 33 fluidounces, 6¹/₂ fluidraehms]. Mix thoroughly." U. S.

The present U. S. syrup is made in accordance with the suggestions of Laidley of Richmond, Va., who found the syrup, as formerly prepared, to spoil on keeping. (A. J. P., xxvi, 103, and July, 1879.) (See a practical paper on this subject by A. Bobbins in A. J. P., Aug., 1879.)
substitution of glycerin for a portion of the syrup in the U. S. process is an improvement, but the addition of the very small quantity of Acetic Acid is of questionable utility. For formulae in which the drug ipecac is employed, the reader may consult A. J. P., 1870, p. 127; 1871, p. 104; May, 1881.

If strictly official fluidextract of ipecac is used in making this syrup, and the process is carried out in all its details, the syrup will remain transparent; but if commercial fluid-extract is used, or if the fluidextract has not been very carefully made, it will be necessary to modify the process somewhat to secure a transparent syrup. This may be effected by allowing the diluted fluidextract in the official process for making this syrup to remain for two or three days in a cool place before filtering, and adding to the sugar.

One fluidounce of this syrup should contain the virtues of about thirty grains of ipecac.

Although this syrup possesses all the virtues of ipecac, it is used almost exclusively as a nauseating expectorant in acute bronchitis.

Dose, for an adult, as an expectorant, from fifteen to thirty minims (0.9-1.8 mils); as an emetic, half a fluidounce (15 mils).

SYRUPUS LACTUCARIU. U. S.

SYRUP OF LACTUCARIUM Syr. Lactucar.

"Tincture of Lactucarium, one hundred mils [or 3 fluidounces, 183 minims]; Glycerin, two hundred mils [or 6 fluidounces, 366 minims]; Citric Acid, one gramme [or 15 grains]; Orange Flower Water, fifty mils [or 1 fluidounce, 331 minims]; Syrup, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix the tincture of lactucarium with the glycerin, add the orange flower water in which the citric acid has been previously dissolved, and filter, if necessary. Finally, add a sufficient quantity of syrup to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." U. S.
The only disadvantage of this syrup is the slight petroleum-like taste which seems to be inseparable from lactucarium preparations made by extracting the resinous principles with petroleum benzine; the new tincture of lactucarium, notwithstanding all the care that can be given to the purification of the petroleum benzine, will still hold a trace of the benzine-residue flavor, which it communicates to the syrup. The recommendations made by various pharmaceutical writers to add a solution of an alkali to cloudy syrup of lactucarium, in order to make it transparent, are inadmissible, for Aubergier has conclusively shown that alkalies destroy the bitter principles of lactucarium.

Jos. W. England and N. D. Streeter both prefer to make the syrup directly from the lactucarium. For processes, see A. J. P., 1883, pp. 393, 593.

Louis Emanuel presents an interesting contribution on the subject in the Proc. P. P. A., 1912, p. 151, in which all processes as well as the product are criticised.

This syrup for half a century has been largely used on the assumption that it possessed properties similar to those of opium without the habit-forming tendency of the latter, and Aubergier's syrup has been in great vogue in Europe and to a less extent in this country. After the passage of the Food and Drugs Act in 1906, the Aubergier preparations of lactucarium were found to contain a declaration on the label of the presence of morphine. In France it is evident that lactucarium had failed to sustain its reputation, for the French Codex introduced Sirop de Lactucarium Opiace (1884), which contained alcoholic extract of lactucarium, with the addition of one-half the proportion of extract of opium. This was an official recognition of the feeble character of lactucarium, and inasmuch as many persons used the syrup as a substitute for opium or morphine, the fact remained that thousands were deceived and in many cases the opium habit was established. We are of the opinion that lactucarium and its preparations should no longer receive recognition. The formula for Aubergier's syrup will be found in the U. S. D., 19th edition, page 1230.

Dose, two to three fluidrachms (7.5-11.25 mils).
SYRUPUS LIMONIS. Br.

SYRUP OF LEMON

Syrupus Succus Citri; Sirop de Limon (de Citron), Sirop de sue de Limon (de citron), Fr.; Citronensirup, Citronensaftsirup, G.; Jarabe de limon, Sp.

"Lemon Peel, in thin slices or grated, 20 grammes; Alcohol (90 per cent.), a sufficient quantity; Lemon Juice, 500 millilitres; Refined Sugar, 760 grammes. Macerate the Lemon Peel in thirty millilitres of the Alcohol for seven days; press; filter; add sufficient of the Alcohol to produce forty millilitres. In the Lemon Juice, clarified by subsidence or filtration, dissolve the Refined Sugar by the aid of gentle heat; cool; add the forty millilitres of alcoholic liquid; mix." Br.

The U. S. P. 1880 syrup of lemon was dropped at the 1890 revision; as it is frequently used, the process is appended.

"Lemon Juice, recently expressed and strained, forty parts [or seventeen fluidounces]; Fresh Lemon Peel, two parts [or one ounce av.]; Sugar, in coarse powder, sixty parts [or twenty-eight ounces av.]; Water a sufficient quantity, to make one hundred parts [or about two pints]. Heat the Lemon Juice to the boiling point; then add the Lemon Peel, and let the whole stand, closely covered, until cold. Filter, add enough Water through the filter to make the filtrate weigh forty parts [or measure seventeen fluid-ounces], dissolve the Sugar in the filtered liquid by agitation, without heat, and strain." U. S. 1880.

The addition of lemon peel to the preparation is an improvement, but the internal white portion of the peel should be carefully removed before adding to the hot lemon juice, or the finished syrup will have a bitter taste. (See Limonis Cortex.) This syrup forms a cooling and grateful addition to beverages in febrile complaints, and serves to conceal the taste of saline purgatives in solution.

SYRUPUS PICIS LIQUIDS. U. S.

Syrupus cum aqua picea; Syrupus Piceus; Sirop de Goudron, Fr. Cod.; Theersirup, G.; Jarabe de brea, Sp.
"Tar, five grammes [or 77 grains]; Alcohol, fifty mils [or 1 fluidounce, 331 minims]; Magnesium Carbonate, ten grammes [or 154 grains]; Sugar, eight hundred, and fifty grammes [or 29 ounces av., 430 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Dissolve the tar in the alcohol, add the magnesium carbonate and fifty grammes [or 1 ounce av., 334 grains] of sugar, and after thorough trituration add four hundred and ten mils [or 13 fluid-ounces, 415 minims] of water. Stir the mixture occasionally during two hours and then filter it, returning the filtrate to the filter until the liquid is clear. Dissolve the remainder of the sugar in the clear filtrate obtained from the treatment of the tar, and strain the syrup, adding sufficient water through the strainer to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Syrup of Tar may also be made in the following manner: Prepare a percolator in the manner described under Syrupus. Pour the clear filtered liquid obtained from the treatment of the tar as directed above upon the remainder of the sugar, return the first portions of the percolate until it runs through clear, and, when all the percolate has passed, follow it with water until the sugar is all dissolved and the product measures one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." U. S.

In many sections of our country this syrup has been largely used. The process of the U. S. P. IX is an improvement on the one formerly official; the proportion of tar being reduced from 75 Gm. to 5 Gm. It is similar to the U. S. P. VIII process except that the washing of the tar to remove acid constituents has been omitted because these would not be present in a tar which conforms to the U. S. P. tests. The tar is dissolved in alcohol, magnesium carbonate and a little sugar added, the mixture filtered, and more sugar dissolved with the aid of a gentle heat. This syrup affords an excellent method of administering small quantities of tar in the milder forms of subacute or chronic bronchitis.

Dose, from one to two fluidrachms (3.75-7.5 mils).
SYRUPUS PRUNI VIRGINIANÆ. U. S., Br.

Syrup of Virginian Prune, Br. 1898; Sirop d’Ecorce de Cerisiel, Fr.; Wildkirschenrindensirup, G.

"Wild Cherry Bark in No. 20 powder, one hundred and fifty grammes [or 5 ounces av., 127 grains]; Sugar, eight hundred grammes [or 28 ounces av., 96 grains]; Glycerin, fifty mils [or 1 fluidounce, 331 minims]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix the glycerin with two hundred mils [or 6 fluid-ounces, 366 minims] of water, moisten the wild cherry bark with one hundred mils [or 3 fluid-ounces, 183 minims] of this mixture, pack it firmly in a cylindrical percolator and pour the remaining one hundred and fifty mils [or 5 fluidounces, 35 minims] of the menstruum upon it. When the glycerin-water menstruum has disappeared from the surface of the drug, add sufficient water to saturate the powder and leave a stratum above it. Close the lower orifice, and, having closely covered the percolator, allow the drug to macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding water as a menstruum until the percolate measures five hundred mils [or 16 fluidounces, 436 minims]. Dissolve the sugar in the percolate by agitation without heat, strain and pass enough water through the strainer to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly. Syrup of Wild Cherry may also be made in the following manner: Prepare a percolator in the manner described under Syrupus. Pour the percolate obtained as directed in the preceding formula upon the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it with water, until the sugar is all dissolved and the product measures one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly. This Syrup should be stored in non-metallic, tightly-closed containers, in a cool place, as it rapidly loses hydrocyanic acid even under the most favorable conditions." U. S.

"Wild Cherry Bark, in No. 20 powder, 150 grammes; Refined Sugar, in coarse powder, 750 grammes; Glycerin, 65 millilitres; Distilled Water sufficient to produce 1000 millilitres. Moisten the Wild Cherry Bark with Distilled Water; set aside for twenty-four hours in a closed vessel; pack
in a percolator; percolate with Distilled Water until four hundred and fifty millilitres have been collected; dissolve the Refined Sugar in the percolated liquid, without heat; add the Glycerin and sufficient Distilled Water to produce the required volume." Br.

The British Pharmacopoeia introduced this syrup into the 1898 edition. The process is modelled after the U. S. formula.

The U. S. process affords a handsome syrup with the virtues of the bark unimpaired by the injurious effects of heat. It is based upon a formula proposed by Procter and Turnpenny in A. J. P., xiv, 27. The introduction of the glycerin into the receiving bottle instead of mixing it with the menstruum was dropped in the process of the U. S. P., which, in our opinion, is a mistake. The glycerin is not needed in the menstruum to increase the astrin-gency of the syrup but it serves a useful purpose in keeping the infusion from decomposing and precipitating a reddish, insoluble substance in the receiving bottle. This syrup should never be made by adding fluidextract to simple syrup, as the fluidextract is likely to vary greatly in quality, and frequently precipitates when mixed with syrup, the syrup when made by the above process is far superior in flavor. It is largely used as a vehicle for cough mixtures.

Dose, one to four fluidrachms (3.75-15.0 mils).

**SYRUPUS RHEI. U. S., Br.**

**SYRUP OF RHUBARB Syr. Rhei**

Sirop de Rhubarbe, Fr.; Sirupus Rhei, P. G.; Rhabarber-sirup, Rhabarbersaft, G.

"Fluidextract of Rhubarb, one hundred mils [or 3 fluidounces, 183 minims]; Spirit of Cinnamon, four mils [or 65 minims]; Potassium Carbonate, ten grammes [or 154 grains]; Water, fifty mils [os.1 fluidounce, 331 minims]; Syrup, oa sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix the spirit of cinnamon with the fluidextract of rhubarb, and add the potassium carbonate previously dissolved in the water, and gradually add this mixture to enough syrup to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]." U. S.
“Rhubarb, in No. 20 powder, 70.0 grammes; Oil of Coriander, 0.5 millilitre; Refined Sugar, 840.0 grammes; Alcohol (90 per cent.), 280.0 millilitres; Distilled Water, sufficient to produce 1000.0 millilitres. Mix two hundred and seventy millilitres of the Alcohol with three times its volume of Distilled Water. Moisten the Rhubarb with seventy millilitres of this diluted alcohol and set aside for twenty-four hours in a closed vessel; pack in a percolator; pass the remainder of the diluted alcohol slowly through the moistened powder; evaporate the percolate to four hundred and seventy-five grammes; filter; dissolve the Refined Sugar in the filtrate by the aid of heat; cool; add the Oil of Coriander dissolved in ten millilitres of the Alcohol; mix, and finally add sufficient Distilled Water to produce the required volume.” Br.

The Br. process is a troublesome and imperfect method.

The U. S. syrup differs from that official before 1890 in several particulars, and, in our opinion, it is greatly improved; the activity of the rhubarb and the corrigent effects of the cinnamon are both secured without impairing the appearance of the finished syrup, while the simplicity of the manipulation must commend the process to all. In the Br. Pharm. 1914 oil of coriander replaced coriander fruit official in the former pharmacoposia.

The official syrup is a mild cathartic, adapted for use with infants, to which it may be given in the dose of a fluidraehm (3.75 mils).

Dose, for adults, two to three fluidrachms (7.5-11.25 mils).

SYRUPUS RHEI AROMATICUS. U. S.

AROMATIC SYRUP OF RHUBARB
Syr. Rhei Arom. [Spiced Syrup of Rhubarb]

Sirop de Rhubarbe aromatique, Fr.; Gewurzter Rhabarbersaft, G.

"Aromatic Tincture of Rhubarb, one hundred and fifty mils [or 5 fluidounces, 35 minims]; Potassium Carbonate, one gramme [or 15 grains]; Syrup, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. Dissolve the potassium carbonate in the tincture and add this to sufficient syrup to make the product measure one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. Mix
thoroughly." U. S.

A small amount of alkali is added here to prevent the syrup from becoming turbid.

The aromatic syrup of rhubarb is a warm stomachic laxative, too feeble for adult cases, but well calculated for the bowel complaints of infants; which are so frequent in our cities during the summer season, and as a remedy for which this preparation, or one analogous to it, has been long in use, under the name of spiced syrup of rhubarb. The dose for an infant with diarrhea is a fluidrachm (3.75 mils), repeated every two hours until the passages indicate by their color that the medicine has operated. It should be borne in mind that the syrup, as prepared by the present formula, contains one-seventh of diluted alcohol, which, though not injurious in most cases in which this syrup is used, might render it too stimulating in some instances of diarrhea in the very young infant.

Dose, one to three fluidrachms (3.75-11.25 mils).

**SYRUPUS RHOEADOS. Br.**

**SYRUP OF RED POPPY**

"Red-Poppy Petals, 260 grammes; Refined Sugar, 720 grammes; Alcohol (90 per cent.), 50 millilitres; Distilled Water, sufficient to produce 1000 millilitres. Add the Red-Poppy Petals gradually to four hundred millilitres of Distilled Water kept hot upon a water-bath, stir frequently, and afterwards, the vessel being removed, infuse for twelve hours. Then press out the liquid; strain; add the Refined Sugar, and dissolve by the aid of heat. When nearly cold, add the Alcohol, and sufficient Distilled Water to produce the required volume." Br.

The object of introducing the petals into water heated by a water bath is that they may shrink by being scalded, as otherwise they could not be completely immersed in the quantity of water directed. After this has been accomplished, they should be immediately removed from the fire, lest the liquor become too thick and ropy. The fine red color of this syrup is its only recommendation. It is very liable to ferment; according to Enders, this can be obviated by evaporating the recently prepared
syrup to dryness, keeping the powdered residue in well-stoppered bottles, and dissolving it, as wanted, in four-fifths of its weight of water.

Dose, as stated in the Br. Pharmacopoeia, one-half to one fluidrachm (1.8-3.75 mils).

**SYRUPUS ROSÆ. Br.**

**SYRUP OF ROSE**

Syrup of Roses, Br.; Syrupus Rosarum Rubrarum; Syrup of Red Rose; Sirop de Rose rouge, Fr.; Rosensirup, G.

Syrup of Rose was deleted from the U. S. P. IX, but the process was introduced into the National Formulary IV.

"Dried Red-Rose Petals, 50 grammes; Refined Sugar, a sufficient quantity; Distilled Water, boiling, 500 millilitres. Infuse the Red-Rose Petals in the Distilled Water for two hours; strain; press; heat the infusion to the boiling point; filter; add to the filtrate twice its weight of Refined Sugar and dissolve by the aid of heat.” Br.

Syrup of rose is mildly astringent, but is valued most for its fine red color, on account of which it is occasionally added to mixtures. The color is developed by the small amount of diluted sulphuric acid which is added.

Dose, a fluidrachm (3.75 mils).

**SYRUPUS SARSAPARILLA COMPOSITUS. U. S.**

**COMPOUND SYRUP OF SARSAPARILLA Syr. Sarsap. Co.**

“Fluidextract of Sarsaparilla, two hundred mils [or 6 fluidounces, 366 minims]; Fluidextract of Glycyrrhiza, fifteen mils [or 243 minims]; Fluidextract of Senna, fifteen mils [or 243 minims]; Oil of Sassafras, two-tenths of a mil [or 3 minims]; Oil of Anise, two-tenths of a mil [or 3 minims]; Methyl Salicylate, two-tenths of a mil [or 3 minims]; Alcohol, nineteen and four-tenths mils [or 314 minims]; Syrup, seven hundred
and fifty mils [or 25 fluidounces, 173 minims]; to make about one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]. Mix the fluidextracts and add the alcohol, in which the methyl salicylate and the oils have been dissolved. Gradually add this solution to the syrup and mix thoroughly." U. S.

An important change was made in this compound syrup in the U. S. P. 1890, through the substitution of fluidextracts and volatile oils for the drugs used in the U. S. P. 1880 process. It was further improved in the U. S. P. VIII by doubling the amount of volatile oils. The present syrup is not perfectly transparent, but the U. S. P., 1890, syrup had the same fault, The simplicity of the present formula is a welcome improvement.

In the original edition of the U. S. Pharmacopoeia, published in 1820, a process for a syrup of sarsaparilla was adopted, intended to present the famous French sirop de cuisinier. This process has been variously modified from time to time, but the present preparation possesses any possible therapeutic virtues of the original preparation.

**Uses.**—The compound syrup of sarsaparilla is a senseless survival of an ancient superstition. As pointed out elsewhere in this work, it is improbable that sarsaparilla possesses any therapeutic virtue, and even if it did the proportion in the compound syrup is too small to exert any effect upon the system. While the syrup has a pleasant flavor, owing to the licorice and volatile oils it contains, as a vehicle it would be improved by omitting the sarsaparilla and the senna.

Corrosive sublimate, which is often given in connection with this syrup, is said to be completely decomposed by it, being converted into calomel. Samuel Kennedy (Ph. Rec., 1888, p. 201) showed that when corrosive sublimate was dissolved in this syrup precipitation invariably occurred; if an equal amount of sodium chloride was added, precipitation was greatly retarded. Lepage of Gisors, proposes as a substitute potassium iodohydrargyrate, which he has found not to undergo decomposition.

Dose, of the syrup, half a fluidounce (15 mils), equivalent to somewhat less than a drachm (3.9 Gm.) of the root, to be taken three or four times a day.

**Off. Prep.**—Syrupus Bromidorum, N. F.
SYRUPUS SCILLÆ. U. S., Br.

SYRUP OF SQUILL Syr. Scill.

Syrupus Aceti Scillae; Sirop de Scille, Fr.; Meerzwiebel-airup, G.

"Vinegar of Squill, four hundred and fifty mils [or 15 fluidounces, 104 mins]; Sugar, eight hundred grammes [or 28, ounces av., 96 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. Dissolve the sugar in the vinegar of squill with the aid of a gentle heat, then strain the syrup and, when the liquid is cold, add enough water, through the strainer, to make the product measure one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. Mix thoroughly." U. S.

"Vinegar of Squill, 175 millilitres; Refined Sugar, 650 grammes; Distilled Water, sufficient to produce 1000 grammes. Mix the Vinegar of Squill with an equal volume of Distilled Water. In the mixture dissolve the Refined Sugar by the aid of gentle heat; add sufficient Distilled Water to produce the required weight." Br.

The present British formula is almost identical with U. S. IX, and differs from that of 1864 in taking the vinegar already formed, instead of preparing it as the first step of the process. Vinegar of Squill of the Br. Pharm. 1914 is double the strength of that formerly official. The heating should be performed as quickly as possible, to prevent undue loss of acetic acid.

This syrup is much employed as an expectorant, especially in combination with a solution of tartarized antimony. It is incompatible with ammonium carbonate, but not with ammonium chloride.

Dose, about a fluidrachm (3.75 mils).

SYRUPUS SCILLÆ COMPOSITUS. U. S.

COMPOUND SYRUP OF SQUILL Syr. Scill. Co. [Hive Syrup]

Coxe'a Hive Syrup; Sirop de Scille compose, Fr.; Zusam-mengesetzter Meerzwiebelsirup, G.
"Fluidextract of Squill, eighty mils [or 2 fluidounces, 338 minims]; Fluidextract of Senega, eighty mils [or 2 fluidounces, 338 minims]; Antimony and Potassium Tartrate, two grammes [or 31 grains]; Distilled Water, ten mils [or 162 minims] Syrup, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 6 1/2 fluidraehms]. Dissolve the antimony and potassium tartrate in the distilled water with the aid of heat, add this solution to seven hundred and fifty mils [or 25 fluidounces, 173 minims] of syrup and mix thoroughly. Then gradually add the fluidextracts, previously mixed, and finally, sufficient syrup to make the product measure one thousand mils [or 33 fluid-ounces, 6 1/2 fluidraehms]." U. S.

This is intended as a substitute for the popular preparation called Coxe's hive syrup, from which it differs chiefly in containing sugar instead of honey. Prepared as originally directed in the Pharmacopoeia, it invariably fermented from the want of sufficient concentration. This defect was corrected many years ago when sugar was substituted for honey, in consequence of the uncertain consistence and constitution of the latter. The present formula is a decided improvement, fluidextracts of squill and senega being used. Percolation has been found very well adapted for dissolving the sugar and producing a transparent syrup. The present U. S. P. process has the merit of simplicity, but, unfortunately, the fluidextract of squill is never a wholly satisfactory preparation.

The name Coxe's hive syrup, which is meaningless because it is not used in the treatment of hives, is said to owe its origin to a period when croup, for which the remedy is often used, was known popularly as "hives."

Compound syrup of squill combines the virtues of senega, squill, and tartar emetic, of the last of which it contains about one grain in a fluidounce. It is emetic, diaphoretic, expectorant, and frequently cathartic, and may be given with advantage in mild cases of simple croup, also in the latter stages of severe cases when the object is to promote expectoration. The dose of this syrup is, for children, from two to twenty minims (0.12-1.3 mils), according to the age, and it may be repeated in cases of croup every fifteen or twenty minutes until it causes vomiting.
Dose, for adults as an expectorant, from twenty to thirty minims (1.3-1.8 mils).

**SYRUPUS SENEGÆ. U. S.**

**SYRUP OF SENEGA Syr. Seneg.**

Sirop de Polygala, Fr.; Sirupus Senegae, P. G.; Senega-sirup, G.

"Fluidextract of Senega, two hundred mils [or 6 fluidounces, 366 minims]; Syrup, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6⅓ fluidrachms]. Mix the fluid-extract with sufficient syrup to make the product measure one thousand mils [or 33 fluidounces, 6⅓ fluidrachms]." U. S.

The syrup affords a very convenient mode of exhibiting senega in pectoral complaints. Owing to the pectinous principle present in senega, the syrup made directly from the root as in the process of 1870 was always turbid. It has been frequently pointed out that the addition of an alkali renders the syrup transparent, and the 1890 process directed the use of a small quantity of ammonia water, although, if the fluidextract of senega which contains alkali be used as in the U. S. P. IX, this addition is unnecessary. This syrup may be given as a nauseating expectorant.

Dose, one or two fluidrachms (3.75 or 7.5 mils).

**SYRUPUS SENNÆ. U. S., Br.**

**SYRUP OF SENNA Syr. Senn.**

Sirop de Senna, Fr.; Sirupus Sennae, P. O.; Sennasirup, G.

"Fluidextract of Senna, two hundred and fifty mils [or 8 fluidounces, 218 minims]; Oil of Coriander, five mils [or 81 minims]; Syrup, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6⅓ fluidrachms]. Mix the oil of coriander with the fluidextract of senna and add sufficient syrup to make the product measure one thousand mils [or 33 fluidounces, 6⅓ fluidrachms]. Mix thoroughly." U. S.
"Senna Leaves, 440.0 grammes; Oil of Coriander, 0.2 millilitre; Alcohol (90 per cent.), 2.0 millilitres; Refined Sugar, 540.0 grammes; Alcohol (20 per cent.), 760.0 millilitres. Moisten the Senna Leaves with four hundred and forty millilitres of the Alcohol (20 per cent.); pack tightly in a vessel which can afterwards be closed; set aside for three days; press strongly; reserve the liquid obtained; break up the marc; moisten it with one hundred and sixty millilitres of the Alcohol (20 per cent.); set aside for twenty-four hours; press strongly; add the liquid obtained to the portion previously reserved; break up the marc; mix it with the remainder of the Alcohol (20 per cent.); set aside for three hours; press again; evaporate the resulting liquid until it is reduced to such a volume that when added to the reserved liquid the whole measures four hundred and forty millilitres. Mix the evaporated liquid with the reserved liquid; heat the product in a covered vessel to 82° C. (179.6° F.) for a few minutes; set aside for twenty-four hours; filter, and pass Distilled Water through the filter until the filtrate measures four hundred and forty millilitres; add the Refined Sugar, and dissolve in a covered vessel by the aid of gentle heat; cool; add the Oil of Coriander dissolved in the Alcohol (90 per cent.); mix."

The process was improved in the U. S. P. VIII by simply adding the fluidextract and oil of coriander to syrup, and this process has been retained in the Ninth Revision.

Dose, of the U. S. syrup of senna, for an adult, from one to four fluidrachms (3.75-15.0 mils); of the Br. syrup from one to two fluidrachms (3.75-7.5 mils).

SYRUPUS TOLUTANUS. U. S., Br.

SYRUP OF TOLU Syr. Tolu.

"Tincture of Tolu, fifty mils [or 1 fluid-ounce, 331 minims]; Magnesium Carbonate, ten grammes [or 154 grains]; Sugar, eight hundred and twenty grammes [or 28 ounces av., 405 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Rub the tincture of tolu in a mortar with the magnesium carbonate and sixty grammes [or 2 ounces av., 51 grains] of the sugar.
Then gradually add four hundred and thirty mils [or 14 fluidounces, 259 minims] of water, with constant trituration, and filter. Dissolve the remainder of the sugar in the clear filtrate, with the aid of a gentle heat, strain the syrup while hot, and add sufficient water to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Syrup of tolu may also be made in the following manner: Prepare a percolator in the manner described under Syrupus. Pour the filtrate obtained as directed in the preceding formula upon the remainder of the sugar, return the first portions of the percolate until it runs through clear, and, when all of the liquid has passed, follow it with water, until all of the sugar is dissolved and the product measures one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix thoroughly." U. S.

"Balsam of Tolu, 25 grammes; Refined Sugar, 660 grammes; Distilled Water, sufficient to produce 1000 grammes. Add four hundred grammes of the Distilled Water, boiling, to the Balsam of Tolu; cover lightly and heat on a water-bath for half an hour, stirring frequently. Remove; add Distilled Water, if necessary, so that the liquid, when cold, measures four hundred millilitres. Filter the solution, add the Refined Sugar, dissolve by the aid of a water-bath, and finally add sufficient Distilled Water to produce the required weight." Br.

The U. S., 1890, process for this syrup was more satisfactory than that formerly official. It was practically a return to the U. S., 1870, method (based on Finley's process, substituting precipitated calcium phosphate for magnesium carbonate, and using a freshly made strong tincture for the official tincture of tolu.

The U. S. Pharmacopoeia VIII and IX process reintroduced magnesium carbonate with much advantage, and has the further improvement of using the official tincture of tolu instead of making the latter from the balsam by a special process. In the British process the soluble principles of the balsam are extracted by boiling it with water, but with great waste of the material, as the water dissolves but a small portion of the active matter. To obviate this waste, the same portion of balsam is, according to Brande, usually employed in successive operations, and it long continues to impart odor and taste to boiling water. W. H. Hostelley's modification is as follows: For making twenty-five ounces of syrup, take one ounce of balsam of tolu, one pound of granulated sugar,
and water which has been previously filtered through animal charcoal, enough to make twenty-five ounces; rub the tolu to a fine powder, aided by some of the sugar, and mix this with the remainder of the granulated sugar; now prepare a percolator by placing a piece of cotton in the neck, pack the powder in it, pour in the filtered water, and receive twenty-five ounces of percolate. (A. J. P., 1887, p. 290.) Syrup of tolu is used chiefly to impart its agreeable flavor to mixtures. If a stronger preparation is desired, tincture of tolu may be added in the desired quantity, directing the bottle to be shaken.

Dose, one to four fluidrachms (3.75-15.0 mils).

**SYRUPUS URGINEA. Br.**

**SYRUP OF URGINEA**

"Vinegar of Urginea, 175 millilitres; Refined Sugar, 650 grammes; Distilled Water, sufficient; to produce 1000 grammes. Mix the Vinegar of Urginea with an equal volume of Distilled Water. In the mixture dissolve the Refined Sugar by the aid of gentle heat; add sufficient Distilled Water to produce the required weight." Br.

This syrup corresponds to the Syrup of Squill of the British Pharmacopoeia and is used for the same purpose.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

**SYRUPUS ZINGIBERIS. U. S., Br.**

**SYRUP OF GINGER** Syr. Zingib.

Sirop de Gingembre, Fr.; Ingwersirup, G.

“Fluidextract of Ginger, thirty mils [or 1 fluidounce, 7 minims]; Alcohol, twenty mils [or 325 minims]; Magnesium Carbonate, ten grammes [or 154 grains]; Sugar, eight hundred and twenty grammes [or 28 ounces av., 405 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Mix the fluidextract of ginger and the alcohol, then triturate the liquid in a mortar with the magnesium carbonate and sixty grammes [or 2 ounces av., 51 grains] of the sugar. Then gradually add four hundred and thirty mils [or 14
fluidounces, 259 minims] of water, with constant trituration, and filter. Dissolve the remainder of the sugar in the clear filtrate, with the aid of a gentle heat, strain the syrup while hot, and add sufficient water to make the product measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Syrup of Ginger may also be made in the following manner: Prepare a percolator in the manner described under Syrupus. Pour the filtrate obtained as directed in the preceding formula above the remainder of the sugar, return the first portions of the percolate until it runs through clear, and, when all the liquid has passed, follow it with water, until all of the sugar is dissolved and the product measures one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Mix thoroughly. U. S.

"Ginger, in powder, 25 grammes; Alcohol (90 per cent.), a sufficient quantity; Syrup, sufficient to produce 1000 millilitres. Prepare fifty millilitres of a strong tincture of the Ginger by the process of percolation with the Alcohol. To this add sufficient of the Syrup to produce the required volume." Br.

The U. S. P. process has been improved by the addition of magnesium carbonate as an aid in distributing the resinous fluidextract so as to facilitate its solution in water. It is practically a return to the U. S. 1870 method.

The British syrup, being made by the simple incorporation of the tincture with syrup, has of course all the strength of the ginger, but is inferior to the U. S. preparation in appearance and flavor. The old plan of using water as the menstruum for the drug has been abandoned, as the syrup thus made is encumbered with mucilage and starch, and consequently rendered more liable to decomposition. In order that the preparation may be of the proper strength, it is necessary that the fluidextract should have been made with the best ginger and with the official menstruum. The syrup of ginger is much used as a warm stomachic addition to tonic and purgative infusions or mixtures, and to impact flavor particularly to carbonic acid water.

Dose, one to four fluidrachms (3.75-15.0 mils).
Tacamahac. Tacamahaca.—These names are applied to a resinous substance which is sometimes substituted for or admixed with Elemi resin. There are two classes of these products: (1) one having an odor resembling Elemi and including the East Indian Tacamahac which is probably obtained from Calophyllum Inophyllum L. (Fam. Guttiferae), and Bourbon Tacamahac, obtained probably from C. Tacamahaca Willd. The West Indian and East Indian Resin Anime is a product of one of the Burseraceae; (2) a second class having an odor of incense and including Cayenne Incense, obtained probably from Icica heptaphylla Aubl. (now Protium heptaphyllum March. (Fam. Burseraceae), a West Indian Tacamahac obtained from Protium heptaphyllum and related species. There are also several gums and resins of this same character which are obtained from Bursera gummitifera L. and other plants of the Burseraceae. The resinous substance derived from Bursera tomentosa Triana, a tree of considerable size, of the Fam. Burseraceae, growing in the island of Curacoa and in Venezuela, is in irregularly shaped pieces of various sizes. The color is usually light yellowish or reddish-brown, but in the larger masses is more or less diversified. The pieces are in general translucent, though frequently covered with powder upon their surface, so as to render them apparently opaque. They are heavier than water, brittle, and pulver-izable, yielding a pale yellow powder. Their odor is resinous and agreeable, their taste bitter, balsamic, and somewhat acrid. Exposed to heat, they melt and exhale a stronger odor. Tacamahac ia partially soluble in alcohol, and completely so in ether and the fixed oils. It consists of resin with a little volatile oil.

The East Indian tacamahac and called tacamahaca orientale, or tacamahac in testis, comes into the market in gourd shells covered with rush leaves. It is of a pale yellow color inclining to green, slightly translucent, soft, and adhesive, of an agreeable odor, and an aromatic bitterish taste. It is at present very rare in commerce. The tree which yields this resin produces a drupe, about as large as a plum, from the seeds of which 50 per cent. of a greenish-yellow fixed oil is obtained by expression, which is used in India for lamps, and as a local application in the itch. (J. P. C; 1861, 23.) Guibourt describes several other varieties of tacamahac, which, however, are little known. Among them is a soft, adhesive, dark, green oleo-resin (J. P. C., 3e ser., xxiv, 396), said to be procured from the Calophyllum Tacamahaca Willd., growing in the islands of Reunion and Madagascar. (See also Pennetier, Matières Premières, 642.)
Tacamahac was formerly highly esteemed as an internal remedy, but is now used only in ointments and plasters. Its properties are analogous to those of the turpentines. It is sometimes used as incense.

**Tachia.** Tachia guianensis Aubl.—The root of this tree (Fam. Gentianaceae), is used under the name of Caferana, in Brazil, as an antiperiodic and tonic. According to Peckoldt it contains an organic, crystalline substance, caferanine. (See Merck's Bericht, 1889; also Ber. d. Chem. Ges., 1899, No. 7.)

**TAMARINDUS. Br.**

**TAMARIND**

"Tamarinds are the fruits of Tamarindus indica, Linn., freed from the brittle outer part of the pericarp and preserved with sugar." Br. The preserved pulp of the fruit of Tamarindus indica Linne (Fam. Leguminosae)." N. F.

The tamarind tree {Tamarindus indica) is the only species of this genus. It rises to a great height, sends off numerous spreading branches, and has a beautiful appearance. The trunk is erect, thick, and covered with a rough, ash-colored bark. The leaves are alternate and pinnate, composed of many pairs of opposite leaflets, which are almost sessile, entire, oblong, obtuse, unequal at their base, about half an inch long by a sixth of an inch broad, and of a dark-green color. The flowers, which are in small lateral racemes, have a yellowish calyx, and yellow petals beautifully variegated with red veins. The fruit is a broad, compressed, reddish ash-colored pod, much curved, from two to six inches long, with numerous brown, flat, quadrangular seeds, contained in loculi formed by a tough membrane. Exterior to this membrane is a light-colored acid pulpy matter, between which and the shell are several somewhat branched tough ligneous strands, running from the stem to the extremity of the pod, the attachment of which they serve to strengthen. The shells are fragile and easily separated.

The tree appears to be a native of the East and West Indies, Egypt, and Arabia, though believed by some to have been imported into America. Barth, the African traveller, found it abundant in the interior of Africa.
De Candolle was doubtful whether the East and West India trees are of the same species. It is stated by writers that the pods of the former are much larger than those of the latter, and have a greater number of seeds, the East India tamarinds containing six or seven, those from the West Indies rarely more than three or four; but this seems not to be correct.

Calcutta appears to be the chief emporium for the tamarinds of the European markets. Tamarinds are also sent from the West Indies and Ecuador to England; when from this source they are preferred. The latter are known as American tamarinds, and are obtained from *T. indica*, var. *occidentalis* Gartn. They are of a light brown color, less cohesive and possess less acidity than the tamarinds from the Old World. Tamarinds are brought to us chiefly from the West Indies, where they are prepared by placing the pods, previously deprived of their shells, in layers in a cask, and pouring boiling syrup over them. A better mode, sometimes practised, is to place them in stone jars, with alternate layers of powdered sugar. They are said to be occasionally prepared in copper boilers. In the East Indies tamarinds are often prepared for market by stripping off the outer shell and pressing the pulpy interiors into a mass; sometimes they are packed as in the West Indies.

**Properties.**—Fresh tamarinds, which are sometimes, though rarely, brought to this country, have an agreeable, sour taste, without any mixture of sweetness. In the United States they are usually met with only in the preserved state, this is a dark-colored adhesive mass, consisting of syrup mixed with the pulp, membrane, strong, somewhat branching fibres or string-like strands, and seeds of the pod, and having a sweet acidulous taste. The brown, flattish, quadrangular seeds, each enclosed in a tough membrane, should be hard, clean, and not swollen, the string-like fibers tough and entire, and the odor without mustiness. Tamarind is officially described as "a reddish-brown, moist, sugary mass, containing strong branched fibres, and brown, shining seeds, each enclosed in a tough membrane. Taste agreeable, subacid. The pulp yields no characteristic reactions for copper." Br.

"A pulpy mass of a light reddish-brown color, changing with age to a dark brown, containing some branching fibers and numerous reddish-brown, smooth, oblong or quadrangular, compressed seeds, each enclosed in a tough membrane. Odor distinct; taste sweet and agreeably add." N. F.
From the analysis of Yauquelin, it appears that in 100 parts of the pulp of tamarinds, independently of the sugar added to them, there are 9.40 parts of citric acid, 1.55 of tartaric acid, 0.45 of malic acid, 3.25 of potassium bitartrate, 4.70 of gum, 6.25 of pectin, 34.35 of parenchymatous matter, and 27.55 of water. K. Muller, after analyzing nine commercial varieties, states that only traces of citric and malic acids are present, but that tartaric acid and acid potassium tartrate are present in considerable amount. Copper may often be detected in preserved tamarinds, derived from the boilers in which they are prepared. Its presence may be ascertained by the reddish coat which it imparts to the blade of a spatula or other steel implement immersed in the tamarinds.

**Uses.**—Tamarinds are laxative and refrigerant, and infused in water form a highly grateful drink in febrile diseases. Convalescents often find the pulp a pleasant addition to their diet, and useful when a laxative action is desirable. It is sometimes prescribed in connection with other mild cathartics. Though frequently given with infusion of senna to cover its taste, it is said to weaken its purgative power, and the same observation has been made of its influence upon the resinous cathartics in general. For a formula for fluidextract of tamarind, see Nat. Drug., 1892, 101.

Dose, from a drachm to an ounce (3.9-31 Gm.).

**Off. Prep.**—Confectio Sennae, Br., N. F.

**Tanghinia.** Ordeal Bean of Madagascar.—Tanghinia venenifera Poir. (Cerbera Tanghin Hook.) (fam. Apocynaceae), has been investigated, and, according to C. E. Quinquaud, is both a respiratory and a cardiac poison. (C. R. A. S., cl, 534; see also T. G., vol. ii, 610.) The active principle, tanghinin, occurs in colorless lustrous scales, efflorescing in the air, having a bitter and sharp taste, soluble in alcohol, ether, and acetic acid.

**Tang-kui or Man-mu.**—Under the name of tangkui the Chinese have used for a long time a root obtained from some umbelliferous plant closely allied to the Levisticum officinale, which, according to Lezenius (Ph. Centralh., 1910, p. 221), is probably from the Ligusticum acutilobum. A fluidextract of this root has been introduced into European medicine under the name of eumenol and is recommended by a number of authors in the treatment of dysmenorrhea and other uterine complaints. The dose of this fluidextract is one table-spoonful three times a day. Bufalini, having searched in vain for an active alkaloid, believes that the activity of the substance depends upon
an ethereal oil.

**Tansy.** Tanacetum. U. S. 1890.—Under this name the U. S. Pharmacopoeia formerly recognized the tops and leaves of the *Tanacetum vulgare* L., a perennial herbaceous plant rising two or three feet in height, which is cultivated in our gardens, although growing wild in the roada and in old fields. It was originally introduced from Europe. It is in flower from July to September.

Tansy was officially described as follows:

"Leaves about 15 Cm. long; bipinnatifid, the segments oblong, obtuse, serrate or incised, smooth, dark green, and glandular; flower-heads corymbose, with imbricated involucre, a convex, naked receptacle, and numerous yellow, tubular florets." U. S., 1890. The odor is strong, peculiar, and fragrant, but much diminished by drying; the taste ia warm, bitter, somewhat acid, and aromatic. These properties are imparted to water and alcohol. According to Leppig (Inaug Dis., Dorpat, 1882), both the flowers and the leaves contain the following constituents: tanacetin, tannic acid (tanacetum-tannic acid), traces of gallic acid, volatile oil, a wax-like substance, albuminoids, tartaric, citric, and malic acids, traces of oxalic acid, a laevogyrate sugar, resin, metarabic acid, parabin, and woody fiber. Of these the most important are the bitter principle tanacetin, to which Leppig gives the formula $C_{11}H_{16}O_4$, and which forms a very hygroscopic, brownish, amorphous mass, easily soluble in alcohol and in water, insoluble in ether. It possesses a taste at first characteristically bitter like willow bark, and then cooling and caustic. The essential oil was investigated by Bruylants (Ber. d. Chem. Ges., xi, 449), according to whom it consisted of a terpene, $C_{10}H_{16}$, boiling at from 155° to 160° C. (311°-3200 F.), of which 1 per cent. only is present, an aldehyde, $C_{10}H_{16}O$, boiling at from 195° to 196° C. (383°-384.8° F.), of which 70 per cent. was obtained, and an alcohol (borneol), $C_{10}H_{18}O$, boiling at from 203° to 205° C. (397.4°-401° F.), of which 26 per cent. was present. Semmler (Ber. d. Chem. Ges., xxv, 3343, 3352, 3513) has specially investigated the constituent boiling at 195° C. (383° F.), and having the composition $C_{10}H_{16}O$. He finds it to be not an aldehyde, but a ketone, and calls it tanacetone. It is identical with the ketone found in sage oil, wormwood oil, and thuja oil. As it was first identified in this last-named oil by Wallach, and named by him thujone, this name is now applied to it to the exclusion of the other. (See also Schim. Rep., April, 1893, and April, 1897; and Gildemeister and Hoffmann, Aetherische Oele)

Tansy adds to the medicinal properties of the aromatic bitters those of an irritant narcotic. It has been recommended in intermittents, hysteria, and amenorrhea, but in this country is little employed in regular practice. The seeds are said to be most effectual as a vermifuge. Tansy has been used to a considerable extent 'as a domestic abortifacient, but is not only very uncertain, but also very dangerous in its action, and has in various cases produced death. The symptoms caused by it have been abdominal pain, vomiting, violent epileptic convulsions often followed by profound coma, dilated pupils, great disturbances of respiration, frequent and feeble pulse, and death, which has been said to be from heart failure, but is probably the outcome of a paralytic asphyxia. The minimum fatal dose can scarcely be considered to have been
positively ascertained, but a fluidrachm (3.75 mils) of the oil is said to have caused death, although recovery in one case occurred after taking half a fluidounce. Tansy tea has also caused death. (For cases, see Am. J. M. S., xvi, xxiii, xxiv; J. P. C; April, 1870; J. A. M. A. xlvii, p. 509.) Post-mortems have been reported in which no inflammation of the gastro-intestinal mucous membranes could be discovered.

The dose of the powder is from thirty grains to a drachm (2.0-3.9 Gm.) two or three times a day; but the infusion is more frequently administered.

**Tapioca.**—Under this name the U. S. P. formerly recognized the starch grains obtained from the bitter cassava (Manihot utilissima Pohl), and the sweet cassava (M. palmata var. Aipi Pohl) (Fam. Euphorbiaceae). The starch is extracted from the thickened root and is known in commerce by the names of Cassava, Tapioca or Manioca Starch, and as Bahia, Rio or Para Arrowroot. The plant is cultivated in Brazil and other parts of tropical America. It is also grown in Florida and other of the Southern States. In the production of the starch from the bitter cassava the hydrocyanic acid which is present in fresh roots is entirely eliminated by the process of washing and drying.

The root of the sweet cassava may be eaten with impunity; that of the bitter, which is the most extensively cultivated, abounds in an acrid, milky juice, which renders it highly poisonous if eaten in the recent state. Henry and Boutron Chalard affirm that the bitter cassava contains hydrocyanic acid (J. P. G., xxii, 119), but Peckdolt claims that its poisonous effects are due to manihotoxine (Ph. Rund., iv, 1890).

The preparation of tapioca in Malacca is thus described by James Collins: The fresh root-stocks are thoroughly washed in tubs in a constant stream of water by the Chinese, and then peeled like turnips; they are then sliced in one machine and pulped in another, the pulp being removed in cane baskets to large wooden frames, with calico bottoms; a powerful stream of water is allowed to fall upon the pulp, a sifting motion being communicated to the strainer; as the starch is washed out, it is received into inclined troughs, and, while in a state of suspension, run into settling vats. There it is stirred and washed, and, while moist, it is removed to the drying room. Two kinds of tapioca are prepared. The flour is made by heating slightly by fires placed underneath; it is constantly stirred and turned over with iron shovels, to prevent agglutination and insure equal drying. Granular tapioca is made as follows: A long range of quallies, or small, shallow iron pans, are slightly tilted forward on ledges of brickwork, and heated with a wood fire. Each operator has a quallie and fire to himself. Taking a quantity of damp starch, he stirs it round and round with an iron shovel, and the heat is sufficient to cause the tapioca to become agglutinated together in small masses, and coated with dextrin. The drying is done with great skill over an open fire. (C. D., 1884.)

Tapioca is in irregular, hard, white, rough grains, possessing little taste, partially soluble in cold water, and affording a fine blue color when iodine is added to its filtered solution. The partial solubility in cold water is owing to the rupture of the starch granules by heat. Examined under the microscope, the granules appear somewhat
plano-convex or bell-shaped and more or less compound. The individual grains vary from 0.006 to 0.030 mm. in diameter and have a distinct central circular or radiating cleft. They polarize light strongly, showing a distinct cross. Tapioca meal, called sometimes Brazilian arrow-root, and by the French moussache, is the fecula dried without heat. Its granules are identical with those already described. Being nutritious, and the same time easy of digestion and destitute of irritating properties, tapioca forms an excellent diet for the sick and convalescent. It is prepared for use by boiling it in water. Lemon juice and sugar are usually grateful additions, and in low states of disease or cases of debility it may be impregnated with wine and nutmeg or other aromatic.

A factitious tapioca is found in commerce, consisting of very small, smooth, spherical grains, and supposed to be prepared from potato starch. It is sold under the name of pearl tapioca.

Cassaripe is the thickened gum obtained from the root of the bitter cassava, which is said to be innocuous and so actively antiseptic as to be habitually used in Brazil for the preservation of meat. According to S. D. Risley (Phila. Med. Journ., 1899), the 10 per cent. ointment of cassaripe is useful in suppurating conjunctivitis and ulcers of the cornea, applied with gentle massage three or four times a day.

**TARAXACUM. U. S. (Br.)**

**TARAXACUM Tarax. [Dandelion]**

"The dried rhizome and roots of Taraxacum officinale Weber (Fam. Compositae). Preserve the thoroughly dried drug in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." U. S. "Taraxacum Root is the fresh root of Taraxacum officinale, Wiggers. Collected in the autumn." Br.

**Taraxaci Radix**, Br., Taraxacum Root; Dandelion Root, Blowball, Milk, Witch, or Yellow Gowan, Lion's-tooth, Cankerwort; Pissenlit, Dent de Lion, Fr. Cod.; Radix Taraxaci cum herba, P. G.; Lowenzahn, G.; Tarassaco, It.; Taraxacon, Diente de Leon, Sp.

The dandelion is an herbaceous plant, with a perennial fusiform root. The leaves, which spring immediately from the short upright rhizome, are long, pinnatifid, generally runcinate, with the divisions toothed, smooth, and of a fine 'green color. The common name of the plant was derived from the fancied resemblance of its leaves to the teeth of a lion. The flower-stem rises from the midst of the leaves, six inches or more in
height. It is erect, simple, naked, smooth, hollow, fragile, and terminated by a large golden-colored flower, which closes in the evening and expands with the returning light of the sun. The involucre is smooth and double, with the outer scales bent downward. The florets are very numerous, ligulate, and toothed at their extremities. The receptacle is flat and naked. The pappus is stipulate, and at the period of maturity is disposed in a spherical form, and is so light and feathery as to be easily borne away by the wind, with the achene attached. Another plant resembling the common dandelion, the achenes of which, however, are narrower and bright red or reddish brown, known as the red-seeded dandelion, is the product of T. erythrospermum, Andrz., and is supposed by some to be naturalized from Europe.

The common dandelion, Taraxacum officinale, grows spontaneously in widely separated parts of the globe. It is abundant in this country, adorning our grass plots and pasture grounds with its bright yellow flowers, which, in moist places, show themselves with the first opening of spring, and continue to appear until near the close of summer. In India the plant is cultivated in various parts of the country, and its root collected for use between the months of September and February. (P. J., Dec. 1871, 523.) All parts of the plant contain a milky bitterish juice, which exudes when they are broken or wounded. The leaves, when very young and blanched by the absence of light during their growth, are tender and not unpleasant to the taste, and are sometimes used as a salad. When older and of their natural color, they are medicinal, but the leaves of the wild plant in various stages of its early growth are used for salads by those who have cultivated a taste for this vegetable. The Pharmacopoeias recognize only the root. It should be full grown when collected, and should be employed in the recent state, as it is then most active. It does not, however, as stated by Duncan, lose nearly all its bitterness by drying, and the root dug up in the warmer seasons might, if dried with care, be employed with propriety in the succeeding winter. The juice of the root is thin and watery in the spring; milky, bitter, and spontaneously coagulable in the latter part of summer and autumn, and sweet and less bitter in the winter when affected by the frost. The months of July, August, and September are, therefore, the proper periods for collecting it.

Henry Barton, of Brighton, England, prepared the juice from the flower-stalks by crushing and pressure, adding 25 per cent. of spirit, and, after allowing it to stand for some weeks in glass bottles, filtering to
separate a very small quantity of deposit, and setting aside for use. According to Barton, it remains bright, and retains its characteristic taste. Though not so rich in solid constituents as the juice of the root, yet, having an equal bitterness, it is probably not less efficacious as a medicine, if it be true, as stated by Bentley, that the efficacy of the medicine does not depend solely on the amount of its solid constituents, but principally if not entirely on the bitter principle it contains. Barton stated that the juice is certainly one of the best preparations of taraxacum. (A. J. P., 1872, p. 509.)

Properties.—The official description of Taraxacum follows: "Cylindrical or somewhat flattened, gradually tapering, usually in broken pieces, from 6 to 15 cm. in length and from 5 to 15 mm. in thickness; externally brown or blackish-brown, longitudinally wrinkled, having numerous root and rootlet-scars; crown simple or branched with numerous leaf-bases showing annulate markings; odor slight or inodorous; taste bitter. Under the microscope, transverse sections of the root of Taraxacum show a porous, pale yellow wood from 1 to 4 mm. in diameter, surrounded by a light brown bark from 2 to 6 mm. in thickness, the latter composed of concentric layers of lacticiferous vessels and sieve tissues, alternating with whitish inulin-bearing parenchyma. The rhizome portions show a small pith. The powder is light brown; when examined under the microscope it exhibits parenchyma cells which are large, thin-walled and contain irregular masses of inulin; fragments with yellowish-brown lacticiferous vessels; trachea; reticulate; intermediate fibers non-lignified, with irregular, simple and oblique pores. Taraxacum yields not more than 10 per cent. of ash." U. S. "Fresh root frequently three decimetres or more long, and twelve millimetres or more thick, smooth and yellowish-brown externally, whitish within. Fracture short, the exposed surface showing a small yellow porous wood, surrounded by a thick nearly white cortex exhibiting a variable number of irregular concentric rings, from which a milky juice exudes. Inodorous; taste bitter." Br.

Taraxacum should be free from the root of Cichorium Intybus Linne, which closely resembles it, but is usually paler, more bitter, and has the milk vessels in radiating lines. The drug consists in part of the rhizome which shows from ten to fifteen fibro-vascular bundles surrounded by the parenchyma-tissue of the pith, the diameter of which in some instances exceeds the thickness of the woody zone several times. In other respects the structure of the rhizome resembles the root, the
concentric' arrangement of the laticiferous ducts in particular excluding any possibility of mistaking the specimens for chicory, etc. (Am. Drug., 1887, p. 2.) The active properties of taraxacum are yielded to water by boiling, and do not appear to be injured in the process. Dragendorff obtained from the root gathered in October and dried at 100° C. (212° F.) 24 per cent. of inulin and some sugar. The root gathered in March from the same place yielded 1.74 per cent. of inulin, 17 of uncrystallizable sugar, and 18.7 of levulin. This last-named substance, discovered by Dragendorff, has the same composition as inulin, but dissolves in cold water, and is devoid of any rotatory power. Mannite, which has been found in the infusion of the root, has been demonstrated by Smith, of Edinburgh, not to pre-exist in the root, but to be formed by spontaneous changes consequent on exposure.

A crystallizable principle has been extracted from the juice of the root by Pollex, who has named it taraxacin. It is bitter and somewhat acrid, fusible, but not volatile, sparingly soluble in cold water, but very soluble in boiling water, alcohol, and ether. It is obtained by boiling the milky juice in distilled water, filtering the concentrated liquor, and allowing it to evaporate spontaneously in a warm place. The taraxacin crystallizes, and may be purified by repeated solution and crystallization in alcohol or water. Kromayer (A. Pharm. (2), cv, 6) also obtained taraxacin, and, in addition, a second crystalline principle, taraxacerin, C₈H₁₆O, insoluble in water, but soluble in alcohol. According to Vogel, the infra-cellular substance of the root consists chiefly of pectose, which is the result of a metamorphosis of the substance constituting the membrane of the cells. L. E. Sayre found that the yield of taraxacin varies in roots collected at different seasons. (See Proc. A. Ph. A., 1893, 1894, 1895, 1896, 1897.)

F. B. Power (C. D., 1912, p. 822) contributed the results of some investigations of this drug, in which he states that besides inulin, resin and sugar, no definite substances have previously been isolated. The taraxacin of Polex (1839), and the taraxacerin of Kromayer (1861), to which was assigned the formula C₄₀H₈₀O₅, are both alleged to be definite mixtures. Power found in the air dried English root, an enzyme, essential oil, oily resin, fatty acids, including melissic, and p-hydroxy-phenylacetic acid, which had never before been isolated from a plant.

The roots of various plants have been largely substituted for dandelion in England and on the Continent by the herb gatherers, and we are
informed that fraudulent substitution is not unfrequent, in this country, of the root of Cichorium Intybus, or chicory. It is rare to find chicory mixed with dandelion, the former being usually boldly substituted for the latter.

**Uses.**—Taraxacum was formerly supposed to possess cholagogic as well as diuretic powers. It has been used in various conditions accompanied with congested or torpid liver. There is, however, no sufficient reason for believing it possesses any therapeutic virtues. The dried root is sometimes mixed, in powder, with ground coffee, the taste of which covers that of the dandelion. It is roasted and powdered and then prepared in the same manner.

Dose, one to three drachms (3.9-11.6 Gm.).

**Taxus.** Taxus baccata L. Yew Tree (cornmun, Fr. Eibe, G. (Fam. Taxaceae)—The fruit of this handsome evergreen appears to be a deadly poison. In a fatal case the child was found semi-comatose, with convulsions, a cold and clammy skin, difficult respirations, dilated pupils, and making attempts at vomiting. The poison is probably in the seeds. (See 16th edition, U. S. D.; also James Thompson, L. L., 1868, 530. For fatal cases in adults, see M. T. G., 1870, ii; also L. L.; 1870, 471; also P. J. viii, 361.) W. Marme obtained from yew seeds and leaves an alkaloid, $C_{37}H_{51}NO_{10}$, to which the name of taxine has been given. It was a white, poisonous, crystalline powder, only slightly soluble in water, easily soluble in ether, alcohol, chloroform, benzene and carbon disulphide, but not in petroleum benzin. It fused at 80° C. (176° F.). With concentrated sulphuric acid it gave a red color, but dissolved without color in nitric and phosphoric acids. (A. J. P., 1876, 353.) For Vreven’s method of isolating taxine, see P. J. 1806, 215. Amato and Capparelli (Gazz. Chim., x, 349) prepared from the leaves a volatile alkaloid, which was soluble in cold sulphuric acid with yellow color, becoming red on heating. They also isolated a nitrogenous crystalline and colorless principle, fusing at from 86° to 87° C. (186.8°-188.6° F.), soluble in alcohol, insoluble in water, named milossin.

Lefebvre (A. Pharm., ccxiv, 486) has isolated from the twigs of the yew a crystalline glucoside to which he gives the name "taxicatin." It had the formula of $C_{13}H_{22}O_{7} + 2H_{2}O$ and a melting point of 165° C. (329° F.).

**Tayuya.**—The root of the Dermophylla (Cayaponia) pendulina Manso (Fam. Cucurbitaceae), is used in Brazil, under the name of tayuya, in syphilis, etc. (N. R., 1877, 234); also, under the same name, the root of the Trianosperma ficifolia Mart.
Cayaponia Martiana Cogn.), also of the Fam. Cucurbitaceae (P. J., x, 667), and probably various other roots. In C. ficifolia Cogn. two alkaloids, trianospermine and trianospermitine, and a bitter principle, tayuyin, have been found by Peckoldt (P. J., x, 667), and in T. dermophylla a green resin, bitter extractive, and tannic acid were found by the same investigator. (B. G. T., Ixxxiv, xci. See also Proc. A. Ph. A., xxiv.)

Tea. Thee, Fr. Thee, G.—The plant which furnishes tea—Thea sinensis L. (Fam. Theáceae) — is an evergreen shrub. It has numerous alternate branches, furnished with elliptical-oblong or lanceolate, short petiolate, pointed leaves, which are serrate except at the base, smooth on both sides, green, shining, pinnately veined and having a prominent midrib. They are two or three inches long, and from half an inch to an inch in breadth. The flowers are either solitary or supported, two or three together, at the axils of the leaves. They are of considerable size, not unlike those of the myrtle in appearance, consisting of a short green calyx with five or six lobes, of a corolla with from four to nine large unequal snow-white petals, of numerous stamens with yellow anthers and connected at their base, and of a pistil with a three-parted style. The fruit is a three-locular and three-seeded capsule.

There are two principal varieties of T. sinensis, viz. viridis L., which is a large spreading shrub, having light green lanceolate leaves from 12 cm. long to 4 cm. wide; and a second variety, Bohea L., which is an upright shrub with dark-green elliptical leaves 6 cm. long and 3 cm. wide. The flowers of the latter occur in groups of two or three, whereas in viridis they are single. There are a great many varieties of tea, on the market, and their trade value is influenced by the peculiarities of mother plant and climate and the degree of ripeness and preparation of the leaves. As a rule only the youngest leaves are gathered. The so-called black and green teas are due to the method of preparation of leaves. In the first the chlorophyll is destroyed, whereas in the latter it is unaffected. Winton gives the following characters as common to all tea leaves: "The firm, rather thick texture; the glossy upper surface; the short stem into which the base of the leaf tapers; the thick margins, rolled a little towards the inner surface, with cartilaginous teeth; the veins which branch from the midrib, at angles usually greater than 45 degrees, and at some distance from the margin form loops uniting adjoining ribs. The teeth on the margin of the leaf are shrunken multicellular glands which break off readily from the old leaves." (For discussion of microscopical characteristics, see Winton and Moeller, "The Microscopy of Vegetable Foods."

The tea plant is a native of China and Japan, and is cultivated in both countries, but most abundantly in the former. It has been more recently cultivated in India (Assam), Ceylon, Java and in South Carolina. In Japan it forms hedge rows around the rice and corn fields; in China, whence immense quantities of tea are exported, whole fields are devoted to its culture. It is propagated from the seeds. For particulars as to the cultivation of tea, see P. J., 1871, 386.

(An elaborate article on tea, with methods of cultivation, etc., by Win. B. Marshall, U. S. Nat. Museum, will be found in A. J. P., 1903, p. 79.)

The odor of the tea leaves themselves is very slight, and it is customary to mix with
them the flowers of certain aromatic plants, as those of the orange, different species of jasmine, the rose, Osmanthus fragrans Lour. (Olea fragrans Thumb.), of the Oleaceae, and Camellia Sasanqua (Thumb.?), in order to render them pleasant to the smell. The flowers are afterwards separated by sifting or otherwise. (See P. J., xv, 112.) Under the name of flowers of tea was at one time sold a waste product consisting of the hair of young leaves, but the flowers themselves have been used to make a beverage. (P. J., lxxi, p. 453.)

Bush Tea and Honig Thee, used at Cape Colony, South Africa, as a substitute for tea, are the dried leaves and tops of several species of Cyclopia, among which are C. subternata Vog., C. latifolia DC., C. genistoides Vent. and C. sessiliflora Eckl. and Zeyh. (Fam. Leguminosae.) According to the analysis of Henry G. Greenish, they do not contain theine, but a glucoisidal body, cylopin, C\textsubscript{25}H\textsubscript{28}O\textsubscript{13}. (P. J.; xi, 549.)

The United States imported in 1915, 96,987,942 pounds of tea, valued at $17,512,619. The largest consumer is the United Kingdom, which in 1914 took 317,664,000 pounds, and the next Russia, which took 166,064,003 pounds. Numerous varieties exist in commerce, differing in the shape communicated by rolling, in color, in flavor, or in strength; but they may be all arranged in the two divisions of green and black teas, which, at least in their extremes, differ so much in properties that it is difficult to conceive that they are derived from the same species.

Under the name of tea oil there has appeared in the London markets a Chinese fixed oil said to be derived from Camellia drupifera Lour. [C. oleifera Wall.], a detailed description of which, with tests, may be found in the P. J., vol. xvi, 634. A similar oil is prepared in Japan from the seeds of Camellia japonica L. (Ibid., 637, 764.)

Green tea is characterized by a dark green color, sometimes inclining more or less to blue or brown. It has a peculiar, refreshing, somewhat aromatic odor, and an astringent, slightly pungent and agreeably bitterish taste. Its infusion has a pale greenish-yellow color, with the odor and taste of the leaves. According to Warington, who examined numerous varieties of tea carefully, both by the microscope and chemical tests, many of the green teas imported into Great Britain owe their color to a powdery coating, consisting of calcium sulphate and Prussian blue; others to a mixture of these with a yellowish vegetable substance; and others, again, to calcium sulphate alone. (P. J., iv, 37.)

Black tea is distinguished by a dark brown color. It is usually less firmly rolled and lighter than the green, and contains the petioles of the plant mingled with the leaves. Its odor is fainter, and of a somewhat different character, though still fragrant. Its taste, like that of green tea, is astringent and bitterish, but is less pungent, and to many persons less agreeable. To hot water it imparts a brown color, with its sensible properties of taste and odor. These vary exceedingly in degree in the different varieties, and some black teas are almost wholly destitute of aromatic or agreeable flavor. According to Blyth, green tea is prepared from young leaves which are roasted over a wood fire within an hour or two after being gathered; while the black tea leaves, on the other hand, are allowed to lie in heaps for ten or twelve hours after they have
been plucked, during which time they undergo a sort of fermentation; the leaves then pass through certain processes, and are slowly dried over charcoal fires. (Wynter Blyth, *Foods, Composition and Analysis*, 1903.) A sophisticated tea is largely exported from China, consisting of powdered tea mixed with sand and other earth, and agglutinated with gum; that which is to pass for black being colored with plumbago, and the green with the coating above referred to. On analysis, these teas were found to afford from 35 to 45 per cent. of ashes, while the genuine yields only 5 per cent. A very full account of the adulteration of tea and the methods for the detection of the same may be found in Allen, *Cow. Org. Anal.*, 2d edition.

The analyses below by Y. Kozai (Bulletin No. 7, Imperial College of Agriculture, Japan) have a special value, owing to the author’s knowledge of tea manufacture. Unusual precautions were taken in sampling the leaves, to insure strictly parallel specimens being taken. The figures refer to the moisture-free leaves in each case.

Rochleder found also a peculiar acid, which he calls boheic acid, $C_7H_{10}O_6$. According to Stenhouse, the tannin of tea, though always accompanied by a little gallic acid, differs essentially from that of galls; not being, like it, a glucoside, but yielding, under the influence of sulphuric acid, a dark brown substance, almost insoluble in water. (See A. J. P., 1862, 254.) For article on the methods of analysis of tea and a series of analyses of different varieties, see A. J. P., 1887, 626. The volatile oil is citron-yellow, lighter than water, has a strong odor of the tea plant, solidifies easily by cold, and resinsifies on exposure to air. It is probably one of the principles upon which depend the effects of tea upon the nervous system. Hence old teas are less energetic than the recently imported; and it is said that the fresh leaves have often produced dangerous effects in China. Nevertheless, the tannic acid is not without influence upon the system; and it is not improbable that the extractive contributes to the peculiar influence of this valuable product. Of these active ingredients, the volatile oil, tannic acid, and extractive are found most largely, according to the analysis of Mulder, in the green tea. Théine, $C_8H_{10}N_4O_2$, is a crystallizable principle discovered by Oudry. It was afterwards proved by Jobst to have the same composition as caffeine (see page 247). Kossel discovered, in 1888, a related principle, theophylline (dimethylxanthine), but only in very small amounts. It is now made synthetically and is official.

The proportion of théine found in tea varies considerably, the general range being...
from three to four per cent. India and Ceylon tea usually contain slightly more than
four per cent.

Tea is astringent and gently excitant, and exerts a decided influence over the nervous
system, evinced by the feelings of comfort and even exhilaration which it produces,
and the unnatural wakefulness to which it gives rise when taken in unusual
quantities or by those unaccustomed to its use. It is almost exclusively used as a
beverage. Taken moderately, and by healthy individuals, it may be considered as
practically harmless; but long continued in excessive quantity it is capable of inducing
unpleasant nervous and dyspeptic symptoms. Green tea is decidedly more injurious in
these respects than black, and should be avoided by dyspeptic individuals, and by
those whose nervous systems are peculiarly excitable. It is rarely used as a medicine,
but the infusion is popularly employed to relieve neuralgic headaches.

**Telfairia Pedata** Hook. (Fam. Cucurbitaceae.) —The seeds of this East African
plant yield a deep yellow fragrant oil, of specific gravity 0.918, containing telfairic
acid. (Chem. Zeit. R., xxiv, 24.)

Hoary Pea. Devil's Shoestring. Tephrosie, Fr., G. (Fam. Legummosae)—Several
species of Cracca and Tephrosia are employed in different parts of the world, though
unknown in general commerce. They are leguminous plants, shrubby or herbaceous,
with odd-pinnate leaves and white or purplish racemed flowers. They are generally
possessed of cathartic properties, their leaves or roots being employed. Plugge (Proc.
A. Ph. A., 1897, 560) examined the root of *T. macropoda* and found a poisonous active
principle, not identical with cytisine.

Hanriot isolated from *T. vogelii*, a crystalline principle, tephrosin, which occurs in
small glistening crystals which are almost insoluble in water, slightly soluble in
alcohol or glycerin, more readily soluble in acetone, and freely soluble in chloroform.
Its formula is $C_{34}H_{26}O_{10}$. Tephrosal, $C_{10}H_{16}O$, is a volatile, aromatic liquid, slightly
soluble in water, more readily soluble in alcohol, ether, benzin, and chloroform. (T. C.,
li, 302."

Tephrosiavirginiana L. grows in most parts of the Eastern United States. It is a foot
or two high, with pubescent stems and leaves and handsome terminal flowers. (See
Griffith's Med. Bot., 237.) The roots, which are slender, long, and matted, are tonic and
aperient, and are said to have been used by the Indians as a vermifuge, given in the
form of decoction.

According to Holmes (P. J., 1910, lxxiv) the *T. vogelii* is used in Africa as a fish
poison. Its toxicity seems to be due to the neutral principle, tephrosin. There is no
evidence as to its noxiousness for human beings.
TEREBINTHINA CANADENSIS. Br.

CANADA TURPENTINE

“Canada Turpentine is the oleo-resin obtained from Abies balsamea, Mill." Br.

Canada Balsam, Balsam of Fir; Balsamum Canadense; Baume du Canada, Fr. Cod.: Terebenthine du Canada, Fr.; Canadischer Terpentin, G.

The term turpentine is usually applied to certain vegetable juices, liquid or concrete, which consist of resin combined with a peculiar volatile oil, called oil of turpentine. They are generally procured from different species of pine, fir, or larch, though other trees afford products which are known by the same general title, as, for instance, Pistacia Terebinthinus L., which yields the Chian turpentine. Some French writers extend the name of turpentine to other juices consisting of resin and essential oil, without benzoic or cinnamic acid, as copaiba, balm of Gilead, etc. We shall describe particularly, in this place, the turpentines which are either now official or have recently ceased to be so. A brief botanical view of the plants from which they are respectively derived will be in accordance with the plan of this work. It is proper to observe first that the family Coniferae includes about three hundred and fifty species. These may be divided into two sub-orders, as Engler and Pranti suggest—viz., Pinoidae and Taxoidae. Lindley had previously recommended a similar sub-division, but considered each subgroup as deserving of family rank, and gave them the names Pinaceae and Taxaceae, which is commonly followed by the authors of Manuals of Botany. The Pinoidae may be further subdivided into the (A) Abietinae, including Araucaria, Pinus, Cedrus, Larix, Picea, Tsuga, Abies, Sequoia, Taxodium, etc.; and (B) Cupressinae, which include Thuja, Juniperus, etc. The Taxoidae include Ginkgo, Taxus, etc.

The genus Pinus is represented by about seventy species, which are widely distributed throughout the northern hemisphere of both continents. The principal centers of distribution of the species of this genus are in the Western United States (twenty-five species), Eastern United States (thirteen species), and the highlands of Mexico. It is one of the most important genera from an economic standpoint. The following species yield valuable timber: P. palustris, P. Strobus, P. echinata, P. Lambertiana, P. ponderosa, P. monticola, P. heterophylla,
P. sylvestris, P. Laricio, P. nepalensis, P. Thunbergii, and P. densiflora. Turpentine is obtained chiefly from the Eastern American P. palustris and P. heterophylla; it is also obtained from P. Pinaster and P. halepensis of the Mediterranean basin, and from the Himalayan P. Roxburghii. The edible seeds (Pine Nuts) of several species yield important articles of human food, the best being produced by the nut pines of Western North America, by P. pinea of the Mediterranean, P. Cembra of Europe and Asia, and P. gerardiana of Northwestern India. Pine wool, a coarse fiber manufactured from the leaves of P. Laricio, P. sylvestris, and other European species, is used to stuff mattresses and cushions, and woven with animal wool, is made into hospital and military blankets and into underclothing which are reputed to possess medicinal properties. In the Southern United States carpets are woven from the leaves of P. palustris. The bark of several species contains sufficient tannin to make them valuable for tanning leather.

1.—Pinus palustris Mill. (P. australis Michx. f.).—The names by which the tree is known in the Southern States are long-leaved pine, yellow pine, Southern pine, hard pine, Virginia pine, and pitch pine; but the first is the most appropriate. The leaves occur three in a group, being from ten to fifteen inches long, subtended at the base by a conspicuous scaly sheath from one to one and a half inches long. The leaves are crowded at the ends of the branches. The cones are terminal, conical, and armed with a short recurved spine.

This pine is a very large indigenous tree, growing in dry, sandy soils, from the southern part of Virginia to the Gulf of Mexico. Its mean elevation is sixty or seventy feet, and the diameter of its trunk about fifteen or eighteen inches for two-thirds of its height. The leaves are about a foot in length, of a brilliant green color, and united in bunches at the ends of the branches. This tree furnishes by far the greater proportion of the turpentine, tar, etc., consumed in or exported from the United States. (See Pix Liquida.)

2.—Pinus Taeda L.—This is the loblolly or old field pine of the Southern States. "Leaves in threes, elongated, with elongated sheaths; strobiles oblong-conical, deflexed, shorter than the leaf; spines inflexed."

It is abundant in Virginia, where it occupies the lands exhausted by cultivation. It exceeds eighty feet in height, has a trunk two or three feet in diameter, and expands into a wide spreading top. The leaves are
about six inches long, and of a light green color. It yields turpentine in abundance, but the quantity is less than that which flows from the preceding species.

3.—Pinus sylvestris L. Scotch Pine, Norway Pine, Scotch Fir.—Leaves in pairs, rigid; stro-biles ovate-conical, of the length of the leaves; scales linear-oblong, the ends much thickened, their exposed parts (apophysis) oblique, rhom-boidal, with a transverse ridge and central tubercle.

This tree, when of full size, is eighty feet high, with a trunk four or five feet in diameter. It inhabits Scotland and the northern and mountainous parts of Europe. It yields a considerable proportion of the common European turpentine.

4.—Pinus Pumilio Haenke (P. montana Mill.).—This pine is known in gardens under several names which are given to the forms occurring in the different mountain ranges over which it is spread. Beissner, in his Handbuch der Nadelholzkunde, considers P. Pumilio Haenke, a synonym of P. montana, Mill., whereas in the Index Kewensis the latter is brought under the former. Most authors agree with De Candolle and Beissner in bringing P. Pumilio Haenke, under P. montana Mill. The latter is a small tree, with decumbent or knee-like more or less erect branches, which are covered with a dark colored persistent bark. The leaves occur two in a sheath, each of which is from one to two inches long, straight, or scythe-shaped, with obtuse apex; both sides are dull green and slightly glaucous. The cones are ovoid, about one and a half inches long, with a pyramidal protuberance on each scale on the outer or exposed side. It is found in the sub-alpine regions of Central Europe at elevations between 4000 and 8000 feet; also on the Carpathian Mountains at from 4000 to 5500 feet. From its branches by spontaneous exudation or by cutting off their ends, Hungarian balsam is obtained. A volatile oil is obtained from its leaves (see Oleum Pini Pumilionis).

Pinus Pinaster Solan der (P. maritima Poir.), which is found in the southern and maritime parts of Europe, yields much of the turpentine, pitch, and tar consumed in France, and is admitted among the official plants in the French Codex. Pinus Lambertiana of California, produces by exudation a saccharine matter which has been found to contain a peculiar sweet principle called pinite. (C. R. A. S., Sept., 1855.) Pinus Sabiniana Dougl., known as nut-pine or digger-pine (because the nut is largely consumed by the Digger Indians), yields, on being notched, a
turpentine whose volatile oil is extensively used in California under the name of abietene. The Pinus rigida, or pitch pine of this country, and probably others besides those mentioned, are sometimes employed in the preparation of tar. Pinus Teocoty Cham. et Schlecht., yields a turpentine known as Mexican or Brea turpentine, which is used in Mexico.

ABIES.—The genus Abies is represented by about twenty-three species, which are distributed in the New World from Labrador and the valley of the Athabasca River to the mountains of North Carolina and from the mountains of Alaska to the highlands of Guatemala, and in the Old World from Siberia and the mountains of Central Europe to Southern Japan, the Himalayas, Asia Minor, and the mountains of Northern Africa. The species of this genus yield soft, perishable woods and balsamic exudations, which are employed in medicine and the arts.

Abies balsamea (L.) Mill., (A. balsamifera Michaux).—"Leaves solitary, flat, emarginate or entire, glaucous beneath, somewhat pectinate, sub-erect above, recurved spreading; cones cylindrical, erect; bracts abbreviate, obovate, conspicuously mucronate, sub-serrulate."

This is the American silver fir, or balm of Gilead tree, inhabiting Canada, Nova Scotia, Maine, and the mountainous regions farther south. It is an elegant tree, seldom rising more than forty feet, with a tapering trunk, and numerous branches, which diminish in length in proportion to their height and form an almost perfect cone. The leaves are six or eight lines long, inserted in rows on the sides and tops of the branches, narrow, flat, rigid, bright green on their upper surface, and of a silvery whiteness beneath. The cones are large, erect, nearly cylindrical, of a purplish color, and covered with a resinous exudation, which gives them a glossy, rich, and beautiful appearance. It is from this tree that the Canada balsam is obtained.

Several other species of Abies are important. The A. Picea Lindl. (Abies pectinata of De Candolle, Pinus picea of Linnaeus), or European silver fir, growing in the mountainous regions of Switzerland, Germany, and Siberia, yields the Strassburg turpentine (Terebenthine d'Alsace or des Vosges), which is much used in some parts of Europe. By the distillation of its cones with water it also affords a variety of oil of turpentine called in France essence de templine. By boiling the young branches of the allied Picea Mariana (Mill.), B. S. P. (Pinus nigra Link.), or blade or bog spruce of this country, and evaporating the decoction, the essence of
spruce is prepared. It is a thick, molasses-like liquid, with a bitterish, acidulous, astringent taste, and is used for making spruce beer. (See U. S. D., 19th edition, page 1244.)

Abies Fraseri Lindley.—This species, commonly called double fir, occurs at high elevations in the mountains of Tennessee and North Carolina. The tree is noted for its hardiness, and is used for ornamental purposes. It is also said to have been used to furnish a balsam of fir similar to that obtained from A. balsamea, but the data concerning this are obscure.

Russian White Pitch, "belji var," "Sos nowaja Smold," which probably derived from the Siberian Fir, Abies Pichta Forb. (Picea obovata Ledeb.), contains, according to A. Tschirch, two free resin acids, the amorphous, beljiabiennic acid, C_{13}H_{20}O_{2}, and the crystalline, belpiabietinic acid besides belpiresene, C_{13}H_{36}O and an essential oil. (A. Pharm., Nov., 1902.)

LARIX.—The genus Larix has eight recognized species, which are now widely distributed over the sub-arctic and mountainous regions of the northern hemisphere, ranging from the Arctic Circle to the mountains of Pennsylvania in the New World and to latitude 30° in the Old World. The species produce hard, durable, valuable timber; turpentine, which is sometimes used in medicine; tar; bark rich in tannin; and a peculiar manna-like substance.

Larix decidua Mill. (Larix europaea De Cand.).—"Leaves fascicled, deciduous; cones ovate-oblong; margins of the scales reflexed, lacerated; bracts panduriform." The European larch is a large tree inhabiting the mountains of Siberia, Switzerland, Germany, and the east of France. It yields the Venice turpentine of commerce, and a peculiar sweetish substance called in France Briancon manna, which exudes spontaneously and concretes upon its bark. When the larch forests of Russia take fire, a juice exudes from the trunk during their combustion, which concretes and is called Orenburg gum. It is wholly soluble in water.

Coniferin is a term which has been given to a principle discovered by Hartig in the cambium of several of the Coniferae. The species in which it has been found are Pinus Strobus and P. Cembra, Picea Abies and A. pectinata, and Larix Europaea, and it probably exists in many others. It is obtained by removing the outer bark, scraping the cambium from the
surface of the "wood, subjecting this to pressure, boiling the viscid juice to coagulate the albuminous substances, filtering, and evaporating the filtered liquid to one-fifth of its volume. The coniferin is deposited in crystals. The mother-water is very sweet, and contains a saccharine substance closely allied to cane sugar. The crystals are purified by dissolving them in water, decolorizing by animal charcoal, and finally crystallizing from weak alcohol. Coniferin was chemically examined by M. W. Kubel, and later by Tiemann and Haarmann, who proved that it is a glucoside and as crystallized from the juice has the composition \( \text{C}_{16}\text{H}_{22}\text{O}_{8} + 2\text{H}_{2}\text{O} \). When treated with dilute acids or ferments it is decomposed as follows: \( \text{C}_{16}\text{H}_{22}\text{O}_{8} + \text{H}_{2}\text{O} = \text{C}_{6}\text{H}_{12}\text{O}_{6} + \text{C}_{10}\text{H}_{12}\text{O}_{3} \). When this latter compound is oxidized (or coniferin itself) by potassium dichromate and sulphuric acid, vanillin is obtained, \( \text{C}_{6}\text{H}_{3} - \{\text{OH}\} \text{CH}_{3} \) \( \text{OCH}_{3} \cdot \text{CHO} \). Vanillin has been thus made commercially, but is now made preferably from the eugenol of oil of cloves or from benzoin.

In Japan, the exudation from the Pinus densiflora Sieb. et Zucc., and that from the Pinus Thunbergii Parl. are used under the respective names of akamatsu and kuromatsu. They are said to contain about 18 per cent. of oil and 81 per cent. of resin. The distilled oil is bright and colorless, having an odor somewhat different from that of the European oil of turpentine. It boils at from 155° to 156° C. (311°-312.8° F.), and has a specific gravity of a little under 0.87. Its index of polarization is from 55° to 61° (dextrogyrate). The resin cannot be distinguished from the European. A turpentine closely resembling the French oil is produced in Burmah from the Pinus Khasya Royler, and Pinus Merkusii Jungh. et De Vries. (See P. J., lvi, 1896, 370.)

PISTACIA.—See Mastiche.

Pistacia Terebinthus L. is a small tree of the family Anaeardiaceae, with numerous spreading branches, bearing alternate, pinnate leaves, which consist of three or four pairs of ovate-lanceolate, entire, acute, smooth, and shining leaflets, with an odd one at the end. The male and female flowers are dioecious, small, and in branching racemes. It is a native of Barbary and Greece, and flourishes in the islands of Cyprus and Chio, the latter of which has given its name to the Chian turpentine obtained from the tree. A gall produced upon tills plant by the puncture of an insect has been used in Eastern Europe in pectoral affections.
We shall treat of the several varieties of turpentine under distinct heads.

1. WHITE TURPENTINE.

_Terebinthina_, N. F. IV; Thus Americanum, Br.; Common Frankincense; Terebenthine de Boston, Fr.; Terebinthina communis; Terebenthine de Bordeaux ou Terebenthine commune, Fr. Cod.; Terebinthina, P.G.; Terpentin, Gemeiner Terpentin, G.; Trementina comune. It.; Trementina de pina, Sp.

"A concrete oleoresin obtained from _Pinus palustris_ Miller, and from other species of _Pinus_ (Fam. _Pinaceae)._" N. F. IV.

Turpentine, or as it is more frequently called, white turpentine, was deleted from the U. S. VIII and the Br. Pharm., 1914. It was introduced in the N. F. IV as an ingredient in compound rosin cerate, or Deshler's salve, which was official in the U. S. VIII.

This variety of turpentine is derived chiefly from the _Pinus Palustris_ and the _P. Taeda_. It occurs in the sap wood and is obtained by making incisions through the bark and wood and collecting the exudation in cavities or boxes made lower down on the trunk, from which it is dipped into barrels or other receptacles. It gradually thickens and ultimately acquires a soft solid consistence. White turpentine as found in commerce occurs in yellowish, opaque masses, lighter internally, sticky and more or less glossy, brittle in the cold. Odor and taste characteristic. It is freely soluble in alcohol, ether, chloroform, or glacial acetic acid. Its alcoholic solution is acid to litmus." N. F. The following test is of value in testing the purity of turpentine:

"Dissolve about 1 Gm. of Turpentine, accurately weighed, in 25 mils of alcohol and collect the insoluble residue, if any, on a filter which has been dried at 100° C. (212° F.) and weighed. Then wash the residue and filter with about 25 mils of alcohol and dry at 100° C. (212° F.). The weight of the residue does not exceed 2 per cent. (mechanical impurities)." N. F.

In former times, large quantities were collected in New England, but the turpentine trees of that section have long been entirely exhausted, and our commerce has been until recently almost exclusively supplied from North Carolina and the southeastern parts of Virginia. Latterly
attention was turned to the collection of this valuable product of Georgia and Florida, and now an abundant supply is derived from the vast pine forests which occupy the southern portion of our country bordering on the Gulf of Mexico.

During the winter, deep notches or excavations of the capacity of about three pints are made in the trunk of the tree three or four inches from the ground, and for about three feet above these so-called "boxes" the tree is deprived of its bark and some of the wood scraped off. Into these the turpentine or "crude" begins to flow about the middle of March, and continues to flow throughout the warm season, slowly at first, rapidly in the middle of summer, and more slowly again in the autumn, the tree being scraped every eight or ten days to prevent clogging. The liquid is removed from the "boxes" as they fill, and transferred into casks, where, if left, it gradually thickens, and ultimately acquires a soft solid consistence, but most of it is separated at once by distillation into the rosin and the volatile oil of turpentine.

When a tree is boxed, it is weakened and falls easily before the wind. To obviate the former destructive method, Herty has devised "the cup and gutter system." (See Bulletin No. 40, Bureau of Forestry.) By this method a small incision is made through the bark and a strip of galvanized iron is inserted. The turpentine flows along this strip and is caught in an earthenware receptacle much resembling a medium-sized flower pot inserted upon the tree. While this method increases the yield of turpentine, it has not been generally adopted. Large quantities of turpentine are prepared directly from the wood of the trees which have been destroyed by the older or box method of collecting the oleoresin. "Wood" turpentine is not recognized as equivalent to "turpentine" by the Pure Food and Drugs Act, and must be labelled as "Wood Turpentine." The latter has a peculiar odor and is not used in medicine but is widely used in the arts.

White turpentine, as found in commerce, is yellowish white, of a peculiar somewhat aromatic odor, and a warm, pungent, bitterish taste. It is somewhat translucent, and of a consistence varying with the temperature. In the middle of summer it is almost semi-fluid and very adhesive; though brittle in the winter it is often so firm and hard as to be incapable of being made into pills without heat. "In yellowish, opaque masses, brittle in the cold; lighter internally, sticky and more or less glossy; odor and taste terebinthinæ. The alcoholic solution of
Turpentine has an acid reaction." U. S. VIII.

Exposed to the air it ultimately becomes perfectly hard and dry. In the recent state it affords about 17 per cent. of volatile oil. (See Oleum Terebinthinae.) It is likely to contain small pieces of bark, wood, or other impurity. Tschirch and Koritschoner found the following constituents in white turpentine: palabiennic acid, $C_{13}H_{20}O_2$, 5 per cent.; palabietinic acid, $C_{20}H_{30}O_2$, which is crystalline, 6 to 7 per cent.; $\alpha$- and $\beta$-palabietinolic acids, together 53 to 57 per cent. Both the latter are amorphous and are separated by the differing solubility of their lead salts. All the acids are soluble in sodium hydroxide solution. The portion of the resin insoluble in NaOH solution consists of essential oil, 20 to 22 per cent., and paloresene, 10 per cent., with traces of a bitter principle. The essential oil has a characteristic turpentine-like odor. The sp. gr. is 0.864. (See Oleum Terebinthinae.) It is dextrogyrate, while the resin itself and palabietinic acid are leevogyrate. The authors have furthermore examined Russian white pitch, a product known as "belji var," and probably derived from the Siberian fir. (A. Pharm., Nov., 1902.)

2. COMMON EUROPEAN TURPENTINE.

This is the Terebinthina vulgaris of the old London Pharmacopoeia. It is furnished by several species of pine, but chiefly by P. sylvestris L. and P. Pinaster Soland. For details as to the varieties of European turpentine and the methods of procuring them, consult A. J. P., 1878, 69, 479; Proc. A. Ph. A., xxiv, 203; P. J., viii, 283; x, 447. From the latter tree it is obtained largely in the maritime districts of the Southwest of France, especially in the department of the Landes, and is exported from Bordeaux. Hence it is called in commerce Bordeaux turpentine. It is procured by making incisions into the trunk, or removing portions of the bark, and receiving the juice which flows out, in small troughs, or in holes dug at the foot of the tree. It is purified by heating, and filtering it through straw, or by exposing it to the sun in a barrel, through holes in the bottom of which the melted turpentine escapes. Thus prepared, it is whitish, turbid, thickish, and separates, upon standing, into two parts, one liquid and transparent, the other of a consistence and appearance like that of thickened honey. As found in European commerce, it often
consists wholly of this latter portion. It speedily hardens on exposure in thin layers to the air. The most liquid specimens are completely solidified by the addition of one part of magnesia to thirty-two parts of the turpentine. (J. P. C., xxv, 499.) Tschirch and Bruening (A. Pharm., 1900, ccxxxvii, 630) find this oleoresin to have the following composition: 6 to 7 per cent. of pimaric acid, $C_{14}H_{22}O_2$; 8 to 10 per cent. of pimarinic acid, $C_{20}H_{30}O_2$; 48 to 50 per cent. of alpha- and beta-pimaric acids, $C_{18}H_{26}O_2$; 5 to 6 per cent. of bordoresin, together with traces of succinic acid. The acid resins are soluble in sodium hydroxide solution, the pimarinic acid being separable from the other two by its property of forming with ammonium carbonate a water-soluble double salt. The volatile oil consists of two fractions, the larger fraction, amounting to about 85 per cent. of the whole, distilling easily. It is scarcely ever given internally, but furnishes large quantities of oil of turpentine and rosin. We do not import it into this country. The substance which the French call galipot, or barras, is that portion of the turpentine which concretes upon the trunk of the tree when wounded, and is removed during the winter. (Thenard.) This, when purified by melting with water and straining, takes the name of yellow or white pitch, or Burgundy pitch. When turpentine, whether the European or the American, has been deprived of its oil by distillation, the resin which remains is called rosin, and sometimes colophony, from the Ionian city of Colophon, where it was formerly prepared. It is the official rosin (resina), and is sometimes called yellow rosin (resina flava). White rosin (resina alba) is prepared by incorporating this, while in fusion, with a certain proportion of water. (See Resina.) Tar (pix liquida) is the product extracted from the wood by slow combustion and chemically altered by heat. Common pitch (pix nigra, or resina nigra) is the solid residue left after the evaporation by boiling of the liquid parts of tar.

3. CANADA TURPENTINE.

Baume du Canada, Fr. Cod.; Canadischer Balsam, Canadischer Terpentin, G.; Trementina del Canada, It.

Terebinthina Canadensis, U. S., Br., is collected in Canada and the State of Maine from the Abies balsamea, by breaking the vesicles which naturally form upon the trunk and branches, and receiving their liquid contents in a bottle. "Pale yellow or greenish-yellow, transparent, viscous. Agreeable terebinthinate odor; taste feebly bitter and acrid. Dries very slowly to a transparent varnish when exposed to the air.
Solidifies when mixed with about one-sixth of its weight of heavy magnesia moistened with a little water." Br.

"It is completely soluble in ether, chloroform, or benzene." U. S. VIII.

For a paper on its miscibility in alcohol, by J. E. Morrison, see Proc. A. Ph. A., 1894, 309. By time and exposure it becomes thicker and more yellow, and finally solid. It is usually brought into market in bottles under the name of Canada balsam or balsam of fir. Under the microscope the hard balsam is found to be entirely free from any granular or crystalline structure. In Europe it is sometimes called balm of Gilead, from its supposed resemblance to that celebrated medicine. The term balsam, as at present understood, is improperly applied to it, as it contains no benzoic or cinnamic acid, and is in fact a true turpentine, consisting chiefly of resin and volatile oil. Bonastre obtained from 100 parts of Canada turpentine 18.6 parts of volatile oil, 40.0 of resin easily dissolved by alcohol, 33.4 of sub-resin of difficult solubility in that fluid, 4.0 of caoutchouc similar to sub-resin, and 4.9 of bitter extractive and salts, besides traces of acetic acid. Fluckiger found in 100 parts 24 parts of an essential oil, C10H16, with a very small proportion of an oxygenated oil, 60 parts of a resin soluble in boiling alcohol, and 16 parts of a resin soluble only in ether. (Pharmacographia, 2d ed., 614.) Emmerich obtained by fractional distillation of the oil, bornyl or terpinyl acetate, pinene, and a fragrant liquid resembling oil of lemon. (A. J. P., 1895, 135. See also a paper by Hunkel, A. J. P., 1895, 9.) The chief distinction between it and Strassburg turpentine, which is sometimes sold for it in commerce, is in the odor.

According to Tschirch, Wiegel and Bruening, Canada turpentine contains about 63 per cent. of acid resins, from 23 to 24 per cent. of volatile oil, and from 11 to 12 per cent. of indifferent resin. The acid portion consists of four acids, of which one—canadinic acid, C19H34O2—obtained by treating the oleoresin with ammonium carbonate, with which it combines; a small amount of crystalline canadolic acid, C19H28O2, and two amorphous isomeric acids—a- and β-canadinolic acids, C19H30O2—which constitute the main portion of the acid resins. The indifferent resin has the formula C21H40O. The greater part of the volatile oil boils between 160° and 167° C. (320° and 332.6° F.). (A. Pharm., 1900, Aug. and Sept., 401, 411 and 487.)
Abies Menziesii Lind.—From this a Balsam of Fir of the Pacific Slope, has been obtained; it is a turpentine similar to Canada balsam and is extensively sold under the names Oregon Balsam or Oregon Balsam of Fir. Roberts and Becker (Proc. P. P. A., 1913, p. 328) state that Canada balsam is thicker than Oregon balsam, dries to a solid, transparent film, while Oregon balsam remains sticky, has a lower acid value than Oregon balsam, and solidifies when mixed with 20 per cent. of magnesium oxide, which Oregon balsam does not.

4. VENICE TURPENTINE.

*Terebinthina Laricis*, N. P. IV; Larch Turpentine; Terebenthine de Venise, Fr. Cod., Terebenthine de Meleze, Fr.; Venetianischer Terpentin, G.; Trementina di Venezia, It.; Trementina de alerce, Trementina de Venecia, Sp.

"A viscid oleoresin obtained from Larix europoea De Candolle (Fam. Pinaceae)." N. F.

"Venice turpentine is a nearly transparent, yellowish or yellowish-green, thick liquid, heavier than water, and having a distinctive odor and a bitter characteristic taste. Completely soluble in alcohol, glacial acetic acid, acetone, or chloroform. Almost entirely soluble in petroleum benzine with the separation of a light flocculent deposit. One part of Venice turpentine dissolves completely and forms a clear solution in 3 parts of 80 per cent. alcohol. It may possess a slight, greenish fluorescence when viewed by reflected light but exhibits no violet or purple fluorescence (rosin oil). Dissolve 5 Gm. of Venice turpentine in 25 mls of alcohol, add a few drops of phenolphthalein T.S. and render the solution slightly alkaline by the addition of a 10 per cent. solution of potassium hydroxide. The resulting solution is clear and transparent and no separation of oily drops occurs (rosin oil). Its acid number is not more than 80 when determined as directed in the U. S. Pharmacopoeia IX." N. F.

This turpentine was named from the circumstance that it was formerly an extensive article of Venetian commerce. It is procured in Switzerland, and in the French province of Dauphiny, from the Larix decidua (L. europoea), which grows abundantly upon the Alps and the Jura Mountains. The peasants bore holes into the trunk about two feet from the ground, and conduct the juice by means of wooden gutters into small tubs placed at a convenient distance. It is afterwards purified by filtration through a leather sieve. Genuine Venice turpentine is a viscid...
liquid, the consistence of honey, flowing with difficulty, cloudy or imperfectly transparent, yellowish or slightly greenish, of a strong not disagreeable odor, and a warm bitterish, and acrid taste. It does not readily concrete on exposure, is not solidified by one-sixteenth of magnesia, and is entirely soluble in alcohol. (Guibourt, J. P. C., xxv, 500.) H. Beckurts and W. Brueche found the specific gravity at 15° C. (59° F.) from 1.060 to 1.190; acid number from 76 to 101 (Kremel found from 68 to 70.3); ester number from nothing to 6; saponification number from 81 to 101, and the iodine number from 137 to 149. (A. Pharm., 1892, cxx, 83.) It yields on an average 15 per cent. of essential oil, of the composition C_{10}H_{16}, which has been found to be nearly pure pinene. The residual resin is soluble in two parts of warm alcohol of 57 per cent., and more copiously in absolute alcohol.

Tschirch and Wiegel investigated the constituents of Larch Turpentine. According to these investigators, this oleoresin contains from 60 to 64 per cent. of acid resins soluble in soda, from 20 to 22 per cent. of volatile oil, and from 14 to 15 per cent. of indifferent resin. The acid resins consist mainly of two isomeric amorphous bodies, $\alpha$- and $\beta$-larinolic acid, C_{17}H_{26}O_{2}, and a smaller quantity of the crystalline laricinolic acid, C_{20}H_{30}O_{2}. The greater portion of the volatile oil boils between 155° and 170° C. (311° and 338° F.); a smaller quantity of higher boiling sesquiterpene commencing to boil at 190° C. (374° F.). The recently distilled oil has the sp. gr. 0.872, and possesses a characteristic turpentine odor. It is soluble in all proportions in alcohol and other solvents. (A. Pharm., 1900, Aug. and Sept., 401, and 411, 487.) What is sold under the name of Venice turpentine, in commerce, is usually quite brown, and is a factitious substance, prepared by dissolving rosin in oil of turpentine. According to G. Fabris the nature of these spurious Venice turpentines can readily be detected by dissolving 5 Gm. of the sample in 20 mils of 95 per cent. alcohol, adding a few drops of phenolphthalein and sufficient of a 10 per cent. solution of potassium hydroxide to render it alkaline. With genuine Venetian turpentine a clear solution is obtained, while the spurious drug yields a turbid solution, from which, on standing, drops of oily resin separate.

5. CHIAN TURPENTINE.

Terebenthine de Chio, Fr. Cod.; Cyprischer Terpentin, G.; Trementina Cipria, It.
This variety of turpentine is collected chiefly in the island of Chio, or Scio, from the Pistacia Terebinthus, and it is said that the whole annual product of the island is only about two hundred and twenty-four pounds. During the summer the juice flowing spontaneously, or from incisions in the bark, falls upon smooth stones, or bundles of twigs, placed at the foot of the tree, from which it is procured by boiling and straining. After straining it is again boiled with a little water until all the water is evaporated, when it is finally poured into a vessel of cold water and kneaded. At first it is of a dirty yellow color, but after kneading it becomes quite white. (P. J., xvi, 385.) The annual product of each tree is very small, and the turpentine, therefore, commands a high price even in the place where it is procured. Very little of it reaches this country. It is said to be frequently adulterated with the other turpentines. It is a thick, tenacious liquid, of a greenish-yellow color, or it occurs as a viscid opaque mass. The odor is peculiar, penetrating, and more agreeable than that of the other substances of the same class. The taste is mild, without bitterness or acrimony. Fluckiger found nearly 14½ per cent. of essential oil, which contained a small quantity of an oxygenated oil. It leaves a glutinous residue when treated with strong alcohol. (Guibourt.) Its alcoholic solution does not redden litmus paper. (Martindale.) On exposure, liquid Chian turpentine speedily thickens, and ultimately concretes into a translucent solid, yellowish or yellowish-brown when in small pieces, greenish-brown in mass.

The odor of Chian turpentine is variously described. As the only tests we now have of the purity of the drug are its physical characteristics, and of these the odor is the most important, we give the following description by Wm. Martindale. (P. J., April, 1880.) Chian turpentine "has when fresh a distinctive odor, slightly like the pinaceous turpentines, but much more agreeable and aromatic, according to some* resembling citron and jasmine; but there is always a background smell like that of mastic, which becomes more developed and distinct with age, when it has lost the more volatile portion, the essential oil. According to Pereira, the turpentine-like odor is combined with the odor of fennel, and Guibourt says, when kept in a covered glass vessel the odor is strong and agreeable, analogous to that of fennel or the resin of elemi. It probably loses this rapidly. A specimen, bearing Guibourt's name, in the Ph. Society's Museum, has now no trace of it, but the mastic odor is very persistent. If the fennel odor be very evident in it I should fear the sample was not genuine, as in a statement made in the Lancet the writer says what is sold as Chian turpentine (is either greatly

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - T - Page 29
The Southwest School of Botanical Medicine http://www.swsbm.com
adulterated or a wholly factitious article, manufactured from black resin, Canada balsam, and the essential oils of fennel and juniper. The taste of genuine Chian turpentine resembles that of mastic; it is agreeable and free from the characteristic bitterness and acridity of the pinaceous turpentines."

Besides the turpentines mentioned, various others are noticed in books on Materia Medica, though not found in commerce in this country. There are the Strassburg turpentine, much used in France, and obtained from the Abies Picea (Abies pectinata of De Candolle), or European silver fir, which grows on the mountains of Switzerland and Germany and bears a close resemblance, as well in its appearance as in its product, to Abies balsamea of Canada; the Russian turpentine, from Pinus sylvestris; the Damara turpentine, which speedily concretes into a very hard rosin, and is derived from Pinus Damaris Lam., the Agathis damara of Richard, growing in the East India islands; the cowrie or cowdie resin, procured by incision from another species of Agathis, A. australis, in New Zealand; and the Dombeya turpentine, a glutinous, milky-looking fluid, of a strong odor and taste, derived from the Araucaria Dombeyi of Richard, also called Dombeya excelsa, which inhabits Chili.

Finnan Turpentine, the oleoresin of Pinus sylvestris, is found by Tschirch and Niederstadt to consist of: 1.5 per cent. silveolic acid, $\text{C}_{14}\text{H}_{20}\text{O}_2$; 58 to 60 per cent. of $\alpha$-silvinolic acid, $\text{C}_{15}\text{H}_{26}\text{O}_2$, and $\beta$-silvinolic acid ($\text{C}_{14}\text{H}_{24}\text{O}_2$); 20 to 21 per cent. of resene; 15 per cent. of volatile oil; and traces of bitter principle and suceinic acid. Silveolic acid is crystalline; $\alpha$- and $\beta$-silvinolic acids are both amorphous. The volatile oil has the sp. gr. 0.840 at 15° C. (59° F.), is soluble in all proportions in alcohol, ether, and chloroform, and is neutral when recently distilled, but becomes acid when exposed to the air. (A. Pharm., 1901, ccxxxix, 167.)

Jura Turpentine.—A. Tschirch and E. Bruening have determined the following constituents of the oleoresin of Picea vulgaris: From 2 to 3 per cent. of $\text{picea}$-pimaric acid, $\text{C}_{18}\text{H}_{20}\text{O}_2$; from 1.5 to 2 per cent. of $\text{picea}$-pimaric acid, $\text{C}_{20}\text{H}_{30}\text{O}_2$; from 48 to 50 per cent. of $\alpha$- and $\beta$-$\text{picea}$-pimarcic acid, $\text{C}_{25}\text{H}_{44}\text{O}_2$; from 32 to 33 per cent. of volatile oil; from 10 to 12 per cent. of resene, $\text{C}_{21}\text{H}_{36}\text{O}$; and traces of suceinic acid, coloring matter and bitter principle. (A. Pharm., 238, Nov. 10, 1900, 616.)
Tschirch and Weigel (A. Pharm., 1900, Aug. and Sept., 401, 411, 487) investigated Strassburg turpentine—the oleoresin of Abies Picea; it contains from 8 to 10 per cent. of an acid resin, abieninic acid, \( \text{C}_{13}\text{H}_{20}\text{O}_{2} \); from 1.5 to 2 per cent. of a crystalline acid resin, abietolic acid, \( \text{C}_{20}\text{H}_{28}\text{O}_{2} \); from 46 to 50 per cent. of two amorphous isomeric acid resins, \( \alpha \)- and \( \beta \)-abietinolic acid, \( \text{C}_{16}\text{H}_{24}\text{O}_{2} \); from 12 to 16 per cent. of a neutral resin, abieto-resin; and from 28 to 30 per cent. of volatile oil, together with traces of succinic acid, bitter principle, coloring matter, moisture and impurities. The oil when recently distilled has the sp. gr. 0.860, boiling between 148° and 165° C. (298.4° and 329° F.); the major fraction distils between 162° and 163° C. (323.6° and 325.4° F.). It has a greenish fluorescence and a lemon-like odor. When the oleoresin is distilled with potassium hydroxide a pleasant rose or orange-flower odor is developed, possibly due to the liberation of a fragrant alcohol.

**Properties.**—The turpentines resemble one another in odor and taste, though distinguished by shades of difference. Liquid at first, they become thick and gradually solid by exposure, in consequence partly of the volatilization, partly of the oxidation of their essential oil. They are rendered more liquid or softened by heat, and at a high temperature take fire, burning with a white flame and much smoke. Water extracts only a minute proportion of their volatile oil. They are almost wholly soluble in alcohol and ether, and readily unite with the fixed oils. They yield by distillation a volatile oil, called oil of turpentine, the composition of which is essentially uniform, it being composed of several terpenes (pinene, dipentene, and sylvestrene) of the formula \( \text{C}_{10}\text{H}_{16} \), the residue consisting exclusively of rosin. (See Oleum Terebinthinae and Resina.) Both the cones and leaves of Abies Picea yield oils known respectively as pine cone oil and pine needle oil. According to Schimmel’s Report for April, 1897, they both contain pinene, limonene, and bornyl acetate. The oil from Pinus sylvestris, known as fir oil, also contains bornyl acetate to the amount of 12 per cent., according to Schimmel’s Report for October, 1897, 47. On the other hand, the oil from Larix Europoea, known as larch needle oil, contains 8.1 per cent. of bornyl acetate and 6.14 per cent. of free borneol. (Ibid., 61.)

Schiff affirms that the odor of turpentine is due to the presence of a product of oxidation, probably a camphoric aldehyde, \( \text{C}_{10}\text{H}_{16}\text{O}_{2} \), which, with the odor, may be removed by shaking the turpentine with sodium
bisulphite. A non-odorless turpentine may also be obtained by washing with solution of sodium hydroxide and distilling in an atmosphere of carbon dioxide. From the experiments of Faure, of Bordeaux, it appears that some of the liquid turpentines, like copaiba, may be solidified by the addition of magnesia. (Journ. de Chim. Med., 1830, 94.) According to Thierry, the same result is obtained by the addition of one part of calcium hydroxide to thirty-two parts of common European turpentine. (J. P. C., 3e ser., i, 315.) Crouzel (P. J., 1892, 11) found tannin in the bark of P. Pinaster, associated with a peculiar reddish-yellow coloring matter, representing tannin in the process of formation.

Ed. Hirschsohn made experiments with the object of determining a reliable method for distinguishing artificial turpentine from the common, natural turpentine and larch turpentine, this becomes possible by the difference in the solvent effect of official ammonia water and alcohol, sp. gr. 0.863 at 15.6° C. (60° F.), upon them, under the conditions indicated in the following table:

<table>
<thead>
<tr>
<th>Kind of Turpentine</th>
<th>Ammonia Solution (sp. gr. 0.900), 1 p. turpentine and 3 p. ammonia solution.</th>
<th>Alcohol (sp. gr. 0.863), 1 p. turpentine and 3 p. alcohol.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Venice turpentine</td>
<td>Is not disintegrated; produces a milky fluid in the water-bath.</td>
<td>Yields a nearly clear solution.</td>
</tr>
<tr>
<td>Common turpentine</td>
<td>Easily disintegrated, forming a milky mixture, then gelatinous; becomes clear in the water-bath.</td>
<td>Large quantities are deposited, but the mixture becomes clear in the water-bath.</td>
</tr>
<tr>
<td>Artificial turpentine</td>
<td>Is disintegrated, becomes clear in the water-bath for a moment, then turbid.</td>
<td>Turbid solution and precipitation; turbid in the water-bath with precipitation.</td>
</tr>
</tbody>
</table>

A mixture of common turpentine with larch (Venice) turpentine is recognized by the turbidity of, and precipitate from, the solution of 1 Gm. of the sample in 3 Gm. of alcohol sp. gr. 0.863. The same occurs if the common is replaced by artificial turpentine, but the latter is differentiated by ammonia, from the fact that in the presence of 20 to 30 per cent. of common turpentine the sample is easily disintegrated, and the solution becomes clear in the water bath, while in the presence of artificial turpentine the behavior is the same as with the pure Venice turpentine. (Ph. Centralh., Nov. 26, 1903, 825 to 828.)

**Uses.**—The physiological activities of turpentines depend upon their volatile oils. They are so inconvenient of administration, and so variable in their activity that at present they are very rarely, if ever, used internally by regular practitioners of medicine. For an account of their
physiological and therapeutic properties, see Oleum Terebinthinae. If given at all they should be administered in emulsion. Chian turpentine has been recommended as a specific in cancer, given in emulsion in doses of five grains (0.32 Gm.), increased pro re nata, and also applied locally. It is probably without value. Turpentine vapor baths have been found useful in the treatment of chronic rheumatism; they may be given by simply evaporating oil of turpentine in the ordinary cabinet or other vapor bath, or by driving the vapor through the fine branches and leaves of a terebinthinate plant. They probably differ in their action from the simple hot vapor bath by the stimulation of the skin due to the local action of the turpentine, and by the copious sweating which they produce. The bath should always be so arranged that the terebinthinate vapor is not inhaled by the patient.

Dose, twenty to thirty grains (1.3-2.0 Gm.).

**Tetragastris.** Tetragastrispanamensis (Engl.) O. Kuntze. Bois Cochon, or Sucrèr de Montagne, Fr. (Fam. Burseraceae)—This native of Panama has been examined by Gaucher, Combemale and Marestang (FranceMéd., October, 1888), who find in it an alkaloid and a resin. The extract of the root and sterna produces in the guinea pig rapid and considerable lowering of temperature, progressive paralysis, general convulsions, dilatation of the pupils, respiratory irregularity and cardiac paresis. The alkaloid was found to be a convulsive agent, acting upon the spinal cord. The resin, which seemed much more active than the alkaloid, acted as a paralyzant.

**Tetranthera.**—From the bark of the lauraceous plant, T. citrata Nees (now Litsea citrata Blume), J. D. Filippo has extracted an alkaloid, laurotetanine (See A. Pharm., 1898, 601.)

Charabot and Lalone examined the volatile oils from various parts of Tetranthera (Litsea citrata). The oil from the bark has the sp. gr. 0.8673 at 15° C. (59° F.), that from the leaves 0.9013 at 15° C. (59° F.) and that from the fruits 0.8872 at 15° C. (59° F.). (P. J., 1908, 351.)

**Teucrium.** Teucrium Chamaedrys L. Germander. Chamaedrys. Petit Chene, Fr. Edlar, Gamanderlein, Frauenbiss, G.—A small European labiate, which has been employed as a mild corroborant in uterine, rheumatic, gouty and scrofulous affections and intermittent fevers. Germander was an ingredient in the Portland powder, noted as a remedy in gout. This powder, according to the original prescription, consisted of equal parts of the roots of Aristolochia rotunda L. and Gentiana lutea L. of the tops and leaves of TeucriumChamaedrys and ErythraeaCentaurium (L.) Pers. and of the leaves of Ajuga Chamaepitys Schreb., or ground pine. The dose was a drachm every morning before breakfast for three months, then forty grains for three months, afterwards half a drachm for six months, and finally half a drachm every other day for a year. (Parr.)
Two other species of Teucrium have been used in medicine,—T. Marum L., cat thyme, or Syrian herb mastich, indigenous in the south of Europe, and T. Scordium L., or watergermander, growing in the higher latitudes of the same continent. The former is a warm, stimulating, aromatic bitter, and has been recommended in hysteria, amenorrhea and nervous debility; the latter has the odor of garlic and a bitter, somewhat pungent taste, and was formerly highly esteemed as a corroborant in low forms of disease; but neither of them is now much employed. T. Marum is an errhine, and was formerly an ingredient of the Pulvis Asari Compositus.

A plant said to have been used advantageously in cholera in the Levant, a specimen of which was sent to Paris, proved to be Teucrium Polium L. (J. P. C., xv, 352.) Moorhof (Ph. Cent., 1893, 89) prepared a purified liquid extract from T. Scordium, and named it teucrin, which he recommends in the treatment of fungoid diseases and abscesses.

The dose of either of the three species is about half a drachm (2.0 Gm.).

Thalictrum.—It appears probable that many species of this genus (Fam. Ranunculaceae) have active medicinal or toxic properties. In 1879 Henriot and Doassans asserted that they had separated from the roots of the Thalictrum macrocarpum Gren., a shrub of the Pyrenees, a crystalline yellow substance, having very pronounced toxic principles, analogous to those of curare; and subsequently stated (C. R. S. B., 1880) that this substance really consists of two principles,—an alkaloid, thalictrine, obtained in the form of prismatic needles, insoluble in water, soluble in alcohol, forming crystalline salts with acids, and macrocarpin, a yellow crystalline body, soluble in water, representing the coloring principle of thalictrum. Subsequently berberine was found by Doassans and Mousset in Thalictrum flavum L., Fen Rue or Monk's Rhubarb, a shrub widely distributed in Europe and Asia, macrocarpin being, according to this authority, very closely allied to berberine, but differing in that its color is not affected by ammonia. Rochebrune (Toxicolog. Africaine, i) has found both thalictrine and macrocarpin in the roots of Thalictrum glaucum Pesf., of Spain. Thalictrine he states to be a very active cardiac poison, producing loss of power, convulsive movements, irregularity and depression of the heart's beat, and finally death in some cases in convulsions. According to Rochebrune, thalictrine also exists in the African species Thalictrumrhyynchocarpum Q. Dillon and A. Rich.

Thapsia T. garganica L. Thapsie Faux Fenouil, Fr.—An umbelliferous plant, growing in Southeastern Europe, and well known to the ancients, named from the isle of Thapsos, where it was obtained. Theophrastus speaks of its root as emetic and purgative. After long neglect this plant has obtained a foothold in the French Codex, which recognizes a Resina Thapsiae prepared by exhausting the bark of the root with alcohol and evaporating to a soft extract. From this extract the Codex further directs that an Emplastrum Thapsiae shall be so prepared as to contain 7 per cent. of the resin combined with yellow wax, turpentine and colophony. The bark of the root and the resin are both objects of commerce. The bark is described by Stanislaus Martin
as almost always doubly quilled, unless where altogether in small fragments, exteriorly rugose with the epidermis here and there detached in patches larger or smaller, and of a deep brown color, interiorly smooth and whitish and of a fibrous fracture. The size of the pieces varies, the largest not exceeding 6 dm. in length and 2.5 in width. It is said that great care is necessary, in removing the root from the bales, not to be injured by the powder which escapes, and which causes itching and swelling of the face and hands. By submitting thapsia to the successive action of alcohol and ether Pressoir obtained two resins. (J. P. C., 4e ser., xi, 328.) Canzoneri finds that the ethereal extract is an amber-colored syrupy resin possessing vesicating properties. From it he has obtained two acids, octoic or caprylic acid, and thapsic acid, besides a neutral non-nitrogenous vesicating substance. (See A. J. P., vol. xiv, 325.) Cazenave objects to the plaster prepared from the resin and kept in masses, as it deteriorates by time. He proposes the following method of preparing a plaster extemporaneously when wanted. Dissolve the resin in alcohol and with the aid of a brush spread it on a suitable recipient, which may be of ordinary plaster, waxed taffetas, or simply gummed paper. A single layer is sufficient for the purpose of an active revulsion, but the effect may be increased at pleasure by increasing the number of layers. (J. P. C., 1868, 29.) The French thapsia plaster is an exceedingly active counter-irritant, producing much inflammation of the skin with an eczematous eruption and intolerable itching and, if the application be maintained, finally an ulcerated and suppurated surface, which on healing leaves behind it pronounced scars. The therapeutic action of the plaster is that of a severe counter-irritant.

The resin from the root of Thapsia Sylphium St.-Laz., an Algerian plant, which most botanists believe to be a simple variety of T. Garganica L. is, according to Herlaut, more active than that of the official plant. (Proc. A. Ph. A., xxvi, 250.) Heckel and Schlagdenhauffen (N. R., June and July, 1887) find in the root of Thapsia villosa L. a vesicant resin, which acts more slowly and gently than does that of T. Garganica.

**Thevetia.** Yccotii.—Inhabiting the damp, hot valleys of the Mexican Cordilleras is a large tree belonging to the Apocynaceae, whose fruits are known by the natives as huesos o codos defraile, or friar's elbow bones, and are used as a topical application in hemorrhoids. The tree is the *Thevetia* Yccotii A. DC. In the seeds Herrera found a glucoside, thevetin. (A. J. P., 1877, 145.) Closely allied to T. Yccotii is T. nereifolia Juss., a tree which probably grows also in Mexico, but has been found by botanists chiefly, if not solely, in the West Indian Islands, Colombia, Peru and other parts of South America. De Vrij very many years ago discovered in its seeds a glucoside which was closely studied by Bias. (Neues) Ahrb. f. Pharmacie, Bd. xxxiv, 1854, 1.) He gave it the name of thevetin and the formula C_54H_84O_24 and believed it to be identical with cerberin, previously found by Oudemann in *Cerbera Odallam* Ham., also an apocynaceous plant, but Plugge (A Pharm., 1893, 10) after a thorough study found that cerberin was not identical with either tan-ghinin or thevetin. With the former it is isomeric, showing the same percentage composition, but has different crystalline form and melting point—cerberin 192° C. (377.6° F.), tan-ghinin 182° 0. (359.6° F.). From thevetin it differs not only in composition, but in the nature of the decomposition products. Cerberin, C_27H_40O_8, is decomposed into cerberin, C_19H_26O_4, a citron-yellow amorphous powder melting at 85.5° C. (186° F.), and
glucose, while thevetin, $C_{54}H_{84}O_{24}$, is split into theveresin, $C_{48}H_{70}O_{17}$, a white powder, and glucose.

Merck (Jahresb. fur, 1892, 57) described a glucoside cerberin to which he gives the formula $C_{25}H_{38}O_{12}$, which name he changed to cerberid in 1911. He states that it was obtained from a Mexican plant, probably Thevetia Yccotli. Whether this glucoside is identical with the thevetin of Bias cannot be definitely stated. Bias found that the thevetin of De Vrij boiled in diluted sulphuric acid splits into glucose and theveresin, which has the formula $C_{48}H_{70}O_{17}$. Thevetin occurs in minute crystals, odorless, of a bitter taste, slightly soluble in cold water (twelve parts), freely so in boiling water, diluted and strong alcohol, acetic acid, insoluble in ether. Its most characteristic reaction appears to be its dissolving in concentrated sulphuric acid, with the production of a reddish-brown color, changing to a cherry-red, and after some hours to a violet color. In commerce it occurs as a yellowish-white, amorphous bitter powder, easily soluble in water and alcohol. Theveresin is only slightly soluble in boiling water. These substances are active poisons. Thvetosin, a crystalline glucoside, was made by Herrera from the seeds of T. Yccotli. It is a cardiac poison. (M. R., 1911.) A number of cases of poisoning by the seeds of the East Indian thevetia has occurred; the symptoms have been repeated vomiting, a slow, very feeble pulse, delirium, convulsive movements and coma. The physiological action of the thevetin from T. nereifolia has been investigated chiefly by König. (A. E. P. P., Bd. v, 228.)

David Cerna finds that the glucoside of T. Yccotli (P. M. T., ix, 396) with sulphuric acid affords a clear greenish-yellow solution gradually passing to brown and brownish-violet and finally becoming a permanent cherry-brown color, which changes on the addition of potassium bicarbonate to an emerald-green; also that it is in moderate doses stimulant both to the circulation and respiration, but finally paralyzes the heart muscle and the respiratory apparatus; that it causes cerebral convulsions and spinal paralysis, abolishing sensation and reflex activity before voluntary movement by an influence upon the sensory nerves or spinal tract. Zotos N. Zotos (In. Dis., Dorpat, 1892) states that cerberin belongs physiologically to the digitalin group.

Thuja. N. F. IV. Arbor Vitae. White Cedar — "The recently dried, leafy young twigs of Thuja occidentalis Linne (Fam. Pinaceae), with stems not over 4 mm. in diameter, and without the presence of more than 1 per cent. of foreign substances." It is specifically characterized by the appressed-imbricated leaves, the pointless cone-scales, and the broad wings extending all around the seeds. It attains a height of 20 m., and grows in swampy grounds from Pennsylvania northward and westward, often forming extensive "cedar swamps." In Canada and the extreme northern parts of the United States it is commonly called white cedar, a name sometimes applied to Chamaecyparis thyoides (L.) B. S. P., which latter is more properly called Southern white cedar. The wood is reddish, soft, fine-grained, and very durable. The leaves, or small twigs invested with the leaves, have an agreeable, balsamic odor, specially when rubbed, and a strong, balsamic, camphoraceous, bitter taste. The twigs ;are described as "fan-shaped, flattened, bearing the scale-like leaves appressed in four rows; leaves of the edges boat-shaped, the intermediate flat, those at the tips of the twigs very broad, the lower elongated, all bearing conspicuous glands on the back. 

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - T - Page 36
The Southwest School of Botanical Medicine http://www.swsbm.com
Odor strongly balsamic, aromatic and pungent; taste camphoraceous, tere-binthinate and bitter. Thuja yields not more than 7 per cent. of ash. N. F. A. Kawalier, of Vienna, found in them volatile oil, a bitter principle called pinipicrin, \( C_{22}H_{36}O_{11} \), which occurs also in Pinussylvestris, sugar, gelatinous matter, a variety of wax, resin, and tannic acid; also a peculiar crystallizable coloring principle, thujin, to which he gives the formula \( C_{20}H_{22}O_{12} \). It is of a citron-yellow color and an astringent taste, soluble in alcohol, inflammable, and when its alcoholic solution is heated with diluted hydrochloric or sulphuric acid it splits up into glucose and thujigenin,

\[
C_{20}H_{22}O_{12} + H_2O = C_6H_{12}O_6 + C_{14}H_{12}O_7
\]

and by continuing the reaction another molecule of water is taken up by the latter and thujetin, \( C_{14}H_{14}O_8 \), is formed. Thujetin is possibly identical with quercetin. When thujin is heated with barium hydroxide, instead of thujetin is obtained another product, thujetic acid, \( C_{28}H_{28}O_{13} \). The same chemist determined that the tannic acid of this plant is identical with pinitannic acid, which he had previously obtained from the leaves of Pinus sylvestris L. (See, for details, Chem. Gas., Nos. 392, 393, 1859.) According to Hubschmann, the leaves and twigs of Thujaoccidentalis yield also 1 per cent. of an essential oil of sharp, camphor-like taste, sp. gr. 0.925, boiling point from 190° to 206° C. (374°-402.8° F.), and easily soluble in alcohol. According to Schim. Rep., April, 1897, thuja oil (oil of white cedar)contains pinene, fenchone, thujone, and probably carvone.

F. K. Bailey has reported a case of poisoning in a girl, aged fifteen, who took sixteen drops of the oil of white cedar, and directly afterwards fell unconscious, with clonic spasms followed by epileptiform convulsions lasting at intervals for several hours. Long-continued irritation of the stomach resulted. (N. R., 1872.)

In the form of decoction, thuja has been used in intermittent fever, and, according to Schoepf, in crouches, fevers, scurvy, and rheumatism, and as an emmenagogue. Made into an ointment with lard or other animal fat, the leaves are said to form a useful local application in rheumatic complaints. Sicard and Larue (Gaz des. Hop., 1909) assert that the injection of the tincture of thuja into warts will cause their rapid disappearance. A yellowish-green volatile oil, which may be obtained from the leaves by distillation, has been used with success in worms. According to Hilde-brand both fenchone and thujone act as stimulants to the heart muscle. (A. E. P. P., xlvi.) According to Prochnow (A. I. P. T., xxi, p. 314) the infusion of thuja has a stimulating effect upon the isolated uterus similar to that of hydrastis. The dose of the fluidextract made with alcohol is half a fluidrachm (2 mils) from three to six times a day.

**Thyme.** N. F. IV. Thymus. Common or Garden Thyme.—"The dried tops of Thymus vulgaris Linne (Fam. Labiatae), collected when the plant is in flower." N. F. It is extensively grown in the United States for flavoring purposes. It is also used to some extent in medicine. The N. F. description is as follows: "Stems quadrangular, about 0.5 mm. in diameter, grayish-brown or purplish in color, pubescent, nodes from 5 to 20 mm. apart, occasionally with the opposite leaves attached; leaves linear, linear-lanceolate, or ovate-oblong, from 0.5 to 4 mm. in length and from 0.5 to 2 mm. in breadth, summit acute, base obtuse tapering into a petiole from 0.5 to 2 mm. in..."
length, margin revolute, upper surface grayish-green, puberulent, with numerous one-celled, thick-walled, non-glandular hairs; lower surface grayish, pubescent, with non-glandular, one- to four-celled, thick-walled, rough simple hairs, up to 0.135 mm. in length and usually curved at the first joint in the bases; numerous compound glandular secreting hairs, with short one-celled stalk occurring chiefly on the upper surface and depressed in the cuticle, which give the leaf a glandular-punctate appearance; inflorescence in about twelve-flowered axillary whorls; flowers polygamous, calyx tubular, about 4 mm. in length, ovoid or slightly curved on the lower side near the base, from nine- to twelve-nerved, pubescent, the throat bearded with longitudinally striated, straight simple hairs up to 1 mm. in length, bilabiate, upper lip three-toothed, lower lip with two hairy, ascending, attenuate divisions, corolla about twice as long as the calyx, purplish, smooth within, slightly pubescent without, upper lip emarginate, lower spreading and three-lobed, stamens slightly didynamous and exerted, stigma bifid; nutlets about 0.5 mm. in diameter, spheroidal and finely tuberculate. Odor agreeable, aromatic; taste aromatic and warming. Thyme yields not more than 14 per cent. of ash. N. F.

Thyme owes its therapeutic virtues to its volatile oil. (See Oleum Thymi.). It is occasionally used in domestic medicine, like other aromatic plants, in the form of a hot infusion as a diaphoretic. Fluidextract of Thyme N F. IV is made with a menstruum of 10 volumes of glycerin, 25 volumes of alcohol and 65 volumes of water followed by 1 volume of alcohol and 3 volumes of water. The dose is one fluidrachm (4 mils).

**Tilia.** Linden Tree.—The dried flowers of Tilia europaea L., and of other species of tilia (Fam. Tiliaceae), are official in the German Pharmacopoeia under the head of Flores Tiliae. The flowers are yellowish or greenish-white having 5 sepals and 5 petals. The 5 original stamens, by chorisis have each developed a cluster and at the base occurs in addition, a spatulate petal-like body opposite each of the petals. The pistil has a, 5-locular ovary which is surmounted by a single style and a 5-toothed stigma. The flowers contain a colorless, fragrant, volatile oil. The bark has been said to contain a neutral body, tiliajin, and a glucoside, tilicin. (See A. J. P., 1890; P. J., 66, 105.) The infusion is used as a household remedy to relieve hysteria and indigestion.

**Timbo.**—This name is applied in Brazil to various sapindaceous plants, used as fish poisons. Among these is Serjania curassavica, Radlk. (Paullinia pinnata L.), in which Stanislaus Martin (B. G. T., xcii) has found an alkaloid, timbonine; F. Pfaff have obtained from a timbo of unknown origin two alkaloids, timboin and anhydrotimboin, also an oily compound, timbol. (A. J. P., Nov., 1891.)

**TINCTURA ACONITI. U. S., Br.**

**TINCTURE OF ACONITE**

Tr. Aconit. [Aconiti tinctura P. I.]

"One hundred mils of Tincture of Aconite yields not less than 0.045 Gm.
nor more than 0.055 Gm. of the ether-soluble alkaloids of aconite. If assayed biologically the minimum lethal dose should not be greater than 0.0004 mil for each grammie of body weight of guinea-pig." U. S. "Tincture of Aconite contains in 100 millilitres 0.04 gramme of the ether-soluble alkaloids of Aconite Root." Br.

"Aconite, in No. 60 powder, one "hundred grammes [or 3 ounces av., 231 grains], to make about one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using a mixture of seven volumes of alcohol and three volumes of water as the menstruum and adjusting the volume of the finished Tincture so that each one hundred mils contains 0.05 Gm. of the ether-soluble alkaloids of aconite." U. S.

"Aconite Root, in No. 40 powder, 150 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with seventy-five millilitres of the Alcohol, and produce, by the percolation process, one thousand millilitres of a strong tincture. Determine the proportion of ether-soluble alkaloids present in this strong tincture, by evaporating one hundred millilitres to dryness in a shallow porcelain evaporating basin, and proceeding as directed under 'Aconiti Radix' Dilute the remainder of the strong tincture with sufficient of the Alcohol to produce a Tincture of Aconite containing 0.04 gramme of ether-soluble alkaloids in 100 millilitres of the Tincture. Examined by the foregoing process Tincture of Aconite is found to contain in 100 millilitres 0.04 gramme of the ether-soluble alkaloids of Aconite Root. Limit of error 0.002 gramme in excess or defect. This Tincture is of approximately the same strength as the Tinctura Aconiti of the International Agreement, and about twice as strong as the corresponding preparation of the British Pharmacopoeia, 1898." Br.

The old tincture of the U. S. Pharmacopoeia, 1890, had seven times the strength of the British, and the title was changed from Tinctura Aconiti Radicis to Tinctura Aconiti in the U. S., 1880, revision. It was much stronger than the Tincture of Aconite Leaves, which is still used occasionally, and made of the strength of two troyounces of powdered aconite leaves in a pint of diluted alcohol, and too much caution cannot
be observed to avoid mistaking one tincture for the other. A very important change was made in the strength of Tincture of Aconite in the U. S. P. VIII. The former 35 per cent. tincture was replaced by a tincture of 10 per cent., which is now the strength of the official tincture, 1914. A chemical assay process was also appended and the U. S. P. IX further recommends a biological standard and assay. The latter is desirable because faulty manipulation or storage changes the aconitine to inert bodies, and this would not be detected by the chemical assay. In preparing it, each step of the process must be carefully attended to. The root should be thoroughly comminuted, and very carefully packed in the percolator, and the displacing menstruum very gradually added. Tartaric acid which was formerly used in accordance with the researches of Duquesnel in the U. S., 1880, tincture has been abandoned, as it was found to be unnecessary. For a paper on Tincture of Aconite, by M. I. Wilbert, see Proc. A. Ph. A., 1902, 348. The external use of the tincture requires care, as serious symptoms have followed its too free employment. (Case, B. M. S. J., Feb., 1872, 74.)

Fleming's Tincture of Aconite—This should always be expressly designated when prescribed. It is considerably stronger than the official; and several deaths have occurred from the use of it. The following is Fleming's formula: Take of the root, carefully dried and finely powdered, sixteen (troy) ounces; Alcohol, sixteen fluidounces. Macerate for four days, put into a percolator, and add alcohol until twenty-four fluidounces are obtained. Not more than two drops of this should be given as a commencing dose, to be increased till its peculiar effects are experienced.

Dose, U. S. tincture, 3-10 min. (0.2-0.6 mil); Br. tincture, 5-15 min. (0.3-0.9 mil); if frequently repeated, 2-5 min. (0.12-0.3 mil).

**TINCTURA ALOES. U.S.**

**TINCTURE OF ALOES Tr. Aloes**

Teinture (alcoole) d'Aloes, Fr. Cod.; Tinctura Aloes, P. G.; Aloetinktur, G.; Tinctura alcoholica de acibar, Sp.

"Aloes, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; Glycyrrhiza, in No. 40 powder, two hundred grammes [or 7
ounces av., 24 grains] to make one thousand mils [or 33 fluidounces, 
6\(\frac{1}{2}\) fluidrachms]. Prepare a Tincture by Type Process M, using diluted 
alcohol as the solvent." U. S.

Tincture of aloes was deleted from the Br. Pharm., 1914. The process of 
the previous British Pharmacopoeia is appended.

"Extract of Barbados Aloes, 1/2 ounce (Imperial) or 25 grammes; Liquid 
Extract of Liquorice, 3 fl. ounces (Imp. meas.) or 150 cubic centimetres; 
Alcohol (45 per cent.), a sufficient quantity. Place the Extract of 
Barbados Aloes in a closed vessel with sixteen fluid ounces (Imp. meas.) 
or eight hundred cubic centimetres of the Alcohol; set aside for forty- 
eight hours, occasionally shaking until dissolved; add the Liquid Extract 
of Liquorice; filter; pass sufficient of the Alcohol through the filter to 
produce one pint (Imp. meas.) or one thousand cubic centimetres of the 
Tincture." Br., 1898.

The strength of the British tincture, 1898, was only one-fourth that of 
the U. S. tincture. The formula of the U. S. (8th Rev.) directed 
glycyrrhiza instead of extract of licorice, but has returned to the process 
of maceration for its preparation. Meniere says of the tincture of aloes 
that it deposits crystals of aloin, which adhere to the sides of the bottle, 
and in the upper part of it a yellow resinous matter is seen.

Dose, as a purgative, from two to four fluidrachms (7.5-15.0 mils); as a 
laxative, from one-half to one fluidraehm (1.8-3.75 mils).

**TINCTURA ALSTONIÆ. Br.**

**TINCTURE OF ALSTONIA**

"Alstonia, in No. 20 powder, 125 grammes; Alcohol (60 per cent.), 1000 
millilitres. Prepare by the maceration process." Br.

This tincture represents whatever therapeutic properties alstonia bark 
may possess. It is used in malaria.

Dose, one-half to one fluidrachm (1.8-3.75 mils).
TINCTURA ARNICA. U. S. (Br.)

TINCTURE OF ARNICA
Tr. Arnic. [Tinctura Amicce Florum, U. S. 1890]

Tinctura Arnicae Florum, Br., Tincture of Arnica Flowers;

"Arnica, in No. 20 powder, two hundred grammes [or 7 ounces av., 24 grains]; Diluted Alcohol, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6¼ fluidrachms]. Moisten the drug with five hundred mils [or 16 fluidounces, 435 minims] of diluted alcohol, transfer it to a percolator, and, without pressing the powder, allow it to stand well covered for twenty-four hours, then pack it with moderate pressure and allow the percolation to proceed slowly, pouring on additional diluted alcohol as needed. When the percolate measures two hundred and fifty mils [or 8 fluidounces, 218 minims] stop the flow, macerate the drug for an additional twenty-four hours, and then continue the percolation until the total percolate measures five hundred mils [or 16 fluid-ounces, 435 minims]. Again interrupt the percolation, macerate the drug for another twelve hours and afterwards collect an additional two hundred and fifty mils [or 8 fluidounces, 218 minims] of percolate. Again macerate the drug for twelve hours and then allow the percolation to proceed slowly, pouring on sufficient diluted alcohol to make one thousand mils [or 33 fluid-ounces, 6¼ fluidrachms] of Tincture." U. S.

"Arnica Flowers, in No. 20 powder, 100 grammes; Alcohol (45 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

The U. S. IX and Br. Pharm., 1914, have dropped arnica root and tincture of arnica flowers alone represents arnica in both Pharmacopoeias. Tincture of Arnica Root, Br., 1898, was made by percolating 50 grammes powdered arnica rhizome with 70 per cent. alcohol, until one thousand mils were obtained. Tincture of arnica root was solely intended for internal administration and confusion arose from the similarity in names.
The U. S. P. tincture of arnica differs from that official in 1870 in the menstruum selected, which is now diluted alcohol in place of alcohol. The change was advocated by numerous pharmaceutical writers, and there is no question of the ability of the menstruum to exhaust the arnica flowers, if they are tightly packed in the percolator. The principal objection to the change is the greater difficulty that will be experienced in mixing the tincture with liniments containing oily and alcoholic liquids.

Either alone, or diluted with water, soap liniment, etc., tincture of arnica is often applied popularly to bruises, sprains, tumors and local rheumatic pains, under the impression that it has extraordinary healing powers. It probably acts merely as a counter-irritant. On some skins it produces a violent eczematous inflammation. If given internally, the dose would be from ten to thirty minims (0.6-1.8 mils), increased until some effect was produced.

Dose, of the British tincture of the root, twenty minims to half a fluidrachm (1.3-1.8 mils).

**TINCTURA ASAFŒTIDÆ. U. S. (Br.)**

**TINCTURE OF ASAFETIDA Tr. Asafoet.**

_Tinctura Asafetidæ_, Br.; _Teinture (alcoole) d'Asafoetida_, Fr. Cod.; _Asanttinktur, Stinkasanttinktur_, G.; _Tinctura alcoholica de asafetida_, Sp.

"Asafetida, bruised, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms], Prepare a Tincture by Type Process M, using alcohol as the solvent." U. S.

"Asafetida, bruised, 200 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Macerate the Asafetida in a closed vessel with seven hundred and fifty millilitres of the Alcohol for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

This tincture becomes milky on the addition of water, in consequence of the separation of the resin.
Dose, thirty minims to a fluidrachm (1.8-3.75 mils).

Off. Prep.—Mistura Magnesii, Asafoetidae et Opii, N. F.

**TINCTURA AURANTII AMARI. U. S. (Br.)**

**TINCTURE OF BITTER ORANGE PEEL Tr. Aurant. Amar.**

Tinctura Aurantii, Br.; Tincture of Orange; Teinture (alcoole) d'Ecorce d'Orange amere, Fr.; Tinctura Aurantii, P. G.; Pomeranzentinktur, Pomeranzenschalentinktur, G.

*Bitter Orange Peel, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, using a mixture of three volumes of alcohol and two volumes of water as the menstruum." U. S.

"Fresh Bitter-Orange Peel, cut small, 250 grammes; Alcohol (90 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

It is the peel of the Seville orange that is directed in this process, and the outer part only is active. The substitution of fresh for dried orange peel was proposed in England, and its propriety considerably discussed. (See P. J., Nov. 9, 1872, also April 4, 1874.) Indeed, it met with so much favor as to be introduced in the 1885 revision of the British Pharmacopoeia, and was used in the Tinctura Aurantii Recentis, Br.; but in the Br. Pharm., 1898, the name was changed to Tinctura Aurantii. The two tinctures differ also because of the fact that the Br. "orange peel" is only of the outer layer, while the U. S. includes also the inner, white, portion of the rind. The U. S. tincture has a greenish-brown color and a bitterish taste, the latter due to the presence of hesperidin from the inner layer of the rind. The Br. tincture of orange more closely resembles the U. S. Tinctura Aurantii Dulcis in sensible properties. The tincture of bitter orange peel is employed as a grateful addition to infusions, decoctions, and mixtures.

Dose, from one to two fluidrachms (3.75-7.5 mils).
Off. Prep.—Syrupus Aromaticus, Br.; Syrupus Aurantii, Br.; Elixir Aurantii Amari, N. F.

TINCTURA AURANTII DULCIS. U. S.

TINCTURE OF SWEET ORANGE PEEL Tr. Aurant. Dulc.

Téinture de Zeste d’Orange douce, Fr.; Apfelsinenschal-entinktur, G.

"Sweet Orange Peel, grated from the fresh fruit, five hundred grammes [or 17 ounces av., 279 grains], to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process M, macerating the drug in one thousand mils of alcohol and completing the preparation with alcohol. Use purified cotton as the filtering medium," U. S.

This tincture was designed to furnish a highly flavored alcoholic preparation of orange and has no medicinal properties. It is used as a pleasant adjuvant and flavoring agent.

Off. Prep.—Syrupus Aurantii, U. S.

TINCTURA BELLADONNA FOLIORUM. U. S. (Br.)

TINCTURE OF BELLADONNA LEAVES Tr. Bellad. Fol. [Belladonna tinctura P. I.]

"One hundred mils of Tincture of Belladonna Leaves yields not less than 0.027 Gm. nor more than 0.033 Gm. of the total alkaloids of belladonna leaves." U. S. "Tincture of Belladonna contains in 100 millilitres 0.035 gramm of the alkaloids of Belladonna Leaves." Br.

Tinctura Belladonnae, Br., U. S. P. 1880; Tincture of Belladonna; Teinture de feuille de Belladone, Fr. Cod.; Belladonnatinktur, G.; Tindura alcohólica de belladonna, Sp.

“Belladonna Leaves, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains], to make about one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using diluted alcohol as the menstruum and adjusting the volume of the finished Tincture so that each one
hundred mils contains 0.03 Gm. of the total alkaloids of belladonna leaves." U. S.

"Belladonna Leaves, dried and in No. 20 powder, 100 grammes; Alcohol (70 per cent.) sufficient to produce 1000 millilitres.

"Moisten the Belladonna Leaves with one hundred millilitres of the Alcohol, and complete the percolation process. Determine the proportion of alkaloids contained in the tincture so prepared by the Br. process below." Br.

"Assay.—Evaporate 100 mils of Tinctura of Belladonna Leaves on a water bath until it measures about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under Fluidextractum Belladonnae Radicis, second line of the Assay, beginning with the words ( add 10 mils, modifying the process there given by increasing the ammonia water to 5 mils which, with about 5 mils of distilled water, is to be used in divided portions to rinse out the dish in which the mixture was evaporated; before titrating treat the residue twice with 5 mils of ether, evaporating to dryness each time." U. S.

"Evaporate 100 millilitres in an evaporating basin on a water-bath until it measures about 10 millilitres, add, if necessary, sufficient alcohol (90 per cent.) to dissolve any separated substance and transfer to a separator, rinsing the dish with a little water. Add 10 millilitres of water, 20 millilitres of chloroform, and 2 millilitres of solution of ammonia. Shake well and separate the chloroformic layer. Repeat the extraction with two successive portions of 10 millilitres of chloroform. Mix the chloroformic solutions, and shake them with 10 millilitres of N/1 solution of sulphuric acid diluted with twice its volume of water. Separate the chloroformic solution. Repeat the shaking with a further 10 millilitres of the acidified water. Mix the acid solutions, add 20 millilitres of chloroform and 4 millilitres of solution of ammonia. Shake well, draw off the chloroformic solution into a beaker, and repeat the extraction with two further portions, each of 10 millilitres, of chloroform. Allow the mixed chloroformic solutions to evaporate, dry the residue on a water-bath for thirty minutes, dissolve it in 10 millilitres of N/20 solution of sulphuric acid and titrate with N/20 solution of sodium hydroxide, using tincture of coch'neal as indicator. Deduct the number of millilitres of alkaline solution required from 10, and multiply the difference by
0.01446; the product will be the weight in grammes of the alkaloids contained in 100 millilitres of the tincture. This quantity should be not less than 0.035 gramme. Should the tincture contain more than this proportion it must be diluted with the necessary quantity of Alcohol (70 per cent.).

"Examined by the foregoing process, Tincture of Belladonna is found to contain in 100 millilitres 0.035 gramme of the alkaloids of Belladonna Leaves. Limit of error 0.002 gramme in excess or defect. This Tincture contains seven-tenths of the proportion of alkaloids contained in the Tincture of Belladonna of the British Pharmacopoeia, 1898. It may be used when the Tinctura Belladonna of the International Agreement is required." Br.

In the U. S. P., 1890, the name of this tincture was changed to Tinctura Belladonna Foliorum, for the sake of greater precision. In the U. S. P. VIII its strength was reduced to 10 per cent. to conform to the International Protocol standard.

The tincture is an efficient preparation when made from the recently dried leaves and assayed by the official process.

Dose, from five to fifteen minims (0.3-0.9 mil).

TINCTURA BENZOINI. U. S.

TINCTURE OF BENZOIN Tr. Benz.

"Benzoin, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; to make one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. Prepare a Tincture by Type Process M, using alcohol as the solvent." U. S.

This tincture was introduced into the Pharmacopoeia chiefly for the purpose of adding to ointments to prevent rancidity. This, however, is bad pharmaceutical practice and is hardly ever followed.

Dose, fifteen to thirty minims (0.9-1.8 mils).
TINCTURA BENZOINI COMPOSITA. U. S., Br.

COMPOUND TINCTURE OF BENZOIN Tr. Benz. Co.

Tinctura Balsamica, Balsamum Commendatoris, Elixir Traumaticum; Friars' Balsam; Teinture (alcoole) balsamique, Fr. Cod.; Baume du Commandeurde Permes, Fr.; Persischer Wundbalaam, G.

"Benzoin, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; Aloes, in No. 40 powder, twenty grammes [or 308.6 grains]; Storax, eighty grammes [or 2 ounces av., 360 grains]; Balsam of Tolu, forty grammes [or 1 ounce av., 180 grains]; to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M, using alcohol as the solvent." U. S.

"Benzoin, in powder, 100 grammes; Prepared Storax, 75 grammes; Balsam of Tolu, 25 grammes; Aloes, 20 grammes; Alcohol (90 per cent.), sufficient to produce 1000 millilitres.

"Macerate the Benzoin, Storax, Balsam of Tolu, and Aloes with eight hundred millilitres of the Alcohol in a closed vessel for two days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

Compound tincture of benzoin now contains 10 Gm. of benzoin to each 100 mils instead of 12 as in the U. S. P., 1890.

Uses.—Compound tincture of benzoin is chiefly employed both for its antiseptic and protective effect as a local application to minor wounds, chapped hands or nipples, indolent ulcers, etc. It is the balsamum traumaticum of the older Pharmacopoeias, and may be considered as a simplified form of certain complex compositions, such as baume du commandeur, Wade's balsam, Balsam de Maltha, Friar's balsam, Jesuit's drops, Turlington's balsam, etc., which were formerly in great repute, and are still esteemed by the people, as pectorals and vulneraries. The compound tincture of benzoin is precipitated by water. A variety of court plaster is made by applying to black silk, by means of a brush, first a solution of isinglass, and afterwards an alcoholic solution of benzoin.
It is occasionally employed internally as a stimulating expectorant in chronic bronchitis. More frequently it is used as an inhalant by adding a teaspoonful of the tincture to a pint of hot water and breathing the vapors; this mode of treatment is especially useful in the early stages of acute bronchitis. It has also been recommended in chronic dysentery with the idea that it would exercise its local action upon the ulcerated surface of the colon, but is of doubtful utility.

Dose, fifteen to sixty minims (0.9-3.75 mils).

**TINCTURA BERBERIDIS. Br.**

**TINCTURE OF BERBERIS**

"Berberis, in No. 60 powder, 100 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres,

"Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process." Br. This tincture is used as a bitter tonic.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA BUCHU. Br.**

**TINCTURE OF BUCHU**

"Buchu Leaves, in No. 20 powder, 200 grammes; Alcohol (60 per cent.) sufficient to produce, 1000 millilitres. Moisten the powder with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

This tincture has the virtues of buchu leaves.

Dose, from one to two fluidrachms (3.75-7.5 mils), either simply diluted with water or as an addition to the infusion of the leaves.

TINCTURE OF CALUMBA Tr. Calumb.

"Calumba, in No. 20 powder, two hundred grammes [or 7 ounces av., 24 grains]; to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, packing the moistened drug moderately, and using a mixture of three volumes of alcohol and two volumes of water as the menstruum." U. S.

"Calumba Root, in No. 20 powder, 100 grammes; Alcohol (60 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

This tincture was doubled in strength at the U. S. P. (VIII) in order to bring it into the class of 20 per cent. non-potent tinctures. The British tincture 1914 retains the strength of 10 Gm. of drug in each 100 mils.

Joseph Ince recommends that the tincture be prepared from the root as found in commerce, without further slicing or powdering it. Made as he proposes, the tincture is clear and bright; while if the powdered root is used it will be very turbid, even after filtration. (P. J., xiv, 491.) No. 20 powder is now directed instead of the No. 50 powder used in older Pharmacopoeias. Tincture of calumba may be added to tonic 'infusions or decoctions, to increase their stimulant power, but, like all the other bitter tinctures, should be used with caution.

Dose, of the U. S. tincture one-half to one fluidrachm (1.8-3.75 mils), of the Br. tincture one to two fluidrachms (3.75-7.5 mils).

TINCTURA CANNABIS. U. S. (Br.)

TINCTURE OF CANNABIS Tr. Cannab.
[Tinctura Cannabis Indicae, U.S.P. VIII]

"When assayed biologically Tincture of Cannabis produces incoordination when administered to dogs in a dose of not more than 0.3 mil per kilogramme of body weight." U. S.
Tinctura Cannabis Indicae, Br.; Tincture of Indian Hemp; Tincture of Hemp; Teinture (alcoole) de Chanvre de l’Inde, Fr. Cod.; Indischhanftinktur, G.

"Cannabis, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; to make about one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using alcohol as the menstruum, and adjusting the volume of the finished Tincture to conform with the above biological standard." U. S.

"Extract of Indian Hemp, 50 grammes; Alcohol (90 per cent.) sufficient to produce 1000 millilitres. Dissolve." Br.

"Assay.—Proceed as directed under Biological Assays." U. S. (Also see Cannabis).

Tincture of cannabis is assayed by tests upon dogs and it is generally advisable, for this purpose, to concentrate the tincture to about one-fourth its bulk. Care should be observed in the process of evaporation that the temperature does not rise above 60° C. (140° F.).

The American reader must take care not to confound the Indian Hemp here referred to with Apocynum cannabinum, known by the same name in this country. The term "Indian Hemp" should be dropped entirely, as its continued use has been the cause of at least one fatal mistake. The strength of the present tincture is about 33 per cent. less than that of the 1890 tincture.

Dose, ten to thirty minims (0.6-1.8 mils), to be gradually increased until some effects are experienced.

TINCTURA CAPSICI. U. S., Br.

TINCTURE OF CAPSICUM Tr. Capsic.

Tincture of Cayenne Pepper; Teinture (alcoole) de Piment des Jardins, Fr.; Tinctura capsici, P. G.; Spanischpfeffertinktur, G.
"Capsicum, in No. 50 powder, one hundred grammes [or 3 ounces av., 231 grains]; to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, using a mixture of ninety-five volumes of alcohol and five volumes of water as the menstruum." U. S. "Capsicum, in No. 20 powder, 50 grammes; Alcohol (60 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

The U. S. P. tincture is double the strength of the British. The alcoholic strength of the menstruum is of unusual proportions, 19 volumes of alcohol to 1 volume of water, the reason for this is that, on account of oleoresinous constituents of capsicum, alcohol is required and on account of a small quantity of a constituent soluble in water and insoluble in alcohol a little water must be added to the menstruum to prevent cloudiness. It is used in atonic conditions of the stomach, especially in alcoholic gastritis. It may also be used locally in various sluggish conditions of the throat and for the various purposes for which red pepper is applicable. (See Capsicum.) Applied by means of camel's-hair pencil to the relaxed uvula, it sometimes produces contraction and relieves prolapsus of that part.

Dose, of the U S. tincture, five to ten minims (0.3-0.6 mil); of the Br. preparation, ten to twenty minims (0.6-1.3 mils).

Off. Prep.—Tinctura Chloroformi et Morphinae Composita, Br.; Mistura Chloroformi et Morphinae Composita, N. F.; Mistura Opii et Chloroformi Composita, N. F.; Mistura Opii et Rhei Composita, N. F.

TINCTURA CARDAMOMI. U. S.

TINCTURE OF CARDAMOM Tr. Cardam.

Teinture (alcoole) de Cardamome, Fr.; Kardamomentink-ur, G.

*"Cardamom Seed, in No. 40 powder, one hundred and fifty grammes [or 5 ounces av., 127 grains], to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, using diluted alcohol as the menstruum." U. S.

The strength of this tincture was doubled in the U. S. P. (VIII) in order to bring it into the 20 per cent. class; it is an agreeable but strong
aromatic, and may be advantageously added to tonic and purgative infusions.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA CARDAMOMI COMPOSITA. U. S., Br.**

**COMPOUND TINCTURE OF CARDAMOM Tr. Cardam. Co.**

"Cardamom Seed, in No. 40 powder, twenty grammes [or 308.6 grains]; Saigon Cinnamon, in No. 60 powder, twenty-five grammes [or 386 grains]; Caraway, in No. 40 powder, twelve grammes [or 185 grains]; Cochineal, in No. 60 powder, five grammes [or 77 grains]. To make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms], Prepare a Tincture by Type Process M, macerating the mixed powders in seven hundred and fifty mils [or 25 fluid-ounces, 173 minims] of a mixture of fifty mils [or 1 fluidounce, 331 minims] of glycerin and nine hundred and fifty mils [or 32 fluidounces, 59 minims] of diluted alcohol and completing the preparation by using first the remainder of the mixture prepared as directed above and then diluted alcohol." U. S. "Cardamom Seeds, in No. 20 powder, 14 grammes; Caraway Fruit, in No. 20 powder, 14 grammes; Cinnamon Bark, in No. 20 powder, 28 grammes; Cochineal, in No. 20 powder, 7 grammes; Glycerin, 100 milli-litres; Alcohol (45 per cent.) sufficient to produce 1000 millilitres. Moisten the mixed powders with fifty millilitres of the Alcohol, and prepare, by the percolation process, eight hundred and fifty millilitres of tincture. Add the Glycerin and sufficient of the Alcohol to produce the required volume." Br.

In this tincture and the one immediately preceding, the proportion of cardamom seems to be reduced, but official cardamom seed now means the seed recently removed from the capsules.

This is a very agreeable aromatic tincture, occasionally used as a carminative, but more frequently as an addition to mixtures, infusions, etc., which it renders pleasant to the taste and acceptable to the stomach. It is one of the most highly prized vehicles, not merely because of its pleasant flavor, but also on account of its beautiful color. The substitution of glycerin in the U. S. formula of 1880 for the honey
formerly used was an improvement, as it increases the stability of the preparation.

Dose, one to two fluidraehms (3.75-7.5 mils).

**TINCTURA CASCARILLÆ. Br.**

**TINCTURE OF CASCARILLA**

Teinture (aloole) de Cascaiille, Fr. Cod.; Kaskarilltinktur, G.

"Cascarilla, in No. 40 powder, 200 grammes; Alcohol (70 per cent.) sufficient to produce 1000 millilitres. Moisten the powder with one hundred and fifty millilitres of the Alcohol, and complete the percolation process." Br.

This tincture has the properties of cascarilla, but is seldom, if ever, used in this country.

Dose, from thirty minims to two fluidraehms (1.8-7.5 mils).

**TINCTURA CHIRATÆ. Br.**

**TINCTURE OF CHIRETTA**

Tincture of Chirata; Teinture (alcoole) de Chirette, Fr.; Chirettatinktur, G.

"Chiretta, in No. 40 powder, 100 grammes; Alcohol (60 per cent.) sufficient to produce 1000 millilitres. Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process." Br.

This tincture is used as a bitter tonic; Although no longer recognized by the U. S. P., it is still prescribed in this country. The tincture of the U. S. 1890 was of twenty per cent. strength.

Dose, from one to two fluidraehms (3.75-7.5 mils), three or four times a day.
TINCTURA CINCHONA. U. S., Br.

TINCTURE OF CINCHONA Tr. Cinch.

"One hundred mils of Tincture of Cinchona yields not less than 0.8 Gm. nor more than 1 Gm. of the alkaloids of cinchona." U. S. "Tincture of Cinchona contains in 100 millilitres 1 gramme of the alkaloids of Red Cinchona Bark." Br.

Tinctura Cinchonsae Flavae; Tincture of Yellow Cinchona; Tincture of Peruvian Bark; Teinture (alcoole) de Quinquina jaune, Fr. Cod.; Tinctura Chinae, P. G.; Chinatinktur, G.; Tintura di china, It.

"Cinchona, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; to make about one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using as the first menstruum a mixture of seventy-five mils [or 2 fluidounces, 257 minims] of glycerin, six hundred and seventy-five mils (or 22 fluidounces, 396 minims] of alcohol, and two hundred and fifty mils [or 8 fluidounces, 218 minims] of water and completing the percolation with a mixture of two volumes of alcohol and one volume of water. Then adjust the volume of the finished Tincture so that each one hundred mils contains 0.9 Gm. of the alkaloids of cinchona." U. S.

"Red Cinchona Bark, in No. 40 powder, 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with two hundred millilitres of the Alcohol; set aside for seven days in a closed vessel; percolate with more of the Alcohol, until seven hundred millilitres of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter.

"Take ten millilitres of the strong tincture so prepared, and determine the proportion of alkaloids contained in it by the process described under 'Extractum Cinchona Liquidum.' Add to the bulk of the strong tincture such a quantity of the Alcohol that 100 millilitres of the resulting Tincture contain 1 gramme of the alkaloids of Red Cinchona Bark. Examined by the process described under 'Extractum Cinchonas Liquidum' Tincture of Cinchona is found to contain in 100 millilitres 1 gramme of the alkaloids of Red Cinchona Bark. Limit of error 0.05 gramme in excess or defect." Br.
This tincture is very properly made with a large proportion of bark, as in the bitter tinctures it is important that the alcohol should bear as small a proportion to the tonic principle as possible. Even when strongest, however, it cannot, in ordinary cases, be given in doses sufficiently large to obtain the full effect of the bark, without stimulating too highly. The tincture of the Br. Pharm. 1898 and 1914 is now made from 70 per cent. alcohol instead of the old menstruum 50 per cent., and is assayed so that it has a definite strength (100 mils containing 1 Gm. of alkaloids); these are undoubted improvements. A deposit is apt to form in the tincture when kept, consisting chiefly of cinchonic red holding probably a portion of the alkaloids in combination. This was found by J. Adams to be perfectly dissolved by heat, though it uniformly reappeared on the cooling of the tincture. The addition of diluted sulphuric acid did not cause its solution, and, even though it was removed by filtering the tincture, the deposition was afterwards renewed. (P. J. April, 1868, 470.) In reference to a mode of obviating in some measure this tendency to deposition, the reader is referred to the statements of M. Vauflart on the subject of deposition in the tinctures prepared by percolation. A. B. Taylor, in experimenting on this subject, prepared a tincture in which the menstruum consisted of two parts of alcohol, one part of water, and one part of glycerin, and which was kept three months without undergoing deposition. (A. J. P., Jan. 1865, 50.) This suggested the addition of glycerin to the official formula, and there can be no doubt that the tincture has been thereby improved, experience having demonstrated the utility of glycerin in liquid preparations of cinchona. Tincture of cinchona is rarely employed, but may be used as a tonic.

Dose, from one to two fluidraehms (3.75-7.5 mils).

**Off. Prep.**—Tinctura Cinchonae Composita, Br.

**TINCTURA CINCHONA COMPOSITA. U. S., Br.**

**COMPOUND TINCTURE OF CINCHONA** Tr. Cinch. Co.

"One hundred mils of Compound Tincture of Cinchona yields not less than 0.4 Gm. nor more than 0.5 Gm. of the alkaloids of cinchona." U. S. "Compound Tincture of Cinchona contains in 100 millilitres 0.5 grammes of the alkaloids of Red Cinchona Bark." Br.
Compound Tincture of Peruvian Bark; Huxham's Tincture of Bark; Teinture de Quinquina composee, Elixir febrifuged'Huxam, Fr.; Tinctura Chinas Composita, P. G.; Zusammen-gesetzte Chinatinktur, G.

"Red Cinchona, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; Bitter Orange Peel, in No. 40 powder, eighty grammes [or 2 ounces av., 360 grains]; Serpentaria, in No. 60 powder, twenty grammes [or 308.6 grains], to make about one thousand mils [or 33 fluidounces, 61/2 fluidraehms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using as the first menstruum a mixture of seventy-five mils [or 2 fluidounces, 257 minims] of glycerin, six hundred and seventy-five mils [or 22 fluidounces, 396 minims] of alcohol and two hundred and fifty mils [or 8 fluidounces, 218 minims] of water and completing the percolation with a mixture of two volumes of alcohol and one volume of water. Then adjust the volume of the finished Tincture so that each one hundred mils contains 0.45 Gm. of the alkaloids of cinchona." U. S.

" Dried Bitter-Orange Peel, bruised, 50 grammes; Serpentary Rhizome, in No. 40 powder, 25 grammes; Cochineal, in powder, 3 grammes; Tincture of Cinchona, 500 millilitres; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Mix the solid ingredients with five hundred millilitres of the Alcohol; set aside in a closed vessel for seven days, shaking frequently; strain, and then press; mix the two liquids thus obtained; add the Tincture of Cinchona, and sufficient of the Alcohol to produce the required volume; set aside for twenty-four hours; filter. Examined by the process described under (Extractum Cinchona Liquidum ' Compound Tincture of Cinchona is found to contain in 100 millilitres 0.5 gramme of the alkaloids of Red Cinchona Bark. Limit of error 0.05 gramme in excess or defect." Br.

This is the preparation commonly known by the name of Huxham's tincture of bark. It differs from that official in the U. S. P., 1890, only in the alcoholic strength of the menstruum, which is now about in the proportion of 2.7 volumes of alcohol to 1 volume of water; it was formerly 3 volumes of alcohol to 1 volume of water. The use of glycerin is an improvement, precipitation being thus largely prevented. In the U. S. P. VIII the drugs are not directed in the powdered state, the intention being to mix the drugs together and then to reduce the mixture to a uniform powder; in this way the volatile principles in the Serpentaria
and Orange Peel are retained, and thorough exhaustion by percolation is secured. In the U. S. P. IX this principle was omitted probably on account of the difficulty of its execution. The process for the British tincture (1898) presents some novel features. Half of the quantity of the tincture is first made from four of the ingredients; this is then mixed with an equal bulk of tincture of cinchona. The reason for this was probably to avoid assaying a mixed product during the process; but the final test has to deal with the finished tincture, and the utility of the whole method is doubtful. Compound tincture of cinchona is an excellent bitter tonic, useful for its local effect on the stomach but too feeble in the principles of cinchona to serve when the systemic action of the drug is required.

Dose, one to two fluidrachms (3.75-7.5 mils).

**Off Prep.**—Gargarisma Guaiaci Composita, N. F.

**TINCTURA CINNAMOMI. U. S., Br.**

**TINCTURE OF CINNAMON Tr. Cinnam.**

Teinture(alcoole) deCannelle, Fr. Cod.; Tinctura Cinnamomi, P. G.; Zimmmttinktur, G.; Tinctura alcoholica de canela, Sp.

"Saigon Cinnamon, in No. 50 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidraehms]. Prepare a Tincture by Type Process P, using a mixture of seventy-five volumes of glycerin, six hundred and seventy-five volumes of alcohol, and two hundred and fifty volumes of water as the menstruum." U. S.

"Cinnamon Bark, in No. 40 powder, 200 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

The British and the U. S. tinctures are now of the same strength. This tincture has the aromatic and astringent properties of cinnamon, and may be used as an adjuvant to cretaceous mixtures and astringent infusions or decoctions. By long keeping it is prone to gelatinize and become unfit for use. According to Greenish, this can be prevented by
using a menstruum composed of six parts of alcohol and two parts of water. (P. J., Feb. 1872, 641). Glycerin is now used in the menstruum for this purpose. It is an agreeable flavoring to other tinctures and because of its astringent powers is especially used in diarrhea mixtures.

Dose, one to two fluidrachms (3.75-7.5 mils).

**Off. Prep.**—Elixir Taraxaci Compositum, N. F.; Mistura Rhei Alkalina, N. F.

**TINCTURA COCCI. BR.**

**TINCTURE OF COCHINEAL**

Teinture (alcoole) de Cochenille, Fr. Cod.; Cochenilletinktur, G.

"Cochineal, in powder, 100 grammes; Alcohol (45 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

This is valued chiefly for imparting color to liquid preparations; four or five per cent. of this tincture will give a deep red color. (See Coccus.)

Dose, from twenty minims to a fluidrachm (1.3-3.75 mils).

**TINCTURA COLCHICI SEMINIS. U. S. (Br.)**

**TINCTURE OF COLCHICUM SEED**

*Tr. Colch. Sem. [Colchici tinctura P. I.]*

"One hundred mils of Tincture of Colchicum Seed yields not less than 0.036 Gm. nor more than 0.044 Gm. of colchicine." U. S.

"Colchicum Seed, in No. 50 powder, one hundred grammes [or 3 ounces av., 231 grains], to make about one thousand mils [or 33 fluid-ounces, 61/2 fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using a mixture of three volumes of alcohol and two volumes of water as the menstruum and adjusting the volume of the
finished Tincture so that each one hundred mils contains 0.04 Gm. of colchicine." U. S.

"Colchicum Seeds, in No. 30 powder, 100 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with fifty millilitres of the Alcohol, and complete the percolation process. This Tincture is of approximately the same strength as the Tinctura Colchici of the International Agreement, and is of one-half the strength of the corresponding preparation of the British Pharmacopoeia, 1898." Br.

The strength of this tincture was lowered to 10 Gm. per 100 mils in the U. S. P. VIII and IX to comply with the rule adopted for potent tinctures. An assay process was also appended.

It was at one time supposed that the tincture was quite as effective made from the unbruised as from the bruised seeds, but the opinion has been shown to be erroneous. (A. J. P., xxvi, 120.) See also a paper by N. Rosenwasser, Ibid., 1877, 436. Subsequently L. I. Morris showed that if the whole seeds were digested with hot diluted alcohol they could be perfectly exhausted. (A. J. P., 1881, p. 6.) Maisch recommended, as a convenient method of comminuting the seeds, to macerate them for two or three days in a portion of the menstruum, then to remove them and bruise them in a clean iron mortar, taking care that none of the menstruum or of the seeds should be wasted. (A. J. P., xxviii, 514.)

This tincture possesses the properties of colchicum, and may be given whenever that medicine is indicated, but the fluidextract, containing less alcohol, is generally preferred.

Dose, from fifteen to thirty minims (0.9-1.8 mils), to be repeated with caution.

**TINCTURA CUBEBAE. Br.**

**TINCTURE OF CUBEBS**

Teinture (alcoole) de Cubebe, Fr. Cod.; Kubebentinktur, G.

"Cubebs, in No. 20 powder, 200 grammes; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process."
The U. S. P. has not recognized this tincture for many years, but it is official in the N. F.. While this tincture represents the therapeutic virtue of cubeb, it is an inelegant form of administering that drug.

Dose, one to two fluidrachms (3.75-7.5 mils).

**TINCTURA DATURÆ SEMINUM. Br.**

**TINCTURE OF DATURA SEEDS**

"Datura Seeds, in No. 20 powder, 250 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Moisten the bruised Datura Seeds with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

This tincture well represents the activities of datura.

Dose, five to fifteen minims.

**TINCTURA GAMBIIR COMPOSITA. U. S. (Br.)**

**COMPOUND TINCTURE OF GAMBIIR** Tr. Gambir; Co.

[Compound Tincture of Pale Catechu To replace Tincture Catechu Composita, U. S. 1890, Compound Tincture of Catechu]

Tincture Catechu, Br.; Tincture of Catechu; Teinture (alcoole) de Cachou, Fr. Cod.; Tinctura Catechu, P. G.; Katechutinktur, G.

"Gambir, in No. 50 powder, fifty grammes [or 1 ounce av., 334 grains]; Saigon Cinnamon, in No. 50 powder, twenty-five grammes [or 386 grains], to make one thousand mils [or 33 fluid-ounces, 6⅓ fluidrachms]. Prepare a Tincture by Type Process M, using diluted alcohol as the solvent." U. S.

" Catechu, in powder, 200 grammes; Cinnamon Bark, bruised, 50 grammes; Alcohol (45 per cent.), 1000 millilitres. Prepare by the maceration, process." Br.

The name of this tincture was changed at the 1880 revision, so that it
more accurately indicated its composition than did its former name. In the U. S. P. (8th Rev.) the name was again changed to Tinctura Gambir Composita. This was due to the introduction of gambir in place of catechu (see Gambir). The present tincture is one-half the strength of the U. S. P., 1890, compound tincture of catechu. Cinnamon has been present in the tincture of catechu of former Pharmacopoeias in the same relatively large proportion—2 parts of cinnamon to 3 parts of catechu—and this disproportion has been usually overlooked. The present tincture contains 2 parts of gambir to 1 part of cinnamon. The British tincture (1898) was increased to 20 per cent. in the proportion of catechu, and is now four times the strength of the U. S. tincture. This is a grateful astringent tincture, useful in all cases to which catechu is applicable and in which small quantities of spirit are not objectionable. It may often be advantageously added to cretaceous mixtures in diarrhea. It may be given with sweetened water or some mucilaginous liquid, or in port wine when this is not contra-indicated. It sometimes gelatinizes when kept, and becomes unfit for use.

Dose, of the U. S. tincture of gambir, two to four fluidrachms (7.5-15.0 mils); of the British tincture of catechu, one-half to two fluidrachms (1.8-7.5 mils).

Off. Prep.—Tinctura Pectoralis, N. F.

TINCTURA GELSEMII. U. S., Br.

TINCTURE OF GELSEMIUM Tr. Gelsem.

Teinture (alcoole) de Gelsemium, F.; Gelsemiumtinktur, G.

"Gelsemium, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains], to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, using a mixture of sixty-five volumes of alcohol and thirty-five volumes of water as the menstruum." U. S.

"Gelsemium Root, in No. 40 powder, 100 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with fifty millilitres of the Alcohol, and complete the percolation process." Br.

This tincture has proven a valuable addition, and will be preferred to
the fluidextract for internal administration, as it is safer, and can be used more satisfactorily in extemporaneous combination. The menstruum of the U. S. P., 1890, and VIII and IX processes is weaker than that formerly official, alcohol having been replaced by alcohol diluted with water in the proportion of 65 to 35. For Farr and Wright's method of estimating this tincture, see C. D., 1892, 263.

Dose, from five to twenty minims (0.3-1.3 mils).

**TINCTURA GENTIANÆ COMPOSITA. U. S., Br.**

**COMPOUND TINCTURE OF GENTIAN Tr. Gentian. Co.**

Teinture (alcool) de Gentiane Composee, Fr.; Zusammengesetzte Enziantinktur, G.

"Gentian, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains]; Bitter Orange Peel, in No. 40 powder, forty grammes [or 1 ounce av., 180 grains]; Cardamom Seed, in No. 40 powder, ten grammes [or 154 grains], to make one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Prepare a Tincture by Type Process P, packing it moderately and using as the first menstruum a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluidounces, 252 minims] of water and completing the percolation with diluted alcohol." U. S.

"Gentian Root, cut small and bruised, 100.0 grammes; Dried Bitter-Orange Peel, bruised, 37.5 grammes; Cardamom iSeeds, in powder, 12.5 grammes; Alcohol (45 per cent.), 1000.0 millilitres. Prepare by the maceration process." Br.

There has always been difficulty from precipitation in this tincture; glycerin has been added to the menstruum to overcome this annoyance, but it is only partially successful. This is an elegant bitter, much used in dyspepsia, and as an addition to tonic mixtures in debilitated states of the digestive organs. There is, however, much danger of its abuse by alcoholics, especially in chronic cases.

Dose, one to two fluidrachms (3.75-7.5 mils).
TINCTURA GUAIACI. U. S.

TINCTURE OF OUAIAC Tr. Guaiac.

Tinctura Guajaci; Teinture (alcool) de Resine de Gayac, Fr.; Guajaktinktur, G.

"Guaiac, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Prepare a Tincture by Type Process M, using alcohol as the solvent." U. S.

Although this tincture can be prepared by percolation if care and skill are used, maceration is doubtless preferable.

This tincture is given in chronic rheumatism and gout, in the dose of from one to three fluidrachms three or four times a day. As it is precipitated by water, it is most conveniently administered in mucilage, sweetened water, or milk, by which the separated guaiac is held in temporary suspension, although it is almost impossible, without actual emulsification, to prevent the resinous material from separating and forming a coating on the inner surface of the bottle. Schar recommends tincture of guaiac as a reagent to detect the presence of ozonizing bodies. (Ph. Rund., 1894, 254.)

Dose, one fluidrachm (3.75 mils) three times a day.

Off. Prep.—Mistura Guaiaci, N. F.

TINCTURA GUAIACI AMMONIATA. U. S., Br.

AMMONIATED TINCTURE OF OUAIAC Tr. Guaiac. Ammon.

Ammoniated Tincture of Guaiacum; Tinctura Guaiaci Composita; Teinture (alcool) de Gayac ammonacale, Fr.; Ammoniakalische Guajaktinktur, G.

* "Guaiac, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms]. Prepare a Tincture by Type Process M, using aromatic spirit of ammonia as the solvent." U. S.
"Guaiacum Resin, in powder, 200 grammes; Oil of Nutmeg, 3 millilitres; Oil of Lemon, 2 millilitres; Strong Solution of Ammonia, 75 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Mix the Strong Solution of Ammonia with seven hundred millilitres of the Alcohol; add the Guaiacum Resin; set aside in a closed vessel for forty-eight hours, shaking frequently; filter; dissolve the Oil of Lemon and Oil of Nutmeg in the filtrate, and pass sufficient of the Alcohol through the filter to produce the required volume." Br.

The British Pharmacopoeia, 1898, improved the process for this tincture by abandoning the distilled aromatic spirit of ammonia used as a menstruum by the former British authority and substituting alcohol containing solution of ammonia and volatile oils, the proportion of oil of lemon having been reduced 60 per cent.

This tincture is celebrated in the treatment of chronic rheumatism, and is frequently also used in amenorrhea. It is more stimulating, and is probably more effectual, than the preceding on account of the presence of the alkali. It is precipitated by water, and should be administered emulsified with gum, so that the guaiac may be held in suspension.

Dose, from one to two fluidrachms (3.75-7.5 mils).

**Off. Prep.**—Gargarisma Guaiaci Composita, N. F.

**TINCTURA HAMAMELIDIS. Br.**

**TINCTURE OF HAMAMELIS**

Teinture (alcoole) de Hamamelis, Fr; Hamamelistinktur, G.; Tinctura alcoholica de hamamelis, Sp.

"Hamamelis Bark, in No. 20 powder, 100 grammes; Alcohol 45 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with fifty millilitres of the Alcohol, and complete the percolation process." Br.

Dose, from thirty to sixty minims (1.8-3.75 mils).
TINCTURA HYDRASTIS. U. S., Br.

TINCTURE OF HYDRASTIS Tr. Hydrast.  
[Tincture of Golden Seal]

"One hundred mils of Tincture of Hydrastis yields not less than 0.36 Gm. nor more than 0.44 Gm. of the ether-soluble alkaloids of hydrastis." U. S.

Teinture (alcoole) de Hydrastis, Fr.; Hydrastistinktur, G.; Tintura alcoholica de hidrastis, Sp.

"Hydrastis, in No. 60 powder, two hundred grammes [or 7 ounces av., 24 grains], to make about one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using a mixture of two volumes of alcohol and one volume of water as the menstruum and adjusting the volume of the finished Tincture so that each one hundred mils contains 0.4 Gm. of the ether-soluble alkaloids of hydrastis." U. S.

"Assay.—Evaporate 50 mils of Tincture of Hydrastis on a water bath until it measures about 10 mils, transfer the evaporated liquid to a separator, and proceed as directed in the assay under Fluidextractum Belladonnae Radicis, second line of the Assay, beginning with the words "add 10 mils," modifying the process there given by using the ammonia water with about 5 mils of distilled water, in divided portions, to rinse out the dish in which the Tincture was evaporated. Use only ether as the immiscible solvent throughout the assay and dry the residue at 100° C. (212° F.) to constant weight, instead of titrating it. The weight of the residue represents the amount of ether-soluble alkaloids in 50 mils of Tincture of Hydrastis." U. S.

"Liquid Extract of Hydrastis, 100 millilitres; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Mix." Br.

The British tincture is half the strength of that of the U. S. P. IX.

This tincture is useful in combination with other tinctures, or as an addition to extemporaneous mixtures where the fluidextract would not be so eligible.
Dose, from one to two fluidrachms (3.75-7.5 mils).

**TINCTURA HYOSCYAMI. U. S., Br.**

**TINCTURE OF HYOSCYAMUS Tr. Hyosc.**

[Tincture of Henbane Hyoscyami tinctura P. I.]

"One hundred mils of Tincture of Hyoscyamus yields not less than 0.0055 Gm. nor more than 0.0075 Gm. of the alkaloids of hyoscyamus." U. S.

Teinture (alcoole) de Jusquiame, Fr.; Bilsenkrauttinktur, G.; Tintura alcoholica de beleno, Sp.

"Hyoscyamus, in No. 60 powder one hundred gramme's [or 3 ounces av., 231 grains], to make about one thousand mils [or 33 fluid-ounaes, 6\(\frac{1}{2}\) fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using diluted alcohol as the menstruum and adjusting the volume of the finished Tincture so that each one hundred mils contains 0.0065 Gm. of the alkaloids of hyoscyamus." U. S.

"Hyoscyamus Leaves, in No. 20 powder, 100 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process." Br.

The strength of the British tincture (1898) was slightly reduced (20 per cent.) in order to bring it into the class of tinctures having the maximum dose of a fluidrachm. The strength was also reduced in the U. S. P. VIII and IX from 15 to 10 Gm. per 100 mils, and an assay process appended. The Br. and U. S. tinctures are now of the same strength.

This tincture possesses the activities of hyoscyamus. When it purges, as it sometimes does, it may be united with a very small proportion of tincture of opium.

Dose, one-half to one fluidrachm (1.8-3.75 mils).
TINCTURA JALAPÆ. Br.

TINCTURE OF JALAP

Teinture (alcool) de Jalap, Fr. Cod.; Jalapentinktur, G.

“Jalap, in No. 40 powder, 200 grammes; Alcohol (70 per cent.), a sufficient quantity. Moisten the powder with one hundred millilitres of the Alcohol; pack in a percolator; gradually add more of the Alcohol until six hundred millilitres of percolate have been collected; press the marc; add the expressed liquid to the percolate; set aside for twenty-four hours; filter. Determine the amount of Jalap Resin present in ten millilitres of the strong tincture so prepared by the process described under ‘Jalapae Resina’ and dilute the remainder of the strong tincture with sufficient of the Alcohol to produce a Tincture of Jalap containing 1.5 grammes of the Resin in 100 millilitres. When 10 millilitres of the Tincture, concentrated by evaporation, are mixed with eight times their volume of water, the resin thus separated, washed with water and dried at a gentle heat, weighs not less than 0.145 or more than 0.155 gramm." Br.

This tincture is no longer official in the U. S. Pharmacopoeia, but is in the N. F. IV (see Part III). The tincture of jalap of the U. S. P. 1870 was made by percolating six troy-ounces of powdered jalap with a mixture of two measures of alcohol and one of water, until two pints of tincture were obtained.

This tincture is now prepared on the basis of proportion of resin, not of crude drug, as formerly. It possesses the medicinal virtues of jalap, and is sometimes added to cathartic mixtures.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

TINCTURA J ALAPÆ COMPOSITA. Br.

COMPOUND TINCTURE OF JALAP

“Jalap, in No. 40 powder, 80 grammes; Scammony Resin, in powder, 15 grammes; Turpeth, in No. 40 powder, 10 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Moisten the mixed powders with one hundred millilitres of the Alcohol, and complete the percolation
This tincture is also official in the N. V. IV. It is a harsh but active purgative, capable of producing serious effects if given in over-dose.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA KALADANÆ. Br.**

**TINCTURE OF KALADANA**

"Kaladana, in No. 40 powder, 200 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process." Br.

This is a new tincture of the British Pharmacopoeia 1914. It is used as a cathartic in doses of one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA KINO. U. S., Br.**

**TINCTURE OF KINO Tr. Kino**

Teinture (alcoole) de Kino, Fr. Cod.; Kinotinktur, G.

"Kino, one "hundred grammes [or 3 ounces av., 231 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Place the kino in a capacious flask and pour on it five hundred mils [or 16 fluidounces, 435 minims] of boiling water. Agitate the mixture thoroughly, then heat it on a water bath, containing boiling water, for one hour, shaking it frequently. Allow the liquid to cool, add enough recently boiled water to make the product measure five hundred mils [or 16 fluidounces, 435 minims] and then add five hundred mils [or 16 fluid-ounces, 435 minims] of alcohol. Stopper the flask, set it aside in a cool place for twenty-four hours and then decant the mixture through cheese cloth. Preserve it in a cool and dark place, in small bottles, tightly corked." U. S.

"Kino, in powder, 100 grammes; Glycerin, 150 millilitres; Distilled
Water, 250 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Mix the Glycerin and the Distilled Water; rub the Kino in a mortar with a sufficient quantity of the mixture to form a smooth paste, gradually adding the remainder of the mixture; transfer to a closed vessel; add five hundred millilitres of the Alcohol; set aside for twelve hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume."

Much inconvenience is caused by the tendency of this tincture to gelatinize and gradually lose its astringency. The present official formula is believed to furnish a tincture free from this objection. It is probable that different specimens of kino vary in their tendency to gelatinize. Groves states that fresh kino will not gelatinize, and Martindale that the Australian kino is much more prone to do so than the East India drug. The air has some effect, for if this be entirely excluded the tincture will keep for a long time without undergoing the change. It should be introduced, when prepared, into very small bottles, which should be kept well corked and be opened only when wanted for use. J. D. Wood obtains a handsome preparation, which he believes to keep well and not gelatinize, by using a menstruum of 2 parts of alcohol sp. gr. 0.835, and 1 part each of water and glycerin.

L. Meyers Connor gets rid of the gelatinizing property by using magnesium carbonate in making the tincture, but it is very probable that a large part of the kino-tannic acid is removed at the same time. (A. J. P., xliv, 260.) P. F. Smith of Louisville, furnished the following formula: "Take of Kino one ounce and a half; Ground Logwood half an ounce; Diluted Alcohol a sufficient quantity. Moisten the Logwood with a portion of the Diluted Alcohol, and introduce it into a displacement apparatus. Dissolve the Kino by triturating with successive portions of Diluted Alcohol, and percolate the solution through the Logwood until a pint of tincture is obtained." We have used this process and have not noticed gelatinization to take place in any instance. Sugar added in equal proportions with the kino employed has been recommended as a preventive of gelatinization, and R. Bother claims permanence for the following formula: Powder one and a half troyounces of kino and half a troy-ounce of catechu, mix them, add ten fluidounces of water, heat for ten or fifteen minutes with constant stirring, and let the mixture cool. Add water to make the mixture twelve fluidounces, and then add four fluidounces of alcohol. Pour the mixture into a bottle containing sixty grains of filter-paper, shake the whole well at intervals, and strain the
tincture after twenty-four hours. (A. J. P., 1886, 333.)

An important change in the process of the U. S. Pharmacopoeia VIII was the employment of heat. This was due to the researches of Edmund White (P. J., 1903, May, 644, and Nov., 702), who with David Hooper believes that the gelatinization of tincture of kino is due to an enzyme or oxydase present in the kino; the activity of this is destroyed by heat. Tincture of kino is one of the most frequently prescribed astringents, especially in the treatment of diarrhea.

Dose. one to two fluidrachms (3.75-7.5 mils).

Off. Prep.—Tinctura Kino et Opii Composita, N. F.

**TINCIURA KRAMERIÆ. Br.**

**TINCTURE OF KRAMERIA**

Tincture of Rhatany; Teinture (alcoole) de Ratanhia, Fr. Cod.; Tinctura Ratanhiae, P. G.; Ratanhiatinktur, G.

Tincture of krameria was deleted from the U. S. P. IX, but retained in the Br. Pharm. 1914 and added to the N. F. IV. The British tincture closely resembles the former U. S. P. preparation.

"Krameria Root, in No. 40 powder, 200 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process." Br.

It is stated that the tincture made from Para rhatany furnishes a clear solution on the addition of water, while that from Peruvian root yields a turbid mixture.

The same precaution should be observed in keeping this tincture as is recommended for tincture of kino. It is a good preparation in cases which admit of the use of small quantities of alcohol.

Dose, one or two fluidrachms (3.75 or 7.5 mils).
TINCTURA LACTUCARII. U. S.

TINCTURE OF LACTUCARUM Tr. Lactucar.

Teinture (alcool) de Lactucarium, Fr.; Lactucariumtinktur, G.

“Lactucarium, five hundred grammes [or 17 ounces av., 279 grains]; Glycerin, two hundred and fifty mils [or 8 fluidounces, 218 minims] ; Alcohol, Purified Petroleum Benzin, Diluted Alcohol, Water, each, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, $6\frac{1}{2}$ fluidrachms]. Beat the lactucarium with clean sand, in an iron mortar, to a coarse powder, and then transfer it to a bottle; add two thousand mils [or 67 fluidounces, 301 minims] of purified petroleum benzin, cork the bottle tightly, and set it aside for forty-eight hours, frequently agitating the mixture. Pour the mixture on a double filter, cover the funnel, and, when the liquid has passed through the filter, wash the residue gradually with fifteen hundred mils [or 50 fluidounces, 345 minims] of purified petroleum benzin, and allow the lactucarium to dry by exposing it to a current of air. When it is dry and free from the odor of benzin, reduce it to a powder, using more sand, if necessary, and pack it moderately in a conical percolator. Mix the glycerin with two hundred and fifty mils [or 8 fluidounces, 218 minims] of water, and five hundred mils [or 16 fluidounces, 435 minims] of alcohol, and gradually pour this mixture on the powder. When the liquid begins to drop from the percolator, close the lower orifice, and having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding first the remainder of the menstruum, and then diluted alcohol until the drug is exhausted. Reserve the first seven hundred and fifty mils [or 25 fluidounces, 173 minims] of the percolate, evaporate the remainder on a water bath, at a temperature not exceeding 70° C. (158° F.), until it measures two hundred and fifty mils [or 8 fluidounces, 218 minims], and mix this with the reserved portion. Filter the mixed liquids and wash the filter with sufficient diluted alcohol to make one thousand mils [or 33 fluidounces, $6\frac{1}{2}$ fluidrachms] of Tincture." U. S.

This tincture was first official in the U. S. 1890. It is based on the formula of J. L. Lemberger, who recommended the extraction of the resinous inert lactucerin by treatment with petroleum benzin. Great
care must be observed to use purified petroleum benzin, as it is almost impossible to get rid of the odor and taste of petroleum in the finished preparation if the ordinary benzin be used. It is as useless as the other preparations of lactucarium.

Dose, half to one fluidrachm (1.8-3.75 mils).

**Off. Prep.**—Syrupus Lactucarii, U. S.

**TINCTURA LAVANDULÆ COMPOSITA. U. S., Br.**

**COMPOUND TINCTURE OF LAVENDER Tr. Lavand. Co.**

[Compound Spirit of Lavender]

Spiritus Lavandulse Compositus, U. S. 1870; Lavender Drops; Teinture (alcoole) de Lavande composee, Fr.; Zusammengesetzte Lavendeltinktur, G.

"Oil of Lavender, eight mils [or 130 minims]; Oil of Rosemary, two mils [or 32 minims]; Saigon Cinnamon, in No. 50 powder, twenty grammes [or 308.6 grains]; Clove, in No. 50 powder, five grammes [or 77 grains]; Myristica, in No. 50 powder, ten grammes [or 154 grains], Red Saunders, in No. 50 powder, ten grammes [or 154 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M, macerating the powders in a mixture of seven hundred and fifty mils [or 25 fluid-ounces, 173 minims] of alcohol, in which the oils have been dissolved, and two hundred and fifty mils [or 8 fluidounces, 218 minims] of water. Complete the preparation with a mixture of three volumes of alcohol and one volume of water." U. S.

"Oil of Lavender, 5.0 millilitres; Oil of Rosemary, 0.5 millilitre; Cinnamon Bark, bruised, 10.0 grammes; Nutmeg, bruised, 10.0 grammes; Red Saunders Wood, rasped, 20.0 grammes; Alcohol (90 per cent.), sufficient to produce 1000.0 millilitres. Macerate the solid ingredients and the Oils with nine hundred millilitres of the Alcohol for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

The compound tincture of lavender of the U. S. Pharmacopoeia is nearly twice the strength of the British preparation, although it is made with a menstruum weaker in alcohol. When properly prepared it is an excellent
preparation to be used for gastric uneasiness, nausea, and flatulence.

Dose, from thirty minims to a fluidrachm (1.8-3.75 mils).

**TINCTURA LIMONIS CORTICIS. U. S. (Br.)**

**TINCTURE OF LEMON PEEL Tr. Limon. Cort.**

Tinctura Limonis, Br.; Tincture of Lemon; Teinture (alcoole) de Zeste de Citron, Fr.; Citronenschalentinktur, G.

"Lemon Peel, grated from the fresh fruit, five hundred grammes [or 17 ounces av., 279 grains], to make one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M, macerating the drug in one thousand mils [or 33 fluid-ounces, 6½ fluidrachms] of alcohol and completing the preparation with alcohol. Use purified cotton as the filtering medium." U. S.

"Lemon Peel, cut small, 250 grammes; Alcohol (90 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

Tincture of lemon peel was a new official preparation of the U. S. P. VIII. Spirit of lemon made from oil of lemon was abandoned, because the poor quality of the oil with which it was likely to be made caused it to have a terebinthinate flavor. The 50 per cent. tincture made by macerating fresh lemon peel in alcohol was proposed by Scoville and the present formula produces a very satisfactory preparation.

This tincture was doubled in strength at the 1898 revision of the Br. Pharm., but is now only about one-half the strength of the U. S. tincture. It is made with strong alcohol instead of proof spirit formerly used. It forms a grateful aromatic addition to tonic infusions, etc.

Dose, from one to two fluidraehms (3.75-7.5 mils).

Off. Prep.—Syrupus Acidi Citrici, U. S.
TINCTURA LOBELIÆ. U. S.

TINCTURE OF LOBELIA Tr. Lobel. [Lobeliae tinctura P. I.]

"Lobelia, in No. 50 powder, one hundred grammes [or 3 ounces av., 231 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, using diluted alcohol as the menstruum." U. S.

The strength of this tincture is the same as that of the U. S. P. VIII, which is one-half that of the U. S. 1890. For method of assay, see C. D., 1893, 454; also P. J., 1895, 141. It possesses the emetic and narcotic properties of lobelia, and is much used in asthma. A saturated tincture is strongly recommended by A. Livezey as a local application in erysipelas, and in the eczematous eruption of Rhus poisoning. (B. M. S. J., lV, 262.)

Dose, as an expectorant, fifteen to thirty minims (0.9-1.8 mils).

TINCTURA MOSCHI. U. S.

TINCTURE OF MUSK Tr. Mosch.

"Musk, five grammes [or 77 grains]; Alcohol, forty-five mils [or 1 fluidounce, 250 minims]; Water, forty-five mils [or 1 fluidounce, 250 minims]; Diluted Alcohol, a sufficient quantity, to make one hundred mils [or 3 fluidounces, 183 minims]. Triturate the musk with the water gradually added until a smooth mixture is obtained; transfer this to a bottle and allow the mixture to macerate for twenty-four hours; then add the alcohol and macerate the mixture for six days, with occasional agitation. Transfer this mixture to a plain paper filter, and, when the liquid has drained off completely, wash the residue on the filter with sufficient diluted alcohol to make one hundred mils [or 3 fluidounces, 183 minims] of Tincture." U. S.

This tincture was reduced in strength about one-half in the U. S. P.
1890, on account of the greatly increased cost of musk. This change, in our opinion, was ill-advised, and does not secure the main object, as the patient will have to take double the dose, even if the alcohol be therapeutically contraindicated. The process has been arranged so as to make the end-product 100 mils, as very few pharmacists will require 1000 mils of tincture of musk. Musk will yield its virtues to the above menstruum if the process be followed; if wanted for its odor it will be economy to add a minim of solution of sodium hydroxide to the water used to rub the musk into a smooth paste. Care should be especially taken to use pure grain musk in this preparation.

Dose, from thirty minims to two fluidrachms (1.8-7.5 mils).

**TINCTURA MYRRHÆ. U. S., Br.**

**TINCTURE OF MYRRH Tr. Myrrh.**

Teinture (alcoole) de Myrrhe, Fr. Cod.; Tinctura Myrrhae, P. G.; Myrrhentinktur, G.; Tintura di mirra. It.; Tintura alcoholic a de mirra, Sp.

"Myrrh, in moderately coarse powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process M, using alcohol as the solvent." U. S.

"Myrrh, in coarse powder, 200 grammes; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Macerate the Myrrh with eight hundred millilitres of the Alcohol in a closed vessel for seven days, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

The strength of this tincture was increased 60 per cent. at the revision of the British Pharmacopoeia (1898) and is now equivalent to the U. S. preparation.

Official alcohol is preferable to diluted alcohol as a solvent of myrrh, because it forms a perfectly clear tincture, which is not attainable with the latter menstruum. The addition of water to the tincture renders it turbid. According to E. B. Shuttleworth (A. J. P., xliii, 369), the gum which is left behind in making the tincture may be utilized for making mucilage. The tincture of myrrh is used solely as a local application to
stimulate indolent and foul ulcers, spongy gums, aphthous sore mouth, and ulcerations of the throat.

Dose, from fifteen to thirty minims (0.9-1.8 mils).

**TINCTURA NUCIS VOMICÆ. U. S., Br.**

**TINCTURE OF NUX VOMICA Tr. Nuc. Vom.**

[Strychni tinctura P. I.]

"One hundred mils of Tincture of Nux Vomica yields not less than 0.237 Gm. nor more than 0.263 Gm. of the alkaloids of nux vomica." U. S. "Tincture of Nux Vomica contains in 100 millilitres 0.125 gramme of strychnine." Br.

"Nux Vomica, in No. 40 powder, one hundred grammes [or 3 ounces av., 231 grains], to make about one thousand millilitres [or 33 fluid-ounces, $6\frac{1}{2}$ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures), using a mixture of three volumes of alcohol and one volume of water as the menstruum and adjusting the volume of the finished Tincture so that each one hundred mils contains 0.25 Gm. of the alkaloids of nux vomica. The rate of flow for the percolate should not exceed ten drops per minute." U. S.

“Liquid Extract of Nux Vomica, 50 millilitres; Distilled Water, 150 millilitres; Alcohol (90 per cent.), sufficient to produce 600 milli-litres. Mix; filter if necessary. Examined by the process described under ‘Extractum Nucis Vomicae Liquidum’ Tincture of Nux Vomica is found to contain in 100 millilitres 0.125 gramme of strychnine. Limit of error 0.005 gramme in excess or defect. This Tincture contains in each millilitre 1.25 milligrams of strychnine; each fluidrachm contains about $1/16$ grain. It contains approximately the same proportion of strychnine as the Tinctura Nucis Vomica of the International Agreement, and one-half of that contained in the corresponding preparation of the British Pharmacopoeia, 1898." Br.

In the U. S. VIII this tincture was made from the extract, the object
being to secure a more reliable and definite tincture than was possible under the process official prior to 1890; for this reason 2 per cent. of the standardized extract was directed to be dissolved in a mixture of 3 volumes of alcohol and 1 volume of water. On account of the very tough structure of nux vomica, percolation was accomplished usually with varying results. The amount of extract present in the percolate was to some extent a measure of its activity; hence, if a weighed portion of the percolate was evaporated to dryness, and the percentage of dry extract noted, it was easy to calculate the amount present in the whole quantity. The standard for Tincture of Nux Vomica was changed in the U. S. P. IX from 0.1 Gm. of strychnine in 100 mils to 0.25 Gm. in 100 mils of the alkaloids of nux vomica and instead of making the tincture from a definite quantity of extract of nux vomica percolation of the powdered drug is used. It is true that the tincture must be assayed, and the pharmacist, for this reason, must depend on the manufacturer for his supply, as it is unprofitable to assay small quantities of the tincture. We believe that more uniform results were obtained for the U. S. P. VIII tincture than will be for that of the U. S. P. IX, although the U. S. P. IX process is supposed to give a product of a more uniform color, which was the principal defect in the U. S. P. VIII product.

The British Pharmacopoeia standardizes the liquid extract, and makes its tincture from it of such strength that 100 mils shall contain 0.125 Gm. of strychnine. R. Rother (A. J. P., Jan., 1883), after experimenting with various substances, found that sodium chloride aided greatly in softening the bassorin-like substance in which the alkaloidal principles of nux vomica are embedded, and he proposes its use by adding it to the menstruum of diluted alcohol in the proportion of 120 grains to the pint (see U. S. D., 16th ed., p. 1527).

The amount of strychnine in this tincture is so small that it is not to be recommended for producing the systemic effects of that alkaloid. Its most important use is as a bitter tonic in gastric atony.

Dose, of the tincture, ten to thirty minims (0.6-1.8 mils), to be increased if necessary.

**Off. Prep.**—Elixir Phosphori et Nucis Vomicae, N. F.
TINCTURA OLIVERI CORTICIS. Br.

TINCTURE OF OLIVER'S BARK

"Oliver's Bark, in No. 40 powder, 100 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with fifty millilitres of the Alcohol, and complete the percolation process." Br.

This tincture has been used in Australia for a number of years and is now official in the Br. Pharm. 1914. It possesses the properties of an aromatic like cinnamon.

The dose is from one-half to one fluidrachm (1.8-3.75 mils).

TINCTURA PHYSOSTIGMATIS. U. S.

TINCTURE OF PHYSOSTIGMA Tr. Physostig.
[Tr. Physostig.]

“This tincture has been used in Australia for a number of years and is now official in the Br. Pharm. 1914. It possesses the properties of an aromatic like cinnamon.

The dose is from one-half to one fluidrachm (1.8-3.75 mils).

TINCTURE OF PHYSOSTIGMA Tr. Physostig.
[Tr. Physostig.]

"One hundred mils of Tincture of Physostigma yields not less than 0.013 Gm. nor more than 0.017 Gm. of the alkaloids of physostigma." U.S.

Teinture (alcoole) de feve du Calabar, Fr.; Kalabarbohnentinktur, G.

"Physostigma, in No. 50 powder, one hundred grammes [or 3 ounces av., 231 grains], to make about one thousand mils [or 33 fluid-ounces, 6 1/2 fluidrachms]. Prepare a tincture by Type Process P, as modified for assayed tinctures, using alcohol as the menstruum and adjusting the volume of the finished tincture so that each one hundred mils contains 0.015 Gm. of the alkaloids of physostigma,

This tincture was reduced from 15 Gm. (U. S. P., 1890) to 10 Gm. of drug per 100 mils in the U. S. P. VIII and an assay process appended; the U. S. P. IX has retained this strength. This tincture of Calabar Bean is much weaker than that proposed by Fraser, which was nearly as strong as a fluidextract— five minims representing three grains of the drug.

Dose, of the official tincture, from ten to thirty minims (0.6-1.8 mils).
TINCTURA PICRORHIZÆ. Br.

TINCTURE OF PICRORHIZA

"Picrorhiza, cut small and bruised, 250 grammes; Alcohol (45 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

Although “this Tincture is of twice the strength of the corresponding preparation of the Indian and Colonial Addendum, 1900," Br., the proportion of alcohol in this tincture is too large for it to be available as an antiperiodic; it is used as a bitter tonic.

Dose, one-half to one fluidrachm (1.8-3.75 mls).

TINCTURA PODOPHYLLI. Br.

TINCTURE OF PODOPHYLLUM

Teinture (alcoole) de Resine de Podophyllum, Fr.; Podophyllintinktur, G.

"Podophyllum Resin, 36.5 grammes; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Add the Podophyllum Resin to nine hundred millilitres of the Alcohol, and set aside for twenty-four hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

The introduction of this tincture is of doubtful utility.

Dose, five to fifteen minims (0.3-0.9 mil).

TINCTURA PODOPHYLLI INDICI. Br.

TINCTURE OF INDIAN PODOPHYLLUM

"Indian Podophyllum Resin, 36.5 grammes; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Add the Indian Podophyllum Resin to nine hundred millilitres of the Alcohol, and set aside for twenty-four hours, shaking occasionally; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

This has been introduced to afford a substitute in the Asiatic provinces.
for the tincture of Podophyllum.

Dose, five to fifteen minims (0.3-0.9 mil).

**TINCTURA PRUNI VIRGINIANÆ. Br.**

**TINCTURE OF WILD CHERRY**

Tincture of Virginian Prune; Teinture (alcool) d'Ecorce de Cerisier, Fr.; Wildkirschenrindentinktur, G.

"Wild Cherry Bark, in No. 20 powder, 200 grammes; Alcohol (90 per cent.), 565 millilitres; Distilled Water, 365 millilitres; Glycerin, 100 millilitres. Mix the powder with the Distilled Water; set aside in a closed vessel for twenty-four hours; add the Alcohol, and complete the maceration process; add the Glycerin to the product." Br.

This was a new official tincture of the Br. Pharm., 1898; its utility is doubtful. The English name has been changed from Virginian Prune to Wild Cherry in the Br. Pharm., 1914. The use of the glycerin serves to retard precipitation.

Dose, from one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA PYRETHRHI. U. S., Br.**

**TINCTURE OF PYRETHRUM Tr. Pyreth.**

[Tincture of Pellitory]

Teinture (alcoole) de Pyrethre (racine), Fr. Cod.; Bertramwurzeltinktur, G.

"Pyrethrum, in No. 50 powder, two 'hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P. using alcohol as the menstruum." U. S.

"Pyrethrum Root, in No. 40 powder, 200 grammes; Alcohol (70 per cent.), sufficient to produce, 1000 millilitres. Moisten the powder with one hundred and fifty millilitres of the Alcohol, and complete the percolation process." Br.
This tincture is a powerful local irritant, and is an ingredient in several well-known mouth and tooth washes. For its uses, which are purely external, see Pyrethrum.

**TINCTURA QUASSIÆ. U. S. Br.**

**TINCTURE OF QUASSIA Tr. Quass.**

Teinture (alcool) de Quassie Amere, Fr.; Quaasiatinktur, G.

"Quassia, in No. 50 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]
Prepare a Tincture by Type Process P, using a mixture of one volume of alcohol and two volumes of water as the menstruum." U. S.

"Quassia Wood, rasped, 100 grammes; Alcohol (45 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

The strength of this tincture was doubled in the U. S. P. VIII and is twice that of the present British tincture. It may be employed as an addition to tonic infusions or mixtures. It has the advantage that, being free from tannin, it may be given in conjunction with salts of iron.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA QUILLAÆ. Br.**

**TINCTURE OF QUILLAIA**

Teinture (alcoole) d'Ecorce de Quillaya, Fr.; Seifenrindeitinktur, G.

Tincture of quillaja was deleted from the U. S. P. IX, but is now official in the N. F. IV..

"Quillaia Bark, in No. 20 powder, 50 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with twenty-five millilitres of the Alcohol, and complete the percolation process." Br.

This tincture is almost exclusively used as an emulsifying agent. Its medicinal activity, however, limits its use. (See Quillaja) The British tincture is only one-fourth the strength of the preparation.
Dose, from one-half to one fluidrachm (1.8-3.75 mils).

**TINCTURA RHEI. U. S. (Br.)**

**TINCTURE OF RHUBARB Tr. Rhei**

*Tinctura Rhei Composita*, Br., Compound Tincture of Rhubarb; Teinture (alcoole) de Rhubarbe, Fr. Cod.; Rhabarbertinktur, G.; Tintura di rabarbaro, It.

"Rhubarb, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains], Cardamom Seed, in No. 40 powder, thirty grammes [or 1 ounce av., 25.5 grains], to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Prepare a Tincture by Type Process P, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluidounces, 252 minims] of water as the first menstruum and completing the percolation with diluted alcohol." U. S.

"Rhubarb, in No. 20 powder, 100.0 grammes; Cardamom Seeds, in No. 20 powder, 12.5 grammes; Coriander Fruit, in No. 20 powder, 12.5 grammes; Glycerin, 100.0 millilitres; Alcohol (45 per cent.) sufficient to produce 1000.0 millilitres. Moisten the solid ingredients with one hundred millilitres of the Alcohol, and prepare, by the percolation process, eight hundred and fifty millilitres of tincture. Add the Glycerin, and sufficient of the Alcohol to produce the required volume." Br.

This tincture was doubled in rhubarb and cardamom strength in the U. S. P. (8th Rev.). The tincture of rhubarb on standing deposits a yellow precipitate. This has been shown by James T. King (A. J. P., xlii) to be in most cases largely composed of chrysophanic acid. He proposed to remedy this by the use of a stronger alcohol, or, as recommended by J. B. Moore (A. J. P., xlv, 306), by the substitution of glycerin for a portion of the alcohol. We have not found that either of these plans entirely prevents precipitation, although glycerin is an aid in this direction.

Dose, from one to two fluidrachms (3.75-7.5 mils).

**Off. Prep.**—Mistura Opii et Rhei Composita, N.F.
TINCTURA RHEI AROMATICA. U. S.

AROMATIC TINCTURE OF RHUBARB Tr. Rhei Arom.

Teinture (alcoole) de Rhabarbe aromatique, Fr.; Aromatische Rhabarbertinktur, G.

"Rhubarb, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains]; Saigon Cinnamon, in No. 40 powder, forty grammes [or 1 ounce av., 180 grains]; Clove, in No. 40 powder, forty grammes [or 1 ounce av., 180 grains]; Myristica, in No. 40 powder, twenty grammes [or 308.6 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms].

Prepare a Tincture by Type Process P, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluidounces, 252 minims] of water as the first menstruum and completing the percolation with diluted alcohol." U. S:

This is the tincture which is used in making the aromatic syrup of rhubarb. It is preferable to separate the preparations, as it is occasionally desirable to prescribe the tincture without the admixture with syrup, while the pharmacist will always prefer to make the tincture in quantity and keep it on hand, since it is permanent, and add to it syrup to make the aromatic syrup when needed.

Dose, for an adult, from one-half to one fluidrachm (1.8-3.75 mils).

Off. Prep.—Syrupus Rhei Aromaticus, U. S.

TINCTURA SANGUINARIÆ. U. S.

TINCTURE OF SANGUINARIA Tr. Sanguin.
[Tincture of Blood Root]

Teinture (alcoole) de Sanguinaire, Fr.; Blutwurzeltinktur, G.

"Sanguinaria, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains]; Hydrochloric Acid, ten mils [or 162 minims]; Alcohol, Water, each, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix six hundred mils [or 20 fluidounces, 138 minims] of alcohol with four hundred mils [or 13 fluidounces, 252 minims] of water. Moisten the drug with a mixture of the hydrochloric
acid and thirty mils [or 1 fluid-ounce, 7 minims] of this menstruum, transfer it to a percolator, and, without pressing the powder, allow it to stand, well covered, for six hours; then pack it firmly and pour on enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, pouring on sufficient menstruum made of alcohol and water, in the same proportion as before, to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms] of Tincture."

U. S.

This tincture was reduced from 15 Gm. (U. S. P., 1890) to 10 Gm. of drug, per 100 mils, in the U. S. P. VIII and IX.

A precipitate will generally be found deposited upon the sides and bottoms of bottles containing this tincture. W. J. McConn (A. J. P., 1884, p. 505) recommended the addition of an alkaline citrate, preferably potassium citrate, as a preventive. He found sanguinarine in the precipitate. See also Homerberg and Beringer (A. J. P., 1913, lxxv, p. 394). The official menstruum now contains hydrochloric acid, with a view of preventing precipitation. This tincture is emetic in the dose of from three to four fluidrachms (11.25-15 mils); but it is rather intended to act as an expectorant or an alterative, for which purpose from fifteen to sixty minims (0.9-3.75 mils) may be given.

**TINCTURA SCILÆ. U. S., Br.**

**TINCTURE OF SQUILL Tr. Scill.**

"If assayed biologically the minimum lethal dose should not be greater than 0.006 mil of Tincture, or the equivalent in Tincture of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." U. S.

Teinture (alcoole) de Scille, Fr. Cod.; Meerzwiebeltinktur, G.; Tintura alcoholica de escila, Sp.

"Squill, in No. 20 powder, one hundred grammes [or 3 ounces av., 231 grains]; Alcohol, Water, each, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Moisten the drug with sufficient menstruum, prepared by mixing three volumes of alcohol and one volume of water, and macerate it in a closed vessel in a
moderately warm place for twenty-four hours, stirring occasionally. Then transfer it to a percolator, shake it down evenly without packing and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding sufficient of the same menstruum to make one thousand mils [or 33 fluid-ounces, 6\(\frac{1}{2}\) fluidrachms] of Tincture.

"Squill, bruised, 200 grammes; Alcohol (60 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

Tincture of Squill was reduced from the strength of 15 Gm. (U. S. P. 1890) to 10 Gm. of drug, per 100 mils, U. S. P. VIII and IX). This tincture yields a grayish, rose-colored, very bitter and acrid deposit, consisting of silky tufts. (Meniere.) The tincture represents the virtues of squill probably better than any other official preparation.

Dose, from ten to twenty minims (0.6-1.3 mils) (from twenty to forty drops).

**TINCTURA SENEGÆ. Br.**

**TINCTURE OF SENEGA**

Teinture (alcoole) de Polygala de Virginie, Fr.; Senegatinktur. G.

"Senega  Root, in No. 40 powder, 200 grammes; Alcohol (60 per cent.), sufficient to produce, 1000 millilitres. Moisten the powder with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

The Br. Pharm. 1898 increased the strength of this preparation 60 per cent. The tincture is efficient, but it is hardly needed while recourse can be had to the fluidextract or the syrup.

Dose, from thirty minims to two fluidrachms (1.8-7.5mils).
TINCTURA SENNAE COMPOSITA. Br.

COMPOUND TINCTURE OF SENNA

Elixir Salutis; Teinture (alcoole) de Sene composee, Teinture de Sene aromatique, Elixir de Salut, Fr.; Zusammengesetzte Sennatinktur, G.

"Senna Leaves, in No. 20 powder, 200 grammes; Caraway Fruit, in No. 20 powder, 25 grammes; Coriander Fruit, in No. 20 powder, 25 grammes; Glycerin, 100 millilitres; Alcohol (45 per cent.), sufficient to produce 1000 millilitres. Moisten the solid ingredients with two hundred and fifty millilitres of the Alcohol, and prepare, by the percolation process, eight hundred and fifty millilitres of tincture. Add the Glycerin and sufficient of the Alcohol to produce the required volume." Br.

The Br. Pharm. 1898 increased the proportion of senna in this preparation 60 per cent.

This tincture is the elixir salutis of the old Pharmacopoeias. It is a warm cordial purgative, useful in costiveness attended with flatulence, and in atonic gout, especially when occurring in intemperate persons. It is also added to cathartic infusions and mixtures. Tincture of senna yields a yellow scaly deposit, containing white crystals of calcareous salts. (Meniere.)

Dose, from two to four fluidrachms (7.5-15 mils).

TINCTURA SERPENTARIÆ. Br.

TINCTURE OF SERPENTARY

Teinture (alcoole) de Serpentaire de Virginie, Fr.; Schlangenwurzeltinktur, G.

"Serpentary Rhizome, in No. 40 powder, 200 grammes; Alcohol (60 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

Tincture of Serpentina was doubled in strength in the U. S. P. VIII, but is now transferred to the N. F. (see Part III). This tincture is little other
than a feebly aromatic, alcoholic stimulant. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent.

Dose, thirty minims to two fluidrachms (1.8-7.5 mils).

**TINCTURA STRAMONII. U. S., Br.**

**TINCTURE OF STRAMONIUM Tr. Stramon.**

“One hundred mils of Tincture of Stramonium yields not less than 0.0225 Gm. nor more than 0.0275 Gm. of the total alkaloids of stramonium.” U. S.

Tincture of Stramonium Leaves; Teinture (alcoole) de Stramoine (feuille), Fr. Cod.; Stechapfelblattertinktur. G.

"Stramonium, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains], to make about one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, as modified for assayed tinctures, using-diluted alcohol as the menstruum and adjusting the volume of the finished Tincture so that each one hundred mils contains 0.025 Gm. of the total alkaloids of stramonium.

" Stramonium Leaves, in No. 20 powder, 200 grammes; Alcohol (45 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with two hundred millilitres of the Alcohol, and complete the percolation process." Br.

This tincture is now made from Stramonium leaves instead of the seeds as directed by the U. S. P. 1890, and the strength made 10 Gm. of drug, per 100 mils, instead of 15 Gm., as in the U. S. P. 1890, and an assay has been appended. The Br. Pharm. 1898 increased the strength of this preparation 60 per cent., but changed the form of the drug from seeds to leaves. The British tincture is now double the strength of the U. S. P. tincture.

Dose, from ten to twenty minims (0.6-1.3 mils); of the British tincture, five to ten minims (0.3-0.6 mil).
TINCTURA TOLUTANA. U. S., Br.

TINCTURE OF TOLU Tr. Tola. [Tolu Tincture]

Tincture of Balsam of Tolu; Teinture (alcoole) de Baume de Tolu, Fr. Cod.; Tolubalsamtinktnr., G.

"Balsam of Tolu, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms] . Prepare a Tincture by Type Process M, using alcohol as the solvent." U. S.

"Balsam of Tolu, 100 grammes; Alcohol (90 per cent.), sufficient to produce, 1000 millilitres. Dissolve the Balsam of Tolu in eight hundred millilitres of the Alcohol; filter; pass sufficient of the Alcohol through the filter to produce the required volume." Br.

This tincture was doubled in strength in the U. S. P. VIII. The British tincture (1914) is half the strength of the U. S. P. tincture.

The tincture of tolu has the properties of the balsam, and may be employed as an addition to expectorant mixtures in chronic bronchitis, but the proportion of alcohol is too large to allow of its advantageous use in some cases. It is used in preparing the syrup of tolu. In smaller quantities it is often employed to flavor cough mixtures. It is precipitated by aqueous liquids.

Dose, one-half to two fluidrachms (1.8-7.5 mils).

Off. Prep.—Syrupus Tolutanus, U. S.

TINCTURA URGINEÆ. Br.

TINCTURE OF URGINEA

"Urginea, bruised, 200 grammes; Alcohol (60 per cent.), 1000 millilitres. Prepare by the maceration process." Br.

This tincture was introduced into India and is intended to be used in place of squill.

The dose is five to fifteen minims (0.3-0.9 mil).
TINCTURA VALERIANÆ. U. S.

TINCTURE OF VALERIAN Tr. Valer.

Teinture (alcoole) de Valeriane, Fr. Cod.; Tinctura Valerianae, P. G.; Baldriantinktur, G; Tinturo di valeriana, It.

"Valerian, in No. 40 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, using a mixture of three volumes of alcohol and one volume of water as the menstruum." U. S.

The proportion of alcohol was increased in the U. S. 1890 tincture, to prevent precipitation, and this strength has been retained in the present revision. It is now three parts of alcohol to one part of water. The tincture possesses the properties of valerian, but cannot be given in some cases, so as to produce the full effects of the root, without stimulating too highly, in consequence of the large proportion of spirit. It deposits on standing a black, very cohesive precipitate, with starch, and a yellow extractive matter. (Meniere.)

Dose, one to four fluidrachms (3.75-15.0 mils).

TINCTURA VERATRI VIRIDIS. U. S.

TINCTURE OF VERATRUMVIRIDE Tr. Verat. Vir.

[Tinctura Veratri, U. S. VIII]

Tincture of Green Hellebore; Tincture of American Hellebore; Teinture (alcoole) de Veratre, Fr.; Tinctura Veratri, P. G.; Nieswurzeltinktur, G.

"Veratrum Viride in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Prepare a Tincture by Type Process P, using alcohol 'as the menstruum." U. S.

The U. S. tincture of American hellebore of 1890 was of the same strength as Norwood's tincture, which was prepared by its author from fresh drug (240 grains for each fluidounce of alcohol), and was supposed to be saturated. The U. S. P. 1890 tincture was made from
dried and powdered veratrum (40 Gm. in 100 mils strength) but was reduced by the U. S. P. VIII from 40 per cent. to 10 per cent. in order that it might conform with the recommendations of the Brussels Congress concerning potent tinctures (see Tinctures). This action has resulted in increasing the use of the fluid-extract, which is a better preparation. The U. S. P. IX has returned to the exclusive use of veratum viride. Veratrum album was also recognized in the U. S. P. VIII.

Dose, of U. S. tincture, ten to thirty minims (0.6-1.8 mils).

**TINCTURA ZINGIBERIS. U. S., Br.**

**TINCTURE OF GINGER Tr. Zingib.**

[Tincture of Jamaica Ginger]

"Jamaica Ginger, in No. 30 powder, two hundred grammes [or 7 ounces av., 24 grains], to make one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Prepare a Tincture by Type Process P, using alcohol as the menstruum. Evaporate 10 Gm. of Tincture of Ginger to dryness in a tared dish on a water bath; the yield of residue does not exceed 2 per cent. When treated with 20 mils of cold distilled water, not more than 15 per cent. of this residue dissolves. Evaporate 10 mils of Tincture of Ginger to dryness in a small flask. Add 5 mils of half-normal alcoholic potassium hydroxide V.S. and boil the mixture gently for thirty minutes under a reflux condenser. Remove the condenser and evaporate the alcohol on a water bath. Then add 50 mils of distilled water to the residue, agitate the mixture, filter it and transfer the aqueous filtrate to a separatory funnel and shake it out with 25 mils of ether. Evaporate the separated ether solution spontaneously by adding it, a few drops at a time, to the center of a watch glass. Cautiously apply the tip of the tongue to the dry residue; the taste should be slightly camphoraceous but not sharp or bitingly-pungent (capsicum or similar pungent substitute). It contains about 90 per cent. of C₂H₅.OH by volume." U. S.

"Ginger, in No. 40 powder, 100 grammes; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Moisten the powder with one hundred millilitres of the Alcohol, and complete the percolation process." Br.
The strength of this tincture was reduced at the 1880 revision one-third, to bring it into the 20 per cent. class; this is not a disadvantage, however, in view of the introduction of the fluidextract, and the dose is not now inconveniently large.

The tincture of the British Pharmacopoeia is still too weak in the proportion of ginger. In consequence of the mucilaginous matter contained in ginger, the tincture made with diluted alcohol or proof spirit is apt to be turbid, and the drug is incompletely exhausted of its resinous and oily constituents. Alcohol or rectified spirit is, therefore, properly preferred. Official Jamaica ginger only should be used; for, while a darker-colored preparation is made when the inferior varieties are substituted, the apparent increase in strength is due to coloring matter, and not to the presence of a larger amount of volatile oil or resin.

The tincture of ginger is a useful carminative, and may often be beneficially added to tonic and purgative infusions or mixtures in debilitated states of the alimentary canal. It is in this country largely used for the preparation of a syrup of ginger, for which purpose, however, the fluidextract is official, and is better even than the strong tincture of the Br. Pharmacopoeia 1885, which was dropped at the 1898 revision.

Dose, eight to forty minims (0.5-2.5 mils).

**TINCTURÆ.**

**TINCTURES**

Tinctures, in the pharmaceutical sense of the term, are alcoholic solutions of medicinal substances, prepared by maceration, digestion, or percolation. Solutions in spirit of ammonia and ethereal spirit are embraced under the same denomination, but are severally distinguished by the titles of ammoniated tinctures and ethereal tinctures. The
advantages of alcohol as a menstruum are that it dissolves principles which are sparingly, or not at all, soluble in water, and contributes to their preservation. when dissolved, while it leaves behind some inert substances which are dissolved by water. In no instance, however, is dehydrated alcohol employed. Because of the slight amount of water in it, official alcohol dissolves more or less of substances which are insoluble in dehydrated alcohol, while its solvent power in relation to bodies soluble in that fluid is sufficient for all practical purposes. Diluted alcohol or proof spirit is often preferable to official alcohol, as it is capable of extracting a larger proportion of those active principles of plants which require an aqueous menstruum, while at the same time it is strong enough to prevent spontaneous decomposition, and has the advantages of being cheaper and less stimulating, although a few tinctures when prepared with weak alcoholic menstrua undergo some deterioration in time, in consequence of acetous fermentation taking place in the alcoholic fluid. The best preventive is to keep them in full and well-closed bottles, at a low temperature. The diluted alcohol of the different Pharmacopoeias is not of the same strength; that of the United States consists of equal volumes of official alcohol and water, and has the sp. gr. of about 0.936 at 15.56 C. (60° F.), while the British has four official diluted alcohols—70, 60, 45, and 20 per cent. Alcohol, or rectified spirit, is preferred as a solvent when the substance to be extracted or dissolved is nearly or quite insoluble in water, as in the instances of resins, guaiac, camphor, and the essential oils. The presence of water is here injurious, not only by diluting the menstruum, but also by exercising an affinity for the alcohol which interferes with its solvent power. Thus, water added to an alcoholic solution of one of these bodies produces a precipitate by abstracting the alcohol from it. Diluted alcohol, or proof spirit, is employed when the substance is a soluble both in alcohol and in water; or when one or more of the ingredients are soluble in the one fluid and one or more in the other, as in the case of vegetable bodies which contain extractive or tannin, or the natural salts of the alkaloids, or gum united with resin or volatile oil. As these include the greater number of medicine's from which tinctures are prepared, diluted alcohol is most frequently used. In the preparation of the tinctures, the drug should be dry, and properly comminuted by being bruised, sliced, or pulverized. It is usually better in a moderately fine than in a very fine powder; the proper degree depends, however, upon the ease with which the menstruum extracts the soluble principles. The recommendations of the International Protocol included the use of 70 per cent. alcohol for the various tinctures, but as this has not proven to
be the best menstruum for some drugs, the U. S. P. has not always followed the suggestion.

In the U. S. P. IX the general article on tinctures is as follows:

"Tinctures are alcoholic preparations made by extracting the valuable principles from drugs by the use of appropriate menstrua or solvents. Tincture of ferric chloride and tincture of iodine are exceptional, not being made by extraction; they are alcoholic solutions of chemical substances. Tinctures of potent drugs are made of the strength of ten grammes [or 154 grains] of drug in one hundred mils [or 3 fluidounces, 183 minims 1 of tincture. The other tinctures vary in the proportion of drug in the finished tincture. Tinctures are made by percolation with few exceptions. Maceration or solution is preferred when from its physical character the drug is not suitable for percolation. The majority of official tinctures are prepared under one or the other of the two type processes described, and in each formula directions are given as to the process to be followed with such modifications as may be necessary. A number of drugs require special manipulation for the preparation of satisfactory tinctures, and for these the formulas in full will be found in the text. Where it has been found possible and desirable to standardize the tinctures a rubric and assay have been added. Tinctures should be stored in tightly-stoppered bottles, kept in a cool place, and protected from light.

**Type Process P—Percolation.**

"Moisten the powdered drug or mixed drugs designated in the formula with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp, transfer it to a percolator, and, without pressing the powder, allow it to stand well-covered for six hours; then pack it firmly, unless otherwise directed, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed slowly, gradually adding sufficient of the menstruum to make one thousand mils [or 33 fluidounces, 6½ fluidrachms] of finished tincture.

"Modification for Assayed Tinctures.—In Tinctures that are directed to be assayed, allow the percolation to proceed until the percolate measures
nine hundred and fifty mils [or 32 fluidounces, 59 minims]. Assay a sample of this percolate as directed and from the alka-loidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the liquid and add to this enough of the menstruum to make the finished Tincture conform to the required alkaloidal standard.

**Type Process M—Maceration.**

"Macerate the drug or mixed drugs designated in the formula in a stoppered container, in a moderately warm place, with seven hundred and fifty mils [or 25 fluidounces, 173 minims] of the prescribed solvent (unless a different amount is specified in the formula). Continue the maceration with frequent agitation during three days or until the drug is practically extracted, transfer the mixture to a filter and, when the liquid has drained off completely, gradually wash the residue on the filter with enough of the solvent to make one thousand mils [or 33 fluidounces, 6½ fluidrachms] of finished tincture." U. S.

The British Pharmacopoeia in the Appendix IX. (see Part III) has provided detailed instruction for both percolation and maceration processes.

Tinctures were at one time universally prepared by maceration or digestion. Our own Pharmacopoeia formerly directed maceration at ordinary temperatures, and extended the period to two weeks. In several instances in which maceration is ordered in the U. S. Pharmacopoeia, maceration for three days is directed, but the Br. process requires seven days. When circumstances require that the tincture should be speedily prepared, digestion may be resorted to. Care should always be taken to keep the vessels well stoppered, in order to prevent the evaporation of the alcohol. The materials should be frequently shaken during the digestion or maceration, and this caution is especially necessary when the substance acted on is in the state of powder. The tincture should not be used until the maceration is completed, when it should be separated from the dregs either by simply filtering it through paper, or, when force is requisite, by expressing it through linen, and filtering.

The plan of preparing tinctures by percolation has been extensively adopted, and has been found to answer well when skilfully executed. In the present edition of our Pharmacopoeia, percolation has been adopted
as the rule, maceration being directed in some instances in which it was deemed preferable. The method of making tinctures by diluting fluidextracts, except in a few special cases, is not to be recommended. The menstruum directed for the fluidextract is most frequently not identical with that used for the tincture, and precipitation of active constituents often ensues when this easy method is employed. Owing to the larger dose of the tinctures, and consequently less degree of concentration, a larger proportion of water can be used in their menstrua than in fluidextracts, and this is a distinct advantage, as tinctures are frequently prescribed in combination with aqueous solutions.

Another mode of exhausting medicines by spirit has been proposed by H. Burton. It consists in suspending in the solvent, immediately under its surface, the solid matter contained loosely in a bag. The liquid in contact with the bag, becoming heavier by impregnation with the matters dissolved, sinks to the bottom; its place is supplied with a fresh portion, which in its turn sinks, and thus a current is established, which continues until the solid substance is exhausted or the liquid saturated. During the maceration the bag should be occasionally raised above the surface of the liquor in the bottle, allowed to drain, and then again immersed. It is asserted that the period of maceration is much shortened in this way. For this mode of preparing tinctures Samuel Gale has proposed the use of a cylindrical stoneware vessel with a diaphragm capable of being supported at different heights by projections from the inner surface of the jar, with corresponding notches in the diaphragm, to permit its easy passage to the lower ledges. The material is to be placed upon the diaphragm and kept covered with the menstruum.

Tinctures prepared by adding alcohol to the expressed juices of plants have been long in use on the continent of Europe, and have been brought into notice in Great Britain. They are sometimes called in England preserved vegetable juices. This method of preparing tinctures has, however, been abandoned by both the U S. and Br. Pharmacopoeias. Preserved juices are often energetic, yet it is obvious that tinctures prepared from the fresh plant must be still more so, as they contain necessarily not only the soluble active matter of the juice, but also that which, when the juice is expressed, is left in the solid residue of the plant. For further information see U. S. D., 19th ed., p. 1293.
A process for making tinctures from fresh drugs was official in the U. S. P. VIII. It was deleted from the U. S. P. IX, but introduced into the National Formulary IV under the heading Tincturæ Medicamentorum Recentium as follows:

"Tinctures of fresh drugs, when not otherwise directed, are to be prepared according to the following general formula: The Fresh Drug, cut, bruised, or crushed, five hundred grammes [or 17 ounces av., 279 grains]; Alcohol, one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Macerate the drug with the alcohol in a closed vessel in a moderately warm place during fourteen days, with occasional stirring; then strongly express the liquid and filter it through paper." N. F.

Tinctures should be kept in bottles accurately stoppered, in order to prevent evaporation, which might in some instances be attended with serious inconvenience, by increasing their strength beyond the official standard.

Medicines which act in small doses are most conveniently administered in tinctures, as the proportion of alcohol in which they are dissolved is insufficient to produce an appreciable effect. Those which must be given in large doses should be cautiously employed in this form, lest the injury done by the menstruum should more than counterbalance their beneficial operation. This remark is particularly applicable to chronic cases, in which the use of tinctures is apt to lead to the formation of habits of intemperance. The tinctures of the weaker medicines are more frequently given as adjuvants of other remedies than with the view of obtaining their own full effects upon the system.

In the revision of the Pharmacopoeia of 1890, wherever practicable, the proportion of drug to finished tincture was made either 20, 15, 10, or 5 Gm. per 100 mils. Progressive pharmacy demands greater uniformity and simplicity in the processes, and hence in the II. S. P. VIII and IX practically all of the tinctures have been brought into two classes, 20 and 10 Gm. of drug per 100 mils. The potent tinctures, which contained mainly 15 Gm. of drug per 100 mils in the U. S. P. 1890, were reduced to 10 Gm. per 100 mils in order to comply with the recommendations of the Brussels Conference of 1902 for the unification of the strength of Potent Remedies.

A tabulated comparison of the tinctures of the P. G. IV and P. G. V as to...
sp. gr., extractive percentage and alkaloidal content, is available for those to whom it would be of value in the Yearbook of the A. Ph. A., 1913, p. 84.

**Tinospora.** Br. Add. 1900.—"The dried stem of *Tinospora cordifolia* Miera (Fam. Menispermaceae), collected in the hot season." Br. Add., 1900. *Tinospora* has long been used in India as a medicine and in the preparation of a starch known as gilaa-ka-sat or as pailo. It is said to be a tonic, antiperiodic, and a diuretic. Fluckiger obtained from it traces of an alkaloid and a bitter glucoside. The Br. Add., 1900, recognized an infusion (Infusum *Tinosporae* Br. Add., 1900, two ounces to the pint), dose one-half to one nuidounce (15-30 mils); a tincture (Tinctura *Tinosporae* Br. Add., 1900, four ounces to the pint), dose, one-half to one fluidrachm (1.8-3.75 mils); and a concentrated solution (Liquor *Tinosporae Concentratatus* Br. Add., 1900), dose, one-half to one fluidrachm (1.8-3.75 mils). *Tinospora crispa* Miers, which is abundant in the Philippines, is used freely by the natives under the name of makabuhay (that is, "You may live"), as a panacea, especially valuable in general debility, in chronic rheumatism, and in malarial fevers. It may be prepared in the same way and given in the same doses as *Tinospora cordifolia*.

**Tissa.** Tissa rubra (L.) Brit. [now *Spergularia rubra* (L.) J. and C. Presl.], is a native of Malta, Sicily, and Algiers, and is found growing in dry, sandy soil from Quebec to Virginia. It has long been used as a popular remedy in diseases of the bladder. It was shown by F. Vigier (J. P. C., 1879, ii, p. 371) to contain a resinous aromatic substance which is probably its active principle. It is strongly recommended by Bertherand in calculous diseases and acute and chronic cystitis. The aqueous extract may be given in doses of thirty grains (2.0 Gm.); or the fluidextract, dose, a fluidrachm (3.75 mils), three or four times a day.

**Tobacco.** Tabacum. U. S. 1890. Nicotiana Tabacum L.—The Virginia tobacco plant is an annual with a large, fibrous root, and an erect, round, hairy, viscid stem, which branches near the top, and rises from three to six feet in height. The leaves are numerous, alternerce, sessile, and somewhat decurrent, very large, ovate-lanceolate, pointed, entire, slightly viscid, of a pale green color, and have a narcotic odor. The seeds, examined by F. M. Brandt, yielded no narcotic principle, though a protein-like substance contained in them was thought by its decomposition to produce nicotine. (Neues, Jahrb. fur Pharm., xxi, 42.) William Procter also failed to find nicotine in the seeds, (Proc, A, Ph. A., 1858, 296.)

There is good reason to believe that this plant is a native of tropical America, where it was found by the Spaniards upon their arrival. It is at present cultivated in most parts of the world, and nowhere more abundantly than within the limits of the United States. Virginia is, perhaps, the region most celebrated for its culture. The young shoots, produced from seeds thickly sown in beds, are transplanted into the fields during the month of May, and set in rows with an interval of three or four feet between the plants. Through the whole period of its growth the crop requires constant attention. The development of the leaves is promoted by removing the top of each plant and thus preventing it from running into flower and seed. The harvest is in
August. The ripe plants, having been cut off above their roots, are dried under cover, and then stripped of their leaves, which are tied in bundles and packed in hogsheads. While hung up in the drying houses, they undergo a curing process, consisting in exposure to a considerable degree of heat, through which they become moist, or, in other words, are said to sweat, after which they are dried for packing.

Other species also of *Nicotiana* are said to be cultivated, especially *N. rustica* L., which yields the Turkish tobacco and is said to have been the first introduced into Europe, and is thought to have been cultivated by the aborigines of this country, as it is naturalized near the borders of some of our small Northern lakes. The *N. quadrivalvis* of Pursh affords tobacco to the Indians of the Missouri and Columbia Rivers; and *N. fruti-cosa*, a native of China, was probably cultivated in Asia before the discovery of this continent by Columbus. Besides these there are *N. Persica* L., cultivated in Persia, and is the source of Persian tobacco; *N. repanda* Willd., cultivated in Central and Southern North America; *N. Bigelowii* Wats., of North America. It is very doubtful, however, whether these plants furnish any large part of the commercial tobacco. Latakia tobacco seems to be the product of the *N. Tabacum*, and Senator Vidal asserts that *N. repanda* is not found in Cuba, *N. Tabacum* being the only species there cultivated. (P. J., viii, 710.) Again, the Persian and Turkish tobacco sold under the name of tumbeki, which has been variously attributed to *N. Persica* and to *N. rustica*, is in all probability the product of *N. Tabacum*. (Kew Bulletin, April, 1891.)

The total annual production of tobacco throughout the world at present is estimated at 1,000,000 tons, of which Asia furnishes 350,000, America 300,000, Europe 250,000, and the rest of the world 100,000 tons. (Zeit. fur Angew. Chem., 1905, p. 1623.)

Tobacco, as it occurs in commerce, is of a yellowish-brown color, a strong narcotic penetrating odor which is wanting in the fresh leaves, and a bitter, nauseous, and acrid taste. These properties are imparted to water and alcohol. They are injured by long boiling, and the extract is, therefore, relatively feeble. An elaborate analysis of tobacco was made by Vauquelin, who discovered in it among other ingredients, an acrid, volatile, colorless liquid, slightly soluble in water, very soluble in alcohol, and supposed to be the active principle. It was separated by a complicated process, of which, however, the most important step was the distillation of tobacco juice with potassium hydroxide. In the results of this distillation Vauquelin recognized alkaline properties, which he ascribed to ammonia, but which were, in part at least, dependent upon the acrid principle above mentioned. To this principle the name of nicotine was given; but its alkalinity was ascertained by two German chemists, Posselt and Reimann. The nicotine obtained by Vauquelin and by Posselt and Reimann was a colorless, volatile liquid, and, as subsequently ascertained by Henry and Boutron, was in fact an aqueous solution of the alkaline principle in connection with ammonia. It was reserved for these chemists to obtain nicotine in a state of purity. It exists in tobacco combined with an acid in excess, and in this state is not volatile. It is easily extracted from tobacco by means of alcohol or water as a malate, from which the alkaloid can be separated by shaking it with caustic soda solution and ether. The ether is then expelled by warming the liquid, which finally has to be mixed with slaked lime.
lime and distilled in a stream of hydrogen, when the nicotine begins to come over at about 200° C. (392° F.). The percentage of nicotine in tobacco varies considerably—from 1.62 per cent. in Havana tobacco and 2 per cent. in Maryland tobacco to 6 per cent. in Virginia tobacco and 8 per cent. in Kentucky tobacco. For a mode of estimating the proportion of nicotine in tobacco, see Harrison and Self, P. J., June 1, 1912. For an analysis of the ashes of Virginia tobacco, by McD. Irby, of New Orleans, and J. A. Cabell, of Virginia, see Chem. News (Sept. 4, 1874, 117). For Liecke's and Schloessing's methods of estimating nicotine, see 17th edition, U. S. D., p. 1346. For Kosutany's method, see Z. An. Chem., 1893, 277.

Nicotine (Nicotina or Nicotia.) β-pyridyl-a-n-methyl-pymolidine.—This is a colorless or nearly colorless fluid, of the sp. gr. 1.027, boiling at 247° C. (476.6° F.), and not solidifying at -10° C. (14° F.); having a faint odor when cold; of an exceedingly acrid, burning taste, even when largely diluted; entirely volatilizable, and, in the state of vapor, very irritant to the nostrils, with an odor recalling that of tobacco; inflammable; very soluble in water, alcohol, ether, the fixed oils, and oil of turpentine; strongly alkaline in its reaction, and capable of forming crystallizable salts with the acids. These salts are deliquescent, having a burning and acrid taste, and, like the salts of ammonia, lose a portion of their base by heat. While nicotine has not been prepared synthetically as yet, two isomeric bases, isonicotine and nicotidine, have been prepared. On treatment with oxidizing agents, nicotine yields nicotinic or β-pyridinecarboxylic acid, C₅H₄N.COOH. In its action on the animal system it is one of the most virulent poisons known. A drop of it, in the state of concentrated solution, is sufficient to destroy a dog, and small birds perish at the approach of a tube containing it. Tannin forms with it a compound of but slight solubility, and might be employed as an antidote. Nicotine exists in tobacco in small proportion; it has been found in the seeds, and, in very small proportion, in the root. There can be little doubt that tobacco owes its activity to this alkaloid, which has also been criminally employed as a poison. (N. Y. Jour. of Med., N. S., ix.) Nicotine has the remarkable property of resisting decomposition amid the decaying tissues of the body, and was detected by Orfila in the bodies of animals destroyed by it two or three months after their death. Mayor concluded from his experiments that nicotine is the active principle in all parts of the plant both before and after curing. (Proc. A. Ph. A., 1865.)

Although Thorns (A. J. P., 1900, p. 227) was unable to detect any nicotine in tobacco smoke, there is no room for doubt that it is present in sufficient amount to be injurious. Lehmann (P. J., Sept. 18, 1909) finds that about 95 per cent. of the nicotine in tobacco passes over into the smoke, and Toth (Chem. Ztg., 1909, p. 866) has shown that the large proportion of nicotine exists in the smoke in uncombined state.

When distilled at a temperature above that of boiling water, tobacco affords an empyreumatic oil, which Brodie proved to be a most virulent poison. It was official in the U. S. P., 1870, under the name of Oleum Tabaci: Oil of Tobacco. A single drop, injected into the rectum of a cat, occasioned death in about five minutes, and double the quantity, administered in the same manner to a dog, was followed by the same result. This oil is of a dark brown color and an acrid taste, and has a very disagreeable odor exactly resembling that of tobacco pipes which have been much used. It has
been stated to contain nicotine. (Ann. Ch. Phys., 3e ser., ix, 465.)

It is quite certain that tobacco leaves undergo considerable chemical changes during the processes of curing and preparation for use. Thus, the characteristic odor of ordinary tobacco is entirely different from that of the fresh leaves, and must be owing to the generation of a new volatile principle. The proportion of nicotine is probably slightly diminished by the process of "curing." (See Mayer, Proc. A. Ph. A., 1865.)

Medicinal Properties and Uses.—Tobacco is locally irritant. Snuffed up the nostrils, it excites violent sneezing, and a copious secretion of mucus; chewed, it irritates the mucous membrane of the mouth and increases the flow of saliva; when injected into the rectum, it sometimes operates as a cathartic; and the alkaloid nicotine injected into the cellular tissue of animals evidently produces much pain. In large doses, or in persons unaccustomed to it, tobacco produces severe nausea, sometimes vomiting, accompanied with profuse perspiration, and great muscular weakness. The alkaloid nicotine is a virulent poison. It primarily excites, and secondarily paralyzes, the ganglia upon the sympathetic nerves, stimulates the intestinal muscles, and, in sufficient quantities, has a paralytic action upon the motor nerves. As a result of its action upon the sympathetic ganglia, it causes contraction of the blood-vessels with marked increase in the blood pressure, followed, after large doses, with vascular dilatation and fall of pressure. The pulse rate is at first decreased, later becomes rapid. There is primary increase in the secretion of the salivary and probably of the other glands, followed, after large doses, by paralysis of secretions.

The use of tobacco was adopted by the Spaniards from the American Indians. In the year 1560 it was introduced into France by the ambassador of that country at the court of Lisbon, whose name—Nicot—has been perpetuated in the generic title of the plant. Sir Walter Raleigh is said to have introduced the practice of smoking into England. In the various modes of smoking, chewing, and snuffing, the drug is now largely consumed in every country on the globe. It must have properties peculiarly adapted to the propensities of our nature to have thus surmounted the first repugnance to its odor and taste and to have become the passion of so many millions. Whether or not nicotine plays any part in the pleasurable effects of tobacco is, despite considerable research and discussion, unsettled, but it is generally agreed that the evil effects of excessive indulgence are due to this alkaloid. The most important disturbances produced are in the digestive and circulatory organs. As a result of the disturbed innervation of the heart, palpitation and cardiac irregularities are common, and the vascular contraction is generally regarded as one of the causes of arterial degenerations.

Formerly much used as a relaxant, tobacco has been superseded by safer and more efficacious remedies, so that it is at present never employed in medicine, except occasionally in chronic asthma. It should always be borne in mind that its active principle is absorbed readily by the skin, and that serious or even fatal poisoning may result from its too free application to the surface of the body. A case of death is on record, occurring in a child eight years old, in consequence of the application of the expressed juice of the leaves to the head, for the cure of tinea capitis. Death has also been produced by the inhalation of the smoke.
From five to six grains (0.32-0.4 Gm.) of powdered tobacco will generally act as an emetic; but should never be used for this purpose.

**Toddalia.** Br. Add. 1900.—“The dried root-bark of Toddalia aculeata Lam.” (Fam. Rutaceae.) This climbing shrub, known also as Lopez root, growing in East Africa, Madagascar, the subtropical Himalayas, Ceylon, and the Philippines, is a tonic stomachic, containing a resin and a volatile oil, which may be readily obtained from the leaves by distillation. This oil has the odor of citron peel, and a bitter, aromatic taste. See also Schim. Rep., 1906, 82, and 1912, 121. The British Addendum recognized an infusion (Infusum Toddaliae, two ounces to a pint), dose, one to two fluidounces (30-60 mils); also a concentrated solution (Liquor Toddaliae Concentratus, Br. Add., 1900), dose, from one-half to one fluidrachm (1.8-3.75 mils).

**Tonga.**—Tonga Bark is a composition of unknown barks compounded by the natives of the Feejee Islands for medicinal purposes. The plants from which this remedy is derived are believed to be Premna taitensis Schan. (Fam. Verbenaceae), and Epipremnum mirabile Schott. (Fam. Araceae.) According to Moeller (Ph. Centhr.), the latter is not a source of tonga. (A. J. P., 1881, 439.) It was introduced to the notice of the medical profession by Sydney Ringer and Wm. Murrell, of London, as a remedy for neuralgia. (L. L., ii, 1880.) Merck reports the presence of tongine and a volatile oil in tonga. (Merk’s index, 1907.) The natives are said to steep the bundle as prepared by them for twenty minutes in half a tumberful of cold water, and then, squeezing it dry, drink the infusion, preserving the bundle in a dry place for further use. A fluidextract has been put upon the market, and evidence of its value brought forward, but we have known a fluidrachm of this extract to be given every two hours for two days without obvious effect; the dose usually recommended is half a fluidrachm (1.8 mils).

**Tonka Bean.** Feve Tonka, Fr. Tonka-bohnen, G.—The seeds of Coumarouana odorata of Aublet, a large tree growing in Guiana and Northern Brazil which yields the Dutch Tonka Bean; and of C. appositifolia (Aubl.) Tanb, which is the source of the English tonka bean. The fruit is an oblong-ovate pod, enclosing a single seed, from 3 to 4 cm. long and about 1 cm. wide, usually somewhat compressed, with a dark brown, wrinkled, shining, thin, and brittle skin, and a light brown, oily kernel. The seed has a strong, agreeable, aromatic odor, and a bitterish, aromatic taste. Its active constituent is a crystallizable, odorous substance, called coumarin or cumarin, C_9H_6O_2. It is the anhydride of coumaric acid, C_9H_8O_2. It is capable of sublimation; but, to obtain it in crystals in this way, a low temperature is necessary. (Waddington, P. J., 1868, 410.) This substance is sometimes found in a crystalline state, between the two lobes of the kernel. Coumarin appears to be a widely spread substance which has been found in many species of plants, notably in species of Melilotus (fam. Leguminosae), sweet vernal grass (Anthoxanthum odoratum L.), and related grasses, and Trilisa odoratissima (Walt.), Cass. (Liatris odoratissima Willd.) (fam. Compositae), a plant sometimes used to protect woollens from moths. (A. J. P., 1859, 556; also 1899, 133; see also Chem. Gaz., 1852; D. C., Nov., 1887.) Gossmann obtains coumarin in the following manner. The beans, cut finely, are heated for a long time with an equal bulk of alcohol of specific gravity 0.863, nearly to boiling, and
tincture being decanted, the residue is treated in the same manner. The tinctures are
mixed, the alcohol distilled off until turbidness appears, when four times the bulk of
water is added, which precipitates coumarin and fatty matter. The precipitate is
then heated to boiling, and the liquid passed through a moistened filter. The fatty
matter remains on the filter, and the hot solution which passes deposits the coumarin
on cooling. More may be obtained by concentrating the liquid, and may be purified by
animal charcoal. One pound of the beans yielded 108 grains of coumarin. Coumarin
has been prepared synthetically by heating salicylic aldehyde with sodium acetate
and acetic anhydride, whereby aceticoumaric acid is formed, which decomposes
further into acetic acid and coumarin. It has also been obtained by the action of
phenol upon the malic acid. Tonka bean is used to adulterate tincture and extract of
vanilla and to flavor snuff, being either mixed with it in the state of powder or put
entire into the snuff box. Coumarin adulterated with acetanilid has been found in the
market. (Schim. Rep., 1893, 67.) Tonquin butter is an article of commerce in Holland.
It is the fatty substance of tonka beans; it was analyzed by M. Duyk, it has the sp.
gr. of 0.888, melting point is 28° C. (82.4° F.), saponification number 25.7. (Rep. de
Pharm., 1908.)

Ellinger (A. E. P. P., 1908, Suppl.) found the fatal dose of coumarin for the rabbit to be
0.3 Gm. per kilo. He confirmed the statement of Kohler (Cb. M. W., 18.75) that it
acted as a narcotic, but could not find evidence of cardiac depression. The fluidextract
of the bean has been used with asserted advantage in whooping cough in doses
equivalent to from five to eight grains (0.32-0.5 Gm.) for children five years old. (A. J.
P., 1869, 27.)

Tormentil. Rhizoma Tormentillae, P. G. Tormentille, Fr. Tormentillwurzel, G.
Tormentilla, It. Tormentila, Sp.—Various species of the rosaceous genus Potentilla
have been employed in medicine. (See A. J. P., 1875, 109.) It is asserted that our
common P. canadensis L. is a valuable sudorific and diuretic.

Potentilla Tormentilla Neck. (Tormentilla erecta L., T. officinalis Curt.)—The
tormentil, or septfoil, which was formerly in the Secondary List of the U. S.
Pharmacopoeia, is a small perennial plant of Europe and Asia. All parts of the plant
are astringent, especially the rhizome, which is the part employed. The rhizome of
tormentil is cylindrical, somewhat fusiform, branching and more or less curved, from
2.5 to 8 cm. long, and from 0.5 to 1.5 cm. thick, brown or blackish externally, and
reddish within. It has a slight aromatic odor and a very astringent taste. It contains a
red coloring principle, soluble in alcohol, but insoluble in water, and considerable
quantities of a peculiar tannin (tormentil-tannic acid, C_{26}H_{22}O_{11}). Rembold found that
tormentilla red has the same composition as rhatany red, and yields the same
products of decomposition when fused with potassium hydroxide. He also obtained
kinovic acid, C_{24}H_{38}O_{4}, and small quantities of ellagic acid, C_{14}H_{6}O_{8}. (A. J. P., 1868,
311; from Ann. Chem., cxliv, 5.) The root is said to be used for tanning leather in the
Orkneys and Western Islands of Scotland, and for staining leather red by the
Laplanders. Tormentil is a simple and powerful astringent, applicable to all cases of
disease in which this class of medicines is indicated. It may be given in substance,
decoction, or extract. The dose of the powder is from thirty grains to a drachm (2.0-3.9
Toxicodendron Capense Thunb. (Fam. Eurphorbiaceae)—The fruits of this South African species are said to be used for the poisoning of hyenas. They have been investigated by von Engelhardt (Kobert's Arbeiten, 1892), who finds in them a neutral, bitter principle, hyananchin, which is a powerful poison, resembling strychnine in its physiological action, from which, however, it differs in that it powerfully affects the cerebrum. The convulsions which it produces are of central origin, the poison having no action upon the nerve trunks or the muscles.

Toxylon. Madura pomifera (Raf.) Schneider. (Madura aurantiaca Nutt.) (Fam. Moraceae) Osage Orange.—The bark of the root of this tree, which is indigenous in the Southern United States, is said to be considerably used in making a yellow dye. Alex. King has found in it moric and moritannic acids. (A. J. P., xlvi, 257.)

Tradescantia Erecta Jacq. (Now Tinantia fugax Scheidw.) (Fam. Commelinaceae)—The natives of South America used an extract of this plant as a haemostatic in cock-fights and it has lately been introduced into medicine, being especially recommended in hemorrhages of the ear and the upper air passages. Nothing definite is known of its actual composition and its styptic virtue has been ascribed, by some, to its tannin content. For description of Commelina communis, a perennial herb of the United States, see Preston, A. J. P., 1808, p. 321.

TRAGACANTHA. U. S., Br.

TRAGACANTH Trag. [Gum Tragacanth]

"The spontaneously dried gummy exudation from the stems of Astragalus gummifer Labillariere, or from other Asiatic species of Astragalus (Fam. Leguminosae)." U. S. "Tragacanth is a gummy exudation obtained by incision from Astragalus gummifer, Labill., and some other species of Astragalus. Known in commerce as Syrian tragacanth." Br.

Gummi Tragacantha vel Astragalorum; Gomme Adragante, Fr. Cod.; Tragacantha, P. G.; Tragant, Tranganth, G.; Gomma adragante, Dragonante, It.; Gomo tragacanto, Sp.

Numerous species belonging to this genus yield a gummy matter having the properties of tragacanth. The drug known in commerce by that name was at first erroneously supposed to be obtained from A. Tragacantha of Linnaeus (A. massiliensis of Lamarck), which grows in Southern Europe and Northern Africa and is now said to yield no gum. It was afterwards ascribed, on the authority of Tournefort, to a species (A. creticus of Lamarck) which grows in Crete and Ionia, and on that of
Olivier, to A. verus, which inhabits Asia Minor, Armenia, and Northern Persia. Labillardiere described a species by the name of A. gummifer which he found growing on Mount Libanus in Syria, and from which tragacanth exudes, though not that of commerce. Only recently it has been denied that Astragalus gummifer is the source of tragacanth. (Cons. and Tr. Rep., 1910, p. 728.)

Sieber denies that any of the above-mentioned species yields the official tragacanth, which he ascribes to A. aristatus, growing in Anatolia, especially upon Mount Ida, where the gum is most abundantly collected. This plant, however, is not the A. aristatus of Villars, which, according to Sibthorp, furnishes tragacanth in Greece. (Merat and De Lens.) Lindley received two specimens of plants, said to be those which furnish tragacanth in Turkestan, one of which proved to be A. gummifer of Labillardiere which was said to yield a white variety, and the other a new species, which he called A. strobiliferus, and which was said to yield a red and inferior product. The fact seems to be that the commercial drug is collected from various sources; and it is affirmed that all the species of Astragalus with thorny petioles are capable of producing it. These form a natural group, and so closely resemble one another that botanists have found some difficulty in distinguishing them. They are very abundant on the mountains of Asia Minor, and, according to information received by M. J. Leon Soubeiran from Balansa, a scientific traveller who derived his knowledge from personal observation, the gum-producing species are closely analogous to the A. creticus of Lamarck. It is in the Anti-Taurus range that the gum is chiefly collected. Transverse incisions are made, near the base of the stem, into the medullary tissues, which alone yield the gum. This exudes very slowly, flowing at night, and ceasing during the day; two weeks usually elapse before the pieces are large enough for collection. The shape of the pieces is influenced by the rapidity of the exudation, and the lines on their surface indicate the daily concretion. The section Tragacantha of the genus Astragalus includes the principal species which yield gum tragacanth.

According to Haussknecht, tragacanth is yielded by the following species of Astragalus: A. adscendens Boiss. et Hausskn. (Southern Persia); A. leioclados Boiss. (in Middle and Western Persia, by Ispahan and Hamadan); A. brachycalyx Fisch. (Kurdistan and Luristan); A. gummifer Labill. (widely distributed from Lebanon to Armenia and in the northern regions of the Euphrates and Tigris); A. microcephalus
Willd. (the same as A. gummifer Labill., and also in Asia Minor); A. pycnocalus Boiss. et Hausskn. (particularly in Western Persia); A. stromatodes Bge. (in Achyr Dagh, in Northern Syria); A. kurdicus Boiss. (Aintab). Other species that yield a tragacanth gum are A. heratensis Bge., of the Khorasan Mountains, which yields a gum known as "kutira," and A. Parnassi Boiss., var. cyllenea, found on the mountains of Peloponneseus.

Harris states that the best Smyrna tragacanth is produced in Asia Minor. It is not, however, collected in the immediate vicinity of Smyrna, but comes from Karahissar, Jalowadsch, and even farther in the interior, where the plant grows wild. This kind of gum consists of white, yellow, and red, hardened pieces, which have become congealed after oozing out of the bush or tree in the hot sun of a Levantine summer. The gum is secured in a similar manner as opium by an incision in the branch. This is done in the spring and summer of each year, and the gum is usually scraped in September, when the first rains begin to fall. During the last twenty years the gum tragacanth trade of Smyrna has decreased. It has been estimated that the trade has fallen from 600,000 pounds to 55,000 pounds in that length of time. (Oil, Paint and Drug Reporter, lxxiii, p. 633.)

Properties.—Tragacanth is odorless and nearly tasteless. It occurs either in flaky, leaf-like pieces, irregularly oblong or roundish, or in tortuous vermicular filaments, rounded or flattened, rolled up or extended, of a whitish, yellowish-white, or slightly reddish color, marked by parallel lines or ridges, somewhat translucent, and resembling horn in appearance. In commerce certain varieties of tragacanth are recognized and usually known by the name of the locality from which they have been produced or through which they have entered commerce. The ordinary tragacanth, tragacanth in sorts, sometimes known as traganton, occurs in irregular pieces; Smyrna tragacanth appears usually in broad thick flakes, yellowish or brownish; Syrian tragacanth, in thin, ribbon-like, white flakes, is said really to be obtained in Kurdistan and Persia. Tragacanth is officially described as in flattened, lamellated fragments varying from ribbon-shaped bands to long and linear pieces, which may be either straight or spirally twisted, and from 0.5 to 2.5 mm. in thickness; whitish to light brown in color, translucent and horny; fracture short; rendered more easily pulverizable by heating to 50° C. (122° F.); inodorous; taste insipid, mucilaginous. Under the microscope, sections made from Tragacanth,
previously softened in water, and mounted in glycerin, show the lamellae of mucilaginous walls and a few starch grains, the latter being mostly spherical and single, occasionally 2- to 3-compound, the individual grains from 0.003 to 0.025 mm. in diameter and colored blue with iodine. Indian Gum, derived from plants of uncertain origin, upon similar treatment and examination, shows numerous threads of a granular substance, sometimes the hyphae of a fungus and chains of bacteria, and occasional fragments of a yellowish-brown or reddish-brown color, containing lignified wood-fibers, a few rosette aggregates of calcium oxalate, from 0.02 to 0.03 mm. in diameter, and a few spherical starch grains, from 0.003 to 0.007 mm. in diameter. Add 1 Gm. of Tragacanth to 50 mils of distilled water; it swells and forms a smooth, nearly uniform, stiff, opalescent mucilage free from cellular fragments. Indian Gum upon similar treatment forms an uneven mucilage containing a few reddish-brown fragments, and on stirring separates in the form of coarse, uneven strings. Shake 2 Gm. of Tragacanth with 100 mils of water until fully swollen and free from lumps, and then add 2 Gm. of powdered sodium borate and shake the mixture thoroughly until the salt is dissolved; the mucilage does not lose its transparency, nor exhibit any change in consistence, and on pouring is not slimy or stringy, even after standing twenty-four hours (foreign gums). Boil 1 Gm. of Tragacanth with 20 mils of water until a mucilage is formed, then add 5 mils of hydrochloric acid and again boil the mixture for five minutes; it develops no pink or red color (Indian Gum). The powder is whitish; forming with water a translucent mucilage and under the microscope exhibiting numerous starch grains, from 0.003 to 0.025 mm. in diameter, varying from spherical to elliptical, with occasional 2-to 4-compound grains, many of the grains being swollen and more or less altered, due to the drying of the Tragacanth before powdering. Powdered Indian Gum shows numerous fragments of lignified vegetable tissue. Tragacanth yields not more than 3.5 per cent. of ash."

"Thin flattened flakes, irregularly oblong, or more or less curved, marked on the surface by concentric ridges. Frequently two and a half centimetres long, and twelve millimetres wide. White or pale yellowish-white, somewhat translucent. Horny, fracture short. Inodorous; almost tasteless. Sparingly soluble in water, but swelling into a gelatinous mass, which may be tinged violet or blue by N/10 solution of iodine. Ash not more than 4 per cent." Br.

It is hard and more or less fragile, but difficult of pulverization, unless
exposed to a freezing temperature, or thoroughly dried, and powdered in a heated mortar at the temperature of 50° C. (122° F.). Its sp. gr. is 1.384. Introduced into water, it absorbs a certain proportion of that liquid, swells very much, and forms a soft adhesive paste, but does not dissolve. If agitated with an additional quantity of water, this paste forms a uniform mixture; but in the course of one or two days the greater part separates, and is deposited, leaving a portion dissolved in the supernatant fluid. Tragacanth is wholly insoluble in alcohol. It appears to be composed of two different constituents, one soluble in water and resembling gum arable, the other swelling in water, but not dissolving. To separate the soluble from the insoluble part requires agitation with separate portions of water; the solutions are to be decanted and filtered, and the process is to be continued until water ceases to dissolve anything.

Von Sandersleben reported the discovery that when heated with dilute acids tragacanth acquired reducing properties, and formed, along with much syrup, arabinose, which crystallized. (Tollens, Handbuch der Kohlenhydrate, 1888, 218.) The explanation of this observation, now generally accepted, is that in tragacanth, like some other gums, part of the arable acid is present in soluble form, mostly combined with bases, while another part is present in insoluble form, and is known as tragacanthin. This latter, however, under the influence of certain enzymes, is converted into the soluble form. (Lippmann, Chemie der Zuckerarten, 2te Auf., 1895, 925.) C. O'Sullivan states that tragacanth consists of cellulose, the portion insoluble in boiling water, cold dilute acids, and alkalies; also soluble gum, yielding a series of gum acids of the nature of geddic acid, and which are called polyarabinon-trigalactan-geddic acids; starch granules; bas-sorin, which yields a-tragacanthan-xylan-bassoric acid, xylan-bassoric acid and bassoric acid. (Proc. Chem. Soc., 1901.) Examined by Kützing by means of the microscope, tragacanth was found to consist of organized cells. (See A. J. P., xxv, 37.) In conformity with this statement is the remarkable fact, discovered by Hugo von Mohl and confirmed by Wigand, that tragacanth is not a secretion of the plant, but the result of the transformation of the cells of the pith and those of the medullary rays which traverse the ligneous part of the stem and older branches. (A. J. P., xxxi, 243.)

It is stated by S. H. Maltass that tragacanth is adulterated, in the Levant, with worthless gums brought from Armenia and Caramania,
which, as they are originally of a dark color and destitute of the flaky form of the genuine gum, are broken into small fragments and whitened by means of lead carbonate before being mixed with the tragacanth. Hanbury states, in confirmation of this, that he has detected lead in the small tragacanth imported into London. (P. J., xv, 20.) Gum tragacanth has been recently admixed with and substituted by Indian gum, the product of Cohlospernum gossypium (Fam. Bixaceae). This occurs in vermiform or rounded tears having a dull, rough surface. It is detected by the official tests. The powdered drug is not only adulterated with the Indian gum, but with powdered acacia, dextrin, wheat and comstarch. Payet gives a test for the detection of acacia in powdered tragacanth which depends on the brown color produced by the oxidase of the former when brought in contact with an aqueous solution of guaiacol in the presence of hydrogen dioxide. (Ann. de Chim. Analyt., x, p. 63.)

Uses.—Tragacanth is demulcent, but, on account of its difficult solubility, is not often given internally. The great viscosity which it imparts to water renders it useful for the suspension of heavy insoluble powders, and it is also employed in pharmacy to impart consistence to troches, for which it answers better than does gum arable, and in making emulsions, although for these purposes it is inferior to acacia. It is also used for its demulcent action in pharyngitis by allowing a piece of the gum to dissolve slowly in the mouth. It is officially employed as the basis of many of the troches.

Trifolium. N. F. IV, Red Clover Blossoms.—"The dried inflorescence of Trifolium pratense Linne (Fam. Leguminosae)." N. F. It is described in the N. F. as "Heads are ovoid with rounded summit, mostly from 12' to 25 mm. in length and breadth, shriveled, purplish and more or less brown from drying, consisting of many small papilionaceous flowers, crowded together and clothed at the base with broad, pointed, ciliate stipules of a pale green color with darker veins and which may or may not be accompanied by diminutive trifoliate leaves. The individual flowers are from 12 to 15 mm. in length, longer than the four nearly equal teeth and shorter than the narrower fifth tooth, calyx-teeth subulate, tapering; petals united into a tube below, the standard longer than the wings, but when recurved appearing shorter; stamens diadelphous (nine and one); style slender. The odor is faintly aromatic and somewhat tea-like, the taste being sweetish, then slightly bitter. Trifolium yields not more than 10 per cent. of ash."
Red clover blossoms were introduced into the N. F. IV and are used to make the fluidextract. For the results of a research of the constituents of *T. pratense* by Power and Solvay, see C. D., 1910, 273. Clover has, by the superstitious, been supposed to possess alterative properties. It also enters into the composition of some antiasthmatic cigarettes. There is, however, no sufficient reason to suspect it of any medicinal virtue.

**Trigonella.** Greek Hay Seed. *T. Foenumgraecum* L. Fenugreek. *Semen Foenugraecii*, P. G. Bockshornsamen, G.—A European annual leguminous plant cultivated in southern Europe, Northern Africa and India for its seeds. These are oblong-cylindrical, somewhat compressed, obliquely truncated at each extremity, 3 to 5 mm. in length, brownish yellow externally, internally yellow and marked with an oblique furrow running half their length. They have a strong peculiar odor resembling that of elm bark, and an oily, bitterish, farinaceous taste, and contain fixed and volatile oils, mucilage, bitter extractive and a yellow coloring substance. E. Jahns (Ber. d. Chem. Ges., xviii, 2518-2523) has obtained choline, $C_5H_{15}NO_2$, and trigonelline, $C_7H_7NO_2$. The yield of the former was 0.05 per cent., and of the latter 0.13 per cent. Trigonelline is isomeric and probably identical with pyridine-betaine. By heating trigonelline with concentrated solution of potassium hydroxide, a distillate is obtained which appears to contain pyridine. An ounce of the seeds, boiled in a pint of water, renders it thick and slimy. They yield the whole of their odor and taste to alcohol. On the continent of Europe they are employed in the preparation of emollient cataplasms, enemata, ointments and plasters. They are never used internally for human beings, but the ground seeds are used to an enormous extent in the manufacture of cattle powders or condition powders and to give a maple flavor to confectionery.

**Trillium.** N. F. IV. Beth Root. Birth Root. Wake Room. Trillium, Fr., G.—"The dried rhizomes of *Trillium erectum* Linne and closely allied species of *Trillium* (Fam. Liliaceae)." N. F.

It is described in the N. F. as follows: "Rhizome oblique, globular, oblong or obconical, truncate, below, terminated by a small bud surrounded by a sheath of scarious leaf bases, annulated by leaf scars and fissured by stem scars. It is from 0.6 to 5 cm. in length and from 0.6 to 2.5 cm. in width, more or less compressed laterally, rootlet scars in several concentric rows on the under side in the upper portions. Externally yellowish to reddish-brown; internally of a pale yellow; fracture somewhat uneven with a more or less spongy appearance. Odor distinct; taste bitter and acrid with a sensation of warmth in the throat and when chewed causing an increased flow of saliva. *Trillium* yields not more than 5 per cent. of ash."

The indigenous species, *T. erectum* L., is said to have been employed by the aborigines, and also used by the early settlers; it still has some vogue under the name of beth root as an astringent and tonic expectorant; also in hemorrhages and to hasten parturition and as a local irritant in skin diseases. Dose, of powdered root, a drachm (3.9 Gm.) three times a day. E. S. Wayne found in it a substance supposed to be saponin. It is said also to contain volatile oil and tannic acid. D. J. Prendergast believes that the
Trillium erectum contains a glucoside similar to convallamarin. (Am. Drug., Nov., 1887.) For details, see 16th edition, U. S. D. Vivian I. Reid (A. J. P., 1892, 67) found a small quantity of fixed oil, saponin to the extent of 4.86 per cent. and an acid crystalline principle which is colored purplish-brown by sulphuric acid and light green with sulphuric acid and potassium dichromate.

This rhizome was introduced into the N. F. IV to use in the preparation of the fluidextract of trillium with three volumes of alcohol and one volume of water. The fluidextract is an ingredient in compound elixir of viburnum opulus.

Triosteum. T. perfoliatum L. Horse Gentian. Bastard Ipecac. Tinker's Weed. Wild Coffee. Fever Root. Feverzvort. Wild Ipecac. Racine de Trieste, Fr. Dreisteinwurzel, G. (Fam. Caprifoliaceae)—This plant is found in rich woods from Massachusetts to Alabama and westward to Nebraska, preferring a limestone soil and shady situations. The rhizome or root, the part used, is horizontal, long, about 15 mm. in diameter, thicker and tuberculated near the origin of the stem, of a yellowish or brownish color externally, whitish within, and furnished with fibers which may be considered as branches of the main root. When dry it is brittle and easily pulverized. On microscopic examination, numerous crystals of calcium oxalate are to be seen. It has a sickening odor, and a bitter, nauseous taste. It is said to contain an alkaloid which Andree believed to be identical with emetine, but which Hartwich has shown to be different. It yields its active properties to both water and alcohol. Triosteum is cathartic, and in large doses emetic and perhaps diuretic. The bark of the root may be given in doses of twenty to thirty grains (1.3-2.0 Gm.), or the extract in half the quantity. For uses, see A. J. P., 1891, 326.

TRITICUM. U. S. (Br.)

TRITICUM Tritic. [Couch Grass Dog Grass]

“The dried rhizome and roots of Agropyron repens (Linne) Beauvois (Fam. Gramineae), gathered in the spring." U. S. “Couch Grass is the dried rhizome of Agropyron repens, Beauv., freed from remains of leaves and rootlets." Br.

Agropyrum, Br.; Rhizoma Graminia; Radix Graminis; Quick-grass, Quitch, Scotch-grass, Twitch-grass, Witch-grass, Quickens; Chiendent officinal ou Petit chiendent, Fr. Cod.; Queckenwurzel, Grasswurzel, G.; Grama (Rizoma de), Sp.

This grass, originally a native of Europe, now abounds in meadows and cultivated grounds in the Northern United States, where it is often very troublesome as a weed. It is specifically characterized by its creeping rootstock, the leaves being flat, thin and finely veined, and the flowering glumes being glabrous or scabrous. It is probable that the rhizome of a number of other grasses share the medicinal properties of
Agropyron repens. Of these the Scotch or Bermuda grass, Capriola Dactylon (L.) Kuntze, is probably as effective as the official species.

Much spurious triticum has appeared upon the market recently. Most of it can be readily distinguished from the official drug by the presence of starch in the spurious article.

Properties.—Triticum is officially described as follows: "Usually in pieces from 4 to 12 mm. in length and from 1 to 2.5 mm. in diameter; externally light yellow or yellowish-brown, longitudinally furrowed, smooth, lustrous, nodes with circular leaf-scars, a few root-scars and occasional slender roots; fracture tough, fibrous; internally lemon-yellow and with a large, hollow pith; odor slight, aromatic; taste sweetish. Roots filiform, irregularly branching, attaining a length of about 5 cm. and not more than 0.5 mm. in thickness, light brown or yellowish-brown, frequently covered with long root hairs. Under the microscope, transverse sections of Triticum show a single layer of strongly lignified epidermal cells; a hypodermis of from 3 to 6 rows of more or less polygonal cells with strongly lignified walls; a cortex of from 10 to 16 rows of thin-walled parenchyma cells, occasionally with nearly spherical starch grains about 0.005 mm. in diameter, or with irregular masses of a more or less soluble carbohydrate; among the parenchyma cells and near the hypodermis occur small, widely separated fibro-vascular bundles, each with a closed sheath of sclerenchymatous fibers; an endodermis, the lateral and inner walls of the cells moderately thickened, strongly lignified and somewhat porous; several layers of sclerenchymatous fibers immediately inside the endodermal ring, in which are imbedded an interrupted circle of collateral fibro-vascular bundles having large tracheas; adjoining these are usually 8 to 10 rows of parenchyma cells with a few fibro-vascular bundles and a pith in which the parenchyma cells are more or less broken or absent. The powder is light yellowish; consisting of irregular, lignified fragments; numerous fragments showing tracheae with annular or spiral thickenings or marked with simple pores and associated with long, narrow, rather thin-walled, strongly lignified sclerenchymatous fibers; fragments of epidermis made up of cells rectangular in outline, the longer walls considerably thickened, strongly lignified and marked with numerous transverse pores; ends of epidermal cells usually separated from each other by a very narrow cell with thin walls and few pores; numerous fragments of parenchyma rectangular in outline and with thin, porous walls. Triticum yields not more than 3 per cent. of ash." U.
"Rhizome pale yellow, rigid, from two to two and a half millimetres in diameter, usually in pieces from three to six millimetres long. Strongly furrowed longitudinally, hollow except at the nodes. Contains no starch. No odor; taste slightly sweet." Br.

The morphology of triticum has been described by Holm (M. R., xix, p. 65). Kebler reports (A. J. P., 1909, p. 75) the adulteration of triticum with Bermuda grass, by which he means probably Capriola Dactylon (L.) Kze., a grass which is naturalized in the United States from Europe and apparently widely distributed.

The Austrian Pharmacopoeia has a requirement of not less than 30 per cent. of aqueous extractive for this drug.

**Uses.**—Triticum is never exhibited for the purpose of affecting the general system, but only for its influence upon the genito-urinary organs. It is much used by some surgeons in irritable bladder, and also in cystitis. It is one of the least stimulant of the remedies of its class, and may be employed very freely. In Europe its decoction is said to be used to a considerable extent as a diluent and slightly nutritious drink. It may be taken ad libitum, or the fluidextract may be given in doses of a fluidrachm (3.75 mils) every three hours in five or six ounces of water.

**TROCHISCI.**

**TROCHES**

Tabellae; Lozenges; Tablettes, Fr. Cod.; Pastilli, Rotulae, P. G.; Pastillen, Platzchen, Tabletten, G.; Pastiglie, It.; Tabletas, Sp.

Troches or lozenges are small, dry, solid masses, usually of a flattened shape, consisting for the most part of powders incorporated with sugar and mucilage. They are designed to be held in the mouth and dissolved slowly in the saliva, and are, therefore, adapted for the administration of those medicines only which do not require to be given in large quantities and which are destitute of any very disagreeable flavor.
Lozenges were formerly much more used and more skilfully prepared in Europe than in this country, but at present those manufactured here are fully equal to the imported lozenges. Tragacanth, from the greater tenacity of its mucilage, is better suited for their formation than gum arable. The following directions for preparing them are taken from the Dictionnaire des Drogues. A mucilage of tragacanth is first prepared with cold water and strained. With this the powders, including sugar, are thoroughly mixed by rubbing upon a marble slab, and are thus formed into a paste, which is spread out by means of a roller upon the surface of the marble, previously powdered over with a mixture of sugar and starch. The thickness of the mass is rendered uniform by a frame upon which the ends of the roller rest. The upper surface is now dusted with sugar and starch, and the mass is divided into small cakes by means of a punch. These cakes are placed upon paper, and, having been exposed to the air for twelve hours, are carried into a drying room moderately heated. When perfectly dry, they are thrown upon a sieve to separate the sugar and starch, and are then enclosed in boxes. Lozenges may be prepared from almost any medicine which it is advisable to administer in this form. The following typical formula may be found useful.

Take citric acid, in powder, a drachm; powdered sugar eight ounces; oil of lemon twelve minims; mucilage of tragacanth a sufficient quantity. Form them in the manner above directed into troches of twelve grains each. Lozenges are sometimes made by saturating blank lozenges with aromatic spirits. Currant paste or jelly has come into use of late years largely as a basis for troches. For formulas for lozenges with currant paste basis, see U. S. D., 19th edition, page 1297.

Lozenges of a cylindrical shape are extensively used, having a basis of licorice, gum, and sugar, and the manufacture of these is now an important industry. Franklin C. Hill devised an improved machine for making Licorice and Wistar's Lozenges. (See A. J. P., 1874, 401.) For Slocum's and Harrison's improved forms of lozenge boards, rollers, etc., see A. J. P., 1879, 589; 1880, 255. A. D. Marcy figured an instrument for shaping troches in N. R., Feb., 1882.

The Br. Pharmacopoeia, 1914, adopted four bases for lozenges, as follows: fruit basis, rose basis, simple basis, and tolu basis. It will be noticed that in the British formulas the quantity of active ingredients
for each lozenge is stated and the kind of basis indicated. This is done merely to avoid repetition.

PREPARATION WITH FRUIT BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge. Mix it with 6.5 grammes of Tragacanth and 26 grammes of Refined Sugar, both in fine powder. Add sufficient of the black-currant paste of commerce to produce 650 grammes, beat into a uniform mass, divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." Br.

PREPARATION WITH ROSE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge. Treat it as described under 'Preparation with Simple Basis,' previously mixing with the Refined Sugar 0.025 millilitre of Oil of Rose." Br.

PREPARATION WITH SIMPLE BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge, mix it with 496 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Make the mixture into a paste with 35 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water, divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." Br.

PREPARATION WITH TOLU BASIS.

"Take five hundred times the quantity of the drug ordered for one lozenge; dissolve such salts of alkaloids as may be ordered in 10 millilitres of Distilled Water; mix the solution with 482 grammes of Refined Sugar and 19.5 grammes of Gum Acacia, both in fine powder. Incorporate 10 millilitres of Tincture of Balsam of Tolu, and any other drugs ordered for the lozenges. Make into a paste with 35.5 millilitres of Mucilage of Gum Acacia and a sufficient quantity of Distilled Water; divide into 500 equal lozenges and dry in a hot-air chamber at a moderate temperature." Br.
TROCHISCUS CATECHU. Br.

CATECHU LOZENGE

"Catechu, 0.06 gramme. Mix with the Fruit Basis to form a Lozenge." Br.

This lozenge was introduced into the Br. Pharm., 1914. It is mildly astringent.

TROCHISCI CUBEBÆ. U. S.

TROCHES OF CUBEB Troch. Cubeb.

Tablettes de Cubebe, Fr.; Kubebenpastillen, G.

"Oleoresin of Cubeb, two grammes [or 31 grains]; Oil of Sassafras, one mil [or 16 minims]; Extract of Glycyrrhiza, in fine powder, twenty-five grammes [or 386 grains]; Acacia, in fine powder, twelve grammes [or 185 grains]; Syrup of Tolu, a sufficient quantity, to make one hundred troches. Rub the powders together until they are thoroughly mixed; then add the oleoresin and the oil, and incorporate them with the mixture. Lastly, form a mass with syrup of tolu, and divide it into one hundred troches." U. S.

Each lozenge contains one-third of a grain (0.021 Cm.) of the oleoresin of cubeb, being about one-fourth the strength of the lozenge of 1870, and one-half the strength of the 1890 troches. The preparation is intended chiefly for effect upon the fauces and other parts of the upper alimentary passages, and may be used advantageously in some cases of chronic cough, and in ulceration or chronic inflammation of the fauces.

TROCHISCUS GUAIACI RESINÆ. Br.

GUAIACUM RESIN LOZENGE

Tablettes de Resine de Gayac, Fr.; Guajakharzpastillen, G,

" Guaiacum Resin, 0.2 gramme. Mix with the Fruit Basis to form a Lozenge." Br.
**TROCHISCUS IPECACUANHAS. Br.**

**IPECACUANHA LOZENGE**

Tablettes d'Ipecacuanha, Fr. Cod.; Brechwurzelpastillen, G.; Pastiglie d'ipecacuana. It.

"Ipecacuanha Root, in powder, 0.015 gramme. Mix with the Simple Basis to form a Lozenge." Br.

These are useful expectorant lozenges in catarrhal complaints.

---

**TROCHISCUS KINO EUCALYPTI. Br.**

**EUCALYPTUS KINO LOZENGE**

Eucalyptus Gum Lozenge, Red Gum Lozenge; Tablettes de Kino d'Eucalypte, Fr.; Eucalyptuskinopastillen, G.

"Eucalyptus Kino, 0.06 gramme. Mix with the Fruit Basis to form a lozenge." Br.

---

**TROCHISCUS KRAMERIÆ. Br.**

**KRAMERIA LOZENGE**

Krameria Lozenge, Rhatany Lozenge; Tablettes de Ratanhia, ø.; Ratanhiapastillen, G.

"Extract of Krameria, 0.06 gramme. Mix with the Fruit Basis to form a Lozenge." Br.

These are astringent troches, which may be used in chronic angina.

*Trompatila.*—This is the stem and branches of Bouvardia triphylla Salisb. (fam. Rubiaceæ), a Mexican plant used by the natives for hydrophobia. (A. J. P., 1874, 51.)
"Turpeth is the dried root and stem of Ipomoea Turpethum, R.Br." Br.

Turpeth Root, Indian Jalap, Trivrit, Nisoth.

Ipomoea Turpethum (operculina Turpethum (L.) Peter) (Fam. Convolvulaceae) is a convolvulaceous plant which is found throughout India, China, Ceylon, Australia, and is occasionally cultivated in botanical gardens as an ornamental plant. There are two varieties, viz., Sveta or white turpeth, and Kirshna or black turpeth, the former being preferred as a mild cathartic. The black variety is said to be a powerful drastic. (Watt, "Dictionary of the Economic Products of India."

According to Merat and De Lens, the root itself formerly came into commerce, but at present turpeth consists of the root and stem of the plant cut into short lengths, usually from 1.5 to 5 cm. in diameter; the central woody portion is often removed by splitting the bark on one side. The pieces are cylindrical, somewhat twisted and externally of a dull gray color. A transverse section shows a porous central wood surrounded by a broad cortical portion, containing yellowish-brown resin cells, lactiferous vessels and crystals of calcium oxalate. The fracture is short in the cortex and fibrous in the central portion. The drug has a faint odor and a nauseous taste, which is perceptible only after it has been some time in the mouth.

"In cylindrical pieces of varying length, from one to five centimetres wide, often split on one side and deprived of the central portion; longitudinally furrowed; dull grey or brown. Fracture of the bark short, of the wood fibrous; internally usually pale grey. In transverse section, a porous wood surrounded by a thick bark in which abnormal wood-bundles are frequently present. Slight odor; taste nauseous, slowly developed." Br.

Boutron-Chalard found in turpeth root, resin, a fatty substance, volatile oil, albumen, starch, a yellow coloring matter, lignin, salts, and ferric oxide. (J. P. C., viii, 121.) The root contains 10 per cent. of resin. (Andouard, Ann. Ther., 1866, 118.) According to Spirgatis this resin is a glucoside, turpethin, $C_{76}H_{128}O_{36}$ like that of other Convolvulaceas,
insoluble in ether, but soluble in alcohol, to which it imparts a brown color not removable by animal charcoal. To obtain it pure, the alcoholic solution is concentrated; the resin precipitated by, and afterwards boiled with, water, then dried, reduced to powder, digested with ether, and finally redissolved by absolute alcohol and thrown down by ether. After being treated several times in this way, it is obtained in the state of a brownish resin, yielding on pulverization a gray powder, which strongly irritates the mucous membrane of the nostrils and mouth, and is fusible at 182.2° C. (360° F.). It is inflammable, burning with a smoky flame and emitting irritant vapors. With strong bases it acts like jalapin, takes up water, and is transformed into a soluble acid, turpethic acid, \( \text{C}_{34}\text{H}_{60}\text{O}_{18} \), while with dilute acids it is decomposed into turpetholic acid, \( \text{C}_{16}\text{H}_{32}\text{O}_{4} \), and glucose. (J. P. C., 4e ser., i, 236.)

Turpeth root is purgative, somewhat less powerful than jalap, and rather slow in its action.

Dose, five to twenty grains (0.32-1.3 Gm.).

**Off. Prep.**—Tinctura Jalapæ Composita, Br.

**Tylophora Leaves**. Tylophoræ Folia. Br. Add. (Fam. Asclepiadacæae) — The dried leaves of Tylophora asthmatica (L.) Wight and Arnott, are used in certain parts of India as a poison for vermin, and have been used with fatal results as a poison. Tylophora asthmatica, which grows in Bengal, Burmah and Ceylon, has been known in Indian medicine since 1780, and has been largely used in both the civil and the military medical service of Madras. It is officially described as "petiolate, entire, from two to five inches (five to twelve and a half centimeters) long and from three-quarters of an inch to two and one-half inches (eighteen to sixty-five millimeters) broad, lanceolate-ovate or ovate or subrotund in outline, somewhat cordate at the base, abruptly acuminated; rather leathery in texture, glabrous on the upper surface, and finely downy on the lower; of a brownish-green color, which is paler on the lower surface. Odor slightly aromatic; almost devoid of taste." Br. Add.

David Hooper has separated from this drug an alkaloid, tylophorine, soluble in ether and alcohol, but scarcely so in water; forming crystalline salts, and striking with nitric acid a purplish-red color, with Frohde's reagents a deep sap-green, and with potassium dichromate and sulphuric acid a dirty violet. Tylophora resembles in its activity ipecac, and is used as a substitute for that drug in bronchitis and in dysentery. In doses of from twenty to thirty grains (1.3-2.0 Gm.) it is used as an emetic. The expectorant dose is from one-half to two grains (0.032-0.13 Gm.).
Ulex. *Ulex europoeus* L. (Fam. Leguminosae), is the common furse, gorse, or whin so conspicuous in the waste places and by the roadsides of Great Britain, from its spiny branches and bright yellow flowers situated on the spines, either solitary or in pairs. The young tops are fed to cattle and horses, but the food value has been questioned. The leaf buds have been used as a substitute for tea and the flowers yield a beautiful yellow dye. In the seeds of this plant, A. W. Gerrard has found an alkaloid, ulexine. In 1890 Kobert (D. M. W., 1890), as the result of an elaborate physiological study, came to the conclusion that ulexine and cytisine are identical. The suggestion has given rise to a considerable chemico-physiological discussion, a brief abstract of which may be found in P. J., Feb., 1891. Kobert found indications of a second alkaloid in ulex. Partheil (A. Pharm., 1892, 448; 1894, 486) and Plugge (A. Pharm., 1894, 444) are in accord as to the identity of ulexine and cytisine. Ulexine has been used in cardiac dropsy. Dose, from one-fifteenth to one-twentieth of a grain (0.004-0.003 Gm.).

**ULMUS. U. S.**

**ELM [Elm Bark Slippery Elm]**

"The bark of *Ulmus fulva* Michaux (Pam. Ulmaceae), deprived of the outer corky layer and dried." U. S.

Red Elm, Moose-elm, and Indian Elm; Cortex Ulmi Interior, Ulmi Cortex; Orme Fauve, Fr. Cod.; Ecorce d'Orme, Fr.%; Ulmenrinde, Ruaterrinde, G.

The slippery elm (*Ulmus fulva*), is a lofty tree, fifty or sixty feet in height, with a trunk fifteen or twenty inches in diameter. The bark of the trunk is brown, that of the branches rough and whitish. The leaves are petiolate, oblong-ovate, acuminate, nearly equal at the base, unequally serrate, pubescent, and very rough on both sides. The buds, a fortnight before their development, are covered with a dense russet down. The flowers, which are apetalous, appear before the leaves, are
sessile, and in clusters at the extremities of the young shoots. The clusters of flowers are surrounded by scales, which are downy like the buds. The calyx is also downy. The stamens are five, short, and of a pale rose color. The fruit is a membranaceous capsule or samara, enclosing in the middle one round seed, destitute of fringe.

Ulmus fulva is indigenous, growing in all parts of the United States north of the Carolinas, but most abundantly west of the Alleghany Mountains. It extends westward to the Dakotas and northward to western Quebec and Lake Huron. It flourishes in open, elevated situations, and requires a firm, dry soil. From the white elm (U. americana L.) it is distinguished by its rough branches, its larger, thicker, and rougher leaves, its downy buds, and the character of its flowers and seeds. Its period of flowering is in April. The inner bark, separated from the cortex, is the part used. Large quantities are collected in the Lower Peninsula of Michigan.

Fremontia californica Torr., or California Slippery Elm, is not botanically allied to Ulmus fulva; its bark is said, however, to have the same properties as slippery elm bark, and to be used for a similar purpose.

Properties.—Elm bark is officially described as follows:

"Usually in bundles consisting of flat, oblong pieces, about 30 cm. in length and from 10 to 15 cm. in width; outer surface of a light brown or buff color with occasional dark brown patches of adhering cork, longitudinally striate and with detachable bundles of bast-fibers, and colored blackish upon the addition of a very diluted iodine T.S.; inner surface light yellowish-brown, nearly smooth and finely striate, only slightly darkened upon the addition of a very diluted iodine T.S.; fracture fibrous with projecting bast-fibers, the broken surface porous, due to the large mucilage cells; odor distinct; taste mucilaginous. The powder is very light brown; under the microscope it shows mostly fibrous fragments, and a finely granular portion made up of small starch grains, the latter being immediately colored bluish-black upon the addition of iodine T.S.; starch grains mostly spherical or more or less polygonal, usually about 0.003 mm. in diameter, but also attaining a diameter of 0.025 mm.; bast-fibers very long, about 0.02 mm. in diameter, with rather thin, slightly lignified walls; calcium oxalate in monoclinic prisms, mostly in crystal fibers, the individual crystals from
0.01 to 0.025 mm. in diameter; fragments of large mucilage cells with adhering starch grains. Macerate 1 Gm. of powdered Elm with 40 mils of distilled water for an hour and forcibly strain; the solution is of a mucilaginous consistence."

Ulmus abounds in mucilaginous matter, which it readily imparts to water. The mucilage is precipitated by solutions of lead acetate and subacetate, but not by alcohol. It contains a variety of tannin which colors iron solutions green, in amount about 6.5 per cent. according to Rink, or, according to Davy, a little less than 3 per cent.

Much of the bark brought into the market is of inferior quality, imparting comparatively little mucilage to water. It has the characteristic odor of the genuine bark, but is much less fibrous and more brittle, breaking abruptly when bent, instead of being capable, like the better kinds, of being folded lengthwise without breaking. To what this inferiority is owing, whether to difference in the species or the age, or to circumstances in the growth of the tree producing it, we are unable to state. Ground elm bark is said to be adulterated, usually with substances containing starch. Roberts found commercial specimens which possessed considerable of a brownish outer bark still adhering to them. One specimen was partly mouldy and had considerable adhering wood. (Proc. Penn. Ph. Assoc., 1913, p. 85.) The following test, devised by Geo. M. Beringer, seems to have practical value: Ten grains of ground or pulverized elm bark, thoroughly shaken with one fluidounce of water, will, if pure and of good quality, in fifteen minutes form a thick jelly-like mass of a fawn color.

C. W. Wright, of Cincinnati, in a communication to the Western Lancet, states that slippery elm bark has the property of preserving fatty substances from rancidity, and that this fact was known to the Indians, who prepared bear’s fat by melting it with the bark, in the proportion of a drachm of the latter to a pound of the former, keeping them heated together for a few minutes, and then straining off the fat. Wright tried the same process with butter and lard, and found them to remain perfectly sweet for a long time. (A. J. P., xxiv.)

Uses. — Elm bark is an excellent demulcent, applicable to all cases in which this class of medicines is employed. It is especially recommended in dysentery, diarrhea, and diseases of the urinary passages. Its mucilage is reputed to be nutritious.
It is commonly used as a drink in the form of infusion. (See Mucilago Ulmi.) The powder may be used stirred in hot water, with which it forms a mucilage more or less thick according to the proportion added. The bark also serves as an emollient application in cases of external inflammation. For this purpose the powder may be formed into a poultice with hot water, or the bark itself may be applied, previously softened by boiling. McDowell, of Virginia, recommended slippery elm bark for the dilatation of fistulas and strictures (Med. Examiner, i, 244); subsequently H. R. Storer, of Boston, used it advantageously for dilating the os uteri (B. M. S. J., liii, 300), and A. Abbe of the same place, succeeded in curing with it a case of stricture of the rectum, (B. M. S. J., liv, 349).

Off. Prep.—Trochisci Ulmi, N. F.

**Umbellularia.** Umbellularia californica (Arn.) Nutt. California Laurel. California Sassafras. Spice Tree (Fam. Lauraceae).—The leaves of this California tree are employed in neuralgic headaches, and in intestinal colic and atonic diarrhea; also externally as a mild counter-irritant. Stillman and O'Neill (N. R., 1883) obtained from the seeds a new acid, umbellulic acid. The leaves are said also to contain about 4 per cent. of a volatile oil, having a specific gravity of 0.936, a warm cam-phoraceous taste, and a strong pungent odor. Burse has separated from the oil by fractional distillation umbillol, an oil having the formula C₈H₁₂O, which dissolves in concentrated sulphuric acid with red color, and is narcotic. (Ap. Ztg., xi.) According to Schimmel & Co. (Schim. Rep., April, 1897), it also contained cineol, C₁₀H₁₈O. It is probable that the volatile oil is a strong local anesthetic, as it has been found to act rapidly when brought in contact with exposed pulp or sensitive dentine. The fluidextract has been used in doses of from ten to thirty minima (0.6-1.8 mils).

**UNGUENTA.**

**OINTMENTS**

These are fatty substances, softer than cerates, of a consistence like that of butter, and such that they may be readily applied to the skin by inunction. When ointments are prepared by merely mixing medicinal substances with simple ointment, hydrous wool-fat, lard, or petrolatum, care should be taken, if the added substance be a powder, that it be brought to the finest possible state of division before being incorporated.
with the unctuous matter. If soluble in water or in alcohol, it may often be advantageously rubbed with a little of one of these liquids. Gritty matter should not be allowed to enter these preparations. When an extract is added, if not uniformly soft, it should be made so by trituration with water or alcohol, according to its nature. Many of the ointments become rancid if long kept, and should, therefore, be prepared in small quantities at a time, or only when wanted for use. The tendency to rancidity may be in a considerable degree counteracted by imbuing the unctuous vehicle with benzoin, or with poplar buds, as recommended by Deschamps (A. J. P., xv, 260); but care should be taken that there be no therapeutic objection to the admixture. Elm bark is said to have the same effect. According, to Geisler, ten drops of spirit of nitrous ether, incorporated with an ounce of ointment, will overcome the disagreeable fatty odor. (Ph. Cb., 1847, 927.) Hydrous wool-fat or lanolin, petrolatum, and glycerite of starch are now used as vehicles for ointments. In the selection of a vehicle for an ointment it is important to consider the object for which the ointment is to be used. Lanolin is a natural emollient of the skin, composed of cholesterin and other substances.

Glycelceum is an oleaginous compound of finely powdered almond meal 1 part, glycerin 2 parts, and olive oil 6 parts. It was proposed by T. B. Groves, C. D., Sept. 14, 1867, as a substitute for plasma and other fatty bodies, and has no doubt advantages, one of which is the facility with which it can be removed from the skin by a wet sponge. It has been proposed to substitute glycerin for oils and fats in the preparation of ointments, either wholly or in part; but ointments thus prepared are altogether unfit for application by inunction, as a portion of the glycerin remains upon the skin, producing a rough sensation of adhesiveness, very different from the softness caused by oleaginous matter, and in some skin diseases glycerin in an ointment would be positively injurious.

The cerates having been abolished as a class in the British Pharmacopoeia, a few of the individual articles have been transferred to the ointments, making the definition of the latter class of preparations, as given above, not exactly applicable to all the individual substances at present included among them in that Pharmacopoeia. We consider no substance to be strictly entitled to the name of ointment which is not of such a consistence as to adapt it to application to the skin by friction or inunction. Ointments should be dispensed in glass, porcelain, or queensware pots or jars, or, if for temporary use, in tight wooden boxes.
We have used a very convenient method of dispensing soft ointments by introducing them into compressible tubes. These tubes are similar to those used for holding artists' colors, and have the advantage of shielding the ointment from the oxidizing action of the air while allowing the use of the desired quantity. Vanderkleed and Heidlberg (Proc. P. P. A., 1913, p. 312) state that the only satisfactory method of determining whether or not the proper degree of subdivision has been attained is by the use of the microscope, and call attention to some of the precautionary measures which should be taken in order to obtain correct results. Their article is illustrated by numerous photographic representations of ointments of different degrees of fineness. For a classification of ointments in accordance with their therapeutic use, by C. S. N. Hallberg, see West. Drug., 1900, 652.

Uses.—Ointments are used either for their local effects upon the skin or as a means of introducing drugs into the system through endermic absorption. The effects of fat-like substances upon the skin are due in part to their softening or emollient properties, and in part to the protection of the epiderm from the air, bacteria, or friction; they may also serve as carriers of antiseptic or other medicaments which influence pathological conditions of the skin. It is manifest that different qualities for an ointment base are desirable according to the purpose for which it is intended. Thus if it is intended to protect the skin the choice should fall on a substance which is not irritant nor readily absorbed nor liable to become liquid at a body temperature. On the other hand, for endermic administration one should choose a base which easily penetrates the skin. Concerning this last factor there has been a considerable amount of experimental investigation with not altogether harmonious results. The most widely used method has been to rub into the skin ointments made with various bases containing some substance easily demonstrable in the urine, and then determining the proportion of the medicament eliminated. Hirschfeld and Pollio (Arch. f. Derm. u. Syph., 1904, lxii, p. 163) found that the iodides were absorbed readily in ointments made with petrolatum or lard, but almost not at all from ointments made from wool fat. Bourjet (Th. M., 1893) found that salicylic acid was absorbed readily from ointments made with true fats but poorly in those made with petrolatum or glycerin as the base. Sauerland (Biochem. Zeit., 1912, xl, p. 56) in an elaborate research found that with vaseline, 40 per cent., with lard, 26 per cent., and with wool-fat. 18 per cent. of the iodine of iothion was absorbed through the skin; likewise methyl salicylate was absorbed in the same order,
although in much smaller proportions. On the other hand, spirosal, a
glycol salicylate, was absorbed scarcely at all from a lard ointment, but
in fair amounts from either wool-fat or vaseline. Gardiner (B. M. J.,
1912, i, p. 238) rubbed ointments containing various stains into the
shaven skin of guinea pigs and then examined the skin microscopically
to observe the depth of penetration. He found that olive oil penetrated
more deeply than any substance with which he experimented, but that
goose grease and lard also penetrated well. Petrolatum remained limited
to the very superficial portions of the skin. Wool-fat, while it penetrated
somewhat more deeply than petrolatum, was noticeably behind lard.
Wild (B. M. J., 1911, ii, p. 161) employed a very different method to
study this subject. He rubbed pure ointment bases into the skin for a
measured time and then scraped off what was left on the skin and
weighed. The difference between the quantity taken and that recovered
he considered to represent the amount absorbed. He found that
petrolatum was absorbed practically not at all, that of lard or olive oil
about 15 per cent., and of hydrous wool-fat about 20 per cent., but that
the absorption of the latter was noticeably less if it was deficient in
water. While the evidence quoted is somewhat contradictory and it is
probable that some ointment bases are better for one drug and some for
another, yet it seems to us that in a general way the conclusion is
justified that where absorption is desired lard is probably the best of the
official ointment bases.

**UNGUENTUM. U. S.**

**OINTMENT Ung. [Simple Ointment]**

Unguentum Adipis, U. S. 1860; Unguentum Simplex; Pommade simple, Fr.;
Unguentum cereum, P. G. Wachssalbe, G.

"White Wax, two hundred grammes [or 7 ounces av., 24 grains];
Benzoinated Lard, eight hundred grammes [or 28 ounces av., 96
grains], to make one thousand grammes [or 35 ounces av., 120 grains].
Melt the white wax, add the benzoinated lard, and heat gently until
liquefied; then stir the mixture until it congeals. For use in southern
latitudes and during the warm season in other localities, 50 Gm. of the
benzoinated lard (or more if necessary) may be replaced by an equal
quantity of white wax." U.S.
Yellow wax was used in this ointment in the U. S. P., 1890, and objection was made to the color of the ointment. It has been very properly replaced by white wax in the U. S. P. VIII and IX, and the lard is now benzoinated.

This is emollient, and is occasionally employed as a mild dressing to blistered or excoriated surfaces, but more frequently as a vehicle, it being the basis of several official ointments.

**UNGUENTUM AQUÆ ROSÆ. U. S., Br.**

**OINTMENT OF ROSE WATER Ung. Aq. Ros.**

Rose Water Ointment; Unguentum Emolliens; Cold-cream, Ceratum Galeni, Galen's Cerate, Fr. Cod.; Cerat cosmetique, Creme froide, Fr.; Unguentum leniens, P. G.; Cold Cream, G.

"Spermaceti, one 'hundred and twenty-five grammes [or 4 ounces av., 179 grains]; White Wax, one Hundred and twenty grammes [or 4 ounces av., 102 grains]; Expressed Oil of Almond, five hundred and sixty grammes [or 19 ounces av., 330 grains]; Sodium Borate, in fine powder, five grammes [or 77 grains]; Stronger Rose Water, one hundred and ninety grammes [or 6 ounces av., 307 grains], to make about one thousand grammes [or 35 ounces av., 120 grains]. Reduce the spermaceti and the white wax to fine pieces and melt them on a water bath, add the expressed oil of almond and stir, continuing the heat until the mixture is uniform. Dissolve the sodium borate in the stronger rose water warmed on a water bath to the temperature of the melted wax and fat, and add the warm solution gradually to the melted mixture, stirring it rapidly and continuously until it congeals and becomes of uniform consistence. Ointment of Rose Water must be free from rancidity. If the Ointment has been chilled, warm it slightly before attempting to incorporate other ingredients with it." U. S.

"Rose Water, 20.0 millilitres; White Beeswax, 18.0 grammes; Purified Borax, 1.0 gramme; Almond Oil, 61.0 grammes; Oil of Rose, 0.1 millilitre. Melt the White Beeswax in the Almond Oil; add, with constant stirring, the Borax previously dissolved in the Rose Water; add the Oil of Rose, and continue to stir until cold." Br.

In the U. S. P., 1890, process the proportion of stronger rose water was...
greatly reduced—i.e., from 30 to 20 per cent.; this makes a more stable preparation, but in our opinion the usefulness of the ointment has been curtailed by the reduction, its soft consistence being one of its most valuable characteristics. Sodium borate was added to increase its whiteness; its presence may, however, prove objectionable when the ointment is used as a basis in prescriptions, by reacting with some of the ingredients ordered by the physician. The U. S. P. VIII formula was retained with but slight changes in the U. S. P. IX. The manipulation was somewhat modified to increase uniformity of the product.

This preparation is a white, very soft, and elegant ointment, deriving a grateful odor from the rose water, which remains incorporated with the other constituents if kept enclosed in glazed vessels. We have found it an improvement to add oil of rose in the proportion of one drop to eight ounces, and, when made in the official quantity, to use an instrument known as the "Dover egg-beater" for giving it the desired creamy appearance. In larger amounts an ice cream churn is well adapted for this purpose. It is a pleasant, cooling application to irritated and excoriated surfaces, and may be used with great advantage for chapped lips and hands, so frequent in cold weather. It is a preparation of very early origin and is sometimes known by the name of Galen's Cerate. "Cold" cream is not recognized in the U. S. Pharmacopoeia IX as an official synonym for ointment of rose water. This course became necessary because of the large number of unofficial ointments of varying composition popularly exploited as cold creams, and these were frequently dispensed, when physicians' prescriptions directed Ointment of Rose Water. The commercial cold creams must be made from substances which are not liable to rancidity, and paraffin oil, liquid petrolatum, white petrolatum, etc., largely form the basis of such, but the official ointment is to be preferred for use in prescriptions. W. C. Alpers furnishes the following formula for a cold cream which is more permanent than the official ointment. One hundred and fifty parts of white wax is melted in 600 parts of paraffin oil with the aid of a gentle beat; 9 parts of borax is dissolved in 240 parts of water; the two fluids are brought to a uniform temperature, not exceeding 60° C. (140° F.), and the aqueous solution is poured into the oily one in a continuous stream, stirring gently for a minute or two; then 1 part of oil of geranium and a little oil of rose are added while stirring, and the product while still warm is poured into jars. The cold cream so obtained is white, soft and smooth, pleasantly odorous, keeps well in the heat of summer and the cold of winter, and becomes only slightly thinner in
summer. As the ointment is liable to become rancid when long kept, and the water to separate upon exposure, Joseph Laidley has proposed the substitution for the rose water of oil of rose and glycerin, the former in the proportion of two drops, the latter in that of four fluidrachms, the quantity of spermaceti being increased by two drachms. (A. J. P., xii, 119.) For some purposes the substitution is useful, but the official preparation is preferable for chapped hands, as the glycerin frequently leaves an unpleasant sensation of stickiness on the skin.

**UNGUENTUM CAPSICI. Br.**

**CAPSICUM OINTMENT**

Pommade de Piment das Jardins, Fr.; Spanisch-Pfeffersalbe, G.

“Capsicum Fruit, bruised, 25 grammes; Hard Paraffin, 10 grammes; Soft Paraffin, 75 grammes; Prepared Lard, 10 grammes. Digest on a water-bath for one hour, stirring occasionally; strain; stir until cold. In India, Prepared Suet (Sevum Preparatum) should be employed instead of Prepared Lard in making this Ointment." Br.

This is an active counter-irritant which may be used in the place of liquid liniments in sprains, bruises, rheumatism, and other inflammations.

**UNGUENTUM EUCALYPTI. Br.**

**EUCALYPTUS OINTMENT**

Pommade d'Eucalypte, Fr.; Eukalyptussalbe, G.

"Oil of Eucalyptus, 10 grammes; Hard Paraffin, 40 grammes; Soft Paraffin, white, 50 grammes. Melt the Hard and Soft Paraffins together; add the Oil of Eucalyptus; stir until cold." Br.

This ointment is used as a stimulant to indolent ulcers and in skin diseases.
UNGUENTUM HAMAMELIDIS. Br.

HAMAMELIS OINTMENT

Pomade de Hamamelis, Fr.; Hamamelissalbe, G.

"Liquid Extract of Hamamelis, 10 millilitres; Wool Fat, 60 grammes; Soft Paraffin, 30 grammes. Mix by trituration in a warm mortar." Br.

This was one of the "Additions" to the British Pharmacopoeia, 1885, and afterwards introduced into the Br. Pharm., 1898, 1914. It is, in our opinion, of doubtful utility, but may be applied to sprains.

UNGUENTUM STAPHISAGRIÆ. Br.

STAVESACRE OINTMENT

Onguent de Staphisaigre, Fr.; Stephanskomersalbe, G.

"Stavesacre Seeds, 20 grammes; Yellow Beeswax, 10 grammes; Benzoated Lard, 85 grammes. Crush the Stavesacre Seeds; digest the crushed seeds with the Benzoated Lard on a water-bath for two hours; strain and press through calico; melt the Beeswax in the liquid mixture; stir until cold. In India, Prepared Suet (Sevum Benzoatum) should be employed instead of Benzoated Lard in making' this Ointment." Br.

This ointment is but half the strength of that official in the British Pharmacopoeia 1885; it is said to be non-irritant, and is largely used in Great Britain for destroying body-lice, also in scabies and prurigo.

UNGUENTUM STRAMONII. U. S.

STRAMONIUM OINTMENT Ung. Stramon.

Pomade de Stramoine, Fr.; Stechapfelsalbe, G.

"Pilular Extract of Stramonium, ten grammes [or 154 grains]; Diluted Alcohol, five mils [or 81 minims]; Hydrous Wool Fat, twenty grammes [or 308.6 grains]; Benzoinated Lard, sixty-five grammes [or 2 ounces av., 128 grains], to make about one hundred grammes [or 3 ounces av., 231 grains]. Triturate the extract with the diluted alcohol until a smooth
mixture is obtained; with this incorporate the hydrous wool fat, then
add the benzoinated lard, and mix thoroughly." U. S.

This is a more certain preparation than that of the former editions of the
U. S. Pharmacopoeia, which was made by boiling the fresh leaves in
lard. The color of the ointment of the U. S. P. IX is different from that of
the earlier Pharmacopoeias, the greenish tint being due to the use of
official extract of stramonium which is now made from the leaves
instead of the seeds. For remarks by A. P. Sharp of Baltimore, on the
preparation of this ointment, see A. J. P. (xxvii, 391). A useful anodyne
application in irritable ulcers, painful hemorrhoids, and bruises.

**Urechites.** Urechites suberecta Jacq. Savannah Flower. Yellow-flowered
Nightshade—This is an apocynaceous plant, which grows abundantly in the West
Indian Islands and to some extent in Florida, is said to be used in Jamaica by the
negroes as a poison. The symptoms which it produces are violent vomiting and
purging, with convulsions. J. J. Bowrey (J. Chem. S., June, 1878) has isolated from it
two glucosides, urechitin and urechitoxin, having respectively the formula C_{28}H_{42}O_{8}
and C_{13}H_{20}O_{5}. Isaac Ott (T. G., 1880) finds the plant to be a powerful cardiac poison,
first increasing and then depressing the arterial pressure, and finally, if the dose be
large enough, killing by producing cardiac arrest. The results reached by Ott are in
accord with those of Ralph Stockman (Laborat. Rep., Royal College of Physicians,
Edinburgh, vol. iv, 1892), who finds that both of the glucosides are very active poisons
belonging to the digitalis group. On the other hand, Vowinkie came to the conclusion
that even small doses of the plant depress the heart, and experiments made upon
man by Bowrey show that in large doses the drug produces nausea, vomiting, general
depression, great perspiration, and slight swelling of the pulse. Stockman (Rev. de
Clin. et de Ther., June 29, 1892) found that the leaves contain a toxic alkaloid, which
he calls urechitine, C_{28}H_{42}O_{8} + H_{2}O, and a glucoside, urechitonin, which is less toxic.
In Jamaica the drug is said to have been used in the treatment of intermittent and
other sthenic fevers. The dose of the fluidextract is from two to ten minims (0.12-0.6
mils).

**URGINEA. Br.**

**URGINEA [Indian Squill]**

“Urginea consists of the younger bulbs of Urginea indica, Kuntfi,
collected soon after the plants have flowered, divested of their dry,
outer, membranous coats, cut into slices, and dried. When powdered
should be kept quite dry over quicklime." Br.

Urginea indica is a plant resembling Urginea maritima. It is easily
distinguished from the latter in that the bulb when entire is scaly and not tunicated as the European Squill. Urginea indica grows in sandy soil near the sea coast throughout India and also extends to the lower Himalayas. The medicinal properties of the drug are apparently identical with the Squill of the Greeks. The outer coats are quite inert and should be removed as indicated in the definition of the Br. Pharm.

"Curved or sickle-shaped strips, separated or connected, several together, to a portion of the shortened axis; usually one to five centimetres long and five to ten millimetres wide; yellowish-white, fleshy, often longitudinally ribbed; tough when slightly moist, but brittle and pulverizable when dry. No odor; taste bitter and acrid." Br.

The bulbs of Urginea indica are rounded, conical or pear-shaped and about the size of an onion; tunicated, consisting of fleshy coats which enclose each other completely; color whitish; taste bitter and acrid. The bulbs of Scilla indica Baker, which were recognized by the Br. Add. 1900, differ in that they are not tunicated but made up of thick fleshy rubricated scales; otherwise, except that they are somewhat smaller, they resemble those of Urginea indica.

**Uses.**—The bulbs of Indian squill have long been used in India for purposes similar to that for which the official squill is employed in Europe and America, but no sufficient chemical examinations have been made to prove the identity of the Indian and European drugs.

Dose, one to three grains (0.065-0.2 Gm.).

**Urtica.** Ortie brulante, Fr. Brennessel, G.—Various species of this genus (Fam. Urticacée) are furnished with poisonous stinging hairs. Urtica gigas A.Cunn. (now Laportea gigas Wedd.), of Eastern Australia is said frequently to kill horses, and to produce in man a sting whose impression lasts for months. (N. R., 1875.) It has generally been thought that the virulence of the hairs is due to the presence of free formic acid (A. J. P., xxii), and David Hooper (P. J., April, 1887) has demonstrated the presence of formic acid, or a substance very closely allied to it, in the hairs of the Nilgri nettle (Girardinia palmata Gaudich.). Nevertheless, it does not seem probable that formic acid is the poison. G. Haberlandt believes it to be a non-volatile albuminoid, and L. Renter has obtained from several nettles a glucoside. (A. J. P., Jan., 1890.) Oddi and Lomonaco (Rif. Med., April, 1892) isolated from the common
nettle a crystalline alkaloid, and found that in mammals the extract acts powerfully upon the vasomotor system, and in frogs causes centric paralysis with diastolic cardiac arrest.

U. dioica L., or common nettle, and U. urens L., or dwarf nettle, European plants naturalized in waste places to some extent in the United States, have been used in medicine as local irritants, as diuretics (A. J. P., 1866), and especially for the purpose of arresting uterine hemorrhage. The fluidextract may be given in doses of half a fluidrachm (1.8 mils) or a decoction of the strength of an ounce to a pint in teacupful doses. Under the name of brandol is marketed a preparation used in the treatment of burns and wounds; it is a liquid consisting of 93 per cent. infusion of urtica, 2 per cent. picric acid and 5 per cent. glycerin.

**Ustilago.** U. S. 1880. Corn Smut—The genus Ustilago belongs to the Ustilaginaceae, all the members of which generally develop their spores in the ovary or anthers of the host plant, forming a slimy mass, which in maturing becomes a black dust made up of spores. They produce the smut in cereals. Ustilago Maydis (DC.) Tul. is produced on the stems, the pistils (corn grains), and the male inflorescence (tassel) of the Indian corn. It is specifically characterized by its minute spherical spores, about 0.007 mm. in diameter. It is abundant in the United States. Upon the corn the smut appears in masses, varying in size from a cherry to a child's head; These masses are smooth, irregularly globose, or sometimes lobulated, having at first a livid, bluish tint, and then becoming blackish, and finally bursting and emitting the black contents, consisting of innumerable globose very minute spores, each of which is covered with beautiful little pointed processes. In a dried state the masses are blackish and covered with a black powder.

C. H. Cressler found in ustilago an alleged alkaloid, secaline (trimethylamine), besides a thick, viscid, fixed oil and a resin soluble in ether, but not in alcohol. (A. J. P., 1861, 306.) Rademaker and Fischer (Nat. Drug., 1887, 296) believed that they had discovered a white, bitter alkaloid, ustilagine, soluble in ether, while H. B. Parsons decided that the fixed oil contained an acid which he provisionally named sclerotic acid; also an amine-like volatile substance extracted by ether. (N. R., March, 1882; also West. Drug., 1894.) A. W. Balch (Journ. Boston Soc. Med. Sci., March, 1901) was not able to find any active substance in the smut.

The belief that corn smut is an abortifacient to the lower animals (A. J. P., Sept., 1861) appears to be without foundation, as in the experiments made by the United States Department of Agriculture in 1898 (Farmers' Bulletin, No. 69) no effect was produced by corn smut given to pregnant cows. The experiments of James Mitchell (T. G. ii, 223) that ustilago abolishes sensation, reflex action, and later general motor power in the frog, is contradicted by the results of Balch, who also found that enormous doses of the substance have no effect upon the color of the cock's comb. In doses of one to two drachms (3.9-7.7 Gm.) it has been claimed by W. A. N. Borland that the fluidextract markedly increases the severity and frequency of the uterine pains in human labor. The whole drift of our present evidence is to show that ustilago is probably inert.
UVA URSI. U. S. (Br.)

UVA URSI [Bearberry]

"The dried leaves of Arctostaphylos Uva-ursi (Linne) Sprengel (Fam. Ericaceae), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." U. S. “Bearberry Leaves are the dried leaves of Arctostaphylos Uva-ursi, Spreng." Br.

The uva ursi, or bearberry, is a low evergreen shrub, with trailing stems, the young branches of which rise obliquely upward for a few inches. The leaves are scattered, upon short petioles, from half an inch to an inch long, obovate, or oblong-spatulate, acute at the base, obtuse at the apex, entire, with a rounded margin, thick coriaceous, smooth, shining, deep green on their upper surface, paler and covered with a net-work of veins beneath; furnished especially near the margin or near the midrib with minute hairs, which are usually abundant in young leaves, but may be few or absent in old leaves, especially those which have been much handled. The flowers, which stand on short reflexed peduncles, are in small clusters at the ends of the branches. The calyx is small, five-parted, reddish, and persistent. The corolla is ovate or urceolate, reddish-white, or white with a red lip, transparent at the base, contracted at the mouth, and divided at the margin into five short reflexed segments. The stamens are ten, with short filaments and bifid anthers; the ovary round, with a style longer than the stamens, and a simple stigma. The fruit is a small, round, depressed, smooth, glossy red berry, with an insipid mealy pulp and five cohering seeds.

This humble but hardy shrub inhabits the northern latitudes and high mountains of Europe, Asia, and America. On the American continent it extends from Hudson's Bay as far southward as New Jersey and Pennsylvania, in some parts of which it grows in abundance. It prefers a barren soil, flourishing on gravelly hills and elevated sandy plains. The leaves are the only part used in medicine. They are imported from Europe, but are also collected within our own limits, and the market of Philadelphia is supplied to a considerable extent from New Jersey. They should be gathered in autumn, and only the green leaves selected. In Europe the uva ursi is adulterated with the inert leaves of the
Vaccinium Vitis-Idaea L. (Cowberry, Mountain Cranberry); these may be distinguished by being obovate, having revolute margins which are sometimes slightly toothed, and the presence of fine blackish dots or bristly points upon their lower surface. Leaves of the Chimaphila umbellata (L.) Nutt., sometimes found among the uva ursi, may be readily detected by their greater length, their cuneiform-lanceolate shape, and their serrate edges.

Arctostaphylos glauca LindL, manzanita, is a small tree or shrub indigenous in California, where it generally grows in dry and rocky places on the west of the mountain ranges. The leaves appear to possess properties similar to those of the official species. (See Flint, A. J. P., 1873, p. 187.) The fruit of A. arguta Zucco, a Mexican species, is said to be a narcotic poison.

**Properties.**—Uva ursi is officially described as: " Usually more or less entire, laminae obovate or oblong-spatulate, from 12 to 30 mm. in length and from 5 to 13 mm. in breadth; summits obtuse or rounded; margins entire, slightly revolute; bases cuneate, tapering into short, stout petioles; upper surfaces dark green, glabrous and shiny, finely reticulate; under surfaces yellowish-green and slightly pubescent, especially on the midribs; coriaceous, fracture short; odor aromatic, tea-like; taste astringent and somewhat bitter. The powder is olive green; under the microscope it shows irregular fragments; epidermal cells polygonal, those of the lower surface showing broadly elliptical stomata about 0.035 mm. in length, surrounded by from 5 to 8 neighboring cells; cells of mesophyll with chloroplastids and frequently irregular masses of a carbohydrate; fragments of fibro-vascular bundles with spiral tracheae associated with narrow, strongly lignified sclerenchymatous fibers and frequently also with crystal fibers with mono-clinic prisms, from 0.006 to 0.015 mm. in diameter ; numerous fragments made up of cells having a yellowish-brown content which are colored a bluish-black upon the addition of ferric chloride T.S. Place 0.1 Gm. of powdered Uva Ursi on a watch crystal and cover with another watch crystal and gently heat the powder; a crystalline sublimate forms, consisting of long rods and feather-like aggregates which polarize light with a brilliant play of colors. Macerate 1 Gm. of powdered Uva Ursi with 10 mils of boiling water, shake the mixture occasionally until cold and then filter it; the filtrate yields a grayish-purple precipitate upon the addition of a few drops of ferrous sulphate T.S." U. S.
"Obovate or spatulate, about two centimetres long, yellowish-green, coriaceous, entire, shortly petiolate. Upper surface glabrous, shining, reticulate; veinlets depressed. Slight odor; taste very astringent." Br.

The commercial drug frequently consists of the entire plants and therefore contains a large quantity of stems. The latter should not be present, according to the official definition, in greater amount than five per cent. Farwell states that the leaves are sometimes very dark or blackish-green, which is probably due to carelessness in drying. (M. R., xvii, p. 35.) Holm has contributed an interesting article on the morphology of the plant. (M. R., xx, p. 95.)

Uva ursi leaves contain—besides tannic and gallic acids, bitter extractive resin, gum, fatty matter, and salts of potassium and calcium—two glucosides, arbutin, C₁₂H₁₅O₇, and ericolin, and a resinous principle, urson. The tannin is so abundant (6 or 7 per cent.) that the leaves are used for tanning in Russia.

Arbutin is somewhat widely diffused in the species of Ericaceae, such as Chimaphila umbellata (L.) Nutt., Chimaphila maculata (L.) Pursh, Epigaea repens L., and Gaultheria procumbens L. Kawalier (Chem. Gaz., 1853, p. 61) obtained it from uva ursi by precipitating the decoction with lead acetate, filtering, treating the liquid with hydrogen sulphide, again filtering, evaporating to the consistence of syrup, and allowing the product to stand for several days. This gradually assumed the form of a crystalline jelly, which, being placed upon linen so as to allow the mother liquor to drain off, and then pressed, yielded nearly colorless crystals, which were purified by solution in boiling water and treatment with animal charcoal. Arbutin thus obtained is in long, acicular, colorless crystals, united in tufts, and of a bitter taste. It is soluble in water, alcohol, and ether, unchanged apparently by a heat of 100° C. (212° F.), bat fusible at 167° to 168° C. (332.6°-334.4° F.), without action on vegetable colors, and not precipitated by ferric salts or by lead acetate or subacetate. It is a glucoside, being resolvable by emulsin, or more rapidly by boiling with sulphuric acid, into glucose and hydroquinone, C₆H₆O₂ (arctuvine of Kawalier). The occurrence of methylhydroquinone among the products of decomposition led Hiasiwetz and Haber-mann to give the formula C₂₅H₃₄O₁₄ to arbutin, but Schiff showed that this was because arbutin was almost always accompanied by methylarbutin, C₁₂H₁₅(CH₃)O₇+H₂O. This compound
has been made synthetically by Schiff (Ber. d. Chem. Ges., 1882, p. 1841) by acting upon arbutin with methylidioxide and potassium hydroxide in methyl alcohol solution, and purely synthetically by Michael (Ber. d. Chem. Ges., 1885, p. 118) by the action of methylhydroquinone and acetochlorhydrose. It is decomposed by dilute acids into glucose and methylhydroquinone. Upon heating 1 part of arbutin with 8 parts of manganese oxide, 2 parts of sulphuric acid, and 1 part of water, it gives off the penetrating odor of quinone. The aqueous solution is rendered blue by a small quantity of solution of ferric chloride, and green by a larger quantity. No precipitate is produced by either acids or alkalies. It blackens ammoniacal solution of silver nitrate after boiling with diluted sulphuric acid, and throws down cuprous oxide from alkaline copper solutions upon heating. It dissolves in sulphuric acid, forming a colorless solution, turning red after a short time; a trace of nitric acid turns this solution yellow-brown. An aqueous solution (1 in 20) is not changed by hydrogen sulphide. A good test for arbutin is that of Julius Jungmann, as follows: When phos-phomolybdic acid is added to a solution of arbutin previously rendered alkaline by ammonia or other alkali, a blue color is produced, which is deep when the solutions are strong, but observable even when they are very dilute. (A. J. P., May, 1871, p. 204.)

After the extraction of arbutin there is obtained from the mother liquor ericolin, C\textsubscript{34}H\textsubscript{56}O\textsubscript{21}. This is also found in many other ericaceous plants. It is glucosidal in nature and yields on decomposition, besides glucose, a volatile oil, ericonol. Another crystallizable principle has been discovered by Trommsdorf, who calls it urson, C\textsubscript{30}H\textsubscript{48}O\textsubscript{3}. It appears to be of a resinous character, although it can be obtained in silky needles, being tasteless and inodorous, insoluble in water, difficultly soluble in alcohol and ether, fusible, at a higher temperature volatilizable, and inflammable in the air. It is obtained by treating uva ursi with a very small quantity of ether by percolation, allowing the ether to evaporate, washing the crystalline extract with ether, and recrystallizing from alcohol. (A. J. P., xxvii, 334.)

A. G. Perkin has obtained from the leaves of uva ursi a yellow coloring principle of the composition C\textsubscript{15}H\textsubscript{10}O\textsubscript{7}, crystallizing in glistening yellow needles. On fusion with alkali, phloroglucinol and protocatechuic acid were formed. Though resembling quercetin in these points, it forms deep green solutions with diluted potassium hydroxide. (A. J. P., 1898, 584.)
**Uses.**—Uva ursi is used to-day almost exclusively in the treatment of catarrhs of the urinary tract, especially acute cystitis. Although by some it is believed to exercise an astringent and alterative influence on these membranes, it is probable that its action is simply that of a mild antiseptic. Lewin (V. A. P. A., 1883, xci, p. 517) attributes its virtues to the arbutin which is decomposed in the system liberating hydroquinone. Bass, however (Z. E. P. T., 1912, x, p. 120), is doubtful whether enough hydroquinone can appear in the urine to exercise any antiseptic effect. But whether or not its virtue is due to arbutin or some other principle, the clinical evidence is strong that uva ursi is a useful drug in these conditions. Formerly it was also employed in gravel, nephritis, urethritis, and menorrhagia, but has been largely abandoned. Because of the formation of hydroquinone in the body the urine often acquires a greenish color from the use of uva ursi.

Arbutin has been employed in medicine not only for its antiseptic effect but also as a diuretic in doses of from one to three grains (0.065-0.2 Gm.).

Dose, powdered uva ursi, from twenty grains to a drachm (1.3-3.9 Gm.), to be repeated three or four times a day; but the fluid'xtract is always preferred.

**Off. Prep.**—Fluidextractum Uvae Ursi, U. S.;

Infusum Uvae Ursi, Br.; Elixir Buchu Compositum (from Compound Fluidextract of Buchu), N. F.; Fluidextractum Buchu Compositum, N. F.

**Uzara.** Uzaron.—Under this name the root of an undetermined African plant, probably belonging to the Asclepiadaceae, has been used both by the natives and European physicians in the treatment of dysentery, especially of the amoebic variety. Guerber and Frey (A. E. P. P., 1913, lxxv, p. 75) have determined that it contains neither alkaloid nor tannin,- but does contain non-nitrogenous glucosides which have a digitalis-like action upon the heart and diminish peristalsis of the intestines. It appears to owe its virtues in part to its amoebicidal action, but in part also to its effect upon the intestinal muscles.

**Vaccinium.** Vaccinium crassifolium Andr. (Fam. Vacciniaceae) —The leaves of this American shrub are said to be astringent and diuretic, and capable of replacing uva ursi. Dose, of the fluidextract, from a half to one fluidrachm (1.8-3.75 mils).
VALERIANA. U. S. (Br.)

VALERIAN Valer.

"The dried rhizome and roots of Valeriana officinalis Linne (Fam. Valerianaceae)." U. S. "Valerian Rhizome is the dried rhizome and roots of Valeriana officinalis, Linn. Collected in the autumn." Br.

Valerianae Rhizoma, Br.; Valerian Root; Radix Valerianae Minoris, R. Valerianae Sylvestris, R. Valerianae Montanae; Common, Garden, Cat's or Great Wild Valerian, All-heal, Summer Heliotrope, Herb Bennet, Vandal Root; Valeriane officinale, Fr. Cod.; Racine de Valeriane, Valeriane, Fr.; Radix Valerianae, P. G.; Baldrian, Wilde Baldrianwurzel, Baldrian-wurzel, G.; Valeriana, It.; Valeriana (Rizoma de), Sp.

Official or great wild valerian (Valeriana officinalis) is a large, handsome, herbaceous plant, with a perennial rhizome, and an erect, round, channelled stem, from two to four feet high, furnished with opposite pinnate leaves, and terminating in flowering branches. The leaves of the stems are attached by abort, broad sheaths; the radical leaves are larger and long petiolate. In the former the leaflets are lanceolate and partially dentate, in the latter elliptical and deeply serrate. The flowers are small, white or rose-colored, agreeably odorous, and disposed in terminal corymbs interspersed with pear-shaped bracts. The number of the stamens is three. The fruit is a capsule containing one oblong-ovate, compressed seed. The plant is a native of Europe, where it grows either in damp woods and meadows or on dry elevated grounds. As found in these different situations, it presents characters so distinct as to have induced some botanists to make two varieties. Dufresne makes four, of which three prefer marshy situations. The variety which affects a dry soil (sylvestris L. Ph.) is not more than two feet high, and is distinguished by its narrow leaves.

The valerian plant is cultivated to some extent in New England and New York, and in Europe, in England and Holland. In this country it will grow in light, well-prepared, and well-drained soil, and is propagated by dividing the roots in the fall and setting these portions acids mentioned, forming corresponding esters with them: (4) at from 285° to 290° C. (545°-554° F.), a greenish, syrupy oil, which when rectified is colorless, and seems to have the composition of a borneol oxide, (C_{10}H_{17})_{2}O. Schim-mel & Co. (Schim. Rep., April, 1897) summarize the most recent researches upon valerian oil from different sources. In the oil from Dutch and Thuringian roots, the amount...
varying from 0.5 to 1 per cent., they find pinene, camphene, borneol, bornyl formate, bornyl acetate, and bornyl isovalerate, together with a sesquiterpene and an alcohol, C_{10}H_{20}O_{2}. In the oil from Japanese roots (amounting to from 6 to 6.5 per cent.) (Kesso oil), they find pinene, camphene, dipentene, terpineol, borneol, bornyl acetate, bornyl isovalerate, and kessyl acetate. Trommsdorff ascertained the existence in the oil of valeric acid.

This acid is a colorless volatile liquid, of an oleaginous consistence, having an odor analogous to that of valerian, and a very strong, sour, disagreeable taste. It is soluble in thirty parts of water, and in all proportions in ether and alcohol. It combines with salifiable bases, forming soluble salts, which retain, in a diminished degree, the odor of the acid. (J. P. C., xx, 316.) The acid does not pre-exist in the oil, but is produced by the decomposition of its borneol ester. Valeric acid is obtained by distilling the impure oil with magnesium carbonate, decomposing by sulphuric acid the magnesium valerate which remains, and again distilling. The following process by T. and H. Smith, of Edinburgh, avoids the inconvenience of distilling so bulky a root as valerian, while it answers the same purpose as that of Rabourdin. Boil the root for three or four hours with rather more than its bulk of water in which an ounce of sodium carbonate is dissolved for every pound of the root, replacing the water as it evaporates. Express strongly, and boil the residuum twice with the same quantity of water, expressing each time as before. Mix the liquids, add two fluidrachms of strong sulphuric acid for every pound of the root, and distil until three-fourths of the liquid have passed over. Neutralize this with sodium carbonate, concentrate the liquid, decompose the sodium valerate contained in it by sulphuric acid, and collect the valeric acid set free, by a separator, funnel, or by distillation. (A. J. P., xvii, 253.) Lefort obtains the acid by the rapid oxidation of the volatile oil. He distilled 100 parts of the root with 500 of water, 10 of sulphuric acid, and 6 of potassium dichromate, and in this way procured a larger proportion of acid than by any other process. (J. P. C., 3e ser., x, 194.)

Uses.—Valerian is used as a sedative to the higher nerve centers in conditions of nervous unrest, hysteria, hypochondriasis, neuralgic pains, and the like. The virtues of the plant seem to depend chiefly on the esters of valeryl which are contained in the volatile oil. According to Chevalier (Nouv. Rem., 1912, xxix, p. 169), the volatile oil of valerian is a depressant to the whole central nervous system, including both the
motor and psychical centers of the brain and the motor cells of the spinal cord. The esters contained in this drug are unstable bodies and in the process of drying largely oxidized with the formation of valeric acid. As the latter is practically without physiological action much of the virtue of the plant is lost during the drying process. Probably for this reason preparations of this drug are very uncertain in their activity and valerian has largely fallen into disrepute. Chevalier has introduced the juice of the fresh root which he asserts is a valuable remedy not only for the conditions mentioned above, but even as a narcotic in insomnia and an anticonvulsant in epilepsy. The dose of this juice, which has been introduced under the name of energetene of valerian, is one to three coffeespoonsful. It appears also to have some slight influence upon the circulation, slowing the heart and increasing its force, and causing a rise in blood pressure, and has been used in the treatment of cardiac palpitations.

Dose, twenty to forty grains (1.3-2.6 Gm.). The dose of the oil of valerian, which is occasionally employed, is four to five minims (0.25-0.3 mil).

**VALERIANÆ INDICÆ RHIZOMA. Br.**

**INDIAN VALERIAN RHIZOME**

"Indian Valerian Rhizome is the dried rhizome and roots of Valeriana Wallichii, DC." Br.

Valeriana Wallichii is a perennial herb growing in the temperate Himalayas and in the Khasia Mountains. The rhizome is more largely used as a perfume than in medicine. It is used in preparations for the hair and the dried rhizome is used as an incense. It is officially described as follows: "Rhizome curved, about five centimetres long, from five to ten millimetres thick, dull brown, with raised transverse leaf-scars, numerous prominent root-scars and a few thick roots; the crown bearing the remains of petioles. Fracture short. In transverse section, dark with a large pith and diffuse ring of small wood-bundles. Strong, characteristic, disagreeable odor; taste unpleasant, camphoraceous." Br.
According to Lindenberg (Ph. Z. R., 1886), Indian valerian is practically identical in its composition with the European drug, but contains a slightly larger amount of volatile oil. It may be employed in the same class of cases as valerian.

Off. Prep.—Tinctura Valerianae Indicae Ammoniata, Br.

**Valonia.** Acorn Cups. Vallone, Velanede, Gallon, Fr. Knoppen, Walonen, G.—The great cups of the acorns of the Quercus Aegilops L. (Fam. Cupuliferae), a native of Bosnia, contain a very large percentage of tannin. They are extensively exported for dyeing and tanning, and have been employed as an astringent in diarrhea.

**Vandellia.** Vandellia diffusa L. (Fam. Scrophulariaceae)—This is an herb of Paraguay, said to be used by the natives as an emetic. (P. J., 1872, 849.)

Vanilla planifolia is a fleshy, dark green, perennial climbing plant, with a very long, smooth, dark green stem, much branched, and furnished at the nodes with aerial roots, which cling to the tree or the wooden framework supporting the plant. The dark green, tough leaves are alternate, oval, sessile, attenuate at the apex, fleshy and veinless. The pale greenish-yellow, sessile flowers are about two inches in diameter, and occur in loose, axillary racemes of eight or ten. The fruit is a slender pod, seven or eight inches long, filled with an oily mass containing numerous small, black, shining seeds.

This plant is a native of the West Indies, Mexico and South America, but is now extensively cultivated. The plant does well from the sea-level up to two thousand feet of altitude, requiring for its perfection, however, a moist, hot climate, with an habitual dry summer spell which seems to be necessary to bring good flowering. It is propagated by means of cuttings, sometimes two or three feet in length, but preferably from ten to twelve feet long, taken from growing shoots; these are planted after the dry season is over and should produce flowers in two years. Preferably placed upon trees, but sometimes on long stakes, trellises, wire supports, etc., the slip is placed with one end on the ground, covered with leaves or some light top dressing. In many cases the vines are planted so closely as scarcely to leave room for cultivators to pass, but it has been found that under these circumstances the vanilleries are especially liable to destructive fungous diseases. As the flower does not fertilize itself, fertilization (pollination) by hand is necessary; it is usually performed by women and children. It is said that a fairly trained workman can fecundate over one hundred flowers per hour. In most localities not more than thirty fertilized flowers should be left to a plant. The pods reach their full size in from five weeks to eight months, according to the altitude of the locality and to the amount of shade. The first indication of ripening is a slight yellowing of the whole pod; as soon as this occurs the
pods should be picked, and sorted, and the curing process commenced. If left to ripen further the pods are prone to split and otherwise deteriorate. For the purpose of curing them the pods are kept in a heated room for some days (about 110° F.), then transferred to a cooler one (90° F.), and finished at ordinary temperature. During the process, which lasts some months, there is a loss of 70 to 80 per cent. of weight. For details as to culture, see Bulletin 21, 1898, U. S. Department of Agriculture, Division of Botany. The practice of curing the beans by placing them under blankets in the sun is still in vogue, but that of using a regulated artificial heat is more certain, and it is the modern method.

When thoroughly cured the beans are sorted and tied into bundles, which are wrapped in sheet lead or placed in small metallic boxes. In doing this it is essential that the bundle be wrapped in a thin vegetable parchment paper, as chemical action occurs when the beans come in contact with the metal.

Fruits which have not been picked early enough are inferior and are frequently cut into short pieces and sold as "cuts." If by chance the fruit should be picked too early the quality of the resulting product is distinctly inferior. The fruit as first picked has no aroma, the vanillin during the process of curing being produced from the glucoside coniferin in the interior of the fruit. This was shown to be converted into coniferyl alcohol and glucose, and the former of these subsequently changed into vanillin.

The cultivation of vanilla has extended from South America throughout the tropics, so that at present, although the wild plant is abundant in the Mexican States of Vera Cruz and Oaxaca the vanilla of the markets comes almost exclusively from vanilleries. Holland is supplied from Java plantations; France from Tahiti, Madagascar, Reunion, Guadeloupe, and other of her colonies. From Mauritius and the Seychelles the product goes to London. In the markets most of the varieties are known by the name of the country in which they are produced. The finest of the varieties is the Mexican, although of recent years the Bourbon beans have so improved that they almost rival it in strength and flavor. At present the Mexican bean is sold at somewhat less than double the price of the Bourbon; the Bourbon at almost double the price of the Tahiti, the latter bean being commonly much injured by carelessness in the process of curing.

Of Mexican vanilla, the first quality occurs in pods from 15 to 20 cm., long, flattened, 6 to 8 mm. in diameter, with the lower end slightly attenuated, the upper end gradually tapering for about a quarter of the length of the pod, usually curved and slightly twisted near the point. The color is dark brown, the pods fairly plump, the surface ridged longitudinally, and with an incrustation of fine crystals beginning at the ends, gradually extending; when fresh somewhat viscid, but always roughish to the touch. For an interesting account of the Mexican vanilla plant by Charles E. Hires, see A. J. P., 1893, 576.

Of the Mexican vanillas the most valuable variety, called leg, or vainilla mansa, by the Spaniards, consists of cylindrical, somewhat flattened pods, six or eight inches long, three or four lines, thick, nearly straight, narrowing towards the extremities, bent at the base, shining and dark brown externally, wrinkled longitudinally, soft and
flexible, and containing within their tough shell a soft black pulp, in which numerous minute, black, glossy seeds are embedded. It has a peculiar, strong, agreeable odor, and a warm, aromatic, sweetish taste. The interior pulp portion is most aromatic. In it are more or less numerous, minute crystals. Another variety, called vainilla simarona by the Spaniards, is smaller, of a lighter color, and less aromatic. The pods are said to be very dry and to contain no vanillin. (Nueva Farmacopea Mexicana.) According to Schiede, it is yielded by a distinct species, the Vanilla sylvestris Schiede. A third variety is the vainilla pompona of the Spaniards (boba vainilla, or platano vainilla). In this, the pods are from 12 to 18 cm. long, from 12 to 18 mm. broad, shaped somewhat like a plantain, almost always open, very dark brown or nearly black, soft, viscid, and of a strong odor. Schiede states that it is the product of the Vanilla Pompona Schiede. The variety vainilla vezacate is said to be derived from pods gathered long before maturity. (Nueva Farmacopea Mexicana.) The vainilla pompona of the Spaniard is evidently the vanillons of European commerce, which are usually from 10 to 13 cm. long and from 15 to 25 mm. in diameter, frequently sharply angled, brown to red-brown in color, usually split open and free from efflorescence. Owing to the transverse markings by twine with which they have been wrapped during the process of curing, the beans have a peculiar twisted appearance. Their odor, which resembles that of heliotrope, is due to the presence in them of heliotropin, in lieu of vanillin.

Bourbon vanilla, produced in the Isle of Reunion to the amount of 200,000 pounds a year, resembles Mexican vanilla, but is scarcely so long in the tapering portions, ia of a dark-brown almost black color, is not so firm as the Mexican, has the surface smooth and waxy, and soon becomes covered with a coating of acicular crystals known as "frost." The odor of this vanilla is said to resemble that of Tonka bean rather than that of Mexican vanilla.

The Seychelles and Mauritius vanilla (inferior Bourbon of the trade) has the pods about six inches in length, not over a quarter of an inch in width, and characterized by the pale color, the faint odor, and a smooth but not waxy surface.

South American or Guadeloupe vanilla resembles the Mexican bean, but is usually recognizable, when the bean is entire, by the latter being broad and flattened, usually half an inch or more wide, slightly tapering at the lower end, and at the upper sharply attenuated an inch or so at the point. It has a reddish brown color, and is of a rank odor. It is very pulpy, with a surface intermediate in feel between the Bourbon and the Mexican, and having but few crystals. One variety of this vanilla, sold under the name of vanillons, has the odor of heliotrope and is much used by perfumers and tobacco manufacturers.

Tahiti vanilla, "transplanted Mexican vanilla," has its pods from six to seven inches long, flat, from three-eighths to half an inch wide, with a reddish-brown color. They are almost destitute of vanilla flavor, and have an odor suggesting heliotrope. It is said they contain piperonal and also vanillin. (Ph. Cb., 45.)

Java vanilla, which is almost exclusively consumed in Holland, has a pod from four to six inches long, with a flavor as fine as that of the Mexican bean, and a much stronger
odor.

Vanilla pods are described by the N. F. as:

"Pods linear, flattened, from 15 to 35 cm. in length and from 5 to 9 mm. in breadth: summits terminating in flat circular scars; gradually tapering, more or less bent and curved or hooked at the bases, or in the Tahiti variety, broad in the middle and tapering towards either end, the base closely resembling the summit; externally blackish-brown, longitudinally wrinkled, moist-glossy; occasionally with an efflorescence of vanillin in the form of acicular crystals or mono-clinic prisms; frequently with narrow, elliptical or irregular, more or less wrinkled, dark-brown patches of cork; occasionally split into three parts near the tip, flexible and tough, one-celled, containing a blackish-brown pulp and numerous blackish-brown seeds; the latter being flattened, irregularly triangulate or nearly circular in outline, reticulate and varying from 0.25 to 0.3 mm. in diameter. Odor and taste characteristic and very agreeable. Under the microscope, transverse sections of the pods of Vanilla show an epidermis with a somewhat thickened outer cuticularized layer having occasionally rounded or conical masses of an excretion of a gum-like substance; a layer of collenchyma of one or two rows of cells; a thick sarcocarp composed of parenchyma cells in which are imbedded an interrupted circle of fibrovascular bundles; the parenchyma cells are deeply undulate in outline and usually contain a thin protoplasmic layer enclosing numerous oily globules or may contain bundles of raphides of calcium oxalate; the individual crystals varying from 0.2 to 0.4 mm. in length; some of the parenchyma cells are specially modified and distinguished by their somewhat thickened walls with long, oblique, slit-like pores or the thickening may extend in the form of broad, spiral bands; in the fibrovascular bundles the phloem is central, being more or less surrounded by a few tracheae, the walls possessing; slit-like pores or spiral thickenings, and at the outside of the bundle is a closed circle of sclerenchymatous fibers, the walls being thin, strongly lignified, provided with numerous, transverse, simple pores, the outer wall of the outer row of fibers being irregular or sinuate; from the inner walls of the endocarp arise the placentae bearing numerous brownish-red or blackish seeds, and from the cells of the endocarp also arise numerous long, nearly straight hairs, the ends being rounded, the hairs being more or less matted together by a gummy or resinous mass in which some of the seeds are held; in mounts made in hydrated chloral T.S. or potassium hydroxide T.S., the immature, brownish-red seeds show a deeply reticulate seed-coat, with cells of an oblong-polygonal form in surface view. Place a few of the crystals, occurring as an efflorescence on the fruit, on a microscope slide or watch crystal and add a drop of phloroglucinol T.S. and hydrochloric acid; the solution immediately acquires a carmine-red color (distinction from benzoic acid). The amount of extractive yielded to dilute alcohol should not be less than 12 per cent. Vanilla yields not more than 6 per cent. of ash." N. F.

Transverse sections of the pods of vanilla show an epidermis with a somewhat thickened outer cuticularized layer having occasionally rounded or conical masses of an excretion of a gum-like substance; a layer of collenchyma of one or two rows of cells; a thick sarcocarp composed of parenchyma cells in which are imbedded an
interrupted circle of fibrovascular bundles; the parenchyma cells are deeply undulate in outline and usually contain a thin protoplasmic layer enclosing numerous oily globules or may contain bundles of raphides of calcium oxalate; the individual crystals varying from 0.2 to 0.4 mm. in length; some of the parenchyma cells are specially modified and distinguished by their somewhat thickened walls with long, oblique, slit-like pores or the thickening may extend in the form of broad, spiral bands; in the fibrovascular bundles the phloem is central, being more or less surrounded by a few tracheae, the walls possessing slit-like pores or spiral thickenings, and at the outside of the bundle is a closed circle of sclerenchymatous fibers, the walls being thin, strongly lignified, provided with numerous, transverse, simple pores, the outer wall of the outer row of fibers being irregular or sinuate; from the inner walls of the endocarp arise the placentae bearing numerous brownish-red or blackish seeds and from the cells of the endocarp also arise numerous long, nearly straight hairs, the ends being rounded, the hairs being more or less matted together by a gummy or resinous mass in which some of the seeds are held; in mounts made in hydrated chloral T.S. or potassium hydroxide T.S., the immature, brownish-red seeds show a deeply reticulate seed-coat, with cells of an oblong-polygonal form in surface view.

A characteristic test for the vanillin crystals which occur as an efflorescence on the fruit is as follows: On a microscope slide or watch crystal, place a few crystals and add a drop of phloro-glueinol T.S. and hydrochloric acid; the solution immediately acquires a carmine-red color (distinction from benzoic acid). The amount of extractive which vanilla of good quality yields to dilute alcohol should not be less than 12 per cent. Nor should it yield more than 6 per cent. of ash.

Vanilla beans from which the vanillin has been removed by means of a solvent are sometimes offered for sale. The fraud is to be detected by the absence of flavor and odor. Such beans, and also beans of an inferior quality, are sometimes "improved" in appearance and in odor by the use of benzoic acid. For the detection of this fraud the pharmacist should avail himself of the fact that while the crystals of benzoic acid are flattened and rhomboidal and generally lie upon the bean, those of vanillin are usually acicular and stand out at right angles from the surface of the fruit. The absence of the crystalline coating on the vanilla beans seems to be no proof of inferiority, for Henri Lecomte affirms that it is not rarely absent in the best Mexican bean. (B. Sc. Pharm., 1901.)

According to Bucholz, vanilla does not yield volatile oil when distilled with water, and the aroma appears to depend on chemical changes which may take place during and after the curing of the fruit. Many years since, vanilla was analyzed by Bucholz and Vogel, the former of whom found in it a disagreeable-smelling fixed oil, a soft resin having a feeble odor of vanilla when heated, a bitterish extractive resembling tannin, sugar, starch and benzoic acid. But the characteristic odorous principle was not isolated until Gobley obtained vanillin, by acting on vanilla with solvents. Although the latter substance has been largely manufactured, it does not take the place of the preparations of vanilla, the flavor and odor of the latter being greatly preferred. It passes with water in distillation. If vanilla, finely divided, be distilled with water, a turbid liquid passes, which becomes clear by agitation with ether, and the ether on evaporation yields crystals of vanillin. Vanilla, in the fresh state in which it is
gathered, does not in the least possess the characteristic fragrant odor. H. Lecomte (J. P. C., 1903, 343) studied the conditions which bring about the formation of vanillin. According to his researches, there exist in the vanilla plant two ferments, which differ in a marked degree from each other in their functions. The one, an oxydase, is present in the individual organs of the plant, such as the leaves, shoots and their aqueous extracts, in the green and ripe fruit, and in the prepared commercial fruit. Lecomte detected it in the organs of plants of different origin, by means of G. Bertrand's reactions. At the same time, the presence of manganese salts was observed in all products, which renders it not impossible that they stand in some relation to the above-named ferment. The second ferment is contained in the sap of the vanilla, and acts as a hydrolyzing ferment. With regard to the mechanical treatment of vanilla, it would appear in the first instance as if it counteracted the function of the ferment. It consists, as is well known, of the immersion of the fruit during twenty seconds in water at 85° C. (185° F.), a manipulation which might bring about the destruction of the ferment. But the author has convinced himself that a temperature of about 50° C. (122° F.), such as the interior of the fruit probably only reaches during the short duration of the process, really promotes the function of the oxydase. Both ferments, the oxydase as well as the one possessing the hydrolytic action, appear to be necessary for the formation of vanillin in the plant, and their action may possibly be explained thus: During the preparation, the coniferin produced by the plant is split up into glucose and coniferyl alcohol. This process would explain also the occurrence of grape-sugar in vanilla. The oxydase then converts the coniferyl alcohol into vanillin. Tiemann and Haarmann obtained from Mexican vanilla 1.69 per cent. of vanillin, from Reunion vanilla 2.48 per cent., from Java vanilla 2.75 per cent. Stokeby found in vanilla, resin, wax, a fixed oil, a brown resinous matter, tannic acid changing the salts of iron to green, gum, sugar, phosphates and sulphates: hydrochloric acid separated from it oxalic acid, and potassium hydroxide, humic acid. (J. P. C., 4e ser., iii, 76, 1866; see also paper by Clay W. Holmes, Proc. A. Ph. A., 1887, 526.)

Vanilla is used in the N. F. IV in making the tincture of vanilla (10 per cent. with a menstruum of alcohol and water), which is used as a flavoring agent in elixir of ammonium valerate, elixir of hops, elixir of strychnine valerate and syrup of the bromides.

Vanilla Poisoning.—Many years ago Orfila reported cases of violent gastro-intestinal irritation from eating vanilla ices, and since then others have reported similar instances of poisoning. In 1886 Vaughan in the investigation of an ice cream which had caused serious poisoning in eighteen persons found that the vanilla used to flavor it, in doses of 30 drops failed to produce any symptoms in either himself or his assistants, and he was able to separate the ptomaine tyrotoxicon, which he had previously found in other milk food (see A. J. P., xvi, p. 452). It is highly probable that many of these cases are due to ptomaine poisoning rather than vanilla poisoning; but if the one reported by Rosenthal (P. J. xv, p. 24) be accurately stated it must be allowed that in some instances the vanilla itself is at fault. In this connection the reports of Claverie (J. P. C. Supp. 1908, xxv) of violent dermatitis in workmen handling vanilla beans is of interest. He attributes the symptoms to the oily exudate of the vanilla pods.

VERATRINA. U. S.

VERATRINE Veratrin. [Veratria]

"A mixture of alkaloids obtained from the seed of Asagraea officinalis (Chamisso and Schlechtendal) Lindley (Fam. Liliaceae). Preserve it in well-closed containers, protected from light." U. S.

No process is given in the U. S. P. IX for preparing veratrine and the Br. Pharm., 1914, deleted it. A process will be found in the U. S. D., 19th edition, pages 1327 and 1328.

In the U. S. process of 1870 the first step is to obtain a tincture of cevadilla, which is evaporated to the consistence of an extract. This contains the veratrine combined with a vegetable acid, probably gallic, as it exists in the seeds. From the extract the alkaloid is dissolved by the acidulated water, which at the same time converts it in great measure into a sulphate, a small portion possibly remaining in the solution combined with an excess of the natural acid. The magnesia combines with the acids and throws down the veratrine, which is then taken up by alcohol and again yielded in a purer state by evaporation. To purify it still further, it is redissolved in water by the agency of sulphuric acid, is submitted to the action of animal charcoal, and is finally precipitated by ammonia. In the British process, the tincture was concentrated until it began to let fall a precipitate, and was then poured into water, which throws down the resin and oil with a portion of the coloring matter and retains the salt of veratrine. This is then decomposed by ammonia, and the precipitated veratrine is slightly washed with cold water to free it from adhering impurities. If much water be employed in the washing, a considerable portion of the veratrine will be lost, in consequence of impure veratrine being in some degree soluble in water. The remaining steps of the British process consist in the purification of the veratrine by forming a hydrochloride in solution, decolorizing this by animal charcoal and again precipitating by ammonia.

The U. S. process of 1870 is essentially that of Couerbe. The veratrine obtained by it, though not pure, is sufficiently so for medicinal use. A drachm of it, in this state, may be procured from a pound of cevadilla. Meissner, in 1819, applied the term sabadilline to an alkaloid extracted
by him. Pelletier and Caventou had probably produced the same preparation when they announced the discovery of veratrine in the same year. This substance is the veratrine described as prepared by Couerbe's process. Couerbe, in 1834, announced the discovery of an additional alkaloid, to which he gave Meissner's old name of sabadilline, and Weigelin, in 1871, announced the discovery of a third alkaloid, which he called sabatrine. G. Merck, in 1855, obtained veratrine in a crystallized state by solution and separation from strong alcohol.

Wright and Luff (J. Chem. S., 33, p. 338) have brought order from this confusion by a careful study of the whole subject. They found three alkaloids in sabadilla seeds: cevadine, $C_{32}H_{49}O_{9}N$ (the alkaloid hitherto known as the veratrine of Merck); veratrine, $C_{37}H_{53}O_{11}N$; and cevadilline, $C_{34}H_{53}O_{8}N$. Of these, the cevadine (formerly veratrine) forms, when crystallized from alcohol, needles or compact crystals which fuse at 205° C. (401° F.), effloresce rapidly in the air, and become opaque, are insoluble in water, easily soluble in alcohol and ether, and dissolve in warm concentrated hydrochloric acid with a dark violet color, which on boiling becomes intensely red. When heated with alcoholic potassium hydroxide they are decomposed into methyl-crotonic (tiglinic) acid and cevine, $C_{27}H_{43}O_{8}N$. The veratrine of Wright and Luff is obtained from the mother liquor of the cevadine by extraction with ether. It forms an uncrystallizable resinous mass, fusing at 180° C. (356° F.), but yields crystallized salts. Boiled with sodium hydroxide it is decomposed into dimethyl-protocatechuic (veratric) acid and verine, $C_{28}H_{45}O_{9}N$. Cevadilline remains after the extraction of the veratrine, insoluble in ether. It is also unerystallizable, nearly insoluble in ether and in boiling benzene, but easily soluble in fusel oil.

Fluckiger recognized only two of these alkaloids, and made them both of the composition $C_{32}H_{49}O_{9}N$. The first, which he called cevadine, he stated is decomposed by boiling with barium hydroxide when in alcoholic solution, and yielded products as follows:

$$C_{32}H_{49}O_{9}N + 2H_2O = C_5H_8O_2 + C_{27}H_{45}O_{9}N$$

The first of these products is methyl-crotonic acid, and the second is cevine. The other alkaloid he called veratridine, and gave its decomposition as follows:
2C$_{32}$H$_{49}$O$_9$N + 4H$_2$O = C$_9$H$_{10}$O$_4$ + C$_{55}$H$_{92}$O$_{16}$N$_2$ + 2H$_2$O

The first of these products is dimethyl-protocatechuic acid, and the second he called veratroin. (Fluckiger, Pharm. Chem., 1888, ii, p. 532.) Merck still terms the cevadine of Wright and Luff veratrine, and prepares it in white crystals of the formula C$_{32}$H$_{49}$O$_9$N, fusing at 202° C. (395.6° F.). Frankforter (A. J. P., 1897, 372) confirmed this formula, C$_{32}$H$_{49}$O$_9$N.H$_2$O, but gave to the purified veratrine the melting point from 146° to 148° C. (294.8°-298.4° F.).

Two acids have also been found in sabadilla— the sabadillic or cevadic acid of Pelletier and Caventou, forming needle-like crystals fusing at 20° C. (68° F.), and the veratic acid of Merck, which Koerner showed to be dimethylproto-catechuic acid.

**Uses.**—Probably because of its unfortunate name it has been assumed by some that veratrine represents the therapeutic virtues of veratrum. Its physiological action, however, differs greatly from that of veratrum, and if it possess any therapeutic usefulness it is certainly not for the conditions for which veratrum is employed.

Veratrine is an intense local irritant and somewhat locally anesthetic. Rubbed upon the skin it excites a sensation of warmth and a peculiar tingling. Sometimes an evanescent blush is produced and still more rarely an eruption upon the skin, but generally no decided signs of inflammation are evinced. When taken into the mouth it produces an almost insupportable sense of acrimony, and snuffed up the nostril it produces violent sneezing, and when taken into the stomach in large doses it causes violent vomiting, serous purging with intense burning in the mouth and throat and general muscular weakness. It is a powerful muscle poisoning and if given in sufficient dose in the lower animals it causes an extraordinary prolongation of the contraction of the striated muscles; the time required for relaxation of voluntary muscles may be 20 or 30 times as long as normal. A similar influence is exerted upon the ventricular muscles, at least in the frog, but the slowing of the heart rate seen in warm blooded animals seems to be due chiefly to stimulation of the cardio-inhibitory center. Death in mammals is generally due to depression of the respiration.
The only justifiable therapeutic use of veratrine is as an anodyne counter-irritant in neuralgias and various forms of arthritis. Even for this purpose it has no advantages sufficient to offset the dangers of systemic poison which might follow from its absorption.

Dose, one-thirtieth of a grain (0.002 Gm.).

**Off. Prep.**—Oleatum Veratrinae, N. F.; Uguentum Veratrinae, N. F.

**VERATRUM VIRIDE. U. S.**

**VERATRUM VIRIDE Verat. Vir.**

[Green Hellebore, American Hellebore]

"The dried rhizome and roots of Veratrum viride Alton (Fam. Liliaceae), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." U. S.

Big or False Hellebore, Swamp Hellebore, Indian Poke, Itch-weed, Tickle-weed, Bugbane; Veratre vert, Fr.; Gniner Germer, (?) Vedegambre verdo, Sp.

In the several revisions of the U. S. Pharmacopoeia, veratrum has been handled in a vacillating manner. In 1880 and 1890 the drug was restricted to that obtained from V. viride. In 1900 both V. viride and V. album were recognized, this being done for reason of the large importations of Veratrum (V. album) and there being no practical method of distinguishing between these two drugs. The U. S. Pharmacopoeia IX has wisely restricted the definition, in the interest of uniform medicine, to V. viride. This, however, may offer some practical commercial difficulties as it is not always easy to differentiate its substitution by V. album, and certainly it is almost impossible to detect an admixture with the European drug.

That the two species are very closely allied, and the two rhizomes histologically, chemically, and toxicologically very similar is indisputable, but similarity is not identity. The European plant seems to be more actively poisonous than is the American, and has been said by some chemists to contain a larger proportion of the alkaloids. It usually also has a distinctly greater action upon the intestinal tract and it is probable that the proportionate amounts of the alkaloids differ in the
two species. The conclusions reached in an elaborate physiological research made by H. C. Wood and H. C. Wood, Jr., for the Committee of Revision of the U. S. VIII was that the drugs can scarcely be distinguished physiologically, but that the European plant is more likely to disturb the intestines and that in the absence of any cogent reason for recognizing V. album, veratrum viride should alone be retained.

The American hellebore, Veratrum viride, known also by the names of Indian poke, poke root, and swamp hellebore, has a perennial, thick, fleshy rhizome, the upper portion of which is tunicated, the lower solid, and beset with numerous whitish roots. The stem is annual, cylindrical, striated, pubescent, and solid, from three to six feet in height, furnished with bright green leaves, and terminating in a panicle of greenish-yellow flowers. The leaves gradually decrease in size as they ascend. The lower are from six inches to a foot long, oval, acuminate, plaited, nerved, and pubescent, and embrace the stem at their base, thus affording it a sheath for a considerable portion of their length. Those on the upper part of the stem, at the origin of the flowering branches, are oblong-lanceolate. The panicle consists of numerous flowers, distributed in racemes with downy peduncles. Each flower is accompanied by a downy, pointed bract, much longer than its pedicel. The perianth consists of six oval acute segments, thickened on the inside at their base, with the three alternate segments longer than the others. The six stamens have recurved filaments and roundish two-lobed anthers. The ovary is ovoid, tri-carpellary; styles three and persistent. Some of the flowers have only the rudiments of pistils. Those on the upper end of the branchlets are barren, those below fruitful. The fruit is a three-lobed capsule, three-celled, and containing flat imbricated seeds. This indigenous species of veratrum inhabits swamps, wet meadows, and the banks of mountain streamlets. It is more abundant northward, but reaches as far south as Georgia. From May to July is the season for flowering. It is doubtful whether the rhizome should be collected in autumn or just before flowering. It should be thoroughly dried and carefully preserved, as otherwise it deteriorates.

Veratrum album L. (V. viride Roehl., but not V. viride Alton.).—The specific difference between this plant, which is a native of Europe and Northern Asia, and V. viride of North America has been questioned by various botanists, but it is now generally acknowledged that the two species are distinct. (See Index Kewensis; also Engler and Prantl.) V. album resembles closely the American species, but is distinguished by its
yellowish-white flowers. The rhizome of *V. nigrum* of Central Europe is said to be sometimes substituted for that of *V. album*, but is much smaller. According to the Pharmacographia, that of the Mexican species, *V. frigidum* Schl., exactly resembles that of *V. album*.

Properties.—As found in commerce, veratrum is usually in small pieces or fragments, but sometimes it comes whole or sliced, so that its characteristic form may be observed. In this condition it is seen to consist of a rhizome one to three inches in length by somewhat less than an inch in thickness where broadest, tapering to a very obtuse or truncated extremity, simple or divided, compact but light, of a dark-brown color externally, and either closely invested with numerous yellow rootlets often several inches long, or exhibiting marks on the surface whence they have been removed. When sliced, the cut surface is of a dingy-white color. The rootlets are from three to six inches long, about as thick as a large knitting needle, or somewhat thicker, obviously much shrunk in drying, and marked by numerous closely set indentations, which give them a characteristic appearance. Not unfrequently portions of the dried stem or leafstalks remain attached to the rhizome, which should always be rejected, as they were ascertained by Procter to be inert. (A. J. P., 1864, p. 99.)

Veratrum Viride is officially described as follows: " Rhizome upright, obconical, usually cut longitudinally into 2 to 4 pieces, from 2 to 7 cm. in length and from 1.5 to 3 cm. in diameter, externally light brown to dark brown or brownish-black, frequently bearing at the summit numerous, closely arranged, thin leaf-bases, otherwise rough and wrinkled, somewhat annulate from scars of bud-scales and bearing in the outer portion numerous roots, the lower part more or less decayed; fracture hard and horny; internally yellowish or grayish-white, marked with numerous, irregular fibre-vascular bundles; inodorous but sternutatory; taste bitter and acrid. Roots nearly cylindrical, from 3 to 8 cm. in length and from 1 to 3 mm. in diameter; externally light brown to yellowish-brown, deeply transversely wrinkled; fracture short, bark whitish, very thick, enclosing a porous central cylinder. The powder is grayish-brown to dark brown, strongly sternutatory; under the microscope it exhibits numerous starch grains from 0.003 to 0.02 mm. in diameter, spherical or ellipsoidal, single or 2- to 3-compound, the individual grains being often swollen or otherwise more or less altered; calcium oxalate in raphides, from 0.035 to 0.15 mm. in length; fragments with tracheae, the walls being more or less strongly lignified and marked with scalariform or
reticulate thickenings, frequently containing a lemon-yellow substance and associated with narrow, slightly lignified, porous, sclerenchymatous fibers; reddish-brown or brownish-black cork fragments occasional." U. S.

It has been asserted that the color of V. album is much lighter than that of V. viride, but this certainly is practically incorrect, however it may apply to carefully preserved specimens. Very commonly the roots have been removed from commercial V. album, while in America they are generally allowed to remain on the rhizomes. According to R. H. Denniston, no microscopic differences can be detected in the rhizomes, but in the roots distinction is possible owing to the fact that directly beneath the epidermis in the V. viride the collenchyma region consists of but two or three rows of large, irregular and distorted cells, while in V. album this region is generally made up of seven to eight rows of rounded, thicker-walled and smaller cells, which are not in the least distorted. Any such test is, of course, inapplicable to the drug in powder. In the color test proposed by R. H. Denniston, sulphuric acid is added to the powder; with V. album a brick-red color, with V. viride an orange-red color, will be produced. Of course the test is of little value in determining the character of a powder, as it does not possess sufficient differentiation.

The pharmacognosy of V. viride has been well illustrated by Bastin (A. J. P., 1895, p. 196). The structure of V. album has been presented by Meyer (Arch. d. Pharm., 1882, p. 81; and in "Wissenschaftliche Drogenkunde," vol. 2, p. 46). Rosenthaler has submitted veratrum to pyroanalysis and has obtained a sublimate which is in part crystalline and gives a yellowish-red color with sulphuric acid. (Apoth. Zeit., xxviii, p. 991.)

(much chemistry deleted)

Uses.—The various alkaloids present in veratrum act upon the system in very different manners, and none of them appears to exercise exactly the same action as the whole drug. According to H. C. Wood (Phila. Medical Times, 1874, iv, p. 737), jervine is a depressant to the respiratory center, to the vasomotor center, and to the heart muscle, and also lowers reflex activity by an effect upon the spinal cord, and rubijervine is chiefly a stimulant to the cardio-inhibitory mechanism, but has a more depressant action upon the respiratory center. According to Eden (A. E. P. P., 1892, xxix, p. 440), small doses of protoveratrine
stimulate cardiac inhibition thereby causing a lowering of the blood pressure. In large doses there is a secondary paralysis of inhibition accompanied by rise in the pressure. In large quantities it also exercises a poisonous effect upon the voluntary muscles similar to that of veratrine. Rubijervine is present in such small proportions (according to Breideman, J. P., 1906, lxxxiv, 0.053 per cent.) and is so feeble a substance that it is improbable that it plays any part in the physiological action of the drug. Jervine, although present in larger quantities (0.34 per cent.), according to H. C. Wood, Jr., is less poisonous than the drug itself. Protoveratrine, although present in small amounts (0.06 per cent., according to Breideman), is an extremely toxic substance and is the most important of the ingredients at present known. It appears to differ, however, in some of its properties from the whole drug.

When a moderate dose of veratrum is introduced into the system, the most marked change produced is reduction in the rate of the pulse accompanied with a fall in the arterial pressure. At the same time there may be some slowing in the respiration. With proper doses the slowing of the pulse is extreme and we have seen, in the lower animals, even complete arrest of the heart at this stage of the poisoning. The slowing of the pulse does not occur if the pneumogastric nerves have been divided previous to the injection of the drug, and is at once abolished either by section of these nerve's or by the administration of atropine. It must be regarded, therefore, as due to stimulation of the cardio-inhibitory center. The reduction in the arterial tension in the normal animal may, therefore, be attributed to the slowing of the pulse. The conclusions of H. C. Wood, Jr. (U. P. M. B., March, 1908), that contrary to the older views, veratrum does not lower arterial tone, have been confirmed by the experiments of Pilcher and Sollmann (J. P. Ex. T., 1915, vii, p. 295) on animals and the observations of Collins (A. I. M., 1915, xvi, pp. 54-58) on man. After toxic doses of veratrum there is a late paralysis of the intracardiac terminals of the pneumogastric nerve and consequent increase in the pulse rate with at first a rise of the blood pressure followed by a fall. This toxic fall in the blood pressure appears to be due to a direct depressant action upon the heart muscle. There is, following the toxic dose, also marked reduction in the respiratory activity, death being due eventually to failure of this function.

Veratrum was introduced into medicine about a century ago by the group of physicians who called themselves "eclectics." By them it was attributed with mysterious "adenagic" virtues and used in all sorts of
inflammatory diseases. Later under the belief that it dilated the blood vessels and hence would relieve various local congestions, regular practitioners employed it largely in the treatment of pneumonia, peritonitis, and other sthenic fevers. While it is still employed to some extent in this type of disorder, our knowledge of its physiological action indicates that its true field of usefulness is rather in chronic, than in acute, diseases. Thus it is a very valuable agent for the reduction of excessively high blood pressure in arteriosclerosis, interstitial nephritis, and other conditions of hypertension; in cases with feeble myocardia it should be used cautiously because the stimulation of the cardio-inhibitory mechanism predisposes to cardiac dilatation. For the same purpose it is often employed in threatened apoplexy, in chronic endocarditis, especially in those in which there is considerable degree of cardiac hypertrophy, and in the so-called irritable heart seen in soldiers and athletes. In exophthalmic goitre and various other forms of tachycardia it is frequently of great service to reduce the pulse rate and prevent the heart exhausting itself in excessive activity. In certain of these conditions its line of usefulness more or less parallels that of digitalis. It differs, however, sharply from that drug, in that while digitalis tends to increase the tone of the heart muscle, veratrum rather diminishes cardiac tone. Veratrum has also been used widely by obstetricians in the treatment of puerperal eclampsia. Whether its benefit in this condition is to be attributed to a depressant action upon the motor cord, as some believe, or whether it be due to a lowering of the blood pressure, is as yet uncertain. The dose of veratrum must be gauged by the effect it produces; in general it may be said that if it does not slow the pulse no benefit will be received by the patient. The drug should therefore be pushed until evidence of its action is seen in the reduction of the pulse rate. Ordinarily from one to three minims (0.06-0.2 mil) of the fluidextract may be given every two or three hours until it manifests its action. It should be remembered, however, that in some cases the cardio-inhibitory mechanism is refractory to the action of the drug and no dose will slow the pulse, and if given incautiously it may do great harm. Fortunately in most instances if given in too large dose it will manifest its toxic action by nausea before any more serious symptoms are produced.

**Toxicology.**—The symptoms of veratrum poisoning are vomiting accompanied with great nausea and much retching. There is profound prostration with muscular weakness, the skin bedewed with perspiration and pale in color, the pulse, in the milder cases, or in the
early stage of the severe cases, is extremely slow and easily compressible, later, in the severe types of poisoning, it may become rapid and irregular. The respirations are often shallow and sometimes stertorous. Frequently there is much complaint of dizziness and in a few cases there has been dilatation of the pupil with disturbance of vision. Because of the promptness with which vomiting comes on even very large single doses of veratrum may be recovered from, thus Buckingham (A. J. M. S., 1865) reports a case in which recovery followed a teaspoonful of the fluidextract. But when repeated large doses have been taken, the poisoning is much more dangerous.

In the treatment of veratrum poisoning if the patient be vomiting it is well to give a couple of glasses of water in order to thoroughly cleanse the stomach, at the same time twenty grains (1.3 Gm.) of tannic acid may be exhibited as an imperfect chemical antidote. If for any reason vomiting has not occurred it should be at once provoked or the stomach washed out by means of a stomach pump. The patient must be kept in a horizontal position and should not be allowed to sit up to vomit. After washing out the stomach in the manner described above, efforts should be made to stop the vomiting by the use of counter-irritation over the epigastrium and the cautious employment of morphine. But since when the drug proves fatal death is due to the respiratory arrest the latter should not be given in too large doses. If seen in the early stages when the pulse is slow, atropine is a remedy of great value antagonizing the effect of the veratrum upon the pneumogastric nerve and at the same time checking the excessive sweating and stimulating the respiratory center. Other active respiratory stimulants, such as hypodermic injections of ammonia and strychnine, may be employed, and if the bodily temperature is low it should be maintained by the external application of heat.

Dose, one to two grains (0.065-0.13 Gm.).

**Off. Prep.—** Fluidextractum Veratri Viridis, U. S.; Tinctura Veratri Viridis, U. S.

**Verbascum.** Verbascum Thapsus L. Mullein. Flores Verbasci, P. G. Bouillon blanc, Molène, Fr. Wolkraut, Königskerze, G. (Fam. Scrophulariaceae.—The ordinary mullein weed is too well known to need description. As remedial agents both leaves and flowers have been employed. Mullein Flowers (Verbasci Flores) are official in the N. F. IV and are described as “the dried corollas, with adhering stamens, of Verbascum phlomoides Linne or of Verbascum thapsiforme Schraeder (Fam. Scrophulariaceae).
Preserve the flowers in tightly-closed containers. Corolla light-yellow, the outer surface grayish with a fine, soft, woolly indumentum, the inner surface sparsely hairy and finely veined; tube of the corolla only 1 or 2 mm. in length and almost equally broad, the limb from 14 to 30 mm. in breadth, between wheel-shaped and saucer-shaped, obscurely two-lipped, the unequal lobes rounded-obovate. Stamens five, borne on the base of the corolla, shorter than the corolla, two of them longer than the other three, the filaments thick and fleshy, more or less pilose, especially the three shorter ones, usually orange colored. Stamen-hairs cylindrical, unicellular, non-branching, surface minutely reticulate, apex rounded, frequently enlarged. Pollen grains smooth, triangular and more or less rounded, from 0.025 to 0.03 mm. in diameter. The flowers impart a yellow color to boiling water, and a rather permanent green color with dilute sulphuric acid, the latter color becoming brown upon the addition of alkalies. Odor peculiar, agreeable; taste mucilaginous, not agreeable. Mullein Flowers yield not more than 6 per cent. of ash. N. F. Mullein Leaves (Verbasci Folio) are official in the N. F. IV and are described as "the dried leaves of Verbascum Thapsus Linne (Fam. Scrophulariaceae), and of other species of Verbascum. Obovate with narrowed base, or varying to oblong or oblong-lanceolate, without a true petiole, obtuse or tending toward acuteness at the summit, from 1 to 6 dm. in length and from 3 to 15 cm. in breadth; very thick, rather tough, light yellowish-gray or greenish-gray, densely long-tomentose, with numerous, multicellular, branching, non-glandular hairs. Nearly odorless; taste mucilaginous and slightly bitter. Verbascum yields not more than 14 per cent. of ash." N. F.

Mullein leaves are demulcent and emollient, and are thought to possess anodyne properties, which render them useful in pectoral complaints. On the continent of Europe, an infusion of the flowers, strained in order to separate the rough, hairs, is considerably used in mild. catarrhs. An oil, produced by saturating olive oil with mullein flowers, during prolonged exposure to the sun, is used as a local application in Germany for piles and other mucous membrane inflammations. The mullein oils sold in pharmacies are of this nature, or some of them alcoholic tinctures. The dried leaves are sometimes smoked, to relieve irritation of the respiratory mucous membranes; fomentations with mullein leaves also have some repute as anodynes. Internally, the decoction (an ounce to the pint, flowering tips) may be taken in the quantity of from four to six fluidounces.

According to L. Rosenthal (P. J., July, 1902), the seeds of Verbascum sinuatum L., which are used in Greece as a fish poison, contain 6.13 per cent. of saponin. Traces of the same substance were found in the fruits of V. phlomoides L. and V. thapsiforme Schrad.

Verbascum flowers were introduced in the N. F. IV as one of the ingredients in Pectoral species, and the leaves in Fluidextract of mullein leaves made with diluted alcohol.

Dose, one to two drachms (3.9-7.8 Gm.).

**Verbena.** N. F. IV. Blue Vervain.—"The dried overground portion of Verbena hastata
Linne (Fam. Verbenaceae), collected when flowering." The plant is a tall shrub growing in damp situations throughout the United States. "In broken or cut pieces; stem stout, obtusely quadrangular, rough, pubescent; leaves opposite, petioles from 12 to 25 mm. in length, blades from 6 to 12 cm. in length, lanceolate, acuminate, acute, coarsely and sharply serrate or the lower hastate lobed, deep green above, paler beneath, conspicuously veined; flowers in terminal interrupted panicles of spikes, spikes erect cylindraceous, densely flowered, each flower subtended by a lanceolate acute bract; calyx adherent, little more than half the length of the corolla, tubular, five-lobed, the mouth slightly oblique; corolla small, bright blue, salver-form tube externally pubescent, sub-equally five-lobed; stamens adnate to the corolla tube, included, di-dynamous; fruit dividing at maturity into four one-seeded parts. Odor heavy, especially if dampened; taste bitter and disagreeable. Verbena yields not more than 10 per cent. of ash." N. F. The fluid extract of verbena is official in the N. F. There is no reason to suspect it of medicinal virtue. The dose stated in the N. F. is fifteen grains (1 Gm.).

Veronica officinalis L. Speedwell. Veronique male, Fr. Ehrenpreis, G. (Fam. Scrophulariaceae)—Several species of veronica, common to Europe and this country, have been medicinally employed. Of these, V. officinalis L., and V. Beccabunga L., or European brooklime, are the most conspicuous. V. officinalis has a bitterish, warm, and somewhat astringent taste. Enz found in it a bitter principle soluble in water and alcohol, but scarcely so in ether, and precipitated by the salts of lead, but not by tannic acid; an acrid principle; red coloring matter; a variety of tannic acid producing a green color with ferric salts, a crystallizable fatty acid, with malic, tartaric, citric, acetic, and lactic acids; mannite; a soft, dark green, bitter resin. Mayer, of New York, found evidences of an alkaloid and of a saponaceous principle. (A. J. P., 1863, 209.) Vintilesco found a glucoside in V. officinalis and V. chamaedris. (J. P. C., 1910, No. 4.) The plant has been considered diaphoretic, diuretic, expectorant, tonic, etc., and was formerly employed in pectoral and nephritic complaints, hemorrhages, diseases of the skin, and in the treatment of wounds. V. Beccabunga was used in the fresh state in scurvy.

Viburnum Opulus, cranberrytree or high bush cranberry, belongs to the section of the genus which has peduncled cymes, light red, acid, roundish drupes, with very flat orbicular not sulcate stones, palmately veined leaves, and scaly winter buda. It is a
large bush, reaching the height of ten feet, growing in low grounds from New Brunswick far westward, and southward to Pennsylvania. The leaves are from three-
to five-ribbed, strongly three-lobed, broadly wedge-shaped or truncate at the base,
with the spreading pointed lobes mostly toothed in the sides and entire in the sinuses.
The petioles bear two glands at the apex. The snow-ball tree, or Guelder rose, is a
variety in which the whole inflorescence has been turned into a mass of showy sterile
flowers.

“In strips, or occasionally in quills or chip-like fragments, the bark attaining a
thickness of 3 mm.; outer surface of the thinner pieces of a light gray color with
crooked, longitudinal, purplish-brown stripes and very small brown lenticels, the
thicker pieces purplish-red or occasionally blackish, except when very young, and
more or less finely fissured or thinly scaly; inner surface varying in color from
yellowish to rusty-brown, with very short oblique striae, except where the outer wood
layer adheres; fracture short and weak, the fractured surface mostly whitish, varying
to pale brown in the inner layer, rusty brown in the outer layer, covering the green
tangential layers of phelloderm. Odor strong and characteristic; taste mildly
astringent and decidedly bitter. Under the microscope, sections of Viburnum Opulus
show as outer corky layer, of five to twenty-five rows of cells, the walls being nearly
colorless, frequently thickened on the inner surface, individual cork cells from 0.015 to
0.045 mm. in radial diameter and from 0.030 to 0.075 mm. in tangential diameter;
outer bark of about ten rows of cells containing a brownish-yellow, amorphous
substance, small starch grains or chloroplastids; medullary rays one to two cells in
width, usually not more than one cell wide; inner bark with occasional groups of bast
fibers composed of one to ten cells, the walls being very thick, non-lignified, lamellated
and finely porous; adhering wood with large tracheae having scalariform or reticulate
thickenings, and being surrounded by wood fibers with thick lignified walls; starch
grains, mostly in cells of parenchyma and medullary rays, either single or compound,
the individual grains not exceeding 0.006 mm. in diameter; calcium oxalate in rosette
aggregates, 0.015 to 0.04 mm. in diameter, numerous fragments of parenchyma cells,
the lumina filled with a reddish-brown amorphous substance. The powder of
Viburnum Opulus is light grayish-brown, consisting of irregular fragments; polygonal
cork cells, with thin, colorless walls; parenchyma with rosette aggregates of calcium
oxalate, from 0.015 to 0.04 mm. in diameter; starch grains very small and mostly in
parenchyma cells; fragments of parenchyma containing a brownish-yellow amorphous
substance; occasional tracheal fragments associated with lignified wood
fibers, bast fibers, and stone-cells." N. F.

For studies of Viburnum barks, see A. J. P., 1895, 378, 394; also Ph. Post. 35, 773,
Gibson (Proc. Indiana Pharm. Assoc; 1900, 112) believes that there is a glucoside
present in the bark of V. Opulus; he describes it as resinous, greenish in color, soluble
in alcohol, slightly soluble in water.

The berries of this plant are used to a considerable extent as a substitute for the
ordinary cranberry, and are antiscorbutic, but there is no sufficient reason to believe
the bark has any medicinal properties of any kind. V. obovatum. Walt., a tree shrub
growing from Virginia southward, is said to be an antiperiodic. (A. J. P., 1878.)
Viburnum opulus was dismissed from the U. S. P. IX, but introduced in the N. F. IV. It
is used in making Fluidextract of Viburnum Opulus with a menstruum of 2 volumes of alcohol and 1 volume of water. Compound Tincture of Viburnum, and Compound Elixir of Viburnum Opulus. Dose, thirty to sixty grains (2.0-3.9 Gm.).

**VIBURNUM PRUNIFOLIUM. U. S. (Br.)**

**VIBURNUM PRUNIFOLIUM Viburn. Prun. [Black Haw]**

"The dried bark of Viburnum prunifolium Linne or of Viburnum Lentago Linne (Fam. Caprifoliaceae), without the presence or admixture of more than 5 per cent. of wood or other foreign matter” U. S. "Black Haw is the dried bark of Viburnum prunifolium, Linn." Br.

*Virburnum* Br.; Stagbush, Sheep-berry.

Viburnum prunifolium is a tall, very handsome shrub, which is quite common in the Middle and Southern United States, east of the Mississippi, flowering in May and ripening in the early autumn its ovoid or oblong blackish fruit. It is specifically characterized by its acuminate, glabrous winter buds, by its acuminate, sharply serrulate, ovate leaves on long, slender, sometimes broadened and wavy margined petioles. Its sessile cymes are 2 to 5 inches broad and bear oval bluish-black drupes.

Viburnum Lentago L., Sheep Berry. Sweet Viburnum, resembles the previous species, but has the winter buds smaller, less acute and often reddish pubescent, and its leaves stouter petioled and not acuminate at the apex. Its geographical limit overlaps that of V. prunifolium, but extends much further westward and northward, even to Manitoba. The bark of *V. dentatum* L., or Arrow wood, is said to be sometimes substituted for the official drug.

**Properties.**—The bark is officially described as "in irregular, transversely curved or quilled pieces, from 1.5 to 6 cm. in length, and from 0.5 to 1.5 mm. in thickness; outer surface grayish-brown, or, where the outer cork has scaled off, brownish-red, longitudinally wrinkled; inner surface reddish-brown, longitudinally striated; fracture short but uneven, showing in bark which is young or of medium thickness, a dark brown cork, a brownish-red outer cortex, and a whitish inner cortex in which are numerous light yellow groups of sclerenchymatous tissues; odor slight; taste distinctly bitter and somewhat astringent. The powder is dark brown; under the microscope it exhibits numerous large stone cells, which are often elongated, thick-walled and strongly lignified;
bast-fibers few, crystals of calcium oxalate from 0.015 to 0.035 mm. in
diameter, occurring mostly in rosette aggregates, occasionally in crystal
fibers; monoclinic prisms of calcium oxalate few." U. S.

"In quills or curved pieces, one to four millimetres thick; dull brown or
reddish-brown. Outer surface longitudinally wrinkled or, in older bark,
with shallow fissures and scaly; inner surface longitudinally striated,
reddish-brown. Fracture granular. In transverse section, a dark brown
outer portion and a whitish or reddish bast with numerous groups of
sclerenchymatous cells. Slight odor; taste astringent and bitter." Br.

The morphology of viburnum prunifolium is well illustrated by Holm in
M. R., xxii, p. 35. Illustrations of the bark of the several species of
viburnum are given in Kraemer's "Scientific and Applied
Pharmacognosy"; also see P. J., 1903, lxx, p. 197. Lloyd states that the
bark of all native species of viburnum are collected by root diggers and
sold under the name of black haw. (Ph. Rev., xxiii, p. 333.) The bark of
the root is preferred to that of the stem and the official definition
formerly limited the drug to the root bark. Farwell reported the
substitution of the genuine drug by the bark of some other species of
viburnum than those specified by the Pharmacopoeia. The bark is much
darker than the official bark and consisted largely of stem bark. (M. R.,
xvii, p. 35.)

Herman van Alien found the following constituents in viburnum: (1) a,
brown resinous body, of a very bitter taste, from which it was found
impossible to separate the sugar; (2) a greenish-yellow resin or neutral
principle of a bitter taste, slightly soluble in water, freely so in alcohol,
called by Kramer viburnin; (3) valeric acid; (4) a tannic acid giving a
greenish-black color with ferric salts; (5) oxalic acid; (6) citric acid; (7)
malic acid; (8) sulphates; (9) calcium, magnesium, potassium, and iron
chlorides. (A. J. P., 1880, 443.) As the result of elaborate investigation,
concludes that the Viburnum, prunifolium contains viburnic—i.e.,
valeric—acid, and a nonvolatile alkaloid which, however, he failed to
obtain in a pure condition.

Viburnum has been used quite largely in the treatment of
dysmenorrhea, after-pains, and other uterine disorders. Pilcher (A. I. M.,
Jan., 1917), however, has shown that in the doses ordinarily employed
it has no effect of any kind on the uterine muscle.
R. L. Payne, Jr., has found that when given in toxic amount to the lower animals viburnum produces muscular weakness, ending in complete paralysis, with loss of reflex action, which he believes to be due to an influence upon the motor side of the spinal cord. In warm blooded animals there is also marked lowering of the arterial pressure, believed by Payne to be the result of a direct action of the drug upon the heart. Experiments of Payne have in a measure been confirmed by those of T. Shennan, but as the latter took six drachms of the fluidextract within thirty minutes, with no demonstrable effect except a doubtful decrease of the rate and force of the pulse, it is plain that the drug is very feeble.

The solid extract (dose, from three to ten grains (0.2-0.65 Gm.)) does not represent the drug completely, owing to loss of volatile acid; so that the fluidextract should be preferred, in doses of from one-half to one fluidrachm (1.8-3.75 mils).

Dose thirty to sixty grains (2.0-3.9 Gm.).

**Vieirine.**—This substance is obtained from the lark of the Remijia Vellozii, DC. (Fam. Rubiaceae), of Brazil. It is used in Brazil in doses of from one to four grains (0.065-0.26 Gm.) repeated pro re nata, as a tonic and as an anti-periodic in place of quinine.

**Vinca.**—Under this name are included V. major L., Greater Periwinkle, and V. minor L., Lesser Periwinkle (Fam. Apocynaceae). It is said to be very useful in arresting menorrhagic and other hemorrhages. (P. J., 1871, 961; Ibid., 1873, 963; also A. J. P., 1872.)

**Vincetoxicum.** V. officinale Moench. (now more properly Cynanchum Vincetoxicum (L.) Pers. WhiteSwallow-wort. Vincetoxicum. Asclepiade, Dompte-venin, Hirundinaire, Fr. Schwalbenwurz, Giftwende, G.—A perennial, herbaceous European plant, the root of which was formerly esteemed a counterpoison, and hence the botanical name. It has a bitterish, acrid, taste, and, when fresh, a disagreeable odor, which is diminished by drying. Kubler found a glucoside, vincetoxin, C_{50}H_{82}O_{20}; which he states differs from condurangin which other investigators asserted to be identical. (A. Pharm., 1908, 659.) Taken internally, especially in the recent state, it excites vomiting, and is capable, in larger quantities, of producing dangerous, if not fatal, inflammation of the stomach. Feneulle found in the root a principle analogous to emetin. It has been used in skin diseases and scrofula.
Vinegar of Ipecacuanha. Br. 1898. Acetum Ipecacuanhae.—"Liquid Extract of Ipecacuanha, 1 fluidounce (Imperial measure) or 50 mils; alcohol (90 per cent.), 2 fluidounces (Imperial measure) or 100 mils; Diluted Acetic Acid, 17 fluid-ounces (Imperial measure) or 850 mils. Mix; filter, and, if necessary, add sufficient diluted acetic acid to produce one pint (Imperial measure) or one thousand mils of the Vinegar of Ipecacuanha." Br., 1898. Diluted Acetic Acid is a good menstruum for ipecacuanha, and this vinegar will doubtless prove effective as an expectorant. (For uses see Ipecacuanha.) Dose, five to forty minims (0.3 to 2.5 mils).

Viola. Violet.—The genus Viola (Fam. Violaceae) includes numerous species, many, perhaps all of which are possessed of analogous medicinal properties. Viola tricolor L., the Heart's-ease, Pansy, or Johnny-jump-up of the gardens, was formerly recognized by the U. S. Pharmacopoeia; while V. odorata L., and V. pedata L., have held places in both the British and the United States Pharmacopoëas.

V. odorata L. (Violette, Violette odorante, Fr.; Wohlriechendes Velchen, Velchen, G.; Violetta, It.; Violeta, Sp.), the common violet of Europe, resembles very closely the American blue violet, V. cucullata Ait., from which, however, it is at once distinguished by its delicious fragrance. It is the sweet violet of our gardens. V. pedata L., is an indigenous, stemless violet, characterized by its large blue or variegated beardless flowers, and its deeply three- to five-divided, pointed pedate leaves.

The flowers of V. odorata yield their odor and their slightly bitter taste to boiling water. Their infusion affords a delicate test for acids and alkalies, being reddened by the former and rendered green by the latter. Their odor is destroyed by desiccation, and the degree to which they retain their fine color depends upon the care used in collecting and drying them. They should be gathered before being fully blown, deprived of their calyx, and rapidly dried, either in a heated room or by exposing them to a current of very dry air. The flowers of other species are often mingled with them, and, if of the same color, are equally useful as a chemical test.

In the root, leaves, flowers, and seeds of Viola odorata, Boullay discovered an alkaloid, violine, allied to emetine, but possessing distinct properties. It exists in the plant combined with malic acid. Orfila asserts that it is exceedingly active and even poisonous. It is probably found in other species of viola. Mandolin (J. Ahresb., 1883) obtained a glucoside analogous to quercitrin, which he names viola-quercitrin. It crystallizes out of hot water in fine yellow needles. When boiled with dilute acids, it is decomposed into quercetin, isodulcite and a fermentable glucose, $C_{27}H_{30}O_{16} + 3H_2O = C_6H_{14}O_6 + C_6H_{12}O_6 + C_{15}H_{10}O_7$. He also obtained salicylic acid from several species of viola. (A. J. P., 1882, 10.) Kraemer (., Marking, 1896) detected methyl salicylate and this was later confirmed by Schimmel & Co. See also Gadd's article, Y. B. P., 1905, 466.

The herbaceous parts of various species of violets are mucilaginous, emollient, and slightly laxative, and have been used in pectoral, nephritic, and cutaneous diseases. In Europe a syrup prepared from the fresh flowers of Viola odorata is employed as an
addition to demulcent drinks, and as a laxative for infants. The root, which has a bitter, nauseous, slightly acrid taste, acts in the dose of from thirty grains to a drachm (2.0-3.9 Gm.) as an emetic and cathartic. It is probable that the same property is possessed by the roots of all the violets, as it is known to be by several species of Ionidium, which belongs to the same family. The existence in small proportion of the emetic principle in the leaves and flowers accounts for their expectorant properties.

**Virginia Creeper.** Psedera quinquefolia (L.) Greene (Parthenocissus quinquefolia (L.) Planch. Ampelopsis quinquefolia Michx.) American Ivy. Vignemerge, Fr. Wilder Wein, Amerikanischer Epheu, G.—The bark twigs of this indigenous, woody creeper of the fam. Vitaceae have been used by the eclectics as an alterative, tonic, and expectorant. They contain tartaric acid and potassium and calcium tartrates, albumen, sugar, pyro-catechin, and some other principles. McCall employed the bark collected late in the fall in dropsy, with asserted very good results. *(Penins. and Independ. Med. Journ., June, 1858.)* In two cases of poisoning reported by Bernays, the symptoms were violent vomiting and purging, collapse, and deep sleep, with dilated pupils. *(P. J., vii.)*

**Viscum.** Viscum album L. Mistletoe. Gui de Chene, Gillon, Fr. Mistel, G. [Fam. Loranthaceae]—A European evergreen, parasitic shrub growing on various trees, particularly the apple and other fruit trees, and forming a pendent bush from two to five feet in diameter. The plant is famous in the history of Druidical superstition. In the religious rites of the Druids, the mistletoe of the oak was employed, and hence was afterwards preferred when the plant came to be used as a remedy; but it is in fact identical in all respects with those which grow upon other trees. *(P. J., 1897, 289.)* The fresh bark and leaves have a peculiar, disagreeable odor, and a nauseous, sweetish, slightly acrid and bitterish taste. Viscin, which forms the glutinous constituent in the berries, leaves, and stalks of the mistletoe, is the principal constituent of birdlime. Crude viscin may be obtained by kneading the finely bruised mistletoe bark with water, as long as anything is dissolved, and removing the ligneous impurities mechanically. A purer product may be obtained by boiling the crude product in strong alcohol, macerating the residue with ether, evaporating the ethereal extracts, purifying these extracts by kneading first with alcohol and then with water. The formula C_{20}H_{48}O_8 (C_{20}H_{32} + 8H_{2}O) has been given to it by Reinsch. Pawlevsky *[Bull. Soc. Chim. (2), 34, 348]* obtained from mistletoe a crystallizable acid, slightly soluble in water, insoluble in alcohol and ether, fusing at from 101° to 103° G. (213.8°-217.4° F.), to which he gave the formula CH_{3}O_{3}.OH. The berries, which are white, and about the size of a pea, abound in the peculiar viscid principle, and are sometimes used in the preparation of birdlime, of which this principle is the basis. Mistletoe is said to be productive of vomiting and purging when largely taken. The berries caused in a child three years old vomiting and prostration, coma, a fixed and somewhat contracted pupil, and convulsive movements. *(Ann. Ther., 1859, 36.)* A fatal case is recorded. *(M. T. G., 1867, 26.)* The plant was formerly looked upon as a, powerful nervine, but it is now out of use. The leaves and wood were given in the dose of a drachm (3.9 G.m.) in substance. Viscum has been recommended by Gaultier *(S. M., 1907)* for the reduction of high blood pressure in arterio-sclerosis and other conditions of excessive arterial...
tension. But Dossin (A. I. P. T; 1911, xxi, p. 432) finds that the lowering of blood pressure is of but short duration and is preceded by a rise and concludes, therefore, that the drug is not clinically useful for this purpose. Gaultier employed a watery extract in doses of 3 grains (0.2 Gm.) daily. According to P. Riehl (D, M. W., xxvi, 1900), viscin affords an excellent basis for the making of applications to the skin, a benzene viscin solution mixed with starch affording an excellent plaster mass.

The American Mistletoe is the Phoradendron flavescens (Pursh) Nutt. It is a woody parasite, growing upon the branches of deciduous trees from New Jersey to Florida and westward. It is probably the plant reported as growing upon the elm, by which several children were poisoned. (Henry Dye, Memphis Med. Recorder, iv, 344.) The prominent symptoms were vomiting and great thirst followed by frequent discharge of bloody mucus from the bowels, with tenesmus. One of the children was found in a collapsed state, in which death took place. Dye states also that, in other instances, as he had been informed, children had eaten the berries without any ill effect. In the western part of the United States Arcenthobium Americanum Nutt., and Phoradendron juniperinum Engl., are also known under the name of mistletoe. Crawford (J. A. M. A., 1911, lvii) has found that the extract of P. flavescens or the P. juniperinum, when injected into the blood stream, produces a sharp rise in the blood pressure similar to that produced by epinephrine. He also succeeded in isolating an active base, the composition of which, however, he did not satisfactorily determine, but suggests that it may be phenylethylamine. W. H. Long, confirmed by Lee Payne (North Carolina Med. Journ., vol. vii, 253) asserts (New Prep; ii, 31) that the American mistletoe is a very certain oxytocic, and very efficacious in arresting post-partum and other varieties of uterine hemorrhage. He gives a fluidrachm (3.75 mils) of the fluidextract every twenty minutes in labor until the effect is produced; every four to six hours in menorrhagia. Dalassus proposes a formula for an aqueous extract of mistletoe. Five hundred parts of the ground, dry, young twigs and leaves are infused for 12 hours in 3000 parts of boiling water, expressed and the residue treated with 1500 parts of boiling water. The united liquids are then evaporated to the consistence of an extract. Syrup of mistletoe is made by dissolving 1 part by weight of the above extract in 10 parts by weight of boiling water and adding 990 parts of simple syrup.

**Vitex.**—The various species of this genus have been attributed by the ancients with wonderful powers, and the V. trifolia is still used occasionally for medicating baths.

**White Ash Bark.** N. F. IV. Fraxinus.—It is described as "the dried bark of Fraxinus americana Linne (Fam. Oleaceae) and probably of other species of Fraxinus, deprived of the corky layer. In flat pieces of varying length and width, from 3 to 6 mm. in thickness, externally yellowish or pale brown, sometimes with ridges of a warty nature and fissures of a grayish-brown color with markings of lichens; inner surface, pale brown to yellowish, longitudinally striate; fracture very uneven, fibrous. Odor faintly aromatic; taste bitter, weakly acrid. Fraxinus yields not more than 10 per cent. of ash." N. F. A large forest tree of the northern United States and Canada. It contains a volatile oil, an alkaloid and several resins. The bark has been used in dysmenorrhea by Charles P. Turner and others. A wine is official in the N. F.,
Fraxinus excelsior L. Frene, Fr. Esche, G. Fresco, Sp. (Fam. Oleaceae.)—The bark of the Common European Ash occurs in quills and is of a grayish or grayish-green color. It is bitter and astringent, and at one time was employed in the treatment of intermittent fever. It contains a crystalline glucoside and a bitter principle, and a fixed oil obtained from the seeds. (Chem. Ztg., 1911, 478.) The leaves have long been used in rheumatic affections and gout. Garot has shown that they contain 16 per cent. of calcium malate. (See J. P. C., 3e ser., xxiv, 311; also 4e ser., xii, 60.) Dose, an ounce (31 Gm.), infused in half a pint (236 mils) of boiling water, three times a day. (See Am. J. M. S., N. S., xxv, 492.)

**White Pine Bark.** N. P. IV. Pinus Alba—"The dried inner bark of Pinus Strobus Linne (Fam. Pinaceae)." N. F. "In flat pieces of variable size and from 1 to 3 mm. in thickness; outer surface varying from a pale pinkish-white when fresh, to a light or rather deep yellowish-brown on keeping, occasionally with small patches of the gray-brown periderm adhering; more or less cottony, and often showing small scattered pits; inner surface either lighter or darker than the outer, finely striate; fracture tough, fibrous; transverse section showing an outer yellowish and an inner whitish band. Odor slight, terebinthinate; taste slightly mucilaginous, bitter, sweet and astringent.

The powdered drug, when examined under the microscope, exhibits numerous rounded or oval, simple starch grains, up to 0.03 mm. in diameter, some having a cleft or fissure through the center; few monoclinic prisms of calcium oxalate about 0.02 mm. in diameter; resin in reddish-brown, angular masses; thin-walled parenchyma cells, iso-diametric to elongated, many containing starch grains; tracheids very few or absent. White Pine Bark yields not more than 3 per cent. of ash." N. F. IV.

This bark was introduced into the N. F. IV for the purpose of making Compound Syrup of White Pine and Compound Syrup of White Pine with Morphine. The differentiation of these two syrups was a wise step in the last revision; but in our opinion it would have been wiser to have dropped white pine and all of the preparations; the syrup containing morphine has long been used and has no doubt contributed its share towards cultivating the morphine habit.

**Winter's Bark.** Wintera.—The bark of Drimys Winteri Forst. Cortex Winteranus. Ecorce de Winter, Cannelle de Magellan, Fr. Winter's Zimmt, G. (Fam. Magnoliaceae)—For descriptions of tree, see U. S. D., 16th edition. The tree is a native of the southern parts of South America, growing along the Strait of Magellan, and extending as far north as Chile. According to Martius, it is found also in Brazil. The bark of the tree was brought to England, in the latter part of the sixteenth century, by Captain Winter, who attended Drake on his voyage round the world, and while in the Strait had learned its aromatic and medicinal properties. Since this period, from time to time various barks have appeared in European commerce as Winter's bark, although not any that was the genuine bark. Among those in the London market was at one time the bark of Cinnamodendron corticosum Miers. (Fam. Canellaceae), of Jamaica, which is pungent like true Winter's bark, but is of a much paler brown color, and resembles canella bark except in the absence of the
chalky-white inner surface. More recently this bark has been replaced by the bark of Croton Malambo Karst. (Fam. Euphorbiaceae), which resembles in color and thickness the bark of the Cinnamodendron, but has a bitter taste and a calamus-like flavor. For the description of a specimen which was in possession of George B. Wood many years since, see U. S. D., 19th ed., p. 1696. P. N. Arata and F. Canzoneri (P. J., June 14, 1890) describe a bark which they assert to be a genuine Winter's bark from the Strait of Magellan. From this they separated a volatile oil by distilling the bark with water, exhausting the distillate with petroleum, and distilling off the solvent. The crude oil, amounting to 0.64 per cent. of the weight of the bark employed, was a mixture of several substances. Wintereine, C_{15}H_{24}, is the essential oil separated from this by fractional distillation. It is readily oxidized on exposure to the air, becoming yellow. The formula C_{25}H_{40} was calculated from the ultimate analysis and vapor density, but the authors consider that the ready oxidizability of wintereine and its analogy to similar essences point rather to the formula C_{15}H_{24}, which would place it in the group of sesquiterpenes, such as cedrene, cubebene, etc. The presence of tannic acid and ferric oxide, according to Henry, serves to distinguish Winter's bark from Canella alba, with which it has often been confounded. The bark above described as commercial Winter's bark ia destitute of both tannic acid and ferric oxide, and cannot therefore be the bark examined by Henry.

The bark of the Drimysgranatensis L. f. (now regarded as identical with D. Winteri Forst.), has been imported into London under the name of Merida coto, and it has been stated that it contains cotoin. It occurs in short pieces of a yellowish-gray color, traversed longitudinally by hard cellular layers, which distinguish it at once from coto and paracoto bark. Its odor resembles that of true coto, but is more feeble. A careful chemical study of it by O. Hesse (P. J., vol. iv) shows that it contains no cotoin, but a crystalline substance, C_{13}H_{14}O_{4}, to which the name of drimin was given. From the leaves Hesse obtained a wax alcohol, drimol, C_{28}H_{58}O_{2}. As Drimys granatensis L. f., is recognized as D. Winteri Forst., it is plain that Merida coto must be looked upon as a form of Winter's bark coming from Venezuela.

Winter's bark is a stimulant aromatic tonic, and was employed by Winter as a remedy for scurvy. It may be used in half-drachm (2.0 Gm.) doses for similar purposes with cinnamon or canella alba, but is scarcely known in the medical practice of this country. Drimys chilensis of De Candolle, growing in Chile, yields a bark having similar properties (Carson, A. J. P., xix, 81); also D. aromatica F. MuelL, of Australia. (P J., xxi.)

**Wistaria.** Wistariachinensis DC. (Kraunhiachinensis.) (Fam. Leguminosae.)—Ottow (P. J., Oct., 1886) has obtained from this ornamental leguminous woody climber a crystalline poisonous glucoside, wistarin.

**Withania.** Withania coagulans Dun. (Stocks.) Vegetable Rennet. (Fam. Solanaceae)—This shrub, common in Afghanistan and East India, has the property of coagulating milk, and has been used for preparing a vegetable rennet ferment for making cheese. Sheridan Lea found upon examination that the substance which possesses the coagulating power is a ferment closely resembling animal rennet. The
active principle is soluble in glycerin, and can be extracted from the seeds by this solvent; the extract possesses strong coagulating powers even in small amounts. Alcohol precipitates the ferment body from its solutions, and the precipitate, after washing with alcohol, may be dissolved again without having lost its coagulating powers. The active principle of the seeds will cause the coagulation of milk when present in very small quantities, the addition of more of the ferment simply increasing the rapidity of the change. The coagulation is not due to the formation of acid by the ferment. If some of the active extract be made neutral or alkaline, and added to neutral milk, a normal clot is formed, and the reaction of the clot remains neutral or faintly alkaline. The clot formed by the action of the ferment is a true clot, resembling in appearance and properties that formed by animal rennet, and is not a mere precipitate. Lea prepared an active extract, applicable for cheese making purposes, by grinding the dry seeds very finely in a mill, and extracting them for twenty-four hours with such a volume of 5 per cent. sodium chloride solution that the mass is still fluid after the absorption of water by the fragments of the seeds as they swell up. From this mass the fluid part may be readily separated by using a centrifugal machine (such as is used in sugar refining), and it can then be easily filtered through filter paper; without the centrifugal machine the separation of the fluid from the residue of the seeds is tedious and imperfect; forty grammes of the seeds treated as above, with 150 mils of 5 per cent. sodium chloride solution, gave an extract of which 0.25 mil clotted 20 mils of milk in twenty-five minutes, and 0.1 mil clotted a similar portion of milk in one hour. When added in these proportions the curd formed is quite white. The presence of the coloring matter is, however, perhaps on the whole unimportant, since even if a larger quantity of the ferment extract is added in order to obtain a very rapid coagulation, the coloring matter is obtained chiefly in the whey, the curd being white; by adding sufficient common salt to make the percentage up to 15 per cent., and alcohol up to 4 per cent., the preparation would retain its activity very well. (P. J., 1884, 606.)

**Wrightia**, Wrightia zeylanica R. Br. (W. antidysenterica R. Br.) (Fam. Apocynaceae)—Under the names of Conessi bark, Telicherri bark, and Codaya pala, a spongy, rusty-colored, bitter bark of this apocynaceous tree was formerly used in Europe as a remedy in dysentery and diarrhea, and is said still to be largely employed by the native practitioners of India. Stenhouse obtained from the seeds, besides a fixed oil which they contain in large quantity, a non crystalline alkaloid, called by him wrightine, which seems to be the same substance previously described by Hains under the name of conessine. (P. J. (2), vi, 432.) The alkaloid conessine is now a commercial product prepared by Merck, and the formula C_{24}H_{40}N_{2} is given it. It occurs in delicate, white, interlaced masses of crystals, melting at 121° C. (249.8° F.), sparingly soluble in water, readily so in alcohol. A small quantity rubbed with a few drops of concentrated sulphuric acid affords on the addition of nitric acid a golden and finally orange-yellow color. We are not aware that the medicinal properties of this have been investigated.

A species of the allied genus Holarrhena (H. africana A. DC.), is stated by German missionaries to be used in parts of tropical Africa in dysentery. Polstorx and Schirmer (Ber. d. Chem. Ges., 1886. 78) prepared the alkaloid both from Holarrhena africana
and from Wrightia zeylanica, finding it to be identical in the two cases. When oxidized by iodic acid in sulphuric acid solution, conessine is changed to oxyconessine, \((C_{12}H_{20}NO.)_2\).

**Wurrus.**—Under the name of Vars, Wars, or Wurrus, a powder somewhat similar to kamala has been used as an anthelmintic in Southern Arabia, and exported into commerce from Aden. It is believed to be the product of Flemmingia Grahamiana W. et Arn. (Fam. Leguminosae) (P. J., Sept., 1887.) It is composed of cylindrical or subconical grains, 170 to 200 mm. long by 70 to 100 broad, with oblong resin cells arranged perpendicularly in three or four tiers.

**Xanthium.**—Guichard believes that he has found an alkaloid in the X. spinosum L. (P. J., vii, 249.) In the Xanthium Strumarium L., Cocklebur or Clotbur, which is common both in Europe and in America. A. Zander believes that he has found a glucoside, xanthostrumarin. M. V. Cheatham thinks that there is a second active principle. (See A. J. P., vol. xi, 271; vol. xiv, 134.) Clotbur is stated to be an active styptic, both local and general. Dose, of the fluidextract, from one to two fluidrachms (3.75-7.5 mils).

**Xanthorrhiza.** Yellow-root. Shrub Yellow-root. Xanthorrhiza apiifolia L’Her. (Fam. Ranunculaceae)—This is a low shrub, with a horizontal rhizome, which sends off numerous suckers. The stem is simple, about 6 mm. thick, with a smooth bark and bright yellow wood. The leaves, are compound, consisting of several ovate-lanceolate, acute, doubly serrate leaflets, sessile upon a long petiole, which embraces the stem at its base. The flowers are small, purple, and disposed in long, drooping, divided racemes, placed immediately below the first leaves. Yellow-root grows from Southern New York to Georgia and west to Kentucky. It flowers in April. The root was formerly in the Secondary List of the U. S. Pharmacopoeia, but the bark of the stem possesses the same virtues. The root is from 7 cm. to 1 dm. in length, and about 12 mm. thick near the stem. It shrinks somewhat in drying, and, as found in commerce, is in slender pieces of various lengths, wrinkled longitudinally, with a light yellowish-brown, easily separable epidermis, a thick, hard, bright yellow woody portion, and a very slender central pith. It is inodorous, and of a simple but extremely bitter taste. It imparts its color and taste to water. The infusion is not affected by ferric salts. J. Dyson Perrins found berberine in it. (P. J.; May, 1862.) Samuel S. Jones believed that he had proved the existence in the drug of a second alkaloid. (A. J. P., vol. xvi, 1861.) Xanthorrhiza possesses properties closely analogous to those of calumba, quassia, and other simple tonic bitters, and may be used for the same purposes and in the same manner. Woodhouse employed it in the dose of forty grains (2.6 Gm.).

**Xanthorrhoea Resins.** Gum Acaroides. Gum Acroides. Grass-tree Gum. Botany Bay Gum.—Yellow and reddish resinous substances, the products of Xanthorrhoea hastilis R. Br. and X. australis R. Br. (fam. Liliaceae), have been introduced into England from Australia. They are obtained by spontaneous exudation from the stems of the plants, which are usually shrubs. The yellow variety (from X. hastilis) is in tears, in flattish pieces having on one side the mark of the stem, or in masses of various size and irregular shape. It has a reddish-yellow color, resembling gamboge when broken, and
when heated emits a fragrant odor like that of Tolu balsam. It contains resin, cinnamic and benzoic acids, and a trace of volatile oil, and may therefore be ranked among the balsams. When heated with nitric acid, it yields a large proportion of picric acid. In medicinal properties it is said to bear a close resemblance to storax and the balsam of Tolu. A tincture, made in the proportion of two ounces to a pint of alcohol, may be given in the dose of one or two fluidrachms. The red variety (from X. australis R. Br.) resembles dragon's blood in color, and appears to be analogous to the other variety in properties. (See A. J. P., 1881; also A. J. P., vol. xv, and D. C., 1895, 83.) These resins have been introduced as a shellac substitute in varnish making.

**XANTHOXYLUM. U. S.**

**XANTHOXYLUM Xanthox. [Prickly Ash Bark]**

"The dried bark of Xanthoxylum americanum Miller, known in commerce as Northern Prickly Ash Bark, or Xanthoxylum Clava-Herculis Linne, known in commerce as Southern Prickly Ash Bark (Fam. Rutaceae)." U. S.

X. americanum: Toothache Tree, Angelica Tree, Suterberry, Pellitory Bark, Yellow-wood; Clavalier, Frene epineux. Fr. Zahnwehholz, Zahnwehrinde, G.

Northern Prickly Ash (Xanthoxylum americanum) is a shrub from five to twenty-five feet in height, with alternate branches, which are covered with strong, sharp, scattered prickles. The leaves are alternate and pinnate, consisting of four or five pairs of leaflets, and an odd terminal one, with a common footstalk, which is sometimes prickly on the back, and sometimes unarmed. The leaflets are nearly sessile, ovate, acute, slightly serrate, and somewhat downy on their under surface.

The flowers, which are small and greenish, are disposed in sessile umbels near the origin of the young shoots. The plant is polygamous, some shrubs bearing both male and perfect flowers, others only female. The number of stamens is five, of the pistils three or four in the perfect flowers, about five in the pistillate. The capsules are stipitate, oval, punctate, of a greenish-red color, with two valves, and one oval blackish seed. This species of xanthoxylum is indigenous, growing in woods and in moist shady places throughout the Northern, Middle, and Western States. The flowers appear in April and May, before the foliage. The leaves and capsules have an aromatic odor, recalling that of oil of lemon.

Botanists are not agreed concerning the distinction of the genus Fagara
from Xanthoxylum. Thus, the authors of the Index Kewensis consider the two genera identical, while Engler and Pranti separate them. The most important character separating them seems to be the absence of sepals in Xanthoxylum. Most of the species of the genus Fagara are tropical trees.

Z. Clava-Herculis L. [Fagara Clava-Herculis (L.) Small], or Southern Prickly Ash, varies in size from a large bush to a small tree. Its bark is armed with warty prickles, and large conical cork wings occur on the branches and the petioles. The alternate leaves have from seven to nine ovate-lanceolate, crenate-serrulate, unequal-sided leaflets, smooth and shining on the upper surface. It grows on dry soil, westward as far as Western Texas, and perhaps into Mexico, eastward to the Atlantic coast, and northward to Southern Virginia, especially affecting the coast region.

The fruits (Prickly ash berries) of both of the official species probably contain the same principles found in the barks. The dried berries are recognized by the N. F. under the name of Xanthoxyli Fructus, and are described below.

There has been much confusion in regard to the nomenclature of the prickly ashes. Aralia spinosa L., or angelica tree, which grows in the Southern States, is occasionally confounded with X. Clava-Herculis, in consequence partly of being sometimes called, like the latter, prickly ash. Its bark is nearly smooth externally, is beset with slender prickles in transverse rows and has a taste different from that of F. Clava-Herculis. Besides the official trees, the bark of F. flava (Vahl), Frug. and Urban (X. caribaeum S. Wats.), the satin-wood of semi-tropical Florida and the West Indies, has appeared in commerce under the name of yellow Hercules club or yellow thorn. This bark is thin, with an odor like that of Angus-tura bark, a bitter, disagreeable, acrid taste, and a canary-yellow color, which it imparts to the saliva when chewed. It would seem, also, that under the name of prickly yellow wood, yellow wood, or fustic, the products of other West Indian xanthoxylums and allied plants find their way into commerce.

Xanthoxylum veneficum Bailey, of Australia is, according to J. H. Maiden, a violent convulsive poison, 5 grains of the extract being a fatal dose for a cat. Xanthoxylum scandens is said to be used by the natives of Java as a fish poison, and according to Van der Haar, contains an
Properties.—Although the bark of the Southern prickly ash was not recognized by the U. S. Pharmacopoeia until the revision of 1880, as long ago as 1864 Bridges pointed out that it had entered commerce, and gave the physical characteristics separating it. (Proc. A. Ph. A., xii, p. 270.) The characteristics of the two barks are very well given in the following official description.

"Northern Prickly Ash Bark.—In transversely curved fragments or quills, from 2 to 15 cm. in length; bark from 0.5 to 2 mm. in thickness; outer surface light gray to brownish-gray with grayish patches of foliaceous lichens bearing numerous small black apothecia; longitudinally wrinkled and with numerous whitish lenticels; the cork occasionally abraded, showing the yellowish or orange inner bark; inner surface yellowish-white, finely longitudinally striate and usually with numerous, bright, shining crystals; fracture short, uneven; odor slight; taste bitter, acrid, becoming pungent. Under the microscope, transverse sections of Northern Prickly Ash Bark show an outer corky layer consisting of from 4 to 20 rows of cells, the tangential walls being more or less thickened and lignified; a wide strata of collenchyma inside of the cork cambium composed of from 8 to 10 rows of tangentially elongated cells, with very thick walls and containing plastids; a more or less indistinct row of endodermal cells beneath which occur small groups of primary bast-fibers; the inner bark consists of numerous parenchyma cells among which are included large oil-secretion reservoirs, separated by medullary rays which are mostly one cell in width; the parenchyma cells as well as the oil-secretion reservoirs contain numerous colorless oily globules. Scrapings from either the inner or outer surface show numerous rod-shape crystals and flat prisms, from 0.015 to 0.25 mm. in length, which polarize light with a display of bright colors.

"Southern Prickly Ash Bark.—In transversely curved or irregular, oblong, flattened pieces, or in quills from 2 to 40 cm. in length; bark from 1 to 4 mm. in thickness; outer surface light gray to brownish-gray, marked by numerous large, barnacle-shaped projections of cork, from 0.5 to 3.5 cm. in thickness, otherwise with numerous grayish patches of foliaceous lichens, bearing blackish apothecia, and numerous, elliptical lenticels; inner surface light yellowish-brown to olive brown, obscurely longitudinally striate and free from crystals; odor and taste as in Northern Prickly Ash Bark. Under the microscope, transverse sections of
Southern Prickly Ash Bark show a strong development of lignified cork occurring in the form of rings, the successive layers being separated by several rows of narrow tabular cells strongly thickened on the tangential walls; beneath the cork cambium occurs a thin layer of collenchyma followed by the outer tissues of the primary cortex and consisting of small groups of rather large stone cells and occasional, scattered groups of bast-fibers and parenchyma; the inner bark consists of parenchyma, a more or less indistinct leptome or sieve tissue among which are numerous, large, light yellowish oil-secretion reservoirs, medullary rays from 1 to 2 cells in width and occasional groups of stone cells and bast-fibers; starch grains numerous, nearly spherical, from 0.002 to 0.01 mm. in diameter, and occurring in the parenchyma cells and medullary rays; calcium oxalate chiefly in mono-clinic prisms from 0.01 to 0.025 mm. in diameter, occurring in crystal fibers and in parenchyma cells of the primary cortex. Powdered Xanthoxylum is light grayish-brown, under the microscope it shows mostly irregular fragments of cork cells, nearly colorless and strongly lignified, fragments of parenchyma containing either small starch grains, oily globules or monoclinic prisms of calcium oxalate; stone cells in small groups with thick, colorless walls and containing frequently a reddish-brown substance; bast-fibers few and non-lignified. In the Northern Prickly Ash, the stone cells are usually absent, and the calcium oxalate crystals and the fragments of cork are relatively few." U. S.

Xanthoxylum is practically never adulterated, and hence the drug has never been studied very exhaustively. Kraemer illustrates the inner structure of the Southern prickly ash bark in his work on "Scientific and Applied Pharmacognosy." Recently the bark of a tropical American species, X. Ochroxylum D. C., has been the subject of a pharmacognostical study by Le-prince. (Report. Pharm., 1912, xxiv, p. 215.)

W. L. Cliffe after careful examination demonstrated that the bark of Southern prickly ash exceeded that of the Northern prickly ash in active properties. (A. J. P., 1901, 562.) In 1829, Edward Staples isolated from X. americanum a crystalline xanthoxyline which was again found by J. U. Lloyd in 1876. Subsequently, from the same plant Edward T. Moffet (A. J. P., 1886, 417) obtained a supposed alkaloid in yellow crystals, soluble in alcohol and chloroform, insoluble in petroleum benzin, ether, and benzene. G. H. Colton (A. J. P., 1880, p. 191) separated from the Southern prickly ash, tasteless, colorless, silky acicular crystals, soluble
in alcohol, ether, and chloroform, less soluble in benzene, and insoluble in water. The identity of all these principles was assumed until E. G. Eberhardt (A. J. P., 1890, 231) obtained from the Southern prickly ash a colorless crystalline principle agreeing in solubilities with that of Colton. On analysis it gave figures indicating the formula $C_{20}H_{19}O_6$ or $C_{30}H_{28}O_9$. At the same time he analyzed a sample of Lloyd's crystalline principle from X. fraxineum (X. americanum Mill.), which had been preserved in the cabinet of the Philadelphia College of Pharmacy, and found for it the formula $C_{29}H_{27}O_8$. Numerous reactions also indicated that the two principles were different. Thus, Lloyd's crystals dissolve in concentrated sulphuric acid with light red color, and on the addition of an excess of water produce a whitish precipitate which is taken up by chloroform; the crystals from the X. Clava-Herculis, dissolve in concentrated sulphuric acid with dark red color, and on dilution separate a purplish precipitate, which is not taken up by chloroform. Lloyd's principle melts, moreover, at 129.5° C. (265.1° F.), while Eberhardt's melts at 119° C. (246.2° F.). In 1863, J. D. Perrin separated from the Caribbean Xanthoxylum Clava-Herculis an alkaloid which he considered to be berberine. This had also been described as early as 1826 by Chevallier and Pelletan under the name of xanthopicrite. X. senegalense (artar root) was analyzed by Giacosa and Soave (A. J. P., 1890, 500), who found a fixed oil, a neutral crystalline substance, melting at 120° C. (248° F.), and two alkaloids. The first of these they call artarine, and give to it the formula $C_{20}H_{17}O_4N$ (which makes it agree with berberine), or $C_{21}H_{17}O_4N$, in which case they consider that it may be methylhydroberberine. The second alkaloid, crystallizing in blood-red needles, they did not analyze.

**Uses.**—Xanthoxylum is stimulant, producing, when swallowed, a sense of heat in the stomach, with more or less general arterial excitement, and a tendency to diaphoresis. It is thought to resemble mezereum and guaiac in its remedial action, and is given in the same diseases. As a remedy in chronic rheumatism, it enjoys some reputation in this country. The bark, used as a masticatory, is a popular remedy for toothache. Xanthoxylum is capable of being used as a counter-irritant, and great relief is sometimes afforded in various forms of chronic pelvic disease in women by means of a hot pack, applied to the lower part of the trunk, of two to four ounces of fluidextract of xanthoxylum and an ounce of tincture of cayenne pepper to two quarts of water. A decoction prepared by boiling an ounce in three pints of water down to a quarter
may be given in the quantity of a pint (473 mils), in divided doses, during the twenty-four hours.

Dose, fifteen to thirty grains (1-2 Gm.).

**Off. Prep.**—Fluidextractum Xanthoxyli, U. S.; Elixir Corydalis Compositum, N. F.

**Xanthoxylum Berries.** XanthoxylumFructus. N. F. IV. Prickly Ash Berries.—"The fruit of Zanthoxylum americanum Miller (Northern Prickly Ash), or Zanthoxylum Clava-Herculis Linne (Southern Prickly Ash) (Fam. Rutaceae)." N. F. IV.

Prickly ash berries were introduced in the N. F. IV to be used as an ingredient in compound fluid-extract of stillingia N. F. IV, made with a menstruum of 25 volumes of glycerin, 50 volumes of alcohol and 25 volumes of water, finishing with diluted alcohol. The berries are described as "Capsules with short stalks (X. americanum) or without stalk (Z. Clava-Herculis); when fresh, ellipsoidal, fleshy, gray-brown, when dry, dehiscent; carpels two, convex, summit short pointed; seeds one or two oblong, black, shining, and wrinkled from drying. The carpels have a pungent, warm, aromatic taste and on chewing leave a tingling sensation on the tongue; when breathed upon they emit a faintly aromatic odor resembling that of citral. Prickly Ash Berries yield not more than 7 per cent. of ash." N. F. IV.

**Yohimbine.**—This is an alkaloid which is obtained from the bark of Corynanthe Yohimbi Schum., a rubiaceous tree growing in the Southern Cameroons district in Africa. The bark comes into commerce in flattened or slightly quilled pieces 75 cm. long to 4 to 8 mm. thick, with an external corky layer of a gray-brown color covered with isolated lichens. It shows numerous longitudinal and transverse fissures like some old specimens of cinchona bark. The transverse fracture is of a uniform yellowish-brown color, and presents short, soft fibers like rough velvet. The taste is bitter.

The alkaloid has been obtained in white needles melting at 234° C. (453.2° F.) and having the composition $C_{23}H_{32}N_2O_6$.

The salt of this base that is ordinarily used is the hydrochloride, being preferable on account of its solubility and high percentage of the alkaloid.

It was originally investigated by Oberwarth and Loewy (V. A. P. A., cliii, and B. K. W., No. 42, 1900), who found it to be in animals and also in man a very active excitant to the sexual organs and functions. On the other hand, Kravkoff, as the result of experiments upon the lower animals and upon man, concluded that it has no aphrodisiac effects and frequently produces nausea, salivation, irritability, and other disagreeable results.

Muller (A. I. P. T., 1907, p. 65) found that yohimbine, in small doses stimulated, and in
large doses depressed, the respiratory center. If lethal doses are given the heart continues beating after the respiration has ceased. Small doses have little effect upon the blood pressure, but moderate-sized doses caused a slight rise in the blood pressure with local dilatation of the vessels of the pelvic organs. He believes that its aphrodisiac action is due to an increase in the excitability of the lower centers in the spinal cord. On the other hand, many authors believe that its effect is due to the hyperemia produced. Toff (D. M. W., 1904) has found it useful because of this effect in scanty or irregular menstruation.

It has been used by numerous clinicians in neurasthenic impotence, with reports which are generally favorable to its influence. (For literature, see M. R., 1901, 1902.) It is said to be of no value when the impotence depends upon organic nerve trouble, and to be harmful when it is caused by chronic inflammatory disease of the sexual organs or of the prostate gland. Dose, of the hydrochloride, 0.005 Gm. (one-twelfth grain), either in tablet or solution, three or four times a day. Yohimbine has also been employed in a 1 per cent. solution hypodermically.

This drug is the so-called "silk" of the ear of ordinary Indian corn or maize, cultivated in the warmer temperate and subtropical countries of the world. It consists of slender filaments from 10 to 20 cm. in length, and about 0.4 mm. in diameter; of a light green, purplish-red, yellow or light brown color; stigmas bind, the segments very slender, frequently unequal and from 0.4 to 3 mm. in length. Under the microscope, the styles are seen to consist for the most part of parenchyma and two parallel vascular bundles with narrow, spiral or annular tracheae; the epidermal cells are rectangular, many of these being extended into multicellular hairs, the latter being from 0.2 to 0.8 mm. in length, the basal portion consisting of two to five united cells, the upper portion being usually unicellular; the cells of the hairs are rich in cytoplasm and usually contain a small, spherical nucleus; the purplish-red styles contain a purplish-red cell sap. Digest a small portion of the fresh styles and stigmas in diluted alcohol and filter; a pale purplish-red solution is produced, separate portions of which, on the addition of acids, become distinctly purplish or yellowish-red; on the addition of alkali; green; on the addition of ferric chloride T.S., olive-green changing to greenish-brown; and on the addition of an aqueous solution of alum, bluish or purplish, the color being quite permanent." N. F. Rademaker and Fischer (A. J. P., 1886, p. 369) determined the presence of 2.25 per cent. of maizenic acid in dried corn silk. It was first described, however, by Vautier. It is freely soluble in water, alcohol and ether, but insoluble in benzene. Rademaker and Fischer found, in addition to the acid, fixed oil, resin, chlorophyll, sugar, gum, extractive, albuminoids, phlobaphene salt, cellulose and water.

Used as a mild stimulant diuretic, useful in acute and chronic cystitis and in the bladder irritation of uric acid and phosphatic gravel. It has also been employed in gonorrhea, and has been affirmed by Landreux to be a useful diuretic and even cardiac
stimulant in the dropsy of heart disease. It probably is, however, of little value.

Concerning the activity of maizenic acid we have little definite knowledge, but it probably represents whatever physiological power the drug possesses; it has been given in the dose of one-eighth of a grain (0.008 Gm.).

Corn silk was official in the U. S. VIII but dismissed from the U. S. IX. It was introduced in the N. F. IV. The fluidextract of zeo N. F. is made with a menstruum of diluted alcohol.

Dose, one to three drachms (3.9-11.6 Gm.).

**Zedoary.** N. F. IV. Zedoaria. Radix Zedoariae. Rhizoma Zedoariae, P. G. Zedoarie, Fr. Zitterwurzel, G.—"The dried rhizome of Curcuma Zedoaria (Bergius) Roscoe (Fam. Zingiberaceae)." N. F. There are two kinds of zedoary, the long and the round, distinguished by the old official titles of radix zedoariae longae and radix zedoariae rotundas. Both kinds come from the East Indies. The long zedoary is in slices, from 2.5 to 7.5 cm. in length, and from 1 to 2.5 cm. thick, obtuse at the extremities and exhibiting the remains of the radical fibers. The round is commonly seen in communities, and is "usually cut into transverse rounded sections, twisted and wrinkled, from 1 to 4 cm. in diameter, and from 5 to 10 mm. in thickness; externally grayish-brown, hairy, rough, with few root scars; transverse surface pale reddish to gray-brown; a distinct, dark circular endodermis, which is from 2 to 5 mm. in width, separates the cortex; the stele contains numerous, orange-colored resin cells and irregularly distributed, lighter colored wood bundles which are fewer in the cortex; fracture short, somewhat mealy and waxy. Odor aromatic, camphor-like; taste aromatic, warm, slightly bitter. Under the microscope, sections show a thick cork, a thin epidermis with numerous characteristic hairs, thick-walled, one- to six-celled, up to 1 mm. in length and often thicker in the middle than at the base; the parenchyma of the cortex and of the central cylinder rich in starch; secretion cells isodiametric with suberized walls, contents colorless or yellowish; the endodermis of small, thin-walled quadratic cells, the fibro-vascular bundles collateral, more numerous in the central cylinder and nearer the endodermis; few bast fibers in the cortex and no crystal cells. The powder contains numerous starch-grains which are ovoid, from 0.02 to 0.07 mm. in length and from 0.007 to 0.03 mm in thickness, having the point of origin of growth in the smaller end of the grain; numerous characteristic, thick-walled hairs; rich in parenchyma; very few bast fibers; no calcium oxalate crystals or stone cells. Zedoary yields not more than 7 per cent. of ash." N. F.

Zedoary yields a volatile oil, when distilled with water, and contains a pungent soft resin and bitter extractive.

Zedoary was introduced into the N. F. IV and is used as an ingredient in bitter tincture of zedoary, antiperiodic pills, antiperiodic pills without aloes, bitter tincture, antiperiodic tincture and antiperiodic tincture without aloes.

Zedoary is a warm, stimulating aromatic, useful in flatulent colic and debility of the
digestive organs. It is rarely employed, as it produces no effects which cannot be as well or better obtained from ginger. The dose is from ten grains to half a drachm (0.65-2.0 Gm.).

**Zerechtit.** Tschuking. Landtia Schimperi Benth. and Hook. (Ubioëa Schimperi J. Gay Arctotis Schimperi O. Kze.)—The leaves, flowers and fruit of an Abyssinian composite. (See Proc. A. Ph. A., xxvi, 228.)

**Zerumbet.** Cassumuniar.—Under these names an East Indian root was formerly used, having some analogy in sensible and medicinal properties to ginger, and ascribed to the Zingiber Zerumbet of Roscoe. By some authors the zerumbet has been erroneously confounded with the round zedoary. Greiger describes it as in pieces of the size of a fig or larger, externally grayish-brown and wrinkled, internally yellowish, hard and tough, of a biting, aromatic taste and a spicy odor.

**ZINGIBER. U. S., Br.**

**GINGER Zingib.**

"The dried rhizomes of Zingiber officinale Roscoe (Fam. Zingiberaceae), the outer cortical layers of which are often either partially or completely removed. Preserve it in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." U. S. "Ginger is the scraped and dried rhizome of Zingiber officinale, Roscoe." Br.

There are about twenty species of the genus Zingiber, the commercial ginger being obtained from Zingiber officinale. According to Watt, this species is probably a native of tropical Asia, but is not known except in the cultivated state. It is now extensively cultivated in the tropical countries of both the Eastern and Western Hemispheres.

The ginger plant, Zingiber officinale, has a biennial or perennial, creeping rhizome, and an annual stem, which rises two or three feet in height, is solid, cylindrical, erect, and enclosed in an imbricated membranous sheathing. The leaves are lanceolate, acute, smooth, five or six inches long by about an inch in breadth, and stand alternately on the sheaths of the stem. The flower-stalk rises by the side of the stem from six inches to a foot, and, like it, is clothed with oval acuminate sheaths; but it is without leaves, and terminates in an oval, obtuse,
bracteal, imbricated spike. The flowers are of a dingy yellow color, and appear two or three at a time between the bracteal scales. The flowers have an aromatic odor, and the stems when bruised are slightly fragrant; but it is in the rhizome that the virtues of the plant reside. This is fit to be dug up when a year old. The rhizome of the ginger is lifted from the soil by a single thrust of the fork at the time when the stems of the plant turn white, before the rhizome has begun to get tough and fibrous. The root is scalded in boiling water and rapidly dried, when it constitutes the black or ordinary ginger of commerce.

In Jamaica the so-called white or Jamaica ginger is produced by carefully peeling the fresh rhizomes so that only the epidermis is removed, the cells immediately beneath the epidermis being the richest in volatile oil and resin. The peeled pieces are macerated sometimes in water and sometimes in lime juice, and not rarely the color of the ginger is improved by finally coating it with chalk. (See Kilmer, A. J. P., 1898, p. 65; Harris, P. J., 1909, xxix, p. 379.) An inferior white ginger is also produced in the East Indies. The thoroughness of desiccation is a matter of commercial importance. The moisture in ginger should not exceed 10 per cent., but in the poorer specimens may constitute one-fourth of the whole weight. In China the fresh ginger is rasped into a powder and as such dried. Formerly East Indian ginger was imported into the United States from Calcutta, while the Jamaica or West Indian ginger came usually through London. At present the cultivation of ginger is spread almost over the whole sub-tropical world, and the drug is produced in St. Lucia, Dominica and Africa, Cochin-China, Japan, etc. The world's production of ginger is estimated to be annually over 20,000,000 pounds. Of this nearly 4,000,000 pounds is annually exported from Jamaica, the United States using about 1,500,000 pounds. (C. D., lxxvii, p. 489; Cons. and Tr. Rep., 1910, p. 1085.)

In Martinique a ginger is said to be obtained by the cultivation of Zingiber Zerumbet Rose. The ginger of Siam is said to be produced by Alpinia Galanga, and is the same drug, therefore, as the Greater or Java Galanga Root. The large, ordinary, preserved ginger of China is, according to C. Ford (Kew Bulletin, 1891) also the product of A. Galanga. It is made by boiling young, tender, carefully selected and decorticated rhizomes in syrup. Preserved ginger from the West Indies is made from the official plant. According to Hartwich and Swanlund, the rhizome of the Zingiber Mioga, which is cultivated in China and Japan, has a taste less pungent than that of the official ginger, and distinctly
recalling bergamot. In commerce the varieties of ginger are known by the place of their production. African and Cochin ginger on an average yield more resin and volatile oil than do the older varieties.

The recent root is from one to four inches long, somewhat flattened on its upper and under surface, knotty, obtusely and irregularly branched or lobed, externally of a light ash color with circular rugae, internally yellowish-white and fleshy. It sometimes begins to grow when kept in a damp atmosphere. The common or black ginger is of the same general shape, but has a dark ash-colored wrinkled epidermis, which, being removed in some places, exhibits patches of an almost black color, apparently the result of exposure. Beneath the epidermis is a brownish, resinous, almost homy cortical portion. The interior parenchyma is whitish, the cells being filled with starch. The powder is of a light yellowish-brown color. This variety is most extensively used. The Jamaica or white ginger is white or yellowish-white on the outside. The pieces are rounder and thinner, and afford when pulverized a beautiful yellowish-white powder.

The uncoated ginger of the East Indies resembles the Jamaica, but is darker, being gray rather than white. As the Jamaica commands a much higher price than even the uncoated East India production, the latter is occasionally altered to simulate the former. This is sometimes done by coating the exterior with calcium sulphate or carbonate, sometimes by bleaching with the fumes of burning sulphur or in other ways, by which not only the exterior but also the internal parts are rendered whiter than in the unprepared root. Powdered ginger which has been exhausted in the preparation of essence, technically known as "spent ginger," is used to a large extent in the adulteration of powdered ginger. Its detection without assay of some sort is almost impossible, unless so much is present as to sensibly alter the taste of the powder. Alien and Moor rely upon the proportion of cold water extract yielded and the soluble ash. Dyer and Gilbard state that the fixed ethereal extract is of little value, on account of its variability in genuine ginger, but that the extract obtained by alcohol after ether affords a valuable criterion. In genuine ginger the average yield is 2.9 per cent. while in spent ginger it is 1.2 per cent. They also affirm that in genuine ginger the ash produced is 2.7 per cent., in the exhausted ginger it is 0.3 per cent. A. Russell Bennett concludes that spent ginger can be detected by noting the alcoholic and cold water extracts and the soluble ash, affirming that ginger should yield not less than 5 per cent. of extract.
with 90 per cent. alcohol, 8.5 per cent. of cold water extract and 1.5 per cent. of soluble ash.

Commercial gingers are known as "scraped," "de corticated," and "coated." The "scraped" gingers are those from which the cortex has been removed in whole or in part by peeling, as seen in the Jamaica, Cochin and Japan varieties. In the "coated" gingers a portion of the outer natural layers are retained as in the African, Calcutta and Calicut varieties. "Bleached" and "unbleached" gingers are also distinguished, the former being lighter in color due to careful washing or special treatment. All of the above varieties mentioned are recognized in the U. S. Pharmacopoeia IX, and are described as follows:

"Jamaica Ginger."—Rhizomes free from the outer corky layers, in horizontal, laterally compressed, irregularly branched pieces, from 4 to 16 cm. in length; and from 4 to 20 mm. in thickness; externally light brown, longitudinally striate, ends of the branches with depressed stem-sears; fracture short-fibrous, mealy and resinous; internally yellowish to light brown, cortex thin, endodermis a thin yellow layer enclosing a large central cylinder with numerous groups of fibro-vascular bundles and yellowish oil cells; odor agreeably aromatic; taste aromatic and pungent.

"African Ginger."—Rhizomes with cork partly removed on the flattened sides, the patches without cork smooth and of a light brown color, the portions with cork longitudinally or reticulately wrinkled and grayish-brown; fracture short or short-fibrous, internally lemon-yellow or dark bluish with yellowish oil-secretion cells and light yellow to reddish-brown resin cells; odor strongly aromatic; taste intensely pungent.

"Calcutta Ginger."—Rhizomes resembling the African Ginger, the branches or 'fingers' being somewhat larger, and with a considerable proportion of shrunken pieces, externally grayish-brown or grayish-blue; fracture short and mealy, or homy; internally light yellow or light brownish-yellow with numerous yellowish oil cells and yellowish-brown resin cells; odor aromatic; taste starchy and strongly pungent.

"Calicut Ginger."—Rhizomes resembling African Ginger, more of the periderm being usually removed; externally more or less uniformly light brown; fracture short or short-fibrous, and mealy; internally light-yellow or brownish-yellow with numerous yellowish oil and resin cells;
odor. aromatic; taste very pungent.

"Cochin Ginger."—Rhizomes with most of the corky layer removed on the flattened sides; externally light brown to grayish-yellow, fracture short and mealy; internally yellowish-white with numerous yellowish oil cells and brownish-red or blackish resin cells; odor aromatic; taste pungent but not so persistent as in the African variety.

"Japanese Ginger."—Rhizome somewhat resembling Cochin Ginger but usually with a thin coating of lime; externally nearly smooth or slightly wrinkled and of a whitish color; fracture short and very mealy; internally varying from a yellowish-white to light brown and with numerous brownish-red resin cells; odor aromatic; taste pungent.

"Powdered Ginger is light yellow, or light brown to dark brown; under the microscope it exhibits numerous starch grains varying greatly in form and size in the different varieties, being nearly spherical, ovoid, ellipsoidal or pear-shaped and frequently with a characteristic beak, usually -from 0.005 to 0.04 mm., occasionally from 0.045 to 0.06 mm. in the long diameter; sclerenchymatous fibers long, thin-walled, non-lignified, with oblique pores and distinctly undulate on one side; oil-secretion cells with suberized walls and containing a light yellowish or yellowish-brown, oily substance; cork cells absent in the Jamaica variety. Introduce 4 Gm. of ground Ginger into a 200 mil flask, fill to the mark with distilled water, and agitate at half-hour intervals during eight hours. Then allow the mixture to stand for sixteen hours, and filter. Evaporate 50 mils of the filtrate, representing 1 Gm. of the drug, on a water bath, dry to constant weight at 100° C. (212° F.) and weigh; it yields not less than 8 per cent. of residue. Ginger yields not less than 2 per cent. of a nonvolatile extract soluble in ether and not less than 4 per cent. of an extract soluble in alcohol. Ginger yields not more than 8 per cent. of ash." U.S.

"In flattish, irregularly branched pieces, usually from, seven to ten centimetres long; each branch marked at its summit by a depressed scar. Fracture short with projecting fibres. Agreeable, aromatic odor; taste pungent. When 5 grammes of powdered Ginger are shaken with 100 millilitres of alcohol (90 per cent.) occasionally during twenty-four hours and filtered, 20 millilitres of the filtrate yield on evaporation not less than 0.050 gramme of residue dried at 100° C. (212° F.) and weigh; and when 5 grammes are similarly treated with 100 millilitres of water, 20 millilitres
of the filtrate yield not less than 0.085 gramme of residue dried at 100° C. (212° F.). Ash not more than 6 per cent.; and after deduction of that portion of the ash which is soluble in water not more than 1.5 per cent." Br.

The odor of ginger is aromatic and penetrating, the taste spicy, pungent, hot, and biting. These properties gradually diminish, and are ultimately lost, by exposure. The morphology and pharmacognosy of ginger have been studied by Meyer (Wissenschaftliche Drogenkunde, vol. ii, p. 64) and Tschirch and Oesterle (Anatomischer Atlas., Lief. vi, p. 109). Kraemer and Sindall have published an article on the "Microscopical and Chemical Examination of the Different Varieties of Commercial Ginger" (A. J. P., 1908, p. 303). Spaeth reports on the adulteration and detection of adulterants of ginger and asserts that the more common adulterants are flour, curcurma, linseed and rapeseed cake, cayenne pepper hulls, and extracted ginger. (Zeitschr. f. Unters. d. Nahr. u. Genussm., x, p. 23.)

The use of capsicum in preparations of ginger is not infrequent. When present, it may be detected by the method described under tincture of ginger.

The virtues of ginger are extracted by alcohol. The peculiar flavor of the root appears to depend on the volatile oil, its pungency partly on the resinous or resino-extractive principle. A considerable quantity of pure white starch may be obtained from it. The volatile oil, examined by A. Papousck, was yellow, of the odor of ginger, and of a hot aromatic taste. Its sp. gr. was 0.893, and its boiling point 246.1° C. (475° F.). Deprived of water by distillation over phosphoric oxide, it consisted of carbon and hydrogen, with the formula CloHie, and therefore belongs to the terpenes. Tresh considers that the essential oil is mainly made up of a hydrocarbon, C_{15}H_{24}, or isomers of it, which boil at from 245° to 270° C. (473°-518° F.). (P. J., No. 586, 1881.) Schimmel & Co. (April, 1897) state that the essential oil contains camphene and phellandrene, and hence the terpenes have the formula C_{10}H_{16}, as first stated. Fluckiger obtained from one hundred and twelve pounds of Jamaica ginger four and a half ounces of the oil, or about one-fourth of one per cent. He states, however, that Schimmel & Co., of Leipsie, informed him that they obtained as much as 2.2 per cent. from good ginger. (Pharmacographia, 2d ed., p. 637.) H. von Soden and W. Rojahn (Ph. Ztg., 1900, 414) obtained a new sesquiterpene from oil of ginger by
fractioning the saponified oil. They have named it zingiberene. It has the sp. gr. 0.872 at 15° C. (59° F.). Those pieces of ginger which are very fibrous, light and friable, or worm eaten, should be rejected. The commercial powder of ginger is very frequently adulterated, rice starch, powdered ginger which has been exhausted in making preparations, and even brick dust and chalk, being used, and the loss of pungency made good by the addition of capsicum or mustard.

**Uses.**—Ginger is a grateful stimulant and carminative, and is often given in dyspepsia and flatulent colic. It is an excellent addition to bitter infusions and tonic powders, imparting to them an agreeable, warming, and cordial operation upon the stomach. It is especially valuable in alcoholic gastritis. In the serous type of diarrhea, when due to a relaxed condition of the bowel, it is a remedy of much service but should not be employed in the presence of inflammatory conditions. The hot infusion is popularly employed under the name of "Ginger Tea" for its diaphoretic effect in colds, especially when accompanied with suppression of the menses. Externally it is rubefacient. Under the name of "Essence of Ginger" cheap alcoholic preparations of ginger were formerly sold and used as intoxicants. A number of cases of blindness produced by such use have been recorded, the amblyopia having been due to the large use of methyl alcohol in the making of these "essences." The infusion may be prepared by adding half an ounce of the powdered or bruised root to a pint of boiling water, and may be given in the dose of one or two fluid-ounce's (30-60 mils).

Dose, ten to twenty grains (0.65-1.3 mils).

**Zizyphus.** Zizyphus sativa Gaertn. (Z. vulgaris Lamarck.) J ujube Fr. Brustbeeren, J undornbeeren, G.—A shrub, or small tree, of the Fam. Rhamnaceae growing on the shores of the Mediterranean, and cultivated in Italy, Spain, and the south of France.
The fruit is the part used. This consists of oval drupes, of the size of a large olive, with a thin, coriaceous, red or reddish-brown skin, a yellowish, sweet, acidulous pulp, and an oblong, pointed stone in the center. These have the name of jujuba. By drying, their pulp becomes softer and sweeter, and acquires a vinous taste, evincing the commencement of fermentation. They are nutritive and demulcent, and are used in the form of decoction in pectoral complaints. Jujube paste consists properly of gum arabic and sugar, dissolved in a decoction of this fruit and evaporated to the proper consistence. As a demulcent it is in no respect superior to a paste made with gum arabic and sugar alone, and the preparation formerly sold in this country under the name contains in fact none of the fruit. The fruits of two other species, Z. Lotus Lam., growing in the north of Africa, and Z. Jujuba, Lam., a native of the East Indies, possess properties similar to those of the Z. sativa and are used as food by the inhabitants of the countries where they grow. The Zizyphus Jujuba is stated by Bosisto (A. J. P., 1886) to be one of the main sources of stick-lac, from which shellac is manufactured.

**Zygadenus.** Death Comas.—One or more species of this liliaceous genus, found in the Western United States, are highly toxic to grazing animals, notably to sheep. H. S. Goodell affirms that he has seen violent convulsions produced by the juice of Z. venenosus Watson. Slade (A. J. P., 1905, p. 262) obtained an alkaloid from Z. venenosus, which resembled veratalbine. Heyl and others (J. A. C. S., 1911 and 1913) obtained an alkaloid from the leaves of Z. intermedius, zygadenine, which resembled veratrine.
