The Dispensatory of the United States of America
Twentieth Edition (1918)
Edited by Joseph P. Remington, Horatio C. Woods and others.

[This was the last era in pharmacy when plant drugs were widely prepared, both for Regular School, Eclectic and Irregular physicians, and the Dispensatories were the major reference works used by pharmacists to prepare these products. Official plant drugs and preparations are in larger case, unofficial plant drugs and preparations are in smaller case. I have extracted all plant drugs and preparations, excluded non botanicals and those most reasonably used only by physicians...Opium, Digitalis, etc. Michael Moore]

**Abroma.** Abroma angustum L. f. (Fam. Sterculiaceae)—Under the name of Olutkombul, the glutinous sap of this plant has long been used in India in dysmenorrhea. According to Sircar (Indian Medical Gazette, 1900) and other English practitioners, it is a very efficient remedy in congestive and neuralgic dysmenorrhea when given in doses of two drachms (7.7 Gm.) at the time of the first premonitory pains and continuing to the end. The fresh root is sometimes used. Dose, half a drachm (2 Gm.).

**Abras.** Abri Semina. Jequirity. Prayer Beads. Abrus Seeds. Abrus precatorius L. (Fam, Leguminosae.) —The seeds of this plant, which grows in India and also in Brazil, are employed in India as a standard weight by druggists and jewelers, and also for criminal poisoning. The seeds are ovoid, from 5 to 8 mm. in length, smooth, shiny and of a bright scarlet, having a black marking at the lower, or hilum, portion. They are said to be inert when taken whole into the stomach. They contain abric acid, C_{21}H_{24}N_{3}O, and, according to the researches of Sidney Martin (P. J., Sept., 1887; Proc. Roy. Soc., 1889, vol. xlvi), two proteid poisons, a paraglobulin and an albumose (together called abrin), which are almost identical in their physiological properties with principles found in snake venom, although less powerful. According to Flexner, the toxic action of these substances also closely resembles that of true toxins, the most characteristic result being focal necroses in various organs. Flexner suggests that these in turn are due to a lesion in the blood-vessel walls caused by the abrin. (J. Ex. M., 1897, vol. ii.) The ordinary lethal dose of abrin for animals is said to be 0.00001 Gm. per kilo of weight. (Consult The Non-Bacillous Nature of Abrus Poisoning, J. H. Warden and L. A. Waddel, Calcutta, 1884; Bufalini, Ann. di Chim. e di Farm., No. 2, 1886; Koberl, W. M. Bl., Nov., 1889.) The root of Abrus, known as Indian liquorice, possesses toxic properties like the seeds and should not be used in place of licorice. According to David Hooper, it contains glycyrrhizin. (P. J., 1894.) Abrin is used in the treatment of certain chronic diseases of the eye, especially in corneal opacities, and trachomatous pannus. It excites a purulent inflammation of the conjunctiva, which appears to lead to an increase in the local circulation, provoking thereby an absorption of inflammatory exudates. The remedy is capable of great harm in unsuitable cases, and extreme caution must be employed in its use. The infusion of jequirity, which was formerly employed for this purpose, has been almost abandoned because it was liable to cause an uncontrollable inflammation which in some instances has entirely destroyed vision. The infusion of the crude drug was employed...
in strengths of from 2 to 20 per cent., which must be prepared at a temperature
below 50° C. (112° F.). According to Ehrlich, the solution of abrin should not be
stronger than one part in 500,000; any increase of strength must be made with great
care. Both Ehrlich and Calmette succeeded in immunizing rabbits against abrin, and
obtained an antitoxic serum. P. Romer (Graefe's Archiv. f. Ophthal., vol. lit, 1901) has
introduced two preparations: jequiritol, an abrin solution, sterilized, of four different
strengths; jequiritol serum, which, as commercially supplied, has such immunizing
power that 0.1 mil suffices to protect a white mouse from the effects of a hundredfold
lethal dose of jequiritol when the latter and jequiritol serum are injected conjointly.
(For details and methods of use, see Th. M., May, 1902; M. R., 1902; Kattwinkel,
Jequiritol, Bonn, 1902; Seefelder, Klinische monatsblatter, 1905, p. 273; Schoen,
Hospitalstidende, No. 37, p. 921.)

Absinthium. N. F. IV. Wormwood.—It was official in the U. S. P. 1890 and is now
recognized by the National Formulary. The definition is as follows: "The dried leaves
and flowering tops of Artemisia Absinthium Linne (Fam. Compositae), without the
presence of more than 5 per cent. of foreign matter." N. F. IV. Several species of
Artemisia have enjoyed some reputation as medicines. The leaves of A. Abrotanum
L., or southernwood, are reported by Craveri to contain a crystallizable alkaloid,
abrotine, they were formerly employed as a tonic and anthelmintic. A. pontica, L. has
been substituted for common wormwood, but is weaker. A. vulgaris L., or mugwort,
has been used in Germany in epilepsy, chorea, and amenorrhea. A. ludoviciana Nutt.,
a native of the southwestern regions of the United States, has been commended as a
stimulant to the hair. (A. J. P., 1872, p. 106.) In China, moxa is prepared from A.
chinensis L. and A. indica, Willd.

Wormwood, also known as Madderwort, Wermuth, Mugwort,Mingwort and Warmot, is
a shrubby, more or less herbaceous, finely canescent plant, growing to a height of 2 to
4 feet. The leaves are 1 to 3 pinnately divided, the lobes being lanceolate or obovate,
the basal leaves being petio-late while the floral ones are linear and entire; the flowers
are all fertile, yellowish, and occur in hemispherical paniced heads. The plant is a
native of Europe and is to some extent cultivated in the United States. It is now
naturalized and rather common in eastern Canada to Pennsylvania, growing along
roadsides and waste places. It should be gathered in July or August, during flowering.

The N. F. description is as follows: "Stems and leaves gray-green, finely silky-hairy
and glandular throughout; largest leaves reaching 10 or 12 cm. in length, and of nearly
equal breadth, on long petioles, two to three times pinnately lobed or divided, the
ultimate segments oblong or obovate, obtuse, entire or slightly toothed; upper leaves
becoming shorter petioled, small and narrower, the uppermost being only about 2 cm.
in length and resembling the ultimate segments of the larger ones; heads racemose-
paniculate, drooping on short peduncles, greenish-yellow, from 3 to 4 mm. in breadth,
round-ovoid, the outer bracts linear-oblanceolate, obtuse, the inner broader and
scarious-margined; receptacle hairy; outer flowers sometimes pistillate. Odor
characteristic, aromatic; taste very bitter. The powdered drug is brownish to
yellowish-green and, when examined under the microscope, exhibits numerous,
characteristic, T-shaped, non-lignified hairs, consisting of a short, one- to four-celled
stalk bearing & single apical cell attached near the center and up to 0.8 mm. in length
and 0.035 mm. in width. Many of the hairs are more or less collapsed, twisted or broken; glandular hairs, some with one- or two-celled stalk, the glandular portions consisting of from four to eight secreting cells surrounded by a membrane; few simple hairs from the flowers, some of which are very long and up to 0.085 mm. in width; epidermal fragments with elliptical stomata, the latter up to 0.035 mm. in length; fragments of mesophyll and palisade cells containing chloroplastids; tracheae mostly spiral, up to 0.035 mm. in width; few sclerenchymatos fibers, with thick, usually lignified walls and simple pores, up to 0.02 mm. in width; pollen grains few, somewhat spherical or triangular in outline, up to 0.03 mm. in diameter; calcium oxalate crystals in rosette aggregates about 0.01 mm. in diameter. Absinthium yields not more than 10 per cent. of ash." N. F.

The volatile oil (oleum absinthii) is usually dark green, sometimes yellow or brownish or even blue, having a strong odor of the plant, an acrid peculiar taste, and the sp. gr. 0.925 to 0.950. It is sometimes adulterated with alcohol, oil of turpentine, etc., which lessen its specific gravity. It is composed of: thujone (absinthol), which has the specific gravity 0.926, composition C_{10}H_{16}O, boiling point 200° C. (392° F.) to 205° C. (401° F.), and when heated with phosphorus pentasulphide or zinc chloride yields cymene (C_{10}H_{14}); thujyl alcohol (C_{10}H_{18}O), both free and as the esters of acetic, isovaleric, and palmitic acids; phellandrene and possibly pinene; cadinene; and a blue oil of as yet undetermined composition. (Gildemeister and Hoffmann, AetherischeOele, 1899.) The absinthic acid found by Braconnot is said to be succinic acid. Caventou first obtained absinthin in an impure condition. (See U. S. D., 14th ed., p. 5.) P. Senger (A. Pharm., 230, p. 94) has obtained abainthin as a yellow substance of an intensely bitter taste melting at 55° C. (131° F.). He gives it the formula C_{15}H_{20}O and considers it to be a glucoside, as on boiling with diluted sulphuric acid it yields dextrose and absinthic acid. Kromayer gives the formula for absinthin as C_{40}H_{56}O_{8} + H_{2}O. Absinthin is soluble in water, alcohol, and ether and has been introduced into medicine for use in the treatment of constipation and chlorosis. Dose, one and one-half to three grains (0.1-0.2 Gm.). Adrian and Trillat isolated a new crystalline body (C_{53}H_{51}O_{20}) from wormwood by treating an alcoholic extract with amyl alcohol, the absinthin having been previously removed. They also isolated another crystalline principle, anabsinthin, C_{18}H_{24}O_{4} (P. J., 1899, 1, 75). The old salt of wormwood (sal absinthii) was impure potassium carbonate, made from the ashes of the plant.

Wormwood, which was formerly in vogue as a stomachic tonic, antiperiodic, and anthelmintic, is at present very seldom used. The volatile oil is an active narcotic poison. In dogs and rabbits from thirty to fifty drops (1.5-2.5 mils) of it will cause trembling, stuper, hebetude, and even insensibility; one to two fluidrachms (3.75-7.5 mils) of it causes violent epileptiform convulsions, with involuntary evacuations, unconsciousness, and stertorous breathing, which may or may not end in death. (Marce, B. G. T., Mai, 1864; Amory, B. M. S. J., March, 1868, p. 83.) In man the oil acts similarly; a half ounce (15 mils) of it caused, in a male adult, insensibility, convulsions, foaming at the mouth, and a tendency to vomit; though the patient recovered under the use of emetics, with stimulants and demulcents. (L. L., Dec. 6, 1862.) According to J. L. Corning, the volatile oil is a powerful local anesthetic, locally useful in rheumatic pains. Bohm and Kobert affirm that the oil escapes through the
kidneys unchanged. Dose, of wormwood in substance, from twenty to forty grains (1.3-2.6 Gm.); of the infusion (one ounce in a pint of boiling water), from one to two fluidounces (30-60 mils); of the oil, one to two minims (0.06-0.12 mil).

Absinthe is a liqueur containing oils of wormwood, angelica, anise, and marjoram. According to Baudrimont, the absinthe ordinaire contains 47.66 per cent. of alcohol, the demi-fine 50 per cent., the fine 68 per cent., and the absinthe Suisse 80.66 per cent. The preparation, if manipulated properly, possesses naturally a bright green color, brought to an olive-green by slight addition of caramel coloring; but artificial coloring was formerly often resorted to, and indigo, turmeric, cupric acetate, and aniline green have been used to produce the proper shade. The importation of absinthe liqueur into the United States is now prohibited by law. Absinthism differs from ordinary alcoholism in its manifestations; its characteristic symptoms are restlessness at night, with disturbing dreams, nausea and vomiting in the morning, with great trembling of the hands and tongue, vertigo, and a tendency to epileptiform convulsions.

**ACACIA. U. S. (Br.) ACACIA Acac. [Gum Arabic]**

"The dried gummy exudation of Acacia Senegal Willdenow, and of other African species of Acacia (Fam. Leguminosae)." U. S. "A. gummy exudation from the stem and branches of Acacia Senegal, Willd., and of other species of Acacia, Willd." Br.

**Acaciae Gummi**, Br.; Gummi Africanum; Gummi Mimosa; Gum Acacia; Galam Gum; 'Gomme Arabique Vraie, Fr.; Gummi Arabicum, P. G.; Arabisches Gummi, G.; Gomma Arabica, Gomma del Cordofan. It.; Goma Arabiga, Sp.: Samagh Arabee, Arab.

The name Acacia was employed by the ancient Greeks to designate the gum tree of Egypt, and has been appropriately applied to the genus in which that plant is included.

The most important of the gum-yielding Acacias is the official A. Senegal Willd. This is a small tree rarely exceeding a height of 6 m., with a grayish bark, the inner layers of which are strongly fibrous, bipinnate leaves, dense spikes of small yellow flowers longer than the leaves, and broad pods containing 5 or 6 seeds. It forms large forests in Western Africa, north of the river Senegal, and is abundant in Eastern Africa, Kordofan, and Southern Nubia. It is known by the natives of Senegambia as Verek and of Kordofan as Hashab.

Nearly all species of Acacia growing in Africa yield a gum. The commercial Somali gum, which is usually of fair quality, is yielded by A.
glaucophylla Steud. and A. abyssinica Hochst., shrubs growing in Abyssinia and the Somali country. The following species yield a gum having a brownish or reddish color (called Amrad Gums), and hence are less valuable, viz., A. arabica Willd., A. stenocarpa Hochst., A. Seyal Del. and A. Ehrenbergiana Hayne. Inferior gums are also yielded by the following: A. horrida Willd., which furnishes the so-called Cape gum and is distinguished by being very brittle and yielding a less adhesive mucilage. Talca or Sennarr gum is derived from A. Fistula Schweinf. This gum has a greenish tinge and yields a ropy mucilage. Australian gum has a reddish color, said to be due to the presence of tannin. This gum is also spoken of as Wattle gum or Australian gum, and is derived from the Golden Wattle (A. pycnantha Benth.), a shrub growing in New South Wales, Victoria and Southern Australia. For commercial history of the several varieties of gum arabic, see U. S. D., 19th edition, p. 2. For further information in regard to gum bearing trees of Northern Africa, see P. J., Aug., 1873; C. R. A. S., t. Ixxix, p. 1175; Toxicologie Africaine, vol. ii.

The bark and unripe fruit of the acacia contain both tannic and gallic acids. The dried juice of the pod was used by the ancient Greeks; and an extract is still sold in the bazaars of India under the name of Akakia. This extract is heavy, hard, of an agreeable odor, varying in color from greenish to dark-reddish, or, when seen in bulk, blackish. It has a sweet, astringent taste, and yields a mucilaginous infusion. A similar preparation, acacia nostras, has been prepared in Europe by expression and inspissation from the unripe fruit of Prunus spinosa, or wild plum tree.

The gum of the acacias exudes spontaneously from the bark, and hardens on exposure; but incisions are sometimes made in order to facilitate the exudation. The gum is said also to be found immediately under the bark, where it is sometimes collected in regular cavities. It is formed within the plant by metamorphosis of the cells of the inner bark. The tissues involved are chiefly those of the sieve and the cambiform cells. While to some extent it is a natural change, yet it is usually looked upon as being in part a pathological production, as gummosus develops more largely upon the wounding of the trees. The attack of the Acacia plants by various parasites is held by some to account for the enormous production of gums in these plants. The investigations of Smith tends to show that all vegetable gums are of bacterial origin and that the differences in the several gums are due to the differences in the nature
of the bacteria producing them. (Proc. Linn. Soc. N. S. Wales, 1904, p. 217;) For further discussion on the origin of acacia gum see Tschirch, "Handbuch der Pharmakognosie."

The trees are not tapped for gum until they are about six years old. The annual yield varies very greatly, being from 188 to 2856 Gm. in young trees and from 379 to 6754 Gm. in large trees. The average annual yield of gum from young trees is about 900 Gm. and from old trees over 2 kilos. (Edie, 4th Report of the Wellcome Tropical Research Laboratory.)

It is stated by Jackson that, in Morocco, the greatest product is obtained in the driest and hottest weather, and from the most sickly trees. An elevated temperature appears to be essential, for in cooler climates, though the tree may flourish, it yields no gum. It is probable that some species of acacia yield finer gum than others, but it is also certain that the same tree will often yield some gum of the finest quality in regular tears or globular masses, and some irregular shaped, dark colored fragments of inferior value. Thus, from the same tree it will exude frothy or thick, and clear or dark colored, and will assume, upon hardening, different shapes and sizes; so that the pieces, when collected, require to be assorted before being delivered into commerce. This sorting is usually done on its arrival in European ports and only the selected or picked gum corresponding to the U. S. P. description should be used.

**Commercial History and Varieties.**—There are two principal commercial varieties of gum arabic: 1. The Khordofan, Turkey or Arabian Gum and 2. The Senegal or West African Gum, both of these being derived from A. Senegal. The former of these has the finer commercial qualities, being nearly white or faint yellowish-white and yielding a more or less transparent viscid mucilage.

**KHORDOFAN, TURKEY, OR ARABIAN GUM.**—This variety was formerly the only kind designated as gum arabic and entered commerce almost exclusively through Egypt, being collected in Upper Egypt, Nubia, Khordofan, Darfur, and other regions of the Upper Nile, and carried to Alexandria, from whence it passed directly into the world’s commerce or entered the latter through Smyrna, Trieste, or some other Mediterranean entrepot. At one time the more or less colored varieties were known as gum gedda, while the white and fine drug was known as gum turic, names derived from Jiddah and Tor, Red Sea ports, through which the varieties were supposed to be respectively exported.
Three chief commercial varieties are recognized. (a) Hashabi or Khordofan gum, the finest of these varieties, was collected in the country westward of the White Nile; formerly it constituted the bulk of the superior gum arabic of commerce. (b) Sennari gum was an inferior variety, yielding a mucilage which turned sour more quickly than that produced by Khordofan gum. It was collected in a country eastward of the White Nile, and in the region of the Blue Nile. (c) Ghezzirah or Gezireh gum is obtained from Ghezzirah and neighboring countries and sent to Trieste. It has much of the same appearance as the official Khordofan gum.

Formerly, Khordofan gum was collected in all parts of the Soudan and Upper Egypt, and forwarded on the backs of camels to Assouan, at the head of the Nile navigation, often being many months en route. The closure of the Soudan by the Mahdi caused Egyptian gum almost to disappear from commerce, but the reopening of the region by the British government has resulted in large quantities of the gum being brought by rail to Assouan, whence after being sorted into three varieties it is put in palm-leaf sacks and sent down the Nile. The finest Egyptian gum consists of large roundish or smaller more or less irregular fragments, transparent but usually rendered opaque upon the surface by innumerable minute fissures. The inferior gum varies from yellow to dark-reddish as the quality deteriorates, and often contains impurities.

H. C. Wood found that the gum arabic comes into Assouan in sacks or mats which are simply piled in rectangular roofless spaces surrounded by walls about ten feet high, made of dry mud. He was informed by the traders that the gum is gathered during the months of January, February and March by collectors having vested rights in a certain portion of the forests. Long incisions are made vertically through the bark and the exuding gum allowed to harden, the trees not being injured by the process, the collections going on from year to year. Gedda gum, sometimes spoken of as an Egyptian gum, enters commerce through Geddah, or Jiddah, on the Arabian side of the Red Sea. It seems to be the same as Mecca or El Wisch or Aden gums, which are sometimes spoken of as Egyptian gums, but are probably produced in the triangular peninsula which forms the eastern extremity of Africa.

Suakin gum, Taica or Talha gum, from A. stenocarpa and A. Seyal, is exceedingly brittle, and usually semi-pulverulent. It is a mixture of nearly colorless and brownish gums, is exported at Alexandria, and is sometimes termed gum savakin.
SENEGAL OR WEST AFRICAN GUM.—This variety is sometimes incorrectly referred to as synonymous with the official gum. It is derived from A. Senegal and other species of Acacia growing in the Soudan and Senegal. It yields a good adhesive mucilage and is valuable for technical purposes. Some of the best qualities of Senegal gum are also adapted for certain pharmaceutical uses. There are a number of different commercial varieties named from their geographical sources. It was introduced into Europe by the Dutch. The French afterwards planted a colony on the western coast of Africa, and took possession of the trade. St. Louis, at the mouth of the Senegal, and Portendic, considerably farther north, are the ports in which the commerce in gum chiefly centers. Immense forests exist in the interior, containing many species of the genus Acacia, all of which are said to yield gum, as is affirmed do also various trees belonging to other genera. The chief harvest begins in October and ends in December, although gum is also collected in March. The dry winds, which prevail after the rainy season, cause the bark to crack; the juice flows out and hardens in masses, which are often as large as a pigeon's egg, and sometimes as that of an ostrich. It is affirmed that the exudation is also largely caused by a parasitic plant, Loranthus Acaciae Zucc., the gummy exudation freely oozing out at the point where the parasite penetrates the bark. (Ph. Centralh., Aug., 1895.) Senegal gum is usually in roundish or oval unbroken pieces, or in straight or curled cylindrical pieces of various sizes, in the finest grades whitish or colorless, but generally yellowish, reddish, or brownish red. The pieces are larger than those of Turkey gum, less brittle and puiverizable, and breaking with a more con-choidal fracture. In recent years the commercial supply of gum Senegal has been a variable one. In 1911 the gum was extremely scarce, there was practically none on the market, owing to a failure of the crop.

INDIA GUM.—Persian gum, which is said to be sent from Persia to Assouan to be packed as genuine gum arabic, can be distinguished from the latter, which it closely resembles, by its not dissolving in water. Sickenberger thinks that it is the product of Prunus bokharensis or of P. puddum. India gum is not produced in India, but reaches Bombay from Aden and the Red Sea ports, and is almost certainly the product of the Soudan, being therefore identical with Egyptian gum. It occurs in India in two forms, "Maklai," in large round tears or vermicular pieces, white, yellow or reddish, and much fissured; and "Maswai," in fragments and vermicular pieces similar in color and fissuring to the other variety. It is
often crudely adulterated before reaching Europe, especially with Bassora gum, distinguished by its insolubility in water. Of recent years various India gums have come into commerce in increasing quantities as substitutes for true gum arabic. India gum is brought to this country partly from Calcutta or Bombay, and partly by way of England. It usually comes in large cases. We have seen a parcel said to have come direct from the Red Sea, enclosed in large sacks made of a kind of matting, and bearing a close resemblance to the gum from Calcutta, except that it was more impure, and contained numerous large, irregular, very brittle masses, not much less than the fist in size. The term India gum should not be confused with India gum Tragacanth, which is called simply by the name India gum in the confectionary and ice cream trades where it is used as a filler and to give bulk and firmness; nor with Indian gum. (See Gummi Indicum.)

SUBSTITUTES FOR GUM ARABIC.—According to A. Mander, the East India gums appearing in the London market are:

Amrad, Amra or Oomra Gum.—A name applied to various East Indian gums having a reddish color and being in more or less irregular stalactitic pieces. (See U. S. D., 19th ed., p. 4.)

Ghatti Gum.—A pale gum consisting of rounded or vermiform pieces varying in size, clear internally, but dull and roughened on the surface, apparently caused by shrinkage in drying; from brownish-yellow to perfectly colorless and transparent. According to the Pharmacographia Indica, this gum is readily distinguished from all others by its dull white, roughened surface and glassy fracture free from cracks; it possesses about double the viscosity of gum arabic.

Ghatti gum is said to be obtained from Anogeissus latifolia Wallich in enormous quantities, to be much used in India, and to be exported from Bombay in the pure state.

Small quantities of gum are produced in India by a large number of trees often having no botanical relations with the Acacias. For an account of these gums see Pharmacographia Indica, vol. i.

Under the names of Brazilian gum, Para gum, and gum angico, large quantities of a gum occurring in large dark-amber or dark-brown glossy drops, soluble in water, are occasionally found in commerce. It is said to
be the product of Acacia angico. Its mucilage is very adhesive, but usually too dark in color for pharmaceutical purposes. It must be distinguished from the gum resin often known as Brazilian gum, which is said to be obtained from Hymenaea courbaril, and is used in making varnishes.

Chagual or Maguey gum of Chili occurs in hollow cylindrical pieces from 0.2 to 1.5 cm. in thickness, occasionally having the form of stalactites or irregular tubers. On their inner surface they are longitudinally streaked, while their outer surface is usually numerously fissured, the fissures penetrating deeply toward the interior. In the absence of these, the pieces are of glassy brightness, transparent, and of very dense structure internally. The color varies from colorless, through yellowish and brownish to a tolerably deep brown, isolated pieces being almost black. According to the experiments made by Guehm, the commercial drug is scarcely fitted for technical use as a gum, but the clear pieces when made into a concentrated mucilage by prolonged heating answer the purposes of the calico printer well. Puya chilensis, P. lanuginosa, and P. lanata are commonly said to be the sources of the gum, though the researches of Hartwich make this uncertain. The exudation is asserted to be the result of the bite of a caterpillar, Kastina elegans. (Zeit. Oest. Apoth. Ver., Aug. 1, 1896.)

Specimens of gum arabic are sometimes found in commerce, which are soluble in water with difficulty. According to Kochlin, if ten parts of such gum, fifty parts of water, and three parts of a 12 per cent. solution of hydrogen dioxide be heated together for two or three hours, the gum is rendered easily soluble. (Nat. Drug., 1894, 176.) Related to the acacia gums are wood gum, from the wood of foliage trees, yielding xylose on hydrolysis; cherry gum, the gum of cherry and almond trees, yielding β-arabinose on hydrolysis; peach gum, from the peach tree, yielding arabinose and galactose on hydrolysis; barley gum, obtained in the nitrogen-free extractive material of cereals, yielding galactose and xylose. Martina examined twenty-seven varieties of gum, and the composition of some of the principal ones is given in the table below.
Thos. Maben gives the following method of testing mucilage obtained from various gums sold for gum arabic as the best that he has been able to devise after much experimentation. Two or three drops of the mucilage prepared from the gum are placed on a glass or porcelain slab, and one or two drops of the following reagents added; these are then stirred together with a glass rod and the results compared. In the case of borax, acacia mucilage at once agglutinates or hardens into a gummy mass, similarly with basic lead acetate and ferric chloride, while it gelatinizes or forms a softer mass with potassium silicate. Similar reactions are given by the Senegal gums, the Indian Amrad gums, white Barbary, white and brown Cape, and Geddah gums. Barbary brown and Amrad give a jelly only with borax, otherwise they react as acacia. Australian gum agglutinates with borax, but only gelatinizes with basic lead acetate, and has no reaction with ferric chloride and potassium silicate. Brazilian gum has no reaction with potassium silicate, but gelatinizes with borax and ferric chloride and slightly with basic lead acetate. Ghatti gum gelatinizes with all four reagents, but in a slight degree only with potassium silicate. Oomra gum reacts similarly to acacia, except that it is entirely unaffected by basic lead acetate, and forms a softer jelly with ferric chloride. There are, of course, shades of difference in the various reactions which cannot be indicated by these terms, but, generally speaking, a fair idea is given of the nature of the gum. (P. J., March 1, 1890, 717.)

**General Properties.**—Gum arabic is "In ovoid, more or less spheroidal tears, or in broken, angular fragments from 2 to 30 mm. in diameter, varying from white or yellowish-white to light amber-colored; translucent; very brittle; fractured surface glass-like, sometimes iridescent; nearly inodorous; taste insipid, mucilaginous. Insoluble in alcohol; slowly and almost completely soluble in twice its weight of
water, forming a mucilaginous liquid, which has a slight, characteristic odor and is acid to litmus. When either 0.1 mil of basic lead acetate T.S., or 0.1 mil of a concentrated solution of sodium borate, or 0.1 mil of ferric chloride T.S. is added to 10 mils of a 10 per cent. aqueous solution of Acacia, a gelatinous precipitate is produced. The precipitate produced with ferric chloride T.S. is neither black nor brownish-black (tannin). The powder is whitish, with few or no starch grains or fragments of vegetable tissues. Not more than 1 per cent. of powdered Acacia is insoluble in water (plant tissues, sand, or dirt). Acacia yields not more than 4 per cent. of ash, and the powder contains not more than 15 per cent. of moisture." U. S.

"When dissolved in an equal weight of water, the solution is not glairy, and after admixture with more water, yields no gummy deposit on standing. An aqueous solution (1 in 10) exhibits slight laevorotation (absence of dextrin, certain sugars, etc.). 10 millilitres of the same solution are not precipitated by solution of lead acetate; are not, after previous boiling and cooling, colored blue or brown by 0.1 milli-litre of N/10 solution of iodine (absence of starch and dextrin), or bluish-black by T. Sol. of ferric chloride (absence of tannin). Ash not more than 4 per cent." Br.

The commercial gum arabic contains 17 per cent. of water and 3 per cent. of ash, consisting almost entirely of calcium, potassium and magnesium carbonates.

The gum dissolves slowly, at ordinary temperature, in twice its weight of water, forming a thick glutinous liquid of distinctly acid reaction. It is insoluble in alcohol, ether, and the oils. One hundred parts of 22 per cent. alcohol, by volume, dissolve 57 parts of gum, diluted alcohol containing 40 per cent. alcohol takes up 10 parts, and 50 per cent. alcohol only 4 parts (Fluckiger). On adding hydrochloric acid to the aqueous solution and precipitating with alcohol, a colorless amorphous substance is obtained. This is arabic acid. On hydrolysis, it yields galactose, arabinose, and a pentabiose named arabinon. The arabin (or arabic acid) may also be prepared by placing a solution of gum, acidulated with hydrochloric acid, on a dialyzer, when calcium chloride will diffuse out, leaving behind solution of arabin.

Arabic acid dried at 100° C. (212° F.) has the composition \( 2\text{C}_5\text{H}_{10}\text{O}_5 + \text{H}_2\text{O} \); the water separates when it unites with bases. It has a decided
tendency to form acid salts. Concentrated nitric acid forms with it nitro-
com-pounds; diluted nitric acid, on the other hand, gives rise to mucic
and saccharic acids, together with oxalic and a little tartaric acid.
Diluted sulphuric acid on prolonged boiling gives rise to arabinose, or
arabin sugar (pectinose, or pectin sugar), \( C_2H_{10}O_5 \), which reduces
alkaline copper solution and turns the plane of polarization 121° to the
right. Kiliani (Ber. d. Chem. Ges., 1887, 339) first established the
formula as given above, and it is now recognized as belonging to the
class of pentoses. They are not fermentable, and, on prolonged boiling
with diluted hydrochloric acid, lose the elements of water and yield fur-
furol, \( C_5H_4O_2 \). Neutral lead acetate does not precipitate an aqueous
solution of gum arabic, but the basic acetate forms, even in a very
diluted solution, a precipitate.

Prolonged heating of the dry gum causes it to change readily into
metarabic (metagummic) acid, which is identical with the cerasin found
in the beet and in cherry gum. Sulphuric acid will also change arabic
into metarabic acid. 25 Gm. pure gum arabic are covered with 50 mils
strong alcohol, 10 mils water, and 5 mils sulphuric acid, and allowed to
stand twenty-four hours. On pouring off the fluid, and washing the
residue with alcohol and with water, metarabic acid remains behind as
a voluminous mass, which dries to a white, tasteless, and odorless
powder of acid reaction. (Graeger, Jahresbericht der Chem., 1872, 781.)
The metapaetic acid which is prepared by Scheibler from the sugar beet
is identical with metarabic acid.

The principle separated by cold water from the soluble arabin proves to
be the same as metarabic (metagummic) acid prepared direct from the
pure gum arabic by heating, or by the action of sulphuric acid. It is also
identical with gum extracted from the sugar beet by Scheibler. In the
normal and sound beet this gum is insoluble in water, and merely swells
up like metarabic acid, while in altered beets there is found a portion
(arabin) soluble in water. (Scheibler, Ber. d. Chem. Ges., 1873, p. 612.)

The similarity of the reactions and composition of arabinose and
galactose (from sugar of milk by inversion) led Kiliani to assert the
identity of these two varieties of sugar, but later studies by himself,
Claesson, and Scheibler have shown that they are distinct. Thus,
galactose is fermentable, while arabinose is not; galaetose yields mucic
acid when oxidized with nitric acid, and dulcite when reduced with
sodium amalgam, while arabinose does not yield either ; the fusing
point of the crystallized galactose is given at 142° to 144° C. (287.6°-291.2° F.), while that of arabinose is 160° C. (320° F.); galactose yields with phenylhy-drazin a light yellow compound, fusing at 170° to 171° C. (338°-339.8° F.), while arabinose forms a brownish-yellow compound, fusing at 157° to 158° C. (314.6°-316.4° F.). (Scheibler, Ber. d. Chem. Ges., 17, 1731.) Arabinose is said to be obtainable only from those varieties of gum arabic that yield no mucic acid when treated with nitric acid. (Claesson, Ber. d. Chem. Ges., 14, 1271.)

Gum arabic undergoes no change by age, when kept in a dry place. Its concentrated aqueous solution remains for a considerable time unaltered, but ultimately becomes sour, from the production of acetic acid. The disposition to sour is increased by employing hot water in making the solution. The tendency of a weak solution to become moldy is said to be obviated by adding a few drops of sulphuric acid, and decanting from the calcium sulphate deposited. (A. J. P., 1872, 353.) Solution of gum arabic does not ferment upon the addition of yeast, saliva, or gastric juice; the addition of chalk and cheese, however, starts a fermentation which gives rise to lactic acid and alcohol, but not to mannite or glycerin. The addition of a solution of gum to an acidified albumin solution causes a precipitate, which disappears on further addition of gum, but the solution will then curdle and become flocculent on application of heat. Gum may be distinguished from dextrin by the following tests: 1. Gum contains no dextroglucose, which, however, is present in dextrin, and may be recognized by the copper test. (See Alkaline Cupric Tartrate Volumetric Solution, Part III.) 2. Gum contains a lime compound; hence its solution is rendered milky by oxalic acid, while a solution of dextrin remains almost clear. 3. Gum gives a slimy, yellow deposit when its solution is mixed with a neutral ferric salt.

J. Henry Schroeder examined twelve specimens of powdered acacia, and states that dextrin is not frequently used as an adulterant, and that if in using the alkaline cupric tar-trate test the heat be prolonged during twenty minutes, a well defined reduction was produced even when pure Senegal gum was used. (A. J. P., 1897, 195.) R. G. Shoults (A. J. P., 1900, 267) supplemented the conclusions of Schroeder and proposed to use the difference in rotatory power of acacia and dextrin as a test. He found a solution of pure acacia to have a laevorotatory power of -18°, while one of dextrin was dextro-rotatory varying to the extent of from +120° to +138°. This method of testing the presence of dextrin may be replaced by the simpler one with the microscope. (See also Kebler's
paper, Am. Drug., 1901, 343.) The following test is given in the Ph. Post, 1894, 563. Add 3 mils of a solution consisting of 15 drops of solution of ferric chloride, 15 drops of a saturated solution of potassium ferrocyanide, 5 drops of HCl (1-125), and 60 mils of water to a 20 per cent. solution of the gum. If the gum arabic is pure, it will remain a clear yellow for from eight to ten hours. If there is dextrin present, the color change's to blue.

The properties above enumerated belong to gum arabic generally. There are, however, varieties with differences which deserve notice.

1. Gum that is transparent and readily soluble. This constitutes by far the greater portion of the commercial varieties distinguished by the names of Turkey and Senegal gum. It is characterized by its transparency, ready solubility, and the comparatively slight degree of thickness and viscidity of its solution. Under this head may be included the gomme blanche fendillee of Guibourt. It is distinguished by the whiteness and deficient transparency of the pieces, attributable to the minute cracks or fissures with which they abound, and which render them very brittle and easily pulverizable. This peculiar structure is generally ascribed to the influence of solar heat and light, but is conjectured by Hayne to arise from the exudation of the juice in the frothy state noticed by Ehrenberg. Though the unbroken pieces are somewhat opaque, each minute fragment is perfectly transparent and homogeneous. This variety, in consequence of its prompt and entire solubility, is usually preferred for medicinal use and for most purposes in pharmacy.

2. Gum less transparent and less soluble. Guibourt has proposed for portions of this gum the name of gomme pelliculee, from the circumstance that the masses are always apparently covered, on some part of their surface, by a yellowish opaque pellicle. Other portions of it have a mammillary appearance on the surface. It is less transparent than the former variety, is less freely and completely dissolved by water, and forms a more viscid solution. It dissolves with difficulty in the mouth, and adheres tenaciously to the teeth. It is found in all the commercial varieties of gum, but least in that from Egypt. Its peculiarities have been ascribed to variable proportions of bassorin or cerasin associated with the soluble arabin. Between these two varieties there are insensible gradations, so that it is not always easy to classify specimens.
E. Bourquelot (J. P. C., 1904 [6], 19, 473, 474) states that acacia contains an active oxidizing ferment which renders it unsuitable for use in many pharmaceutical preparations, and that, notwithstanding the wide use of acacia as an excipient, it is possible that certain active ingredients may become altered in its presence. Nor is acacia the only gum which contains a ferment; myrrh, frankincense and bdellium also contain an oxydase. Among the substances stated as being incompatible with acacia are pyrogallol, morphine, vanillin, ordinary phenol, cresylol, ortho- and metaxylol, thymol, carvol, a- and b-naphthol, pyrocatechol, guaiacol, phenols, lysol, cresols, acetylguaiacol, veratrol, creosol, eugenol, acetyleneugenol, methylaniline, ethylaniline, paratoluidine, crude aniline, xylidine, a-naphthylamine, pyramidon apomorphine, eserine, adrenaline, isobarbaloin, caffeotannic acid, gallic acid and tannin. Paraxylenol, hydroquinone, resorcinol, anisol and phenetol do not appear to be affected. Nor is the action confined to chemical substances; acacia is incompatible with the opium and Calabar bean products, suprarenal extract, aloetic preparations, and all substances flavored with vanillin, tannin-containing extracts, such as those of rhatany, catechu, and rhubarb; fluidextract of viburnum prunifolium, and kola preparations. Obviously, in cases where mucilage of acacia is concerned, this oxidizing action may be eliminated by heating the liquid to 100° C. (212° P.), and thus destroying the ferment.

Impurities and Adulterations.—As gum arabic is usually collected in huge piles at Khartoum before being shipped to Port Soudan the sand and impurities are likely to sift to the bottom. As a consequence the first orders are likely to be filled with the cleaner article while the latter containing the siftings may run as high as 4 per cent. of ash. The inferior grades are often mixed with, or substituted for, the better kinds, especially in powder. Very occasionally flour or foreign starch is fraudulently added to the powder, but may be easily detected by the use of the microscope and the blue color which it produces with tincture of iodine. In consequence of the impurities and difference in quality, gum arabic should generally be garbled. In fact, it is surprising what a good effect the removal of 1 or 2 per cent. of objectionable matter has upon the remainder of the drug. It has been proposed to change the arabinitic acid of the sugar beet, by the method of Scheibler, into metarabinic acid, as the foundation of a true artificial gum arabic, but the artificial gums
of the market have no such close chemical relation with the natural gum; many of them are mixtures of various substances, others are produced from starch by the action of sulphuric acid or by other means. Universal gum, a patented product obtained from potato starch, has been highly commended for the permanency and adhesiveness of its mucilage, but is said not to act well as an emulsifier. A substitute has also been made from Irish moss. (See Chondrus.) Gelatin is sometimes added to acacia as an adulterant; formaldehyde has been recommended by Trillet (Ph. Post, 1899, 629) as an agent for its detection. (See also Proc. A. Ph. A., 1900, 643.)

Uses.—Acacia is used in medicine chiefly as a demulcent. Hence it is advantageously employed in catarrhal affections and irritation of the fauces, by being held in the mouth and allowed to dissolve slowly. It has been used as a food, but has very little if any nutritive value. In pharmacy, gum arabic is extensively used for the suspension of insoluble substances in water, and for the formation of pills and troches. Two kinds of powdered gum arabic are used, one a coarse powder called granulated, the other finely dusted. The granulated dissolves more readily in water, according to Hager, because it has lost during desiccation only two per cent. of moisture, while in preparing the "finely dusted" powder the high heat necessarily used to thoroughly dry it drives off ten per cent. of water. Its easy solubility and absence of tendency to form "lumps" cause the coarse powder to be preferred for solutions, emulsions, etc.

Acacia is incompatible with strongly alcoholic solutions, solutions of ferric chloride and lead subacetate, and strong solutions of sodium berate.

**ACACIAE CORTEX. Br. ACACIA BARK**

"Acacia Bark is the dried bark of Acacia arabica, Willd., and also the dried bark of Acacia decurrens, Willd.; obtained from wild or cultivated trees not less than seven years old, and, after being dried, kept for one year before use." Br.
Wattle Bark; Black Wattle; Babul Bark; Neb-neb.

The Acacias are known not only for their gums, but a number of them contain large quantities of tannin and hence are used in tanning. Among the latter are the so-called wattle barks of Australia, and also catechu. The chief of the Australian trees is the black wattle (A. decurrens), the bark of which yields from 24 to 42 per cent. of tannin, and is employed as an astringent. More recently A. arabica has been similarly used in East Africa.

**Characters.**—"Bark of A. arabica hard and woody, rusty brown, and tending to divide into several layers. Outer surface of the older pieces covered with thick blackish periderm, rugged, fissured longitudinally and transversely. Inner surface red, longitudinally striated and fibrous. Taste astringent and mucilaginous."

"Bark of A. decurrens usually in curved or channelled pieces, 1.5 to 3 mm. thick. External surface greyish-brown, darkening with age; often with irregular longitudinal ridges, and, sometimes, transverse cracks. Inner surface reddish-brown, longitudinally striated; fracture irregular and coarsely fibrous, freshly fractured surface pale. Slight tan-like odor; taste astringent."

Acacia bark owes its medicinal properties to the tannin it contains. It is used as an astringent in diarrheas, being usually employed in the form of a decoction (1:16), in doses of one-half to two fluidounces (15-60 mils).

**Acalypha.** Br. Add. 1900.—The fresh and the dried herb, Acalypha indica L. This euphorbiaceous plant is said to have expectorant and emetic properties similar to those of ipecac, and also to be employed by the native Indian practitioners in the form of the fresh leaves as a poultice for ulcers, and as a suppository for constipation in children. The Succus Acalyphae, Br. Add., 1900, is prepared by adding one volume of 90 per cent. alcohol to three volumes of the juice expressed from fresh leaves, with subsequent filtration. It is given in doses of from one to four fluidrachms (3.75-15 mils). The liquid extract (Extractum Acalyphae Liquidum, Br. Add., 1900), made with a menstruum of 90 per cent. alcohol, is given in doses of from five to thirty minims (0.3-1.8 mils).

**Achillea.** U. S. 1870.—The flowering tops of Achillea Millefolium L. Milfoil, or yarrow is a perennial herb, very common both in Europe and America. It is from a foot to eighteen inches in height, and is specifically distinguished by its doubly pinnate, downy, minutely divided leaves, with linear, dentate, mucronate divisions, from which
it derived the name of milfoil, by its furrowed stem and involucre, and by its dense
corymbs of whitish flowers, which appear throughout the summer, from June to
September. The whole herb has medicinal properties. Achillea nobilis, L., and A.
moschata Jacq., or Iva of Europe, are sometimes used as substitutes for A.
Millefolium.

Both the flowers and leaves of A. Millefolium have an agreeable, though feeble,
aromatic odor, which continues after drying, and a bitterish, astringent, pungent
taste. The aromatic properties are strongest in the flowers, the astringency in the
leaves. The plant contains a blue volatile oil, tannin, and a peculiar principle,
achillein, which was discovered by Zanon. (Ann. Ch. Ph., lviii, 21.) As analyzed by von
Planta (Ann. Ch. Ph., civ, 1870) its formula is C_{20}H_{38}N_{2}O_{15}. It occurs in a
brownish-red mass of a strongly bitter taste, soluble in water, more feebly in alcohol,
and not at all in ether. Achilleic acid, also discovered by Zanon, is affirmed by
Hlasiwetz to be identical withaconitic acid. The oil, which may be obtained separately
by distillation with water, has a beautiful azure-blue color, and the peculiar flavor of
milfoil. Schimmel & Co. (Ber. d. Chem. Ges., 1894, p. 50) found its most important
constituent to be cineol, C_{10}H_{18}O. The high boiling blue portion is probably identical
with the assulein of chamomile oil. Ivain, C_{24}H_{42}O_{5}, has also been isolated; it occurs
as a dark-yellow resinous mass, insoluble in water, readily soluble in alcohol, and
producing an intensely bitter solution.

The active principles of the drug are extracted both by water and alcohol. Milfoil is a
mild aromatic sudorific tonic and astringent. Pappi states that achillein given in
divided doses up to from thirty to seventy-five grains (2-5 Gm.) causes marked
irregularity of the pulse. The infusion is sometimes used in acute suppression of the
menses. The dose of achillea is thirty to sixty grains (1.9-3.9 Gm.); the volatile oil has
been used in doses of ten to fifteen minims (0.6-1.0 mil).

**Acocanthera.**—The Wa Nyika, the Wa Gyriama, and the Wa Kamba tribes of
Eastern Africa, and the natives of Obok on the Gulf of Aden, prepare vegetable arrow
poisons probably from different species of plants, although the names wabayo and
ouabaw seem to have been used as synonyms by missionaries and others sending the
extract to Europe.

The botanical sources of these arrow poisons are uncertain. It is certain that several
species of the apocynaceous genus Acocanthera are used for arrow poisons by the
natives of Africa. Of the four principal species, A. schimperi B. and H. is found
abundantly in the highlands of Abyssinia and throughout a great portion of Eastern
Africa; A. deflersii Schwf., which resembles the last-named. species closely, but,
according to Schweinfurth, differs in that its flowers are larger, sweet-smelling and
pure white, has been found in the neighborhood of Yemen; A. ouabaio Arnaud is a
native of Somaliland, and A. venenata Don, of South Africa. For details, see A. de S.,
cvii, p. 1162; abs. in J. P. C., 1889, p. 245. From Acocanthera abyssinica is prepared
Shashi-poison of German Eastern Africa.
In 1882 Arnaud obtained from an unidentified species of the genus Acocanthera (which he named provisionally A. Ouabaio), a crystalline glucoside, and in 1893 Lewin separated from the Acocanthera Deflersii an amorphous glucoside.

Owing to the imperfect identification of the plants from which the principles have been obtained, there has been much confusion in the names which have been applied to the principles which various investigators have separated from these arrow poisons. According to Lewin (B. K. W., 1906, p. 1583), there are two glucosides found in the various species of acocanthera, one of which is crystalline, and the other amorphous. The amorphous substance, or, as it is generally known, amorphous ouabain, corresponds to the abyssinin of Briege (A. I. P. T., 1903), and the carissin prepared by Bancroft from the Carissa ovata R. Br. (Fam. Apocynaceae), an Australian plant. The acocantherin of Frazer he regards as identical with the crystalline ouabain of Arnaud, and probably is isomeric with the amorphous variety. It is generally conceded that the crystalline ouabain is chemically identical with the glucoside discovered by Thoms in the Strophanthus gratus (see page 1068). Its action seems to be precisely the same as that of strophanthus. Ouabain was apparently first employed clinically by Stadelmann (B. K. W., 1906, vol. xliii, p. 1586), and has more recently been used by others with more or less success in the treatment of various forms of cardiac weakness. Stadelmann used an amorphous glucoside prepared by Merck from the wood of the Acocanthera Schimperi, in doses of from one three-hundredth to one two-hundredth of a grain (0.0002-0.0003 Gm.) three times a day.

ACONITUM. U. S. (Br.)

ACONITE Aconit. [Monkshood Aconite Root Aconiti tuber P. I.]

"The dried tuberous roots of Aconitum Napellus Linne (Fam. Ranunculaceæ), without the presence or admixture of more than 5 per cent. of stems or other foreign matter, and yielding not less than 0.5 per cent. of the ether-soluble alkaloids of Aconite. If made into a fluidextract and assayed biologically the minimum lethal dose should not be greater than 0.00004 mil for each gramme of body weight of guinea-pig." U. S. "Aconite Root is the dried root of Aconitum Napellus, Linn." Br.

The name Aconite is derived, according to Pliny, from the Black Sea port, Acone. While the drug was used by the ancient Chinese as well as
by the hill tribes of India, it was introduced into modern medicine by Storck, of Vienna, in 1763. The genus Aconitum is a relatively large one, there being some sixty well-defined species, nearly half of which have been used in medicine. The species which is official and recognized by nearly all the Pharmacopoeias is Aconitum Napellus. It is indigenous to the mountainous regions of Middle Europe and is found growing in Northern Europe, Siberia and Central Asia. It is extensively cultivated in temperate climates for its foliage and flowers and has been successfully grown in the testing garden of the U. S. Department of Agriculture. Schneider reports that it has become naturalized to some extent in California. There are five species of Aconitum which are indigenous to the mountainous regions of the Northern United States, two of these being found in the Rocky Mountains and on the Pacific Coast. Holm describes the morphology and structural characteristics of the wild Monkshood of the United States, A. uncinatum L., in Merck's Rep., 1907, p. 65.

The roots or rhizomes of several other species of Aconitum are found in commerce, these being chiefly used in the manufacture of the alkaloids.

(1) The tuberous roots of A. variegatum L. and of A. Stoerkianum Reich, are sometimes found in the commercial drug. These are smaller, not so pungent, although quite active.

(2) Japanese Aconite is derived from A. Fischeri Reich and A. japonicum Thumberg. The roots are light gray in color, fleshy, being smaller than the official tubers. They have a circular cambium and the starch grains are more than 0.015 mm. in diameter. They are largely imported into Europe and to some extent to this country.

(3) Indian Aconite is derived from A. ferox Wall., a plant growing in the Himalayas and in Nepal. The roots are from 5 to 10 cm. long and from 2 to 4 cm. in diameter, being externally grayish-brown and deeply furrowed. They are hard, the fracture being either horny or mealy and the inner surface is either yellowish-brown or whitish. The cambium is 7- to 9-rayed and the taste resembles that of the official Aconite.

(4) Another species of Aconitum that is very poisonous is A. Lycoctonum L., of Europe and Northern Asia. This, however, does not produce a tuberous root, but develops an oblique rhizome surrounded with numerous roots.
5) The fleshy roots of \textit{A. heterophyllum} Wallich., a plant growing in the West Himalayas, are somewhat ovoid and flattened at the summit and base. Externally they are grayish-brown. The odor resembles that of black pepper and the taste is bitter and acrid. The rhizome contains an amorphous bitter alkaloid, \textit{atisine}, which is not toxic. Under the name of Utees, Atees, or Atis, the rhizome and roots of \textit{A. heterophyllum} are said to be largely employed in doses of 20 grains as an antiperiodic. Wakhma is the root of \textit{A. palmatum} Don, in which Jowett found aconitic acid and the alkaloid \textit{atisine}, \(C_{22}H_{33}NO_3\), which, according to Cash, is physiologically very feeble. (\textit{J. Chem. S.}, 1896.)

\textit{Aconitum Napellus} is a perennial herbaceous plant, with a conical-shaped, tapering root, seldom exceeding 10 cm. in length and 2 cm. in thickness near the summit, brownish externally, whitish and fleshy within, and sending forth numerous long, thick, fleshy rootlets. When the plant is in full growth, there are usually two roots joined together, of which the older is dark brown and supports the stem, while the younger is of a light yellowish-brown, and is destined to furnish the stem of the following year, the old root decaying. The stem is erect, round, smooth, leafy, usually simple, and from two to six or even eight feet high. The leaves are alternate, petiolate, divided almost to the base, from two to four inches in diameter, deep green upon their upper surface, light green beneath, somewhat rigid, and more or less smooth and shining on both sides. Those on the lower part of the stem have long footstalks and five or seven divisions; the upper, short footstalks and three or five divisionis. The divisions are wedge-form, with two or three lobes, which extend nearly or quite to the middle. The lobes are cleft or toothed, and the lacinise or teeth are linear or linear-lanceolate and pointed. The flowers are of a dark violet-blue color, large and beautiful, and are borne at the summit of the stem upon a thick, simple, straight, erect, spike-like raceme, beneath which, in the cultivated plant, several smaller racemes arise from the axils of the upper leaves. Though without calyx, they have two small calycinal stipules, situated on the peduncle within a few millimeters of the flower. The petals are five, the upper helmet-shaped and beaked, nearly hemispherical, open or closed, the two lateral roundish and internally hairy, the two lower oblong-oval. They enclose two pediceled nectaries, of which the spur is capitate, and the lip bifid and revolute. The fruit consists of three, four, or five follicles. The seeds are wrinkled or scaly and very acrid.
The plant is abundant in the mountain forests of France, Switzerland, and Germany. It is also cultivated in the gardens of Europe, and has been introduced into this country as an ornamental flower. All parts of the plant are acrid and poisonous. The leaves and root are used. The leaves should be collected when the flowers begin to appear, or shortly before. After the fruit has formed, they are less efficacious. The fresh leaves have a faint narcotic odor, most sensible when they are rubbed. Their taste is at first bitterish and herbaceous, afterwards burning and acrid, with a feeling of numbness and tingling on the inside of the lips, tongue, and fauces, which is very durable, lasting sometimes many hours. When long chewed, they inflame the tongue. The dried leaves have a similar taste, but the acrid impression commences later. Their sensible properties and medicinal activity are impaired by long keeping. They should be of a green color, and free from mustiness. The root is much more active than the leaves, and an extract from the latter is said to have only one-twentieth of the strength of one made from the former. It should be gathered in autumn or winter after the leaves have fallen, and is not perfect until the second year. It has been mistakenly substituted for horseradish root, as a condiment, with fatal effect. The wild plant is said to be more active than the cultivated. (Schroff.) Procter found the roots of the plant cultivated in this country richer in active alkaloidal principles than the imported roots, having obtained as much as 0.85 per cent. from the former. (Proc. A. Ph. A., 1860.) The studies of P. W. Squire seem to show that in the autumn the root is the most active. So far, however, as concerns the whole plant, the practical difficulty is that the root of *A. paniculatum* Lam. cannot be distinguished from that of *A. Napellus*, except by taste; so that the custom which seems to prevail of gathering the root about the flowering period is probably well founded. The plant is being cultivated to some extent for medicinal purposes in England, but much of the stock is of doubtful nature, owing to the extraordinary tendency of *A. Napellus* to hybridize with other species and to alter under cultivation. (See P. J., 1889, 645.) For Kelleris test for aconite root and leaves, see Proc. A. Ph. A., 1895, 539.

Aconite root is generally brought into market in packages or bales, either from the continent of Europe or from India. It is of variable quality, some parcels being unobjectionable, while others contain a considerable proportion of inert or defective roots. Among these roots that of *Imperatoria Peucedanum Ostruthium* has been especially observed. (P. J., vii, 749.) The best test is the taste; roots should be
rejected which have not in a fair degree the characteristic properties in this respect described below, especially the production of the sensation of numbness and tingling on the tongue, lips, and fauces. One shipment of aconite consisted entirely of Japanese aconite. The powdered drug is sometimes adulterated with the endo-carp of the olive or so-called “olive pits.” The latter is not easily detected, as aconite contains a large number of stone cells. The latter, however, have relatively thin walls and the various forms have been described by Stingel in A. J. P., 1913, p. 391.

Nepaul aconite, known in India as "Bikh" or "Bish" aconite, is supposed to be derived from A. spicatum or A. laciniatum. There is a question about this as the Nepaul aconite of European commerce yields the alkaloid pseudo-conitine and this principle is only present in the roots of A. deinorrhizum and A. Balfourii. (Bulletin of the Imperial Institute, 1906, p. 32.) Nepaul aconite is composed of elongated fusiform or nearly cylindrical roots which are more or less flattened, longitudinally furrowed and from 7.5 to 10 cm. in length.

Properties.—The German Pharmacopoeia restricts aconite to the bud-crowned tubers of wild growing plants. Most of the other Pharmacopoeias permit the use of stem-crowned roots. In the former case the daughter tubers terminated by their buds are employed, whereas in the latter the older tubers which have developed foliage and flower stems are used. The commercial drug shows considerable variation and is usually a mixture of six or seven different kinds of tubers, as follows:

1. Single fleshy tubers which are smooth, light brown and full of starch.

2. Single tubers which are single, somewhat elongated fusiform, crowned with short stems, dark brown and longitudinally furrowed.

3. Twin tubers, one of which is bud-crowned and the other having a short stem at the summit.

4. Very small single tubers usually crowned with stems, the lower portion being acute or pointed.

5. Single tubers which are almost cylindrical, crowned with stems and either fleshy and nearly smooth or more or less shrunken and furrowed.
6. Dark brown resinous tubers.

7. And finally fragments of small and nearly filiform roots.

The root has a feeble earthy odor. Though sweetish at first, it has afterwards the same effect as the leaves upon the mouth and fauces. It shrinks much in drying, and becomes darker, but does not lose its acridity. Aconite root is officially described as being "more or less conical or fusiform, from 4 to 10 cm. in length and from 1 to 2 cm. in diameter at the crown; externally dark brown or grayish-brown, smooth or longitudinally wrinkled, the upper end with a bud, remains of bud-scales or stem-scarś, the other portions with numerous root-scars or short rootlets; fracture short, homy or somewhat mealy; internally, bark light or dark brown, 1 to 2 mm. in thickness, cambium zone usu"ally 5- to 8-angled, with a small fibrovascular bundle in each angle, pith whitish or light brown, from 2 to 7 mm. in diameter; odor very slight; taste sweetish, soon becoming acrid and developing a tingling sensation, followed by numbness. Under the microscope transverse sections, made near the middle of the tuberous root of Aconite, show an outer layer consisting of one or more rows of cells with blackish-brown walls; a primary cortex of 8 to 15 rows of parenchymatous cells and interspersed with characteristic stone cells, which occur either singly or in small groups; a more or less modified endodermis; a secondary cortex, consisting chiefly of starch-bearing parenchyma and interspersed with a few small fibrovascular bundles; a more or less star-shaped and characteristic cambium with from 5 to 12 collateral fibro-vascular bundles; and a pith composed of large, starch-bearing parenchyma cells. The powder is grayish-brown; starch grains numerous, spherical, somewhat plano-convex, single or 2- to 5-com-pound, the individual grains from 0.003 to 0.015 mm. in diameter and frequently with a central cleft; trachea? mostly with slit-like, simple pores, sometimes with spiral or reticulate thickenings or with bordered pores; stone cells single, tabular, irregular in shape or elongated to fibers, from 0.1 to 0.4 mm. in length, walls from 0.008 to 0.025 mm. in thickness, strongly lignified and having large, simple pores; fragments of cork few, yellowish-brown; fragments of parenchyma numerous, the cells being filled with starch grains; bast-fibers from stems few, very long, with lignified walls about 0.005 mm. in thickness, and marked by transverse or oblique, slit-like pores. Aconite yields not more than 6 per cent. of ash." U. S.
The following standards for aconite root are given in the British Pharmacopoeia: "From four to ten centimetres long, and from one to two centimetres wide at the upper extremity. Conical, dark brown, with numerous root scars, and crowned with base of the stem or the remains of a bud. Internally solid and starchy. In transverse section a stellate cambium with small vascular bundles at the projecting angles; primary cortex narrow, with isolated thick-walled sclerenchymatous cells; cells of parenchymatous tissue contain numerous small simple or compound starch grains. No marked odor; taste at first slight, followed by persistent sensation of tingling and numbness." Br.

The British Pharmacopoeia formerly recognized the flowering tops of the Aconite (Aconiti Folia). To be effective they should be collected just as the flowers are beginning to expand, at which time they are richest in alkaloid. The dried leaves are stated to contain about 0.3 per cent. and the flower-buds about 0.4 per cent. of aconitine. In the absence of any reliable chemical tests for aconitine E. R. Squibb suggested that a fluidrachm of a highly diluted solution of the various preparations be taken into the anterior part of the mouth (after the latter has been thoroughly rinsed) and held there for one minute exactly, and then discharged. The peculiar numbing sensation should be experienced within fifteen minutes, and it should continue for fifteen or thirty minutes. Tested in this way, he found the commercial aconitines, in solution of the strength of 1/900 grain in 1 fluidrachm of water, to have the following relative strengths; 1 grain of good powdered aconite root is equal to 1 grain of ordinary commercial aconitine, 1/8 grain of Merck's ordinary aconitine, 1/29 grain of Merck's pseudoaconitine, 1/111 grain of Duquesne's crystallized aconitine (really aconitine nitrate). He also found by this approximate method that 1 grain of powdered aconite root was equivalent to 1.5 minims of Fleming's tincture, 9 grains of powdered aconite leaf, 1.5 grains of alcoholic extract of dried aconite leaf, 1 grain of Alien's English extract of fresh plant, and 72 minims of tincture of aconite leaf. For methods of assaying aconite, reader is referred to A. B. L. Dohme's paper (Proc. A. Ph. A., 1895, 206); also P. J., 1895, 860; D. C., 1900, 69, 132.

Assay. — The quality of aconite root is officially determined by an assay as follows: "Proceed as directed under Belladonna Radix, using 15 Gm. of Aconite in No. 40 powder and ether only as the immiscible solvent throughout the assay. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 64.539 milligrammes of ether-soluble alkaloids.
of Aconite." U.S.

"Yields not less than 0.40 per cent. of ether-soluble alkaloids when assayed by the following process: Into a small stoppered glass percolator, provided with a glass tap and suitably plugged with cotton wool, introduce 10 grammes of Aconite Root in No. 40 powder and 75 millilitres of alcohol (70 per cent.). Macerate for four hours, shaking occasionally. Then allow percolation to proceed slowly until the liquid ceases to drop. Continue the percolation by the addition of more of the same menstruum until 150 millilitres have been collected or the Root is exhausted. Evaporate the percolate to dryness in a shallow porcelain evaporating basin, at a temperature not exceeding 60° C. (140° F.). Dissolve the residue in 5 millilitres of N/10 solution of sulphuric acid diluted with 20 millilitres of water. Filter into a separating funnel, washing the dish and filter with about 30 millilitres of water. Add to the mixed filtrate and washings 25 millilitres of ether and 2 millilitres of solution of ammonia, and shake for one minute. After separation draw off the lower layer into a flask, and filter the ethereal solution into a beaker. Return the contents of the flask to the separator, add 20 millilitres of ether and again shake for one minute, separating the aqueous liquid and filtering the ethereal solution into the beaker. Repeat the operation with two other portions, each of 20 millilitres, of ether. Evaporate the mixed ethereal solutions to dryness, dry the residue at 60° C. (140° F.), dissolve it in 5 millilitres of N/20 solution of sulphuric acid diluted with 20 millilitres of water, and titrate back with N/20 solution of sodium hydroxide, tincture of cochineal being used as indicator. Deduct the number of millilitres of the alkaline solution required from 5, multiply the difference by 0.3217; the result will be the percentage of ether-soluble alkaloids in the powdered Root." Br.

**Biologic Assay.**—Because of the great variation in the activity of the various alkaloids of aconite a chemical assay does not offer an accurate criterion of the activity of a sample of this drug", and the Pharmacopoeia has very properly, therefore, permitted a standard of toxicity. As the different alkaloids resemble each other very closely in the type of their effect varying only in degree, it is not necessary to standardize the drug for any one physiological effect, and, as the sharpest physiological end reaction is death, the best test for the activity of a specimen of aconite is determination of its lethal dose. The test recommended by the Revision Committee for aconite is based upon the determination of the minimum lethal dose for guinea-pigs.
"The guinea-pigs to be utilized should be of average size and not too large; preferably from 250 to 350 Gm. in weight and in healthy condition. The drug may be administered in the form of fluidextract, extract, or tincture, which in the preliminary trial may be injected subcutaneously into a series of guinea-pigs in doses having sufficiently wide limits. If the extract is to be standardized, it must be dissolved in sufficient solvent to produce a liquid preparation before injection. The animals after injection are placed in cages and at the end of the observation (twelve hours), note is taken of those living and dead. After this preliminary test, the limits of the doses for a second series of animals are further narrowed and, if necessary to still further confirm the earlier results, additional series may be injected until the minimum lethal dose for the guinea-pig is found.

"Standard.—A satisfactory preparation of the Fluidextract of Aconite should kill guinea-pigs when administered in doses of 0.00004 mil for each gramme of body weight of guinea-pig; a satisfactory Tincture of Aconite should prove fatal to guinea-pigs when given in doses of 0.0004 mil for each gramme of body weight of guinea-pig and a satisfactory Extract of Aconite should have a minimum lethal dose not greater than 0.00001 Gm. for each gramme of body weight of guinea-pig." U. S.

It is well to take a series of four guinea-pigs, each of which will be injected respectively with 0.03, 0.04, 0.045, and 0.05 milligramme for each gramme of body weight. If none of the animals survive the drug is too strong, if none of them die it is too weak. If some survive and some die it is necessary to test the drug on a second series in which case the test should be 0.038, 0.04, 0.042 milligramme; it is well to have at least two animals who receive the middle dose of these three. If the drug be of official quality those who receive 0.038 should survive, those which receive 0.042 should die, and of those which receive 0.04 some should die and some survive. In testing the crude drug—it may be made up conveniently in the form of a fluidextract and diluted with nine volumes of water. The syringe used must be standardized and graduated in tenths of a mil. The injection should be made subcutaneously, preferably beneath the skin of the abdomen. After the injection the animals are marked or placed in separate cages and at the end of 12 hours notice taken of those living or dead.

Uses.—Aconite was well known to the ancients as a powerful poison,
but was first employed as a medicine by Baron Storck, of Vienna, whose experiments were published in the year 1762.

Locally aconite is actively irritant and also a paralyzant to the peripheral sensory nerves. When applied to a mucous surface it produces at first a burning tingling sensation followed in a few minutes by a numbness. This sensation may even be perceptible after the systemic ingestion of very large doses. When administered internally the most marked changes are seen in the circulation. The first effect is generally a slowing of the pulse, due to stimulation of the cardio-inhibitory centers, with consequent fall in the blood pressure. After somewhat larger doses, however, there is a weakening of the force as well as reduction of the rate of the pulse brought about by a direct action on the heart muscle. After poisonous doses various irregularities of heart action are produced and often there will be complete lack of harmony between the contraction of the auricle and ventricle. After fatal doses the heart is arrested in complete diastole and will respond to neither electrical nor mechanical irritation. In the frog, large quantities of aconite produce a loss of reflex activity, which is apparently due to a paralysis of sensation as voluntary motion is preserved for some time later, although it too may eventually be abolished. The drug appears to affect both the sensory nerves and the receptive side of the spinal cord, although the latter is involved comparatively late in the poisoning. In mammals this depressant action upon the nervous system can scarcely be demonstrated because of the powerful depressant effect upon the circulation.

Aconite is used chiefly as a circulatory sedative in conditions attended with excessive action of the heart or high arterial tension. Thus in valvular lesions of the heart in which the muscle tone is good, but the heart is over acting, in the so-called irritable heart seen in improperly trained athletes and similar conditions, it is often a remedy of great service. The choice between aconite and digitalis in such cases will depend largely upon the condition of the heart muscle; when the latter is strong and of good tone aconite may be used, but if there be a tendency towards dilatation, digitalis is generally preferred. In chronic high blood pressure, by retarding the pulse rate it will often produce a sensible reduction in the tension but in acute hypertension or threatened apoplexy it is less certain in its effects than the nitrites, but may at times be advantageously combined with them. By virtue of the lowering of the blood pressure aconite tends to increase the sweat and is
frequently used as a sudorific, especially in febrile conditions. In sthenic fevers its effect in restraining the heart as well as its diaphoretic tendency often renders it a drug of much use.

Aconite is also frequently employed for its local effects. The combination of local irritant effects with anesthetic action suggests strongly its use in peripheral neuralgias. It must not be forgotten, however, that if used too freely for this purpose it may be absorbed through the skin in sufficient quantities to cause serious poisoning. It is also occasionally employed as a local anesthetic to the stomach in various types of vomiting or gastralgia, but on account of its systemic effect is practically of secondary value.

For internal use the best preparation is the tincture which may be given in doses of from five to fifteen minims (0.3-0.9 mil). For external application the fluidextract may be employed, but generally an ointment is preferred. This may be made by rubbing up the extract with two or three parts of lard, or the ointment of aconitine of the British Pharmacopoeia may be used. The U. S., 1870, recognized a plaster of aconite.

**Toxicology.**—Aconite is a rapidly acting and powerful poison. The symptoms produced by overdose of it are sensations of warmth in the stomach sometimes with nausea but usually without vomiting, with slowing of the pulse and of the respiration, the skin is cool and moist and there is profound prostration. As the poisoning progresses the respirations become more slow and shallow, the pulse more and more feeble and towards the end may become rapid or very irregular. A characteristic symptom, in fact the only symptom of diagnostic importance, is the peculiar numbness and tingling first felt in the lips and mouth, but later also often in the fingers. At times there is dimness of vision, the pupils may be either contracted or dilated and occasionally delirium and stupor or convulsions may precede the fatal termination.

In the treatment of aconite poisoning the patient should be kept absolutely in a horizontal position or with the feet higher than the head. For the purpose of emptying the stomach the stomach pump is preferable to emetics as the latter involve a more or less serious strain upon circulation. Circulatory, stimulants, such as strychnine, ammonia, and atropine, may be given hypodermically. Body temperature should be maintained by external application of heat.
Dose, of aconite root, one-half to one grain (0.032-0.065 Gm.).

**Actaea.** Actaea spicata, L. Baneberry. Herb Christopher. Radix Christophoriana; Racine de Saint Christophe, Fr. Christophswurz, Wolfs-wurz, G.—This is a perennial herbaceous plant (Fam. Ranunculaceae) growing in the woods of mountainous regions from Japan to Central Europe as well as in Siberia. Its dark-brown, bitterish, somewhat acrid root resembles that of Helleborus niger, for which it is said to be occasionally substituted. It is an active emeto-purgative, capable of producing, when in overdose, dangerous effects. There are two American species which probably have medicinal properties similar to those of A. spicata,—namely, A. alba (L.) Mill., or white cohosh, and A. rubra (Ait.) Willd., or red cohosh, distinguished by the color of their berries. Actcra racemosa was the former name of the official Cimicifuga racemosa. (Proc. A. Ph. A., 1858.)

**Actinomeris.** Verbesina helianthoides Michx. (Actinomeris helianthoides Nutt.) (Fam. Compositae.)—At one time known as Gravel Weed, Diabetes Weed, now known as Sunflower Grown-beard. It is a perennial herb growing in the thickets and on dry prairies from Ohio and Missouri to Texas and Georgia. The root is said to be largely used in Upper Georgia in dropsy and chronic cystitis. Dose of infusion (one ounce to a pint), one fluidounce (30 mils).

**Adansonia.** Adansonia digitata, L. Baobab.—A tree of enormous magnitude, belonging to Bombacaceae. It is a native of Africa, extending quite through that continent from Senegal to Abyssinia, and has been introduced into the West Indies. The leaves and bark of this tree abound in mucilage, and have little odor or taste. By the Africans the leaves are used as a diaphoretic, and the subacid pulp of the fruit in dysentery. Under the name of cream-of-tartar tree various trees have been described. Their fruits contain, or have been supposed to contain, potassium bitartrate. The most important of these is the Adansonia Gregorii F. Muell, of North Australia. Another cream-of-tartar fruit is yielded by a tree of South Africa, which, according to E. M. Holmes, is probably the Adansonia madagascariensis Baillon. This fruit has been examined by E. J. Millard (P. J., April, 1890), who found that it contains no cream of tartar at all. It is probably identical with a cream-of-tartar fruit examined by F. L. Slocum. (A. J. P., 1880). Heckel and Schlagdenhauffen (Nouv. Rem., xxi, 487) have found in the fruit of the Adansonia digitata as much as 2 per cent. of free tartaric acid and 12 per cent. of potassium bitartrate. Duchassaing, of Guadeloupe, West Indies, and Pierre, of France, commended the bark of A. digitata highly as an antiperiodic. (A. G. M., 3e ser., xxiii, 535.) It is said to be acceptable to the stomach, and to produce no other observable physiological effect than increase of appetite, increased perspiration, and perhaps diminished frequency of pulse. An ounce may be boiled in a pint and a half of water to a pint, and the whole taken in a day. (J. P. C., 3e
Adenanthera. Adenanthera pavonina L. Zangavara.—Rochebrune (Toxicologie Africaine) states that he has obtained from this plant a crystalline principle which resembles in its activity physostigmine, but does not affect the muscles.

Adenia. Adenia venenata Troost.—A climbing passion-flower of Africa, said by Schweinfurth to be used as a vesicant. (P. J., March, 1874.) The Adenium hongkii is employed by the natives of the Soudan as an ordeal poison. Perrott and LePrince (P. J., 1910, lxxxiv, p. 82) have separated an active principle which is neither glucosidal nor alkaloidal, and which has a strophanthin-like effect.

Adhatoda. Br. Add. 1900. (Fam. Acanthaceae) —The fresh and dried leaves of Adhatoda Vasica Nees. (Justicia Adhatoda, L.) "The fresh leaves are four or six inches (about ten to fifteen centimeters) long and about an inch and a half (nearly four centimeters) broad, they are opposite lanceolate, entire short petiolate, taper-pointed, smooth on both sides. The dried leaves are of a dull brownish-green color which becomes much lighter when the leaves are powdered. They have a strong characteristic tea-like odor and a bitter taste." Br. Add., 1900.

The leaves are stated to contain an alkaloid, vasicine, and an organic acid, adhatodic acid (see Pharmacog. Indica, vol. iii). Vasicine, isolated by Hooper, is soluble in water, sparingly in benzin and carbon disulphide, readily soluble in ether and chloroform. The claim is made for it that it exerts a powerful toxic influence upon lower forms of vegetable and animal life, and is not poisonous to the higher animals. The leaves are stated to be actively poisonous to frogs and are considerably used in India as an expectorant and antispasmodic, especially in the treatment of asthma. The Br. Add. recognized the liquid extract (Extractum Adhatodae Liquidum, Br. Add., 1900), made with alcohol and given, in doses of from twenty to sixty minims (1.3-3.75 mils); the freshly expressed juice (Succus Adhatodae, Br. Add., 1900), dose, from one to four fluidrachms (3.75-15.0 mils); the tincture (Tinctura Adhatodae, Br. Add., 1900), dose, from one-half to one fluidrachm (1.8-3.75 mils).

Adiantum. Maidenhair.—Tradition has attributed to various species of this genus of ferns valuable properties in chronic pulmonic catarrhs. A. pedatum, L., of America, A. Capillus-Veneris, L., of Europe, A. lunulatum Burm., of India, are the most important of these alleged medicinal species. The European species is sometimes employed on the Continent as an emmenagogue under the name of polytrichi, polytrichon, or kalliphyllon, and is given in the form of infusion, sweetened with sugar or honey, and a syrup prepared from it is said to be popular in France under the name of sirop de capillaire, and is official in the French Codex.

Adonis. N. F. IV. Vernal Pheasant's Eye. Sommertäufelsauge. G.—It is official in the N. F. IV, in which it is defined as "the dried, overground portion of Adonis vernalis Linne (Fam. Ranunculaceae), without the presence of more than 5 per cent. of foreign matter." This ranunculaceous plant of Northern Europe and Asia has long been used as an abortifacient, while its rhizome sometimes occurs in commercial black
hellebore as an adulteration. Linderos examined the leaves and found in them 10 per cent. of aconitic acid. (Ann. Ch. Ph., 1876, 340.) Cervello, in 1882, obtained from the plant a glucoside, to which he gave the name of adonidin. For improved method of preparation, see P. J., vol. xvi, 145, and A. J. P., 1887, 609. This glucoside occurs in the form of a somewhat hygroscopic, canary-yellow powder of an intensely bitter taste; soluble in water, alcohol, and in amyl alcohol; insoluble in anhydrous ether, chloroform, oil of turpentine, or petroleum benzin. Its reaction is neutral. It reduces Fehling's solution, if previously heated with a few drops of hydrochloric acid. It exists in small quantities in all portions of the plant. For further details as to reactions, see P. J., xv, 145. Podwyssotzki found commercial samples of adonidin to be mixtures of the active principle with other constituents of the plant. He gives the name of picroadonidin to the active principle, which he describes as an amorphous glucoside having an excessively bitter taste, possessing the properties of a cardiac poison in the highest degree, and being easily soluble in water and alcohol and entirely soluble in ether. (P. J., xix, 1888, 346.) According to Fucikman, confirmed by Mercier (Nouv. Rem., 1914), commercial adonidin is a mixture of a neutral body with a hemolytic acid, adonic acid. Cervello states (A. E. P. P., xv) that adonidin exists also in the Adonis cupaniana of Southern Europe, and F. Borgiotti affirms the value of A. aestivalis, L., in heart affections. (D. M. Ztg., Aug., 1888.) Tahara asserts that the glucoside of Adonis autumnalis, L., is distinct, and calls it adonin (C24H40O9) (Ber. d. Chem. Ges., xxiv), while Y. Inoko (A. E. P. P., xxviii) affirms that the glucoside of A. amurensis of Japan is also peculiar, and assigns to it the formula C20H40O9, allied to adonidin, but much less powerful.

Merck has described an additional crystalline principle, which fuses at 102° C. (216° F.), is very soluble in water and warm alcohol, and crystallizes in clear needle-like prisms. It has a neutral reaction, does not reduce Fehling's solution, and is not colored brown by alkalies. Its analysis seems to indicate a formula C5H12O5, and Merck considers that it is a hitherto undescribed pentatomic alcohol, and calls it adonite. Whether it be identical with the adonidulcite announced in a preliminary communication by Podwyssotzki shortly before his death, Merck is not able to state, as no details of fusing point, formula, or chemical reactions were given by the former. (M. Bull., Jan., 1893.) E. Fischer (Ber. d. Chem. Ges., 1893, 633) confirms the formula C5H12O5 given by Merck, as well as the statement that it is a pentatomic alcohol; by oxidation with sodium hypobromite it is changed into ribose, C5H12O5, which treated with sodium amalgam again yields adonite.

The National Formulary description is as follows: "Glabrous, with the exception of the younger portions, which maybe slightly grayish-puberulent; stems from 15 to 50 cm. in length, thick, but soft and weak; shining, simple or branched, the branches mostly from near the base and similar to the main stem; naked below, except for some scale-like leaf-vestiges, densely leafy above; leaves from 2 to 4 cm. in length and two-thirds or more as broad, pin-nately divided into several segments, the larger of which are again divided, the ultimate segments being narrowly linear, and acute; flowers terminal, yellow but usually drying to a cream color, from 3 to 6 cm. in breadth; sepals five, green or grayish-puberulent, more than half the length of the petals,
oblong, obtuse, finely nerved; petals from five to twenty, oblong, obtuse, finely nerved; stamens indefinite; pistils numerous, in fruit forming an ovoid, obtuse, dense head of ovoid akenes, which are tipped with the very small, persistent styles. Odor faint; taste bitterish, afterward somewhat acrid. The powdered drug is grayish-green and, when examined under the microscope, exhibits numerous fragments of pith parenchyma, the cells with few simple pores, up to 0.05 mm. in width and 0.25 mm. in length; groups of long narrow sclerenchyma fibers, mostly with lignified walls from 0.005 to 0.007 mm. in thickness and having a few rounded or oblique simple pores; tracheae spiral or with bordered pores and up to 0.017 mm. in width; epidermal cells from the stem and petiole, elongated in surface view and with elliptical stomata, the latter about 0.064 mm. in length; fragments of the epidermal tissue from the lamina of the leaf, composed of finely striated cells with wavy, vertical walls; associated with broadly elliptical stomata, the latter up to 0.047 mm. in length; brownish colored fragments from the scales at the base of the stem, composed of elongated cells with somewhat rounded ends and yellowish-brown walls; starch grains and calcium oxalate crystals few or absent. Adonis yields not more than 12 per cent. of ash."

Adonidin belongs physiologically to the digitalis group. Although in Hare's experiments (T. G., 1886) the frog's heart was arrested in diastole. Cervello (A. E. P. P., xv) and De Guirlat found that the arrest is systolic. The pulse is slowed by stimulation of the inhibitory apparatus. In the experiments of Henrijean (B. A. R. B., 1909, xxiii, p. 363) in the early stages of the action, electrical stimulation of the pneumogastric nerve produced an unwonted degree of retardation of the pulse rate, which would indicate an increased excitability of the peripheral ends of the nerves. All investigators are in accord that the slowing of the pulse is to a large extent abolished by section of the vagi, so that the inhibitory influence must be largely also of central origin. There occurs also a pronounced rise of the blood pressure, which, according to Hare, is due partly to a stimulant action upon the heart, and partly to an effect upon the vasomotor mechanism. In the more exact experiments of Henrijean, vasoconstriction appeared only late in adonidin poisoning. After large toxic doses, the heart becomes irregular, and the blood pressure falls. According to Kakowski (A. I. P. T., xv, p. 21), adonidin differs from most of the other digitalis group in that it dilates the coronary arteries, while most of these drugs produce constriction.

Adonis vernalis was introduced as a cardiac tonic by Bubnow in 1879. Clinical experience confirms the conclusion of the pharmacologist, that it resembles digitalis in its action, and is a useful agent in the treatment of chronic heart disease. The advantages which have been claimed for it are, that it is more prompt in its action, and that it manifests less cumulative tendency than digitalis, but it appears to be less certain in its effect. Bechterew asserts that it is a useful remedy in epilepsy when used in conjunction with the bromides. The dose of adonis vernalis is from two to ten grains (0.12-0.6 Gm.), which may be given in the form of an infusion. The glucoside adonidin may be given in doses of one-twelfth to one-fourth of a grain (0.005-0.015 Gm.).

**Aesculus.** Horse-chestnut.—Chestnut (Aesculus Hippocastanum, L.) said to have been originally a native of Asia, but introduced about the middle of the sixteenth
century into Europe, whence it has spread to this country. It is to this species that
this article especially applies, though it is probable that any medicinal properties
which the tree may have are shared by the other species of the genus. The seed or
nut abounds in starch, but its bitter, disagreeable taste has prevented its general use
as a food, although as long ago as 1856 starch was made from it in France, and
recently a pleasant and nutritious article of diet is said to have been prepared by
removing its bitter principle by means of alcohol. For analysis of the oil it contains,
see Stillesen, Proc. A. Ph. A., 1909, lvii, p. 201. In the leaves Rochleder found
quercitrin, and a bitter principle, esculin (aesculin); and in the capsules of the fruit a
peculiar acid, capsulaesic acid (J. P. C., May, 1859; Aug., 1860). (For Rochleder's
method of extracting esculin, see U. S. D., 18th edition; for a second process, see A. J.
P., xlv, 400.) Esulin is in shining, white, prismatic crystals, inodorous, bitter, but
slightly soluble in cold water, more soluble in boiling water, and very readily so in
boiling alcohol and in alkaline solutions. Its solution, which is fluorescent, is
precipitated by lead sub-acetate, and its formula, according to Schiff, is C_{15}H_{16}O_{9}
+ 1\frac{1}{2}H_{2}O. When treated with dilute sulphuric acid, it is converted into grape sugar and
a substance called esculetin, C_{9}H_{6}O_{4}, which is now known to be a dioxycoumarin,

\[
C_6H_5(OH)_2 \xrightarrow{\text{O \text{-CO}}_{\text{CH=CH}}.}
\]

Tannin is found in all parts of the tree, including the leaves as well as the bark and
fruit. According to Rochleder, when pure, it is white and soluble in water, alcohol, and
erther; becomes red by the absorption of oxygen; colors ferric salts green, but violet on
the addition of a little alkali; fluorescent when it is in alkaline solution; in concentrated
solution is precipitated, at least partially, by sulphuric, hydrochloric, and
metaphosphoric acids, but not by acetic acid, and forms also, with potassium and
sodium sulphites and ammonium sulphide, precipitates which are readily dissolved by
dilute acetic acid. (J. P. C., Jan., 1868, 72.)

The powdered kernel of the nut is a sternutatory. The extract of the wood has been
used in dyeing silk black. The fixed oil, extracted from the kernels by ether, has been
employed in France as a topical remedy in rheumatism, and the bark as an
antiperiodic in doses of half an ounce (16 Gm.) in the twenty-four hours, given in the
form of decoction. The flowers are stated to contain quercitrin. In the United States a
decoction of the leaves is popularly employed for whooping cough, and to the seeds
themselves, when "carried in the pocket of the patient," is attributed the marvellous
property of curing hemorrhoids, rheumatism, etc. Esulin has also been administered
in malarial disorders, in fifteen-grain (1 Gm.) doses repeated once during the
interruptions. (Ann. Ther., 1859, 1860.) The glucoside esculin has the property, like
other fluorescent substances, of absorbing ultra violet rays which are then gradually
given off. Because of these properties, it is used on the one hand, as a protective
against the effects of sunlight and on the other as a means of continuing the effect of
heliotherapy. Thus Freund has found it useful not only against sunburn, but as a
prophylactic against snow blindness (Zeit. f. Neuere Physikal. Med., 1908, ii), and
Graham (L. L., 1905, ii, p. 1769) recommends it in the Finsen light treatment of lupus
vulgaris and similar conditions. For this purpose he injected five minims (0.3 mil) of a
2 or 3 per cent. solution immediately beneath the skin in the region to be treated by
the light. Under the name of zeezon and ultra-zeezon there are upon the market
 pastes whose exact compositions are not stated but which are claimed to contain
 oxy-derivatives of esculin.

The fruit of the Aesculus pavia L., or Red Buckeye of the Southern United States, is
said to be an active convulsant. E. C. Batchelor (A. J. P., xlv, 144) found in the
cotyledons of the seeds about 21/2 per cent. of a peculiar glucoside. Aesculus glabra
Willd., the Ohio Buckeye, is asserted to be useful in portal congestion. (N. P., ii, 21.)

Aethusa. Fool's Parsley. Aethusa Cynapium, L. (Fam. Umbelliferae)—A fetid herb
naturalized from Europe and growing in waste places or cultivated grounds in the
northern United States and Canada. In 1859, Walz stated that the fruit of the
Aethusa Cynapium contains a volatile base similar to coniine. This statement has
been confirmed by Power and Tutin (J. Am. C. S., 1905, xxvii) who recovered, besides
various inert matters, about one forty-thousandth of 1 per cent. of the volatile
alkaloid. This plant has been variously attributed with poisonous properties, but
Harley (P. J., 1880, xi, p. 43) denies any noxious quality, and, in the experiments of
Power and Tutin, the extract from five hundred grammes of the dry herb caused in a
small dog, vomiting and salivation, but the animal entirely recovered.

AGAR. U. S. AGAR [Agar-agar]

"The dried muelaginous substance extracted from Gracilaria
(Sphaerococcus) lichenoides Greville and other marine algae growing-
along the eastern coast of Asia, particularly several species of Gelandium,
or Gloiopeltis (Class Rhodophyceae)." U. S.

Quite a number of the algae belonging to the Rhodophyceae, growing
on the coast of Southern and Eastern Asia, contain large quantities of
mucilage which is extracted and sold under the name of agar-agar. The
most important species are those recognized by the U. S. Pharmacopoeia.
The algae are collected, spread out upon the beach until they are
bleached and then dried. They are then boiled with water and the
mucilaginous solution strained through a cloth. The filtrate is allowed to
harden and thoroughly dry in the sun. The algae are usually collected
during the summer and fall, bleached and dried, but the process of the
manufacture of agar-agar does not take place until cold weather and
usually extends from November to February.

The following varieties of agar are known:

1.—Ceylon Agar-agar, consisting chiefly of Gracilaria lichenoides, Ag.,
the alga used by the Hirundo esculenta in the formation of its edible nest.

2.—Macassar Agar-agar, coming from the straits between Borneo and Celebes, consisting of impure Eucheuma spinosum, Ag., incrusted with salt.

3.—Japanese Agar-agar, known as Japanese isinglass, derived from several algea, especially Sphaerococcus compressus, Ag., Gloiopeltis tenax, J. Ag., Gelidium corneum, Lam. and G. cartilagineum Gaill. It occurs in European commerce either in transparent pieces, two feet long and as thick as a straw, prepared in Singapore by putting the algea named in hot water, or, more frequently, in yellowish-white masses, a foot long and upward of an inch in width. It is the latter kind of agar-agar that is suitable for the culture of bacteria, and is employed in medicine. (P. J., 1885, 188.)

Morin has investigated the gelose of Payen, contained in the agar-agar. When a solution of gelose is cooled, even that of 1 in 500 parts of water, a colorless, transparent, and stiff jelly is obtained, which, when heated with moderately strong nitric acid, yields mucic and oxalic acids. It dissolves on heating with acidulated water without yielding a jelly on cooling.

Gelose leaves 3.88 per cent. of ash, and when air-dried contains 22.85 per cent. of moisture. When dissolved there also separates out a flocculent mass amounting to 1.9 per cent. Alcohol precipitates gelose, but it cannot be obtained pure in this manner, as the precipitate contains some ash. (C. E. A. S., No. 90, 921-926.)

Under the name of gelosine a mucilaginous substance, extracted from a Japanese alga, has entered commerce in the form of dry, whitish leaves. Gelosine is soluble in alcohol and water, and is said when wet to gradually contract and expel water and the medicinal substances which it may contain. It has been proposed as a pharmaceutical basis for various preparations for local use. (See B. M. J., vol. ii, 1886.) Glycerin suppositories have been made with agar-agar as a vehicle, but they contain only 70 per cent. of glycerin as compared to 90 per cent. in the official suppositories made with sodium oleate.

Properties.—Agar-agar occurs "mostly in bundles from 4 to 6 dm. in
length, consisting of thin, translucent, membranous, agglutinated pieces from 4 to 8 mm. in width; externally yellowish-white or brownish-white; tough when damp, brittle when dry; odor slight; taste mucilaginous. A fragment mounted in water and examined under the microscope gradually becomes more transparent, showing a granular structure and a few diatoms, notably the frustules of Arachnoidiscus Ehrenbergii Baillon, which are disk-shaped and from 0.1 to 0.2 mm. in diameter, and also fragments of the spiculas of sponges; upon the addition of iodine some of the granules or hyphal portions are colored bluish-black. Insoluble in cold water, but slowly soluble in hot water. A solution made by boiling 0.1 Gm. of Agar in 100 mils of water, upon cooling yields no precipitate upon the addition of tannic acid T.S. (gelatin), and does not produce a blue color upon the addition of iodine T.S. (starch). Boil 1 part of Agar for about ten minutes with 100 parts of water, and replace the water lost by evaporation; it yields a stiff jelly upon cooling. The powder is pale buff; when mounted in water and examined under the microscope it shows transparent, more or less granular, striated angular fragments, occasionally containing frustules of diatoms; with iodine T.S., fragments for the most part are colored bright red, certain more or less definite areas being stained bluish-black. Agar yields not more than 5 per cent. of ash." U. S.

To detect agar in jams, jellies, etc., in which it is often used as an adulterant, it is usually considered necessary to ash the sample and examine the acid insoluble ash for presence of the characteristic diatoms. Albert Schneider (Pac. Pharm., 1912, p. 35) states that the ashing is unnecessary and often destructive of the diatoms and that they may be collected by dissolving 10 Gm. of the sample in 200 mils of distilled water and centrifuging for thirty minutes, after which the sediment may be placed on a microscopic slide and examined.

**Uses.**—Under the name of agar-agar a jelly-like substance has been used as a culture medium by bacteriologists for many years. (See Diagnostic Reagents, Part III.) Although agar contains sixty per cent. of carbohydrates, according to Saiki (J. B. C., 1906), the human digestive tract is able to utilize but a very small percentage of the food value. Its therapeutic importance depends upon the ability of the dry agar to absorb and retain moisture. Being indigestible, it passes through the intestinal tract, swelling up somewhat, owing to the absorption of water from the stomach, and gives bulk to the intestinal contents. In other words, it acts mechanically in an analogous manner to the cellulose of
vegetable foods, and aids in maintaining the regularity of the bowel movements. It has been widely used in the treatment of chronic constipation. Of itself, when there is more or less atony of the intestinal muscles, it does not originate peristaltic movements, and therefore is frequently combined with small doses of eascara, or one of the other vegetable cathartics. It is best administered cut up in small pieces, and eaten like a cereal with the addition, if desirable, of cream and sugar. Ordinarily, from two to four drachms (7.7-15.5 Gm.) of the dry agar may be administered once a day.

Agaric. Agaricus Albus. White Agaric. Larch Agaric. Touchwood. Spunk. Tinder. Funpurgetif, Fr. Larchenschwamm, G.—It is defined in the National Formulary IV as "the dried fruit body of the fungus Polyporus officinalis Fries (Fam. Polyporaceae) [growing on one or more species of Pinus Linne, Larix Adanson, and Picea Link (Fam. Pinaceae)], deprived of its outer rind, and without the presence of more than 10 per cent. of foreign matter." The term Agaric is more properly applied, however, to the fungi of the genus Agaricus, but most medical writers and the N. F. limit it to the fungus from Polyporus officinalis Fries (Boletus laricis Jacquin; B. purgans Persoon), which is found upon the old trunks of the European larch and upon Larix sibirica Ledebour, of Asia. The same species is found on various coniferous trees in some of the western United States and British Columbia. It is of various sizes, from that of the fist to that of a child's head, or even larger, hard and spongy, externally brownish or reddish; but, as found in commerce, it is deprived of its exterior coat, and consists of a light, white, spongy, somewhat farinaceous, friable mass, which, though capable of being rubbed into powder upon a sieve, is not easily pulverized in the ordinary mode, as it flattens under the pestle. That which is most esteemed is said to be brought from Siberia; but it is probably produced wherever the European larch grows. It is described in the N. F. as in "light, fibrous, somewhat spongy pieces of irregular shape; grayish-white to pale brown externally; yellowish and resinous internally; fracture tough, fibrous; friable but difficult to powder. The powdered drug, examined under the microscope, shows numerous non-septate, narrow, mycelial threads and many cubical crystals of calcium oxalate from 0.01 to 0.02 mm. in diameter. It yields to boiling alcohol not less than 50 per cent. of a resinous extract. Agaric yields not more than 2 per cent. of a white ash, rich in phosphates." N. F. Wm. M. McPheeters (St. L. M. S. J., x, 421) found a specimen brought from the Rocky Mountains decidedly cathartic in dose of twenty-four grains (1.6 Gm.).

Agaric has a sweetish, very bitter taste. It owes its medicinal virtues to Agaric acid (N. N. R., 1916), which is also called laridic and agaricinic acid. This is a tribasic acid, \( C_{19}H_{36}O (COOH)_{3} + 1\frac{1}{2}H_{2}O \), occurring as an odorless, tasteless, micro-crystalline powder, melting at 141.5° C. (286.5° F.). According to J. Schmieder, agaric contains a small amount of soft resin, \( C_{15}H_{20}O_{4} \), extracted with petroleum benzin, and from 4 to 6 per cent. of a fatty body, which is made up of (1) agaricol, \( C_{10}H_{16}O \), fusing at 223° C. (433.4° F.); (2) phytosterin, \( C_{26}H_{44}O \);
solid hydrocarbons, $C_{23}H_{46}$ and $C_{29}H_{54}$; 
(4) cetyl alcohol, $C_{16}H_{33}.OH$; 
(5) a liquid aromatic alcohol, $C_9H_{18}O$; 
(6) a fatty acid, $C_{14}H_{24}O_2$; and 
(7) ricinoleic acid, $C_{18}H_{34}O_3$. (Schmidt, Lehrbuch der Pharm. Chem., ii, 3te Auf., 1528.) J. D. Eiedel has produced two phenetidides of agaric acid, for which antipyretic and anhidrotic properties are claimed. (Ph. Ztg., xlvii.) Sodium, Lithium and Bismuth agaricinates have been prepared and introduced into medicine.

According to Hoffmeister (A. E. P. P., 1889, xxv, p. 189), in a moderate dose, agaric acid has no effect upon the system, except to paralyze the nerves of the sweat glands. When given in very large doses, it produced primary excitation of the medulla, followed by paralysis, increasing at first the blood pressure and the respiratory rate, which was followed by diminishing activity in both. The large doses also acted as an irritant to the stomach and intestine, causing vomiting and purging. The depressant action shown on the sweat glands was not shared by the other glands of the body. McCartney (J. P. Ex. T., 1917, x, 83) offers the remarkable theory that its antihydric action is due to spasm of the muscular layer of the skin. The most important use of agaric is in the treatment of the colliquative sweats of wasting conditions, such as phthisis. Its value in these conditions has been abundantly confirmed by clinical experience. Aside from the solanaceous drugs, it is probably the most reliable remedy that we possess for this purpose. Rosenbaum has found the fluid extract of agaric (Med.Klin., 1906) of service in various catarrhal conditions of the alimentary tract, even in intestinal tuberculosis.

Under the name of agaricin are marketed preparations containing the active agaric acid, with larger or smaller amount of impurities. The dose of the pure principle is from one-sixth to one-half of a grain (0.01-0.03 Gm.).

Thoerner obtained from Agaricusatramentosus crystalline, dark-brown scales, which he believed to be dioxykinon. (Ber. d. Chem. Ges., 1878, 533.) According to T. L. Phipson, Agaricus ruber contains a rose-red coloring matter, ruberin, which appears bright-blue by transmitted light; being soluble in water, it is washed out of the head of the fungus by a heavy fall of rain. Ether extracts from the fungus a yellowish-white alkaloid, agarythrine, which has a bitter, afterwards burning taste, somewhat like aconitine; its chloride is soluble, but the sulphate insoluble in water, the latter dissolving in alcohol; it dissolves in nitric acid with red color, and is colored red by chlorinated lime and afterwards bleached. On agitating the solution of the alkaloid with ether, it is oxidized by the air to a red coloring matter, which is probably the cause of the red color of the surface of the fungus. (Chem. News, 1882, 199.) An agaric growing on the Larix leptolepis, and used in Japan as a sacred medicine under the name of Toboshi or Eburiko, has been found by Y. Inoko to contain agaric acid. (Sei-I-Kwai, April, 1891.)

Fungus chirurgorum. Boletus chirurgorum, Wundschwamm, G.—Surgeon's agaric is the product of Polyporus fomentarius (L.) Fries, which is found upon the oak and beech trees of Europe. It is shaped somewhat like the horse's foot, with a diameter of
from six to ten inches. It is soft like velvet when young, but afterwards becomes hard and ligneous. It usually rests immediately upon the bark of the tree, without any supporting footstalk. On the upper surface it is smooth, but marked with circular ridges of different colors, more or less brown or blackish; on the under surface, it is whitish or yellowish, and full of small pores; internally it is fibrous, tough, and of a tawny-brown color. It is composed of short tubular fibers compactly arranged in layers, one of which is added every year. The best is that which grows on the oak, and the season for collecting the fungus is August or September. It has neither taste nor odor. Among its constituents, according to Bouillon-Lagrange, are extractive, resin in very small proportion, nitrogenous matter also in small quantity, potassium chloride, and calcium sulphate, and in its ashes are found iron, and calcium and magnesium phosphate. It is prepared for use by removing the exterior rind or bark, cutting the inner part into thin slices, and beating these with a hammer until they become soft, pliable, and easily torn by the fingers. In this state it was formerly much used by surgeons for arresting hemorrhage, being applied with pressure. P. ignarius (L.) Fries and P. marginatua Fries yield similar products.

When prepared polyporus (so-called agaric) is steeped in a solution of nitre, and afterwards dried, it constitutes spunk, punk, or tinder, the amadou of the French, which occurs in flat pieces, of a consistence somewhat like that of very soft, rotten buckskin leather, of a brownish-yellow color, capable of absorbing liquids, and inflammable by the slightest spark. It is said to be prepared also from various other species of Polyporus, as P. unguilatus, P. ribis, etc.

**Agave.** Agave americana, L. American Agave. American Aloe. Maguey. (Fam. Amaryllidaceae)—An evergreen succulent plant, indigenous to Florida, Mexico, and other parts of tropical America, and largely cultivated, chiefly for hedges, in the south of Europe, especially in Spain. Although the Agave americana is the best known form, botanists have described fifty species of the genus, which are indigenous to South America and the southern portions of North America, and many of which contribute to the economic products produced in that country from the agave plant. The number of these products is very great. Sisal grass or sisal hemp and Tampico hemp, also known as Pita hemp or Pita fiber, are the most important of the various fibers obtained from the agave leaves, though a number of other forms are locally known in Mexico. From a number of species of Agave, are produced in Mexico, large quantities of fermented liquors, known as pulque, and distilled liquors known as mescal or tequila. All of the pulque agaves have thick leaves. When they are about to bloom the central bud is cut out, leaving a large cavity into which the sap (aguamiel or honey water) exudes, rapidly. At first clear green, yellowish or whitish, this sap soon by fermentation becomes milky and acquires a cider-like taste or, if the process is allowed to go on, is rapidly converted into vinegar. Pulque is said to contain about 7 per cent. of alcohol, and is very largely used as a beverage by the Mexicans, but its odor and taste are disagreeable to unaccustomed palates. The juice has in it an optically inactive reducing sugar, agavose, $C_{12}H_{22}O_{11}$. The leaves and roots and stocks of the agave contain saponin and are used in Mexico in the place of soap. The fresh juice is said to be laxative, diuretic, and emmenagogue, and in doses of two fluidounces (60 mils) useful in scurvy. The leaves are said to be used as counter-
irritants, and Lenoble has found in them an acrid volatile oil. (J. P. C., xv.) Agave Gum has been compared to gum arabic, but differs in containing a much larger proportion of lime, and in being only partially soluble in water, the soluble portions resembling pure gum, but the larger insoluble portions having all the characteristics of bassorin.

Agave virginica, L., which grows in our Southern States, is known in South Carolina by the name of rattlesnake's master, has a very bitter root, which is used, in the form of tincture, in colic.

Agelaea. Agelaea Lamarckii Planch.—Under the name of Cephan-Mahi, Soandrou, Vahe-mainti, this African plant is used as an anti-blenorrhagic. According to Rochebrune (Toxicologie Africaine), it contains a poisonous glucoside, agelaeotoxine.

Ageratum. Ageratum conyzoides L. (Fam. Compositae), a Brazilian plant commonly known in cultivation as ageratum, is said by Barker Smith (C. D., May 15, 1876) to be used as an emmenagogue.

Agrimonia. Agrimonia Eupatoria, L. Common Agrimony. Herba Agrimonia; Aigremoine, Eupatoire des Grecs, Fr. Odermoening, Leterklette, G. (Fam. Roseaceae)—This species of agrimony is a perennial herb, indigenous to Europe, and while somewhat resembling one or more species of Agrimonia growing in the United States, it differs, according to Britton, markedly in foliage and fruit from any of our species. Its stem, which rises from one to three feet in height, is hairy, furnished with interruptedly pinnate leaves, and terminated by a long simple spike of yellow flowers. Both the herb and root have been employed. A volatile oil may be obtained from the plant by distillation. Agrimony is a mild astringent and alterative. It also contains a bitter principle. Dose, one drachm (3.9 Gm.) or more. (See 16th ed., U. S. D.)

Ailanthus. Ailanthus glandulosa Desf. Tree of Heaven. Chinese Sumach. Tree of the gods. Ailanto, Gotterbaum, G.—This well-known shade-tree, belonging to the Fam. Simarubaceae in its general aspect and the character of its foliage, appears like a gigantic sumach, and was at one time considered to be a Rhus. In France it is cultivated for the sake of its leaves, upon which the Chinese silkworm is fed, and is known by the name of Japen varnish (vernis de Japen), from its having been mistaken for the true Japen varnish tree, which is a species of Sumach. (P. J., vii, 370.) The powdered bark is of a greenish-yellow color, possesses a strong, narcotic, nauseating odor, in the fresh condition, and has a strongly bitter taste. When chewed, it is said to produce a general uneasiness, a sense of increasing weakness, vertigo, cold sweats, with shivering and a sensation of nausea. It has been found to contain lignin, chlorophyll, a yellow coloring principle, a gelatinous substance (pectin), quassin, an odorous resin, traces of a volatile oil, a nitrogenous fatty matter, and several salts. F. H. Davis detected traces of a crystallizable organic acid, but no alkaloid or glucoside. (A. J. P., 1885, 600.) By the action of alcohol, there is obtained from the bark an oleoresin which has the consistence of tar, a very dark greenish-brown color, and in a high degree the odor and taste of the bark. Hetet found the bark to produce in dogs copious stools and the discharge of worms. The resin purged, but rarely acted as an anthelmintic. The powdered bark has been used successfully...
against the tapeworm. In China the bark is very popular as a remedy in dysentery and other bowel complaints. (A. J. P., 1874, 276; P. J., vii, 372.) Dose, from seven to thirty grains (0.45-2.0 Gm.). The oleoresin produces the same effect in a somewhat smaller dose, and keeps better than the bark, which loses its powers with age. (J. P. C., March, 1859, 163.)

In India the bark of the Ailanthus excelsa Roxb. is used as a bitter tonic. It occurs in rough, dirty-green pieces. Narayan Daji found in it a bitter uncrystallizable principle and a bitter nitrogenous acid, ailanthic acid, to which he attributes medicinal virtues. (P. J., Aug., 1870, Oct., 1876, June, 1877.) This acid is not used medicinally in this country.

**Ajowan.** Ajava. Ajwan.—The ripe fruit of Carum copticum Benth. et Hook. (Carum Ajowan Benth. et Hook., Ptychotis Ajowan D. C.), an annual of the Fam. Umbelliferae. It is cultivated in India, Egypt, Persia and Afghanistan. The fruits resemble those of parsley, but are distinguished by their odor. They yield 3 to 4 per cent. of volatile oil which contains from 45 to 55 per cent. of thymol. This oil is official in the B. P. (see Oleum Ajowan). The fruits also contain from 25 to 32 per cent. of a fixed oil and from 15 to 17 per cent. of protein, making them a very good cattle food. They are used in the form of an extract and water, viz.: Extractum Ptychotis Liquidum P. I. and Aqua Ptychotis P. I. The water known as Omum water is used in India in the treatment of cholera. The dose of the Fluidextract of ajowan is ten to thirty minims (0.6-2.0 mils).

**Ajuga.**—Of this genus A. chamoepitys (L.), or Ground Pine; A. reptans, L., Mountain Bugle, or Common Bugle; and A. pyramidalis, L., all of them European species, the last naturalized in America, have been used in medicine, and are probably mild astringents and tonics. The ground pine is said to contain a volatile oil, and has been used to some extent in amenorrhea and in various forms of rheumatism, in doses of from one to two drachms (3.9-7.7 Gm.). Ajuga Iva, L., of Sardinia, is said to be a depressomotor, an active bactericide, and an antiperiodic. (A. J. B., xxxiv.)

**Akazga.** Boundou. Quai. Ikaga. Icaya.—An ordeal poison, largely used in a district on the west coast of Africa, extending far into the interior, north and south of the equator. The precise botanical character of the plant is unknown, but it is thought to belong to one of the Loganiaceae. Thomas E. Eraser found in the plant an alkaloid, akasgine. The alcoholic extract or the alkaloid acts on the system similarly to nux vomica. (For further description, see U. S. D., 19th ed., p. 1373 and also A. J. P., March, 1867.)

**Alchemilla.** Alchemilla vulgaris, L. Lady's Mantle. (Fam. Rosaceae)—This astringent, bitterish perennial European herb was formerly employed in diarrhea. By the ancients it was highly esteemed; extraordinary powers were ascribed to it by the alchemists. (P. J., 1885, 791.)

Aletris, G. (Fam. Liliaceae)—It is described in the N. F. as "the dried rhizome and roots of Aletris farinosa Linne (Fam. Liliaceae). Rhizome horizontal or slightly oblique, nearly cylindrical or laterally compressed above, from 2 to 4 cm. in length and from 5 to 12 mm. in diameter; externally grayish-brown, upper portion with circular stem scars from 3 to 7 mm. in diameter and with numerous leaf bases, the sides and lower portion with numerous tough, wiry, whitish or reddish-brown roots which are more or less flexuose and provided with short branches; fracture short: internally light brown, cortex from 1 to 2 mm. in thickness, central cylinder with numerous twisted and branching fibre-vascular bundles. Odor slight, acetous; taste sweetish, somewhat bitter. Examined microscopically, the greater part of the drug is found to consist of parenchyma cells filled with spherical or ellipsoidal starch grains from 0.008 to 0.016 mm. in diameter. Some of the parenchyma cells contain raphides, the latter being from 0.025 to 0.045 mm. in length. The tracheae are reticulate or provided with simple pores and around these are several layers of lignified cells with thick walls and simple, large oblique pores. The endo-dermis is composed of several layers of thick-walled and closely-lamellated cells of a deep yellow color and the cortex is readily separated. Aletris yields not more than 16 per cent. of ash."

Algarobilla, the pod of Caesalpinia brevifolia, (Clos.) Benth. (Fam. Leguminosae), a drug containing over 60 per cent. of tannin and a quantity of ellagic acid, is obtained from Chili. (Gehe's Report, N. R., 1878, 332; J. Chem. S., 1891, 918.)

Alisma. Alisma Plantago-aquatica, L. Water Plantain. Plantain d'eau. Pain de grenouilles, Fr. Froschloffel, Wasserwegerich, G. (Fam. Alismaceae)—A perennial herbaceous plant, common to Asia, Europe, and the United States. The root has, when fresh, an odor like that of Florentine orris, but loses it when dried. Its taste is acrid and nauseous. It contains a pungent volatile oil and an acrid resin, to which all its virtues must be ascribed. The Calmucks in Russia are said to use it for food. The leaves are rubefacient, and will sometimes even blister. They have been recommended in gravel and cystitis. Dose, a drachm (3.9 Gm.).

Alkanet, Anchusae Radix. Alkanna Root, Alkanet Root, Orcanette, Fr. Spanish Bugloss. Alkannawurzel, G.—This is the root of Alkanna tinctoria L., or dyers' alkanet, an herbaceous perennial plant, of the Fam. Boraginaceae, growing in the Grecian Archipelago and the south of Europe, where it is cultivated. See E. M.
Holmes, P. J., 1897, p. 61. For an account of Syrian alkanet and allied plants, see Proc. A. Ph. A., 1896, 565. Alkanet, as found in commerce, is in pieces 7 to 10 cm. long, and from 5 to 15 mm. thick, somewhat twisted, consisting of a dark-red, easily separable bark, and an internal ligneous portion, which is reddish externally, whitish near the center, and composed of numerous distinct, slender, cohering fibers. As it comes to us it is usually much decayed internally, very light, and of a loose, almost spongy texture. The fresh root has a faint odor, and a bitterish, astringent taste; but when dried it is nearly inodorous and insipid. Its coloring principle, which abounds mostly in the cortical part, is soluble in alcohol, ether, and the oils, to which it imparts a deep red color, but is insoluble in water. It may be obtained by first exhausting the root with water, and then treating it with a weak solution of potassium or sodium carbonate, from which the coloring principle may be precipitated by an acid. According to Pelletier, by whom it was discovered, it possesses acid properties, forming with the alkalies and earths neutral compounds, which are of a blue color, and soluble in alcohol and ether. Its weak acid character resembles that of alizarin, to which it is chemically related, as when distilled with zinc dust it yields methylanthracene. It has also received the names of anchusin and alkanin. The anchusin has been extracted and studied by C. J. S. Thompson. (A. J. P., 1886, 409.) He finds it to vary in amount between 5.25 and 6.02 per cent. It is red, resin-like, insoluble in water, soluble in oils, alcohol, chloroform, and ether, and with a rich deep blue color in alkaline hydroxides, the color changing again to crimson on addition of an acid. According to A. Gawalowski, the red coloring matter of alkanet root consists of two distinct bodies, the one turning blue, the other green by the action of alkalies. The first of these, alkanic acid, is extracted by ether and alcohol. The second, anchusic acid, is obtained by extraction with benzene. Both form characteristic colored salts. (Ph. Ztg., 1902, 817.) Alkanet is somewhat astringent, and was formerly used in several diseases; but it is now employed exclusively for coloring oils, ointments, and plasters, which are beautifully reddened by one-fortieth of their weight of the root. The best way to use it with this object in view is to suspend the alkanet, after tying it in a piece of flannel, in the melted fat. A fine color is obtained by previously washing the alkanet with water and then thoroughly drying it before suspending it in the fat or oil. It is said also to be used in the preparation of spurious port wine. The Oleum Hypericum, formerly much used under that title or the name Red Oil, consisted of fixed oil colored with alkanet.

Allamanda,—Allamanda cathartica, L., is a shrub of the Fam. Apocynaceae growing in Porto Rio, the extract of whose bark is said to be an excellent hydrogogue cathartic, in doses of one to two grains (0.065-0.13 Gm.).

Alliaria. Alliaria officinalis Andrz. [Sisymbrium Alliaria, Scop. Erysimum Alliaria, L. Alliaria Alliaria (L.) Brit.] HedgeGarlic.—A perennial European herb, a native also of Northern Asia, and naturalized from Canada to Virginia, having an alliaceous odor when rubbed, and a bitterish, somewhat acrid taste. When eaten it communicates its odor to the breath. Wertheim obtained from the root a volatile oil, apparently identical with that of mustard. (Ann. Ch. Ph., liii, 52.) The herb and seeds are esteemed diuretic, diaphoretic, and expectorant, and are used as external applications in gangrenous affections, and to promote suppuration.
**Alnus.** Alder.—Of this genus of small trees or bushes, *A. glutinosa* (L.) Medic., or European Alder, Black Alder; *A. rugosa* (Du Roi) K. Koch (*A. serrulata* Willd.), or American Alder; *A. incana* (L.) Willd., or Tag Alder, are tonic and astringent, and have been used in intermittent fever, the bark being the part employed. *A. glutinosa* has been used for dyeing and also for tanning. According to Eitner, the bark contains from 16 to 20 per cent. of tannic acid. The tannic acid, however, appears to differ from that of galls and oak bark, as, according to Stenhouse, it does not yield glucose when acted on by sulphuric acid. (P. J., Dec., 1861.) F. Dreykorn and E. Eichardt, however, state that it is resolved by sulphuric acid into alnine red and sugar. (A. J. P., xlii, 403.)

**ALOE. U. S., Br. ALOES**

"The inspissated juice of the leaves of *Aloe Perryi* Baker, yielding Socotrine Aloes; or *Aloe vera* Linne yielding Curacao Aloes; or of *Aloe ferox* Miller, yielding Cape Aloes (*Pam. Liliaceae")." U. S. "Aloes is the juice that flows from the transversely cut leaves of *Aloe chinensis*, Baker, *Aloe Perryi*, Baker, and probably other species of *Aloe*, evaporated to dryness. Known in commerce as Curacao aloes, Socotrine aloes, or Zanzibar aloes." Br.

*Aloe Barbadensis; Aloe Socotrina; Aloes socotrin, ou sucotrin, Fr.; Aloes hepatique des Barbades, Fr.; Socotora oder Socotriniache Aloe, G.; Barbados Aloe, G; Musebber, Ar.; Acibar Sucotrino, Sp.*

The 1890 edition of the U. S. Pharmacopoeia agreed with the British in recognizing as distinct varieties Barbados and Socotrine aloes; but both standards now recognize only the general title of *Aloe*.

Most plants belonging to the genus *Aloe* are capable of yielding a bitter juice from which may be prepared an aloes, and there is little doubt that in many cases a commercial aloes exported from one country is the product of several species.

1. *A. Perryi*, J. G. Baker, Tr. Linn. Soc., xxviii. The true Socotrine aloe plant was first described from specimens sent to Kew Gardens by Wykeham Perry, and was subsequently found by Balfour, of Edinburgh, growing abundantly upon the island of Socotra, especially in the limestone tracts, from the sea level to an altitude of 3000 feet; along with it, but much less abundant, was a dwarf species with spotted leaves. It resembles in its general habit the Barbados aloe, but differs in its shorter leaves, and especially in its flowers, which are arranged in...
looser racemes on longer pedicels and have the tube much longer than the segments.

The proper aloetic juice was formerly thought to exist in longitudinal vessels beneath the epidermis of the leaves, and readily flows out when these are cut transversely; but, according to E. Robiquet, who made elaborate researches in relation to this drug, these vessels are air ducts, and the juice flows in the intercellular passages between them. The liquid obtained by expression from the parenchyma is mucilaginous, and possessed of little medicinal virtue. After condensation by artificial or natural heat the aloe juice is poured into gourds, more commonly boxes, or into monkey skins, allowed to harden and sent into commerce.

2. A. vera L.—This species, which is the source of Curacao Aloes, has a very short, woody stem, and lanceolate embracing leaves, which are first spreading, then ascending, of a glaucous green color, somewhat mottled with darker spots, flat on the upper surface, convex beneath, and armed with hard reddish spines, distant from each other, and perpendicular to the margin. A. vera is a native of Southeastern Europe, Northern Africa, and Madagascar. It is cultivated in Italy, Sicily, Malta, and especially in the West Indies, where it contributes largely to furnish the Barbados aloe.

3. Aloe chinensis Baker.—This species was introduced from China into the Dutch Colonies of Curacao by W. Anderson, in 1817. It was described by Haworth from flowerless specimens as a probable variety of A. barbadensis. It is apparently, however, a distinct species and is so recognized in the British Pharmacopoeia. The leaves of A. chinensis are not more than half the length of those in A. barbadensis, and are more or less copiously spotted on the dorsal surface as in A. abyssinica. The flowers have a strong and decidedly unpleasant odor; and occur in loose racemes, the stamens being much shorter than in A. barbadensis. Holmes suggests that A. chinensis may be a native of Africa, Arabia or India. Engler considers that A. chinensis is merely a form related to A. vera. (Baker, in J. L. S.) xviii, p. 161; Holmes, P. J., xxi, p. 205.)

4. A. ferox Miller yields Cape Aloes. It has a simple stem ten to fifteen feet long, four to six inches in diameter; furnished at the top with a dense rosette containing thirty to fifty leaves, which are lanceolate, one and one-half to two feet long, very rigid, with copious prickles on back and face, the margin armed with brown-tipped deltoid or cuspidate
prickles one-eighth to one-sixth of an inch long.

According to L. Pappe, Cape aloes of poor quality is obtained from A. africana and A. plicatilis, of Miller; while in Lindley's Flora Medica, A. purpurascens Haworth, A. arborescens Mill., A. Commmelina Willd., and A. multiformis are all said to contribute to commercial Cape aloes. Curacao Aloes is apparently produced by the following species: A. vera (L.) Webb, A. vulgaris Lam., A. spicata L., and A. socotrina Lam., all of which have been introduced into the island (see P. J., Jan., Sept., 1890), although E. M. Holmes believes it to be at least in part the product of A. chinensis Baker.

Commercial History and Varieties.—Three chief varieties of aloes have been known in comparatively recent commerce: Socotrine, Barbados or Curacao, and Cape.

SOCOTRINE ALOES.—This variety appears to have been the original aloes, having been produced in the island of Socotra at least as early as the time of Alexander the Great, 333 B.C., who is said to have sent a commission to investigate its manufacture. Very little, however, of the true Socotrine aloes at the present time comes into the Western markets, the aloes which reaches European commerce from Bombay, Muscat, Aden, and Zanzibar having various botanical and geographical origins. This form of aloes under the title of "Aloes Socotrina" alone is official in the Spanish Pharmacopoeia. It is said to be derived from Aloe vera Mill., A. spicata Thumb., A. ferox L., A. arborescens Mill., and A. lingua-formis L., and other species of aloes.

It is stated that the production of aloes in Arabia was formerly a government monopoly, but that at present it is entirely free to the inhabitants. The leaves, which are cut at any time of year, are allowed to drain into a goat's or sheep's skin, and the gathered juice permitted to evaporate spontaneously. In the course of about one month, when it has become thick and viscid, it is known by the Arabic name of Jayef Gesheeshah; several weeks subsequently, when it has become hard, it is called Jayef Kasahul. Due to its exposure throughout the long process of desiccation, all the varieties of Socotrine aloes contain much foreign matter, which, according to E. R. Squibb, amounts to from 7 to 22 per cent. of the bulk.

The best Socotrine aloes occurs in pieces varying from a dark ruby-red
to a yellowish or reddish-brown, more or less semi-transparent, with a
glossy surface and a smooth or ragged but not conchoidal fracture, and
yielding a bright golden-yellow powder. Its odor is peculiar, almost
fragrant, especially developed by breathing upon the aloes, and its
bitter, dia-agreeable taste has a somewhat aromatic tang. The poorest
variety of Socotrine aloes, Mocha aloes of the East, is soft, dark, and
malodorous. Much of the drug supplied American dealers in recent years
has consisted of this variety. Even the finest Socotrine aloes may consist
of an orange or yellow colored distinctly fragrant, semi-liquid mass,
while the variety known as Zanzibar aloes usually occurs in liver-brown
masses, with a dull, waxy fracture, a characteristic odor and a
nauseous, bitter taste. The variability of Socotrine aloes probably
depends upon not only different methods of preparation but a different
origin. Both Zanzibar and true Socotrine Aloes " are opaque even in
small splinters, exhibit when examined under the microscope numerous
minute crystals embedded in a transparent mass, and impart to nitric
acid a reddish or yellowish-brown color." Br., 1900.

CURACAO or BONAIRE ALOES.—This aloes, which is produced in the
Dutch West Indian Islands, chiefly in the island of Aruba, appears not
to have entered commerce extensively before the early part of the 19th
century, but at present constitutes a very large proportion of commercial
aloes. It occurs chiefly in three forms; first, an opaque, brittle aloes,
showing abundant crystals under the microscope, and sold in gourds
usually as Barbados aloes; second, aloes having an appearance like the
first variety but sold in cases; third, glossy Curagao or Capey Curacao
aloes, which occurs in cases acd is glossy and transparent.

It is affirmed that the difference in these varieties of Curacao aloes
depends upon the extent of the evaporation by artificial heat, the aloes
being dg|rk colored and opaque when poured into the gourds while still
soft; glossy and transparent when allowed to evaporate to dryness over
the fire. It is said that the juice is obtained by allowing the leaves to
drain into V-shaped troughs, and that it is never evaporated
spontaneously.

According to P. van der Wielden, shining Curacao aloes dissolves
completely in nitric acid with the production of a red color, while the dull
Curacao aloes, giving the same color reaction, fails to entirely dissolve.
Kremel gives a method to distinguish Curacao aloes from other kinds by
adding to it a little cupric sulphate solution, then some saturated
solution of common salt, which makes the color an intense carmine. The reaction is due to cuproaloin. (C. D., 1895, 759.) Curacao aloes is sometimes found in the markets which has been deprived of its aloin; this fraudulent product is then sold as Cape aloes; the odor of the Curacao variety still remains.

BARBADOS ALOES.—This aloes appears to have been brought to London as early as 1693, and to have reached its greatest commercial abundance in the year 1843, when 4227 gourds of it are said to have been exported from Barbados, a gourd containing from twenty to sixty pounds. Occasionally small quantities of Barbados aloes are on the American markets. Most of the Barbados aloes was produced from A. vera, although A. socotrina, A. purpurascens, and A. arborescens are said to have been cultivated.

The method of obtaining Barbados aloes seems to have varied at different periods of time, and possibly in different portions of the island. According to various authors the lower ends of the freshly cut leaves were put into wooden V-shaped troughs, and the exuding juice collected and dried in the sun or boiled in copper pans; again, a decoction of the chopped-up leaves was boiled to the proper consistency; in either case, when the liquor had become so thick that it hardened on cooling, it was poured into calabashes or gourds.

Barbados aloes, as formerly supplied, varied in color from very dark blackish-brown through reddish-brown and liver-colored to orange-brown. It yielded a dull olive-yellow powder, of a disagreeable, even nauseous odor, and it was described in the British Pharmacopoeia as follows: "Fracture either dull and waxy, in which case small splinters are opaque; or smooth and glassy, in which case the splinters are transparent; the opaque variety examined under the microscope exhibits numerous minute crystals embedded in a transparent mass." Br., 1898.

"Mixed with nitric acid, it acquires a red color. Barbados Aloes is not colored, or acquires only a light bluish-green tint, on being mixed with sulphuric acid and blowing the vapor of nitric acid over the mixture (difference from Natal aloes)" U.S., 1890.

According to Marais, Barbados aloes could be distinguished by the fact that its solution in distilled water, 1 to 100,000 parts, yielded on the
addition of gold chloride or of tincture of iodine a fine rose color, all other varieties of aloes producing with the reagents named either a feeble color of slow development, or no change of color whatever.

CAPE ALOES.—The general method of collecting Cape aloes is to allow the excised leaves to drain into a sheep's skin, which has been so placed in a hole in the ground as to force the juice to collect in the center. Later this juice is evaporated by artificial heat, and when sufficiently concentrated, poured into boxes or skins. Cape aloes differs from Socotrine aloes, especially in its brilliant conchoidal fracture and peculiar odor, which is strong, but neither nauseous nor aromatic. When freshly broken it has a very dark olive or greenish color approaching to black, presents a smooth, bright, almost glassy surface, and if held up to the light appears translucent at its edges. The small fragments also are semi-transparent, and have a tinge of yellow or red mixed with the deep olive of the opaque mass. The same tinge is sometimes observable in the larger pieces. The powder is of a fine greenish-yellow color, and, being generally more or less sprinkled over the surface of the pieces as they are kept in the shops, gives them a somewhat yellowish appearance. Cape aloes, when quite hard, is very brittle and readily powdered; but in very hot weather it is apt to become somewhat soft and tenacious, and the interior of the pieces is occasionally more or less so even in winter. This variety alone is official in the Swiss, German, and Austrian Pharmacopoeias.

Uganda or crown aloes is a brand of Cape aloes produced by manufacturers who buy the aloe juice from the collectors, allow it to undergo a slight fermentation, and dry it in the sun in wooden troughs. It is sent into commerce in bags containing coarse or fine powder, or chips, and in bricks wrapped in red paper; it has a very bitter, aromatic taste and a strongly aromatic odor. The bricks are of a hepatic brown color, with a resinous fracture, which has a bronzy-gold luster by reflected light. Splinters are translucent, but not garnet-red. With nitric acid it forms a brown solution, gradually changing through dull brownish-yellow to a deep green color.

Natal aloes is a variety coming from Natal, on the southeast coast of Africa, which occurs in irregular pieces, with a fracture much less shining than that of Cape aloes and a totally different color, having a greenish slate hue. It yields a greenish-brown powder, which has the odor of Cape aloes. It is less soluble than Cape aloes, and has a peculiar
composition, which will be adverted to under the chemistry of the drug.

Besides the chief varieties of aloes, others are, or have been, known in the market. Hepatic aloes, as well as fetid, caballine or horse aloes, have no proper claim to be considered distinct varieties, being simply inferior aloes of various origins, the first liver-colored, the second blackish and fetid and full of impurities. Jafferabad aloes, supposed to be the same as Mocha aloes (A. J. P., 1881, 175), has been shown to be the product of A. abyssinica Lam., and is said by Shenstone to contain b-barbaloin. (A. J. P., 1883, 92.) Aloes made in India from the A. vera is known as Musambra aloes. It appears to be a very inferior variety, and rarely, if ever, reaches Europe. (P. J., Aug., 1889.) Occasionally aloes is found on the market in which the aloin has been removed. Noyes has reported the presence of pea flour in the powdered drug.

It is evident that the labels under which aloes are largely sold often have little or no connection with the place of production, or with the variety of aloes in the package. This fact has probably come about through the indifference of retail druggists to the variety of the aloes which they are using, an indifference largely due to their common habit of buying aloes in powder. Wilbert (A. J. P., 1903) proposed that aloes should be classified as follows:

Aloes A.—Containing barbaloin; responds to Borntrager's test for emodin, but does not give a distinct red color with nitric acid, or with Klunge's test.

Aloes B.—Containing isobarbaloin with barbaloin; responds to Borntrager's test for emodin, and also has a deep red color with strong nitric acid, or with Klunge's test.

Properties.—The commercial aloes are sometimes divided into two groups:

1. Those which are shiny and amorphous, as Cape aloes, and
2. Those which are of a dull color and crystalline. To this latter group most of the other aloes belong. They are also grouped geographically as follows.
1. South African aloes, including Cape and Natal.
2. East African aloes, including Socotrine, the brown and black Zanzibar aloes and Madagascar aloes.
3. The West Indian aloes which includes the Curacao, Barbados and Jamaica varieties.
4. The East Indian aloes which includes Jafferabad and Musumbra aloes. The official description is limited to the three principal varieties, viz., Socotrine, Curacao and Cape aloes and is as follows:

"Socotrine Aloes."—In yellowish-brown to blackish-brown, opaque or smooth and glistening masses; fractured surface somewhat conchoidal; sometimes soft or semi-liquid; odor aromatic or saffron-like, never fetid or putrid; taste nauseous, bitter. Not less than 50 per cent. of Socotrine Aloes is soluble in cold water, the solution being of a yellowish color. The powder is dark brown; when mounted in expressed oil of almond and examined under the microscope, it shows yellowish- to reddish-brown, irregular or angular fragments. On adding nitric acid, it yields a yellowish- to reddish-brown solution.

"Curacao Aloes."—In orange to blackish-brown, opaque masses; fractured surface uneven, waxy, somewhat resinous; odor characteristic but not aromatic as in Socotrine Aloes. Not less than 60 per cent. of Curacao Aloes is soluble in cold water, the solution being of a purplish-red color. The powder is deep reddish-brown; when mounted in expressed oil of almond and examined under the microscope, it shows numerous blackish-brown, irregular, more or less opaque and angular fragments. Upon the addition of nitric acid yields immediately a deep red liquid.

"Cape Aloes."—In reddish-brown or olive-black masses, usually covered with a yellowish powder, or in thin, transparent fragments of a reddish-brown color; fracture smooth and glassy; odor characteristic. Not less than 60 per cent. of Cape Aloes is soluble in cold water, the solution being of a pale yellow color. The powder is greenish-yellow, changing to light brown on aging; when mounted in expressed oil of almond and examined under the microscope, it shows numerous, distinctly angular, bright yellow fragments. Upon the addition of nitric acid, it yields a liquid that is colored reddish-brown, changing to purplish-brown and finally greenish.

The tests which follow apply to Socotrine, Curacao, and Cape Aloes. Aloes contains not more than 10 per cent. of moisture. Add 50 mils of alcohol to 1 Gm. of Aloes, gently heat the mixture and then cool it; a nearly clear solution is obtained (gum and inorganic impurities)*
Intimately mix 1 Gm. of Aloes with 10 mils of hot water and dilute 1 mil of this mixture with 100 mils of water; a green fluorescence is produced upon the addition of an aqueous solution of sodium borate (1 in 20). Dilute 1 mil of the original aqueous mixture of Aloes with 100 mils of water, and shake it with 10 mils of benzene; upon separating the benzene solution and adding to it 5 mils of ammonia water, a permanent deep rose color is produced in the lower layer. Aloes yields not more than 4 per cent. of ash." U. S.

The 1914 British Pharmacopoeia gives the following description: "In hard masses, varying in color from yellowish-brown to dark or chocolate-brown. Fractured surface dull, waxy and uniform (Curacao and Zanzibar aloes), or uneven and somewhat porous (Socotrine aloes). Small splinters examined under the microscope exhibit minute crystals embedded in a transparent mass. Characteristic odor; taste nauseous and bitter. The solution obtained by dissolving 0.1 gramme of Aloes in 10 millilitres of boiling water and adding 0.5 gramme of purified borax acquires a green fluorescence. Nitric acid dropped on a little crushed Aloes acquires a reddish-brown color (Socotrine and Zanzibar aloes), or a crimson color (Curacao aloes). Almost entirely soluble in alcohol (60 per cent.). Loss on drying at 100° C. (212° F.) not more than 10 per cent. Ash not more than 5 per cent." Br.

**Chemical Properties.**—Several distinguished chemists have investigated the nature and composition of aloes. Braconnot found a bitter principle, which he named resino-amer (resinous bitter), and another substance in smaller proportion, which he designated by the name of fleæ-colored principle. These results were essentially confirmed by Trommsdorff, Bouillon-La-grange, and Vogel. Robiquet obtained a product from aloes which he called aloëtin. (For details, reader is referred to 14th ed., U. S. Dispensatory.)

**ALOINS.**—The bitter substances noticed above, viz., the resino-amer of Braconnot, and the aloëtin of Robiquet, probably contain the active principle of aloes, but combined with impurities which render it insusceptible of crystallization. It has been assumed that there exists not one compound, but a set of three closely related compounds, to which the general name of aloins is now given. The first of these, found exclusively in Barbados, aloes, and discovered by T. and H. Smith, is called barbaloin; the second, discovered by Fliickiger in Natal aloes, is called nataloin; the third, found by Histed and Fluckiger in Socotrine
aloes, is called socaloin.

The three aloins, barbaloin, nataloin, and socaloin, are easily distinguished by the following reaction, first noticed by Histed. A drop of nitric acid on a porcelain slab gives, with a few particles of barbaloin or nataloin, a vivid crimson (rapidly fading in the case of barbaloin, but permanent with nataloin unless heat be applied), but produces little effect with socaloin. To distinguish barbaloin from nataloin, test each by adding a minute quantity to a drop or two of sulphuric acid, then allowing the vapor from a rod touched with nitric acid to pass over the surface. Barbaloin (and socaloin) will undergo no change, but nataloin will assume a fine blue. (Pharmacographia, 2d ed., p. 688.) E. von Sommaruga and Egger consider that the three aloins form a homologous series possessing the formulas: barbaloin, $\text{C}_{17}\text{H}_{20}\text{O}_{7}$; nataloin, $\text{C}_{16}\text{H}_{18}\text{O}_{7}$; socaloin, $\text{C}_{15}\text{H}_{16}\text{O}_{7}$, and that they are all derived from anthracene, $\text{C}_{14}\text{H}_{10}$. Tilden subsequently assigned a different composition to the aloins: barbaloin and socaloin, each $\text{C}_{16}\text{H}_{18}\text{O}_{7}$; for nataloin, the formula $\text{C}_{25}\text{H}_{28}\text{O}_{11}$. He further states that barbaloin and socaloin differ in physical and chemical properties on account of the variation in the molecules of water which are associated with them. Leger assigns to nataloin the formula $\text{C}_{23}\text{H}_{26}\text{O}_{10}$. The British Pharmacopoeia (1898) assigns to barbaloin the formula $\text{C}_{16}\text{H}_{16}\text{O}_{7}\cdot 3\text{H}_{2}\text{O}$. Two bases only are recognized now, barbaloin (or simply aloin) and isobarbaloin. According to Leger (P. J., 1902, 21) Cape aloes contains from 5 to 6 per cent. of aloin (barbaloin) without any admixture of the isomeric isobarbaloin. The Barbadoes aloes of English commerce never gave more than 5 per cent. of barbaloin with but minute traces of isobarbaloin, which, however, is always met with in the so-called Barbados aloes of French commerce. Curacao aloes is rich in aloin, containing 10 per cent., of which half is barbaloin and the other half isobarbaloin. Jafferabad aloes is very rich in aloin, yielding 20 per cent., chiefly in the form of isobarbaloin. Socotrine aloes does not contain more than 4 per cent. of aloin, almost wholly barbaloin with a very little isobarbaloin. Since barbaloin is found in almost all varieties, the significance of the prefix “barb” is misleading. The only aloes in which it does not occur is that of Natal.

Hugo Borntrager asserted that one part of aloes in 5000 can be detected in the following manner. A little of the suspected liquid is shaken with
about twice its bulk of benzin, which is allowed to separate, decanted, and shaken with a few drops of stronger water of ammonia. On separation the ammonia will be of a clear red color. With solids a tincture should first be made. According to R. H. Groves (P. J., 3d ser., si, 1045), this test will never succeed with a less concentration than 1 part in 250, and with some aloes 1 in 100, and is due to the tannin-like substance of aloes; he also states that extreme care is necessary to have the benzin solution perfectly clear. (P. J., 1885, p. 633. For Hager's quantitative method for determining the percentage of aloin in aloes, see A. J. P., 1885, p. 237.

R. A. Cripps and T. S. Dymond have given the testing of aloes a lengthy investigation, and they recommend the following method. Place 1 grain of the substance in a glass mortar standing on white paper, now add 16 drops of strong sulphuric acid and triturate until dissolved, then add 4 drops of nitric acid, sp. gr. 1.42, and then 1 ounce of distilled water. If aloes be present, a color varying from deep orange to crimson will be produced, according to the kind of aloes that has been used; the color is deepened by the addition of ammonia. The table below is taken from the paper of Bainbridge and Morrow. (P. J., Jan., 1890.) Under the heading of Kew Specimens are given the results obtained with juice of aloes plants grown in Kew Gardens.

Tschirch, of Berne, has published (B. P. G.) 1898, viii, Heft 6) an important communication, in which he showed that emodin, \(C_{15}H_{10}O_5\), or trioxymethylanthraquinone, is the purgative principle of the aloins. He succeeded in obtaining emodin in orange-red crystals which melt at 216\(^{\circ}\) C. (420.8\(^{\circ}\) F.). Emodin was found in the aloins obtained from Cape, Barbadoes, and Socotrine Aloes; it is extracted by treating barbaroin with ether, which dissolves out the emodin. Tschirch found that if a liquid extract of aloes be deprived of its resin and aloin, an additional quantity of emodin could be obtained by boiling the liquid extract with diluted sulphuric acid, thus pointing to the fact that emodin may be produced through hydrolysis. He also showed that emodin could be obtained from purgative drugs of the same class as aloes: rhubarb, rumes, frangula, cas-cara, senna, rhamnus catharticus, morinda bark, and parmelia.

Aloes yields its active matter to cold water, and when good is almost wholly dissolved by boiling water; but the inert portion, or apotheme of Berzelius, is deposited as the solution cools. It is also soluble in alcohol, rectified or diluted. Long boiling impairs its purgative properties by oxidizing the aloin and rendering it insoluble. The alkalies, their carbonates, and soap alter in some measure its chemical nature, and render it of easier solution. It is inflammable, swelling up and decrepitating when it burns, and giving out a thick smoke which has the odor of the drug.

Those substances only are incompatible with aloes which alter or precipitate the soluble matter, as the insoluble portion is without action upon the system. Among these is the infusion of galls, which we have found, probably through its tannic acid, to afford a copious precipitate with an aqueous solution of aloes. It is said that such a mixture will keep a long time, even for a period of several months, without moldiness or putrescence, though it becomes ropy.

A method for the detection of aloes in mixtures containing other cathartic drugs, such as rhubarb, caseara, etc., has been described by Mossley (Chem. and Drug., 1913, 915). The method depends upon the precipitation of the oxymethyl anthraquinones, which usually interfere in such identification tests, and the subsequent detection of aloes by the addition of bromine T.S., which precipitates aloin, and the green fluorescence produced with aloes by borax.
Uses.—Aloes was known to the ancients, being cultivated in the island of Socotra as far back as the time of Alexander the Great, and is mentioned in the works of Dioscorides and of Celsus. Its cathartic action is due to a stimulation of peristalsis, especially in the larger bowel, probably the result of a local irritant effect upon the mucous membrane, although there is some evidence that it exercises a specific stimulant effect upon unstriped muscles. As its action is largely limited to the colon it is not to be recommended in those conditions in which it is desirable to clean out the whole alimentary canal, and as its effect is largely the result of local irritation it should be avoided in inflammatory conditions of the intestines. In chronic constipation, however, especially when dependent upon an atonic condition of the lower bowel, it is one of the most useful laxatives that we possess. Many believe that it possesses a direct tonic action, not only evacuating the bowel of its contents but encouraging a restoration toward normal conditions. The presence of bile in the bowel seems in some way to be essential for the best effects of this drug, and in those cases in which this secretion is lacking it is well to exhibit some preparation of bile in conjunction with the aloes. Soap also appears to enhance the cathartic action of this drug. It was formerly almost universally believed that aloes possessed emmenagogue properties and it was accordingly largely used in the treatment of various forms of amenorrhea. It is, however, extremely doubtful whether it exercises any action upon the pelvic organs which is not attributable to its cathartic effects.

Crude aloes is rarely used in human medicine, but may be given in doses of from two to ten grains (0.13-0.65 Gm.).

ALSTONIA. Br. ALSTONIA

"Alstonia is the dried bark of Alstonia scholaris, E. Br., and also of Alstonia constricta, F. Muell." Br.

Dita Bark; Australian Fever Bark; Bitter Bark.

Under Alstonia the British Pharmacopoeia recognizes the dried barks of Alstonia scholaris (L.) R. Br. (Echites scholaris L.), of India and the Philippine Islands, and Alstonia constricta F. Muell., of Australia, two apocynaceous trees whose barks are quite dissimilar in appearance, and, as far as our present knowledge goes, contain different alkaloids. These barks are respectively described as follows:

“Bark of Alstonia scholaris usually in irregular fragments, three to twelve millimetres thick; texture somewhat spongy, fracture short and coarse; external layer unevenly rough and fissured, brownish-grey with occasional blackish spots; internal layer bright buff. Transverse section shows numerous small medullary rays in inner layer. Almost odorless; taste bitter. Bark of Alstonia constricta usually in curved pieces or quills about sixty millimetres wide, and twelve millimetres thick. Periderm from two and a half to six millimetres thick, rusty brown, strongly rugose, with large deeply fissured reticulations. Bark internally cinnamon-brown, with strong, coarse longitudinal striae. Transverse section shows dark-brown periderm covering the inner orange-brown tissues, in which numerous small shining particles can be seen with a lens. Fracture short and granular in outer layers, fibrous in inner. Slight aromatic odor; taste very bitter.” Br.

From the bark of Alstonia scholaris M. Gruppe extracted an uncrystallizable, hygroscopic, bitter principle, ditaine. (J. P. C., 4e ser., xviii, 225; xix, 84; P. J., Aug., 1875.) Harnaek (Ber. d. Chem. Ges., 1878) first obtained ditaine in pure crystallized form, and gave it the formula C_{20}H_{30}N_{2}O_{4}. O. Hesse (P. J., Oct. 23, 1880) finds in dita the following principles: three alkaloids: ditamine, O_{16}H_{9}O_{2}N, the relative amount of which he estimates at 0.04 per cent.; echitamine, C_{22}H_{28}O_{4}N_{2} + H_{2}O (identical, according to Hesse, with Harnack's ditaine); and
echitenine, $C_{20}H_{27}O_4N$. Of these, the second is the strongest base, and resembles ammonia in its chemical characters; Hesse considers it with one molecule of water to form the hydroxide of a strong basic radical, echitammonium, $C_{22}H_{29}O_4N_2$. The solutions of echitammonium hydroxide are so strongly basic that they precipitate the hydroxides of copper, iron, aluminum, and lead, and decompose sodium and potassium chlorides, liberating the corresponding hydroxides. Hesse considers echitammonium the most strongly basic of all the alkaloids. Hesse also obtained by extraction with petroleum benzin echicautchin, echiretin, echicerin, echitin, and echitein, of which the three last mentioned are crystalline.

From Alstonia constricta, F. V. Miiller and A. Rummel obtained alstonine. Oberlin and Schlagdenhauffen found in 1879 another alkaloid, alstonicine. Hesse subsequently analyzed the bark and found alstonine, the chlorogenine of a former investigation, which has the composition $C_{21}H_{20}O_4N_2$, prophyrine, $C_{21}H_{25}O_2N_3$, and alstonidine. The alkaloids and their salts in acidulated solutions show decided blue fluorescence.

**Uses.**—This drug has been used for many years in Australia and the Philippine Islands in the treatment of malarial and other fevers, as well as a simple bitter. The alkaloid ditaine has been scientifically studied by Harnach (A. E. P. P., 1877, xvii, p. 126), who finds that it has a paralyzing effect upon the endings of the motor nerve similar to that produced by curara. In large dose it also paralyzes the cardio-inhibitory nerves and lowers blood pressure. There is nothing in this study, which is, as far as we know, the only scientific investigation of the drug which has been made, to explain any action in malaria. Nevertheless some of the clinical reports, especially from the eclectic physicians, have been extremely laudatory, vaunting it even as a substitute for quinine.

Dose, two to four grains (0.13-0.25 Gm.).

**Off. Prep.**—Infusum Alstonia; Br.; Tinctura Alstoniffi, Br.

**ALTHAEA. U. S. ALTHAEA** [Marshmallow root]

"The root of Althaea officinalis Linne (Fam. Malvaceæ) deprived of the brown, corky layer and small roots, and carefully dried. Preserve Althaea in tightly-closed containers, adding a few drops of chloroform or
carbon tetrachloride from time to time, to prevent attack by insects." U.S.

Radix Hibisci, Radix Bismalvae; Wymote, White Mallow, Mortification root; Racine de Guimauve, Guimauve, Fr.; Radix Althaeae, P. G.; Altheewurzel, Althee, Eibischwurzel; Eibisch, G.; Altea, Malvavischio, It.; Altea, Raiz de Malvavisco, Sp.

Althaea officinalis is an herbaceous perennial, with a perpendicular branching root and erect woolly stems, from two to four feet or more in height, branched and leafy towards the summit. The leaves are described under Folio Althaea, p. 120. The flowers are terminal and axillary, with short peduncles, each bearing one, two, or three flowers. The corolla has five spreading, obcordate petals, of a pale rose color. The fruit consists of numerous capsules united in a compact circular form, each containing a single seed. The plant grows throughout Europe, inhabiting salt marshes, the banks of rivers, and other moist places. It is found also in this country, from New England to New York and westward to Michigan and Arkansas. It is largely cultivated in Europe for medicinal use, particularly in Germany, Belgium and France.

The roots should be collected in autumn from plants at least two years old. They are usually prepared for the market by removing the outer layers. The commercial drug sometimes consists of the unpeeled root, which is sliced transversely and diagonally.

Properties.—Althaea is usually cut into small pieces about 5 mm. in diameter, of a uniform grayish-white color and otherwise having the characters of entire roots; occasionally entire, slenderly tapering, attaining a length of 30 cm. and a thickness of 2 cm., externally whitish, longitudinally furrowed, frequently spirally twisted and covered with the somewhat loosened bast-fibers; fracture of bark fibrous, of wood short and granular; internally yellowish-white; bark 1 to 2 mm. thick, porous, due to mucilage cells, and separated from the slightly radiating wood by a distinct, grayish cambium zone; odor slight; taste sweetish, mucilaginous. The powder is whitish; starch grains numerous, from 0.003 to 0.02 mm. in diameter, usually with a long cleft at the point of origin of growth; sclerenchymatous fibers in groups, the walls being quite thick and more or less lignified; trachese with scalariform thickenings or with bordered pores; calcium oxalate crystals few, in rosette aggregates from 0.02 mm. to 0.03 mm. in diameter. Add 1 Gn. of Althaea to 10 mils of cold water, allow it to stand with occasional stirring during
thirty minutes, and filter through cotton; a pale yellow-colored mucilage is obtained, which is neutral to litmus and is colored a deep yellow on the addition of a few drops of potassium hydroxide T.S. The mucilage does not have a sour or ammoniacal odor. Althasa yields not more than 8 per cent. of ash."

The abundant mucilage is situated chiefly in special cells, and can be seen to be in layers when alcohol is added. Kraemer (A. J. P., 1898, p. 285) proposed the use of an alcoholic solution of methylene blue for the differentiation of the mucilage. It, with starch and saccharine matter, is taken out by boiling water. The mucilage, without the starch, is extracted by cold water, which thus becomes ropy. A principle was discovered in the root by Bacon, which has been ascertained to be identical with asparagin, C₄H₈N₂O₃ + H₂O. Boutron-Charland and Pelouze found it to belong to that class of organic principles which are convertible by strong acids, and other agencies, into ammonia and organic acids, and which are designated by the termination amide, being compounds of acid radicals with the group NH₄. When such an amide is acted upon by acids, it is decomposed, the acid radical taking OH to form the free acid and the amide group taking H to form ammonia. Thus asparagin, which in this view should be called asparamide, is converted into ammonia and aspartic acid, C₄H₇NO₄, and one molecule of the resulting ammonium aspartate corresponds with one molecule of asparamide and one of water. (J. P. C., xix, 208.) Asparagin, being now recognized aa a derivative of succinic acid, is called amido-succinamide, and the aspartic acid is called amido-succinic acid. It is found in various other plants besides the marshmallow, as in the shoots of asparagus, in vetches grown in the dark, in all the varieties of the potato, and in the roots of the comfrey and licorice plant.

According to Pira, asparagin has acid properties. It has no therapeutic value. Betaine (trimethyl-glycocoll) has been obtained from Althaea by Orlow. (Ph. Z. R., 1898.)

The roots of other Malvaceae are sometimes substituted for that of marshmallow, without disadvantage, as they possess similar properties. Among these are Althaea rosea Cav., or hollyhock, and Malva Alcea L. The dark purple flowers of a variety of A. rosea have been proposed as a test for acids and alkalies. A strong infusion of these flowers imparts to slips of white filtering paper a permanent purplish-blue color, which is reddened by acids, and rendered bluish-green by alkalies.
ALTHAEA or MARSHMALLOW LEAVES, under the title of Folia Althaeæ, are official in the Swiss, German and Austrian Pharmacopoeias and as Althææ Folia in the National Formulary. The leaves are collected in June or July, while the plant is in flower, and dried. They are described in the N. F. as "the dried leaves of Althææ officinalis Linne (Fam. Malvaceæ), without the presence of more than 5 per cent. of stems or other foreign matter." N. F. As seen in commerce they are "gray-green or yellowish gray-green and densely and finely tomentose throughout; petioles one-sixth to one-fifth as long as the blades; blades varying from 5 to 15 cm. in length and from 3 to 10 cm. in breadth, cordate or rhomboidal-ovate in outline, rounded or occasionally nearly truncate at the base, acute at the summit; margin doubly serrate-dentate, the principal teeth from one to three pairs, the lowest almost large enough to be regarded as lobes, the secondary very irregular, triangular, acute, broader than long, the sinuses acute; two to four occasionally six principal veins originating with the midrib in the petiole, prominent underneath, terete; branches of the midrib arising at a wide angle, nearly straight, each terminating in a marginal tooth. Leaf thin, but appearing thick because of its hairy covering. Odor slight, scarcely characteristic; taste mucilaginous. The powdered drug is grayish to grayish-green and, when examined under the microscope, exhibits numerous unicellular, non-lignified stellate branching hairs, up to 0.6 mm. in length, usually occurring in clusters of two to six; few, short stalked, multicellular glandular hairs; calcium oxalate in rosette aggregates up to 0.025 mm. in diameter; fragments of the epidermal tissue with stomata, the latter about 0.025 mm. in length; few lamellated mucilage cells; usually a few pollen grains, spherical, spiny, up to 0.1 mm. in diameter. Althææ Leaves yield not more than 16 per cent. of ash." N. F.

Uses.—The virtues of marshmallow are exclusively those of a demulcent. The decoction of the root is much used in Europe in irritation and inflammation of the mucous membranes. A syrup of althæae is official in the German Pharmacopoeia, and was introduced into the U. S. Pharmacopoeias of 1880 and 1890 (see U. S. D., 18th edition, p. 1327). Owing to its tendency to ferment rapidly it was not retained in the U. S. P. VIII or IX, but is found in the N. F. IV. (See Syrupus Althææ.) The roots themselves, as well as the leaves and flowers, boiled and bruised, are sometimes employed as a poultice. In France the powdered root is much used in the preparation of pills and electuaries. It enters, as an
ingredient, into one mass and two pills of the U. S. P.

**Amapa Milk.**—The milky sap of the bitter bark of Plumeria Fallax (Fam. Apocynaceae), a Brazilian tree, has come into general use as a vermifuge and antimalarial, having been used and known by the natives of Brazil and South America from time immemorial. It is also used externally in the treatment of cancerous sores. Dose, for children, one minim for each year of age.

**Ambrosia.** Ambrosia trifida, L.  Ragweed, Roman Wormwood, Hog-weed, Bitter-weed, Ambrosie, Fr. Traubenkraut, G. (Fam. Compositae) —This and another indigenous annual, A. artemisiifolia L., are deemed by the eclectics astringent and stimulant, and are given in low forms of fever. L. W. Schwab has found in A. artemisiifolia a bitter glucoside (A. J. P., 1890), and Schimmel & Co. have obtained from it about 0.15 per cent. of a green volatile oil (sp. gr. 0.876). (Schim. Rep., 1904, p. 96.) The pollen of this plant is also said to be one of the causes of hay fever. It is estimated that there are about 90,000,000 pollen grains in a gramme of ragweed pollen.

**AMYGDALA AMARA. Br. BITTER ALMOND**

"Bitter Almond is the ripe seed of Prunus Amygdalus, Stokes, var. amara, Baill." Br.

Semen Amygdali Ama-rum; Amandes ameres, Fr. Cod.; Amygdalae Amarae, P. G.; Bittere Mandeln, G; Mandorle amare, It.; Almendras amargas, It.

Bitter almond was not made official in the U. S. P. IX.

The almond tree resembles that of the cherry. The leaves are elliptical, petiolate, minutely serrated, and are of a bright green color. The flowers are large, of a pale red color varying to white, with very short peduncles, and petals longer than the calyx, and usually stand in pairs upon the branches. The fruit is a drupe with the outer covering thin, tough, dry, and marked with a longitudinal furrow, where it opens when fully ripe. Within this covering is a rough shell, containing the kernel or almond.

There are several varieties of this species of Amygdalus, differing chiefly in the size and shape of the fruit, the thickness of the shell, and the
taste of the kernel. The two most important are the var. dulcis and the var. amara, the former bearing sweet, the latter bitter almonds. Both of these varieties have been known since ancient times. The var. dulcis yields the hard and paper-shelled variety. The latter, owing to the thin endocarp, is particularly suitable for table use. Another variety grows wild in Turkestan and has a nearly smooth endocarp or "stone." The almond tree is a native of sub-tropical China, Middle Asia and probably also Turkestan. It is now cultivated not only in the Orient, but in the Mediterranean countries of Southern Europe and Northern Africa, and also in Southern England, Scandinavia and California. Bitter almonds are chiefly imported from Morocco and Sicily.

Bitter Almonds.—These are smaller than the sweet almonds, and are "ovate or oblong-lanceolate, 20 to 30 Mm. long; seed-coat thin, brown, finely downy; embryo straight, white, and with two plano-convex cotyledons; taste bitter and oily; when triturated with water Bitter Almond yields a milk-white emulsion which emits an odor of hydrocyanic acid." U. S. VIII.

"Resembles the Sweet Almond in general appearance, but is distinguished by being shorter and proportionally broader, by its bitter taste, and by the characteristic odor resembling that of prussic acid given off by its aqueous emulsion." Br.

They have the bitter taste of the peach kernel, and, though when dry, inodorous or nearly so, have, when triturated with water, the fragrance of the peach blossom. They contain nearly the same ingredients as sweet almonds, and like them form a milky emulsion with water. It was formerly supposed that they also contained hydrocyanic acid and volatile oil, to which their peculiar taste and odor and their peculiar operation upon the system were ascribed. It was, however, ascertained by Robiquet and Boutron that these principles do not pre-exist in the almond, but result from the reaction of water; and Wohler and Liebig proved, what was suspected by Robiquet, that they are formed out of a peculiar substance denominated amygdalin, which is the characteristic constituent of bitter almonds. This substance, which was discovered by Robiquet and Boutron in 1830, is white, crystallizable, inodorous, of a sweetish bitter taste, unalterable in the air, freely soluble in water and hot alcohol, very slightly soluble in cold alcohol, and insoluble in ether. It is decomposed by the action of diluted acids or in the presence of water by the nitrogenous ferments, like emulsin, which accompany it in
the bitter almond. The reaction is as follows:

\[
\text{C}_{30}\text{H}_{27}\text{NO}_{11} + 3\text{H}_2\text{O} \rightarrow \text{C}_{12}\text{H}_{28}\text{O}_{15} + \text{HCN} + \text{C}_7\text{H}_6\text{O}_2 + \text{H}_2\text{O}
\]

It is recognized as belonging to the glucoside class, compounds which, when decomposed by diluted acids, alkalis, or ferments, yield glucose and some other characteristic decomposition product. They may be considered as esters of glucose analogous to the esters of glycerin which exist in the fats under the name of glycerides. Liebig and Wohler give the following process for obtaining amygdalin, in which the object of the fermentation is to destroy the sugar with which it is associated. Bitter almonds, previously deprived of their fixed oil by pressure, are to be boiled in successive portions of alcohol till exhausted. From the liquors thus obtained all the alcohol is to be drawn off by distillation, care being taken, near the end of the process, not to expose the syrupy residue to too great a heat. This residue is then to be diluted with water, mixed with good yeast, and placed in a warm situation. After the fermentation which ensues has ceased, the liquor is to be filtered, evaporated to the consistence of syrup, and mixed with alcohol. The amygdalin is thus precipitated in connection with a portion of gum, from which it may be separated by solution in boiling alcohol, which will deposit it upon cooling. If pure, it will form a perfectly transparent solution with water. Any oil which it may contain may be separated by washing with ether. One pound of almonds yields at least 120 grains of amygdalin. (Ann. Pharm., xxii, 329.) Amygdalin appears to be extensively diffused in plants, having been noticed not only in the different genera of the Rosaceae, as Amygdalus, Cerasus, and Prunus, but also by Wieke in various Pomaceae, as Pyrus Malus, Sorbus Aucuparia, Sorbus hybrida, Sorbus torminalis, Amelanchier vulgaris, Cotoneaster vulgaris, and Crataegus Oxyacantha. (Ann. Ch. Ph., lxxix, 79.) It may be advantageously procured from peach kernels, which have been found to yield 80 grains for each avoirdupois pound, or more than 1 per cent. (A. J. P., xxvii, 227.) According to the researches of Johannen, the emulsin is contained in the radicle and plumule, and in the vascular bundles of the cotyledons, while the parenchyma of the cotyledons contains the amygdalin. (P. J., March, 1888.)

Amygdalin, mixed with emulsion of sweet almonds, gives rise, among other products, to the volatile oil of bitter almond and hydrocyanic.
acid,—the emulsin in the sweet almonds acting the part of a ferment, by
causing a reaction between the amygdalin and water; and the same
result is obtained when pure emulsin is added to a solution of
amygdalin. It appears, then, that the volatile oil and hydrocyanic acid
developed in bitter almonds when moistened result from the mutual
reaction of amygdalin, water, and emulsin. Certain substances have the
effect of preventing this reaction, as, for example, alcohol and acetic
acid. It is asserted that emulsin procured from other seeds, as those of
the poppy, hemp, and mustard, is capable of producing the same
reaction between water and amygdalin, though in a less degree. (Ann.
Pharm., xxviii, 290.) Amygdalin appears not to be poisonous when
taken pure in the stomach, unless there be emulsin in the food in the
stomach.

Bitter almonds yield their fixed oil by pressure, and at the present time
this oil is an article of commerce, and is frequently sold as expressed oil
of almond, this being now officially permitted. It is usually produced
from North African bitter almonds; the volatile oil, impregnated with
hydrocyanic acid, may be obtained from the residue by distillation with
water. (See Oleum Amydalae Amarae.)

**Uses.**—Bitter almonds are used solely for their flavoring powers. For
medicinal purposes the oil is preferable. (See Oleum Amygdalae
Amarae.) It has been ascertained that bitter almond paste, and other
substances which yield the same volatile oil, such as bruised cherry-
laurel leaves, peach leaves, etc., have the property of destroying the
odor of musk, camphor, most of the volatile oils, creosote, cod liver oil,
the balsams, etc.; and Mahier, a French pharmacist, has employed them
successfully to free mortars and bottles from the odor of asafetida and
other substances of disagreeable odor. All that is necessary is first to
remove any oily substance by means of an alkali, and then to apply the
paste or bruised leaves.

Bitter almonds, on account of the hydrocyanic acid developed in them,
have sometimes proved poisonous.

**AMYGDALA DULCIS. U. S., Br.**
**SWEET ALMOND Amygd. Dulc.**

“The ripe seeds of Prunus Amygdalus dulcis De Candolle (Fam.
Rosaceae). Preserve Sweet Almond in tightly-closed containers, adding a
few drops of chloroform or carbon tetrachloride from time to time to prevent attack by insects." U. S. "Sweet Almond is the ripe seed of Prunus Amygdalus, Stokes, var. dulcis, Baill. Known in commerce as the Jordan almond." Br.

Semen Amygdali Dulce; Amandes douces, Fr. Cod.; Amygdalae Dulces, P. G; Susse Mandein, G; Mandorle doici, It.; Almendra dulce, Sp.

We are supplied with sweet almonds chiefly from Spain, Italy, France, and Southern California. They are separated into the soft-shelled and hard-shelled, the former of which come from Marseilles and Bordeaux, the latter from Malaga. From the latter port they are sometimes brought to us without the shell. In British commerce, the two chief varieties are the Jordan and Valencia almonds, the former imported from Malaga, the latter from Valencia. The former are longer, narrower, more pointed, and more highly esteemed than the latter.

Properties.—The shape and appearance of almonds are too well known to require description. Each kernel consists of two white cotyledons, enclosed in a thin, yellowish-brown, bitter skin, which is easily separable after immersion in boiling water. Deprived of this covering, they are called blanched almonds. On exposure to the air they are apt to become rancid; but, if thoroughly dried and kept in well-closed glass vessels, they may be preserved unaltered for many years.

Sweet almonds, when blanched, are without odor, and have a sweet, very pleasant taste, which has rendered them a favorite article of diet in all countries where they are readily attainable. They are, however, generally considered difficult of digestion. They are officially described as: "Ovate or oblong lanceolate, 17 to 25 mm. in length, 10 to 13 mm. in breadth and 4 to 7 mm. in thickness; seed-coat light brown with numerous parallel veins, thin and easily removed on soaking the seed in water; embryo straight, white, and with two plano-convex cotyledons; taste bland, sweet. Triturate Sweet Almond with water; a milk-white emulsion is produced which is not acid to litmus, and has no odor of benzaldehyde or hydrocyanic acid (bitter almond). The powder is creamy-white, exhibiting numerous very small oil globules, 0.001 mm. or less in diameter, and larger oil globules and crystalloids, the latter sometimes with adhering globoids; fragments of parenchyma of endosperm, containing oil-globules and aleurone grains; also occasional fragments of seed-coat with characteristic, more or less scattered, large,
elliptical, thin-walled, strongly lignified epidermal cells and narrow, closely spiral tracheae. Starch grains are absent. Sweet Almond yields not more than 4 per cent. of ash." U. S. "About two and a half centimetres or somewhat more in length, nearly oblong in outline, more or less compressed, pointed at one extremity and rounded at the other. Testa cinnamon-brown, thin and scaly. Seed exalbuminous, containing two large planoconvex oily cotyledons. Taste bland; when triturated with water forms a white emulsion with no marked odor." Br. Shelled almonds are sometimes substituted by the kernels of the peach, plum and apricot. The stone cells in the epidermal layer of the almond are much larger than in the kernels of the substitutes. For microscopic distinctions see Win-ton and Moeller, "The Microscopy of Vegetable Foods." Almond cake a by-product in the manufacture of almond oil is largely used in the preparation of a class of detergent powders known as "almond meal." It is also used as a diabetic food and sometimes as an adulterant of ground spices and powdered drugs. By the analysis of Boullay, it appears that almonds contain 54 parts of fixed oil, 24 of protein, 6 of uncrystallizable sugar, 3 of gum, 9 of fibrous matter, 3.5 of water, and 0.5 of acetic acid, comprising loss. The protein is somewhat peculiar, consisting of amandin and emulsin, the latter being an enzyme. It may be obtained separate by treating the emulsion of almonds with ether, allowing the mixture, after frequent agitation, to stand until a clear fluid separates at the bottom of the vessel, drawing this off by a siphon, adding alcohol to it so as to precipitate the emulsin, then washing the precipitate with fresh alcohol, and drying it under the receiver of an air pump. In this state it is a white powder, inodorous and tasteless, soluble in water, and insoluble in ether and alcohol. Its solution has an acid reaction, and, if heated to 100° C. (212° F.), becomes opaque and milky, and gradually deposits a snow-white precipitate, amounting to about 10 per cent. of the protein employed. The distinguishing characteristic of the emulsin is that of producing certain changes noticed previously in amygdalin, which property it loses when its solution is boiled, although not by exposure in the solid state to a heat of 100° C. (212° F.). It consists of nitrogen, carbon, hydrogen, and oxygen, with a minute proportion of sulphur, and is probably identical with the synaptase of Robiquet. L. Portes has reported asparagin in sweet almonds. (N. R., January, 1877.) The fixed oil is described under the head of Oleum Amygdalae Expressum, to which the reader is referred. Sweet almonds, when rubbed with water, form a milky emulsion, free from the odor of hydrocyanic acid, the insoluble matters being suspended by the agency of the albuminous,
mucilaginous, and saccharine principles.

**Uses.**—Sweet almonds have no other influence on the system than that of a nutrient and demulcent. The emulsion formed by triturating them with water is a pleasant vehicle. From their nutritive properties, and the absence of starch in their composition, they are much used in the diet of diabetics, as originally recommended by Pavy. (Guy's Hosp. Rep., 1862, p. 213.) Almond meal or almond press cake is used for cosmetic purposes as an addition to the bath or to the water used in washing the face and hands. Much of the so-called almond meal used for this purpose is factitious or adulterated.

**Anacahuite Wood.**—In the year 1860 considerable quantities of this wood were imported from Mexico, into Germany, as a supposed remedy in phthisis, but it failed to sustain its first reputation. It is the product of Cordia Boissieri DC. (See P. J., Dec., 1862, 272, with figure.)

**Anacardium.** Anacardium occidentale L. West Indian Cashew-nut. Acajou a Pommes, Fr. Caschunuss, G.—A small and elegant tree of the Fam. Anacardiaceae, growing in the West Indies and other parts of tropical America. A gum exudes from the bark, which bears some resemblance to gum arabic, but is only in part soluble in water, and consists of true gum and bassorin. It is the gomme d'acajou of the French writers. Peckoldt describes cashew gum as occurring in hard, fragile pieces which are more or less transparent, yellowish-brown, and stalactite-shaped, and is as soluble in water as acacia. (Zeit. Oest. Apoth. Ver., 1893, 501.) The fruit is a fleshy, pear-shaped receptacle, supporting at its summit a hard, shining, ash-colored, kidney-shaped nut, an inch or more in length and three-quarters of an inch broad, consisting of a pericarp having large balsam canals and of a sweet oily kernel which is now an article of commerce, as a food sold either in the raw state or roasted and salted. The receptacle is red or yellow, and of agreeable subacid flavor with some astringency. It is edible, and affords a juice which has been recommended in uterine complaints and dropsy. This juice is converted by fermentation into a vinous liquor, which yields by distillation a spirit used in making punch, and said to be powerfully diuretic. The black juice contained between their outer and inner shell of the nuts is extremely acid and corrosive, producing, when applied to the skin, severe inflammation, followed by blisters or des-quamation. Staedeler found in it two peculiar principles—anacardic acid and a yellow, oleaginous liquid, cardol. (See J. P. C., 3eser., xiii, 459.) The juice is used in the West Indies for the cure of corns, warts, ringworms, and obstinate ulcers, and even of elephantiasis. It is said to be sometimes applied to the face by women, in order to remove the cuticle, and produce a fresher and more youthful aspect. In a case of external poisoning which came under observation, in a lady who was exposed to the fumes of the roasting nuts, the face was so much swollen that for some time
not a feature was discernible. (N. J. Med. Rep., 1855, 187.) In the case of a boy the
tongue, face, neck, hands, forearms, scrotum, etc., were red and enormously swollen,
and very painful. The tincture of iodine was found useful as a local application. The
black juice of the nut and a milky juice which flows from the tree after incision are
used for almost indelibly marking linen. The Oriental Cashew-nut or Anacardium
Orientale is the fruit of Semecarpus Anacardium, L., a tree quite common in Southern
Asia. It contains principles similar to the West Indian Cashew, and is also said to
contain an alkaloid, chuchunine.

Mouron rouge, Fr. Gauchel, RotheMiere, G. (Fam. Primulaceae)—An annual plant,
growing in Europe and the United States. It has little odor, but a bitterish, somewhat
acid taste. The ancients esteemed it a counter-poison, and Orfila found three
drachms of its extract to cause fatal gastroenteritis in a dog. It has been
recommended as a local application to old and ill-conditional ulcers, and has been used
as a folk-remedy in visceral obstructions, consumption, dropsy, etc. J. A. Heintzelman
obtained from it a volatile oil of a strong, peculiar odor, a pungent and somewhat acid
taste, and the sp. gr. 0.987. Four drops (0.25 mil) of it produced intense headache and
nausea, lasting for twenty-four hours, with pains throughout the body. According to
Dacomo and Tommasoli, anagallis contains an active ferment, which rapidly digests
raw meat. (Rassegna di Sci. Med., 1892, No. 4.) A. caerulea (Schreb.) Ledebs., having
blue petals, is a variety of A. arvensis, and shares its medicinal properties.

Anagyris. Anagyris foetida, L. (Fam. Leguminosae)—Hardy and Gallois have
separated from Anagyris foetida an alkaloid, anagyrine. Parthiel and Spasski found
that the crude alkaloid could be separated into cytisine, C_{11}H_{14}N_{2}O and anagyrine,
C_{15}H_{22}N_{2}O; the latter is not obtainable in crystalline form; it forms a brittle,
resinous-like mass easily reducible to a yellowish powder, but rapidly absorbs
moisture and becomes sticky. It volatilizes at 245° C. (473° F.). (Arch. d. Pharm.,
244, No. 1, 1906, 20.) It forms, however, a crystalline hydrobromide.

Anagyrinehydrobromide, which has the formula C_{14}H_{18}N_{2}O_{2}HBr, occurs in colorless
or faintly yellow crystals and soluble in water. Anagyrine, according to Loewi (A. I. P.,
vol. vii, p. 66), is physiologically related to lobeline, acting primarily upon the nerve
endings as a paralyzant and later upon nerve centers, but having no direct influence
upon the muscles. It lessens the cardiac frequency and decreases the force of the
systole in the frog, but is said in the mammal to have very little influence upon the
blood pressure, death occurring through respiratory paralysis.

Violaceae)—The bark of the root of this Brazilian plant contains anchietine, an
alkaloid isolated by Peckoldt. (Ber. d. Chem. Ges., 1897, p. 98.) It is used in Brazil in
treating scrofula, erysipelas, and eczema. Given in doses of two drachms (7.7 Gm.), it
acts as an aperient, while three drachm (11.6 Gm.) doses produce vomiting.

Anchusa. Anchusa officinalis, L. Bugloss. Ox-tongue. (Fam. Boraginaceae)—The
root, leaves, and flowers of this European biennial plant were at one time recognized
by the U. S. Pharmacopoeia, but probably are practically devoid of medicinal properties. In France the Anchusa italica, which is there known as buglosse, is substituted for A. officinalis and is still in popular use as a diaphoretic and diuretic.

**Andrographis.** Br. Add. 1900. Andrographis paniculata Nees. (Fam. Acanthaceae) —Under the name of Kiryat this plant is stated to be used to some extent in India as a bitter tonic, having similar properties to chiretta. It appears scarcely to enter commerce at all, although exposed in the shops of the herbalists. (See B. P. C., p. 122.) The Br. Add., 1900, recognized the infusion (InfusumAndrographidis, one ounce to a pint), dose one-half to one fluidounce (15-30 mils); the concentrated liquor (Liquor AndrographidisConcentratus), dose, one-half to one fluidrachm (1.8-3.75 mils); and the tincture (Tinctura Andrographidis), dose one-half to one fluidrachm (1.8-3.75 mils).

**Andromeda.** Oxydendrumarboreum (L.) DC., (Andromeda arboreum L.), Sour Wood, or Sorrel-tree, grows in the valleys of the Alleghanies, from Pennsylvania to Florida and west from Indiana to Louisiana. The decoction of the leaves was at one time used as a pleasantly acidulous drink in fevers. The powder of the leaves and buds of Leucothoe racemosa (L.) A. Gray (Andromeda racemosa L.) is said to be a powerful errhine.

J. F. Eykman, of Japan, found a poisonous glucoside, asebotoxin, in Andromeda (Pieris) japonica. (N. R., 1882, 290.) In 1883, Plugg separated from Andromeda japonica a colorless, crystallizable, poisonous principle, andrometoxin. Subsequently he found that various ericaceous plants contain it. (A. Pharm., xxvi; also A. J. P., 1889.) It exists in Azalea indica and Rhododendron maximum L., and has been found by De Zaayer (Chem. Ztg; July, 1887) in Rhododendron ponticum, and in Kalmia angustifolia L., and K. latifolia L.; also in Monotropa uniflora L., by A. J. M. Lasche (Ph. Rund., Sept., 1889). It occurs in acicular crystals, melting at from 228° to 229° C. (442°-444° F.), soluble in alcohol, amyl alcohol, chloroform, ether, benzene, much more soluble in cold than in boiling water, yielding solutions of an alkaline reaction, but not precipitated by ordinary alkaloidal reagents nor by solutions of metallic salts. For further tests, see reference; also P. J., vol. xviii, 171. The poisonous honey of Xenophon, derived from the flowers of Rhododendron ponticum, probably owed its toxic properties to andrometoxin. (See also Ph. Z. R., 1883, xxii.) The oil of Andromeda Leschenaultii, of India, was found by J. Broughton to be methyl salicylate. (P. J., Oct., 1871.)

**ANETHI FRUCTUS. Br. DILL FRUIT**

"Dill Fruit is the dried ripe fruit of Peucedanum graveolens, Benth. and Hook. f." Br.

Garden Dill, Dilly, Anet; Aneth, Fr. Cod.; Fenouil puant, Fr.; Dill, G.; Eneldo, Sp.

Peucedanum graveolens (Anethum graveolens L.), or garden dill,
resembles the fennel plant, but is smaller. It is an annual plant, three or four feet high, with a long spindle-shaped root; an erect, striated, jointed, branching stem; and bipinnate or tripinnate, glaucous leaves, which stand on sheathing footstalks and have linear and pointed leaflets. The flowers are yellow, and in large, flat, terminal umbels, destitute of involucre. The plant is a native of Spain, Portugal, and the south of France, and is found growing wild in various parts of Africa and Asia. It is cultivated in all the countries of Europe, and has been introduced into our gardens. The whole plant is aromatic, the leaves are used as a flavor for soups, sauces and pickles. For a paper by J. C. Umney describing the commercial varieties, see Year Book of Pharmacy, 1898, 374. The seeds, as the fruit is commonly called, are the only part used. They are composed of two mericarps usually separate and freed from the pedicel; each broadly oval, about four millimetres long, and two to three millimetres broad; brown; very strongly compressed dorsally; dorsal ridges inconspicuous, but the lateral ridges prolonged into paler brown wings. In transverse section, six- vittae in each mericarp. Odor and taste agreeably aromatic. Br. These properties depend on a volatile oil, which is present in the fruits to the extent of 2.8 to 4 per cent. (See Oleum Anethi.) The bruised fruits impart their virtues to alcohol and to boiling water.

Uses.—Dill seeds have the properties common to the aromatics, but are very seldom used in this country. They may be given in powder or infusion.

Dose, of the fruit, from fifteen grains to a drachm (1-3.9 Gm.); of the oil, two or three minims (0.12-0.2 mil).

Off. Prep.—Aqua Anethi, Br.

Angelica.—Two species of this genus are used in medicine, the Angelica Archangelica L. (Garden Angelica), a native of Europe, and the A. atropurpurea (Masterwort), which grows throughout the eastern United States. Garden angelica has a long, thick, fleshy, biennial root, furnished with many rootlets, and sending up annually a, hollow, jointed, round, channelled, smooth purplish stem, which rises five feet or more in height, and divides into numerous branches. The plant is a native of the north of Europe, and is found in the high mountainous regions in the southern section of that continent, as in Switzerland and among the Pyrenees. It is often cultivated. The whole plant is aromatic, but the root only is official in the Swiss, Austrian, and German Pharmacopoeias, while the fruit is official in the N. F. IV. The root should be dug up in the autumn of the first year, as it is then least liable to become mouldy and worm eaten. It is spindle-shaped, 4 to 6 cm. thick at the crown, and beset with long
descending rootlets. The fresh root has a yellowish-gray epidermis, a fleshy yellow parenchyma, and when wounded yields a honey-colored juice, having all the aromatic properties of the plant. The dried root is grayish-brown and much wrinkled externally, whitish and spongy within, and breaks with a starchy fracture, exhibiting shining resinous masses. It is very apt to be attacked by insects. The drug and the powder should be conserved by the addition of a few drops of chloroform or carbon tetrachloride. The odor is strong and fragrant, and the taste at first sweetish, afterwards warm, aromatic, bitterish, and somewhat musky. These properties are extracted by alcohol, and less perfectly by water. The constituents of the root are angelic acid, C₅H₈O₂, a monatomic acid of the acrylic series, valeric acid, C₅H₁₀O₂, resin, bitter principle, pectin, malic acid, sugar starch and a volatile oil consisting largely of phellandrene. For further information concerning the constituents of this drug, see U. S. D., 19th ed., p. 1386. Schim. Rep., 1902, 15; 1911, 21; 1913, 26.

Angelica Fructus, N. F. IV, Angelica Seed, is described by the N. F. as "the ripe fruit of Angelica Archangelica Linne (Fam. Umbelliferae) and of other species of Angelica, without the presence of more than 3 per cent. of foreign matter. Cremocarps oval, externally of a pale yellowish-brown color, from 4 to 8 mm. in length, 3 to 6 mm. in breadth and from 1 to 2 mm. in thickness, the base faintly notched, the summit bearing five minute calyx-teeth and the remains of the style; the two mericarps joined by their broad faces, or separate; each mericarp nearly flat upon one surface, which bears a central longitudinal groove and has sharp, slightly upturned margins, convex upon the other surface which is traversed longitudinally upon the back by three strong ribs, separated from one another by narrow grooves and from the margin by much broader grooves; pericarp soft, rather tough and corky, and enclosing a single seed, showing on cross section six large oil-tubes. Odor characteristic and agreeable; taste aromatic, pungent, and sweetish. Angelica Fruit yields not more than 8 per cent. of ash."

Garden angelica is an aromatic tonic. The Laplanders, in whose country it nourishes, esteem it highly as a condiment and medicine. In Europe the stems are frequently made into a preserve. The dose of the root or seeds is from thirty grains to a drachm (2-3.9 Gm.).

The N. F. IV recognizes under the name of Angelica Radix (Angelica Root) "the rhizome and roots of Angelica atropurpurea Linne (Fam. Umbelliferae) and of other species of Angelica, without the presence of more than 5 per cent. of stem bases and leaves or other foreign matter. Preserve Angelica Root in air-tight containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects. Rhizomes short and thick, from 5 to 10 cm. in length, sometimes split, frequently crowned with the bases of stem and leaves; the roots are numerous, from 10 to 20 cm. in length and from 5 to 7 mm. in thickness at the base and gradually tapering to about 1 mm.; frequently twisted or braided together, externally dark gray-brown to reddish- or purplish-brown and with conspicuous, rather deep furrows; when dry breaking with a smooth fracture. On cross section, the rhizome shows a distinct pith, which is absent in the root, and both exhibit a spongy bark
nearly or quite as wide as the woody zone; in the bark are radial rows of brownish canals containing oleoresin. The wood rays are finely porous and narrower than the medullary rays. The bark is rich in starch. Odor strongly aromatic; taste sweetish, pungent, aromatic, and then bitter. The powdered drug is yellowish-brown and, when examined under the microscope, exhibits numerous, mostly simple, irregularly spherical starch grains, up to 0.008 mm. in diameter, sometimes with the cleft at the center and occasionally two- or more compound; tracheae or fragments of tracheae, with reticulate markings or large simple pores up to 0.075 mm. in width; brownish oil canals or fragments thereof, up to 0.23 mm. in diameter, sometimes with adjoining epithelial cells; fragments of parenchyma tissue with some of the cells filled with starch; fragments of large brownish cork cells; sclerenchymatous fibers with thin walls and often with oblique markings; yellowish oil globules. Angelica Root yields not more than 8 per cent. of ash." It has a strong odor and a warm aromatic taste. The juice of the recent root is acrid, and is said to be poisonous; but the acridity is dissipated by drying. The medicinal virtues of the plant are similar to those of the garden angelica of Europe, for which it has been proposed as a substitute. It is, however, inferior to the European angelica. Its uses are similar to those of the root.

**Angrecum.** Angrecum fragans Thouars.—This is an orchidaceous plant, indigenous to the Isle of Reunion and to Mauritius, where the leaves have been long used, under the name of faham, for the same purposes as tea leaves. For description, see P. J.; 1881, 913. They have a somewhat pungent aromatic taste, and a strong and highly agreeable odor, scenting the whole apartment with a delicious perfume. Given in infusion, they appear to have an effect on the system somewhat similar to that of Chinese tea, and they have been introduced into Paris as a rival of that popular beverage. The drink is made by putting the leaves and stalks, in the proportion of fifteen grains (1 Gm.) to a teacupful, into cold water, boiling for about ten minutes, and then pouring into a closed vessel, and sweetening it when used. (A. J. P., 1866, 441.)

**Anhalonium.**—Under the name of Pellote are used in Mexico for narcotic purposes, certain cacti whose tops have entered commerce under the name of Mescal Buttons. These were formerly believed to belong to the genus Anhalonium, but at present are referred to species of Mammalaria and of the genus Echinocactus, which is characterized by a flexible epidermis, its freedom from spines and tubercles and its segments not assuming the form of a projecting or leaf-like organ. (See Schumann in Engler and Prantl's Pflanzenfamilien, and Reports of Missouri Botanical Gardens, 1898.) In a mass of such cactus tops sent to the Pharmaceutical Institute of Leipzig from Mexico as pellote, experts have recognized the products of Mammalaria fissuratus, M. retusus, Echinocactus Williamsii Lem., and E. Leweni Henn. Moreover, from A. jourdanianum, L., Lewin obtained traces of an alkaloid (A. E. P. P., xxxiv). There is little doubt but that various allied species of cactus are represented in the commercial drug. The most important of these plants are E. Leweni and E. Williamsii, which inhabit the valley of the Rio Grande in Mexico, and are furnished with stems reaching about half an inch above the surface of the ground, surmounted by a top composed mainly of the blunt leaves of the plant, bent around a tuft, of from half an inch to an inch in diameter, composed of short, yellow-white filaments or hairs.
It is this top which constitutes the mescal button, which is from an inch to an inch
and a half in diameter, one-fourth of an inch in thickness, with a convex under
surface, a texture which is brittle and hard when dry, but becomes soft when
moistened, a very bitter disagreeable taste, and an odor when moist which is peculiar
and disagreeable, and is especially marked in the powdered drug. According to C. H.
Thompson, the buttons of E. Lewinii and E. Williamsii are readily distinguished by
the fact that the surface of E. Lewinii, is traversed by thirteen shallow narrow
furrows giving the appearance of there being as many irregular or much broken ribs
or obtuse ridges, while in E. Williamsii the furrows and ridges are eight in number
atod regular.

In 1888, L. Lewin separated from E. Lewinii an alkaloid, anhalonine, which has the
formula C_{12}H_{15}NO_3, and crystallizes in small white prisms, soluble in ether, alcohol,
and chloroform. Subsequently, Heftter (Ber. d. Chem. Oes., 1896) separated from E.
Lewinii, besides anhalonine, three alkaloids: mescaline, C_{17}H_{17}NO_3, in white needles
melting at 151° C. (303.8° F.) ; anhalonidine, C_{12}H_{15}NO_3, fusing at 160° C. (320° F.),
and lophophorine, C_{13}H_{17}O_3. (See also A. E. P. P., 1898, xl.)

Kander (A. Pharm., 1899, vol. cxxxvii) has found that in commercial mescal buttons,
besides the alkaloids already mentioned, are two other bases, pellotine and
anhalanine, so that Merck has offered as commercial products the following salts:
Anhaloninae Hydrochloridum cryst., Anhalonidinae Hydrochloridum cryst.,
Lophophorinae Hydro-chloridum cryst., Mescalinae Sulphas cryst., Pellotinae
Hydrochloridum cryst. According to the researches of Heftter, pellotine, C_{13}H_{19}NO_3,
is contained exclusively in L. Williamsii, but as this cactus is present in most, if not
all, of the commercial buttons, it was naturally found by Kander in analyzing the
commercial drug. However, the correctness of the conclusion of Heftter is challenged
by Merck's chemists, who, in the analysis of L. Williamsii, found the same quantity of
the same alkaloids as is present in the true mescal button. For a description of these
alkaloids see M.R., 1898 and 1900. E. White (J. P., xxv) obtained mescaline, 1.16 per
cent.; anhalonidine, 1.16 per cent.; anhalonine, 0.46 per cent.; lophophorine, 0.14 per
cent. Anhaline, C_{10}H_{17}NO, is an alkaloid crystallizing in colorless stellate prisms,
which has been extracted from L. fissuratum.

From time immemorial the Kiowa Indians of the Rio Grande have used the mescal
buttons for the purpose of producing intoxication during their religious ceremonies.
Attention was first called to the peculiar cerebral action of the drug by D. W. Prentiss
and Francis P. Morgan (T. G., 1895), who found that from two hundred and fifteen to
two hundred and thirty grains (14-15 Gm.) (four to five buttons) will produce a
peculiar cerebral excitement attended with an extraordinary visual disturbance,
characterized by an incessant flow of visions of infinite beauty, grandeur, and variety,
of both color and form, often followed after a time by the seeing of monsters,
grotesque faces, and gruesome shapes. During the intoxication there are dilatation of
the pupil, muscular relaxation, and some slowing of the pulse. Loss of sense of time,
partial anesthesia, weakened heart's action, great muscular relaxation, wakefulness,
and in some cases nausea and vomiting also have been noted, but no distinct
alteration of the respiration. These results have been confirmed by several observers.
A. Mogilewa (A. E. P. P., xlix, 137) found that mescaline, anhalonidine, anhalonine, lophophorine, and pellotine acted similarly in lessening the frequency and force of the isolated frog heart, varying simply in quantitative power. The most thorough research upon the anhalonium alkaloids is that of W. E. Dixon (J. P., xxv) whose report is somewhat marred by the fact that he does not state in his experiments which one of the alkaloids was employed; he simply affirmed that anhalonine and anhalonidine are identical in physiological activity, that lophophorine differs only in being more toxic, and that mescaline has a physiological action almost indistinguishable from that of its associated alkaloids. He finds that "the alkaloid" is not locally anesthetic; that increased salivation is one of the most characteristic symptoms of its action; that in therapeautic doses, in man at least, it produces constipation, but that in toxic dose it causes diarrhea and bloody stools; that its main circulatory effect is upon the cardiac muscle and contained ganglia, causing slowing of the heart and a rise of arterial pressure; that it kills by action on the respiratory centers so that in man the most serious result of an overdose is rapid, shallow breathing, with a sense of suffocation; that upon the nervous system it acts most powerfully, producing in the frog, and to a lesser degree in the mammal, increasing loss of muscular power with heightened reflexes, believed to be due to spinal stimulation. The motor nerves appear to be depressed, since they are paralyzed when the drug is applied locally to them. In experiments upon two human subjects, there was wide dilatation of the pupils, with uncertainty of gait like that of alcoholic intoxication, tremors, and heightened reflexes, although sensation was distinctly blunted. The psychical symptoms caused by the largest doses resemble somewhat those from cannabis indica. The dose of the alkaloid used by Dixon was three and eight-tenths grains (0.25 Gm.). In Heffter's experiments pellotine was found to be physiologically feeble, one-thirteenth grain (0.005 Gm.) causing only temporary stiffness in the legs of the frog, two-thirteenth grain (0.01 Gm.) producing stiffness, heightened reflexes, strychnine-like tetanus, lasting from three to four days, ending in recovery. In man, from seven-tenths to nine-tenths of a grain (0.045-0.058 Gm.) produced only temporary sleeplessness with sense of weariness. Pilcz (W. K. W., ix, 1896) has used pellotine as a calmative in fifty-eight cases of insanity in doses of from one-third to one grain (0.021-0.065 Gm.). About half the cases were markedly affected, sleep coming on in from half an hour to an hour and a half after the hypodermic injection and continuing through the night. No disagreeable results and no collapse occurred, although Langstein is said to have seen collapse following the dose of seven-tenths of a grain (0.045 Gm.).

The value of mescal buttons as a remedial agent is doubtful; it has been employed to a slight extent in various forms of neurasthenia and hysteria, and is asserted by S. F. Landry (T. G.; 1888) to be especially valuable in cases of asthma. It has also been alleged to be useful in neuralgic and rheumatic affections. Prentiss and Morgan give the dose of the crude drug as from seven to fifteen grains (0.45-1.0 Gm.); of the fluidextract, from ten to fifteen minims (0.6-0.9 mils); of the 10 per cent. tincture, from one to two teaspoon-fills (3.75-7.5 mils).
ANISUM. U.S. (Br.) ANISE Anis. [Aniseed]

"The dried ripe fruit of Pimpinella Anisum Linne (Fam. Umbelliferae) without the presence or admixture of more than 3 per cent. of foreign seeds or other vegetable matter." U. S. "Anise Fruit is the dried ripe fruit of Pimpinella Anisum, Linn." Br.

Anisi Fructus, Br.; Fructus (Semen) Anisi, s. Anisi vulgaris; Aniseed, Anny, Aneys, Annyle; Anis, Anis vert, Graines d'Anis, Fr.; Fructus Anisi, P. G.; Anissame, Anis, G.; Anice, Anace, Semi d'Aniso, It.; Anis (Fruto de), Simiente de Anis, Sp.; Anison, Ar.

Pimpinella Anisum is an annual plant, about a foot in height, with an erect, smooth and branching stem. The leaves are petiolate, the lower roundish-cordate, lobed, incised-serrate, the middle pinnate-lobed with cuneate or lanceolate lobes, the upper trifid, or undivided, linear. The flowers are white, and in terminal compound umbels, destitute of involucres.

The anise plant is a native of Egypt and the Levant, but has been introduced into Southern Europe and is cultivated in all warm climates, especially Germany, Russia, Italy, Spain, France, Turkey, India, Japan and Chili. It is also cultivated occasionally in the gardens of this country. The Spanish is smaller than the German or French, and is usually preferred; the Russian fruit is very short. It is said also to be extensively cultivated in India and South America, although we are not aware that the product ever comes into American commerce. It is estimated that over a million pounds of anise are imported annually.

It is one of the oldest aromatics, having been used by the old Egyptians, and is spoken of by Theophrastus and cultivated in the imperial German farms of Charlemagne. In 1305 Edward I granted a patent giving the right to levy tolls upon it at the Bridge of London for the purpose of repairing the bridge.

Anise seeds (botanically, fruit) are officially described as follows: "Cremocarp broadly ovoid or pyriform, laterally compressed, from 3 to 6 mm. in length and from 2 to 3 mm. in breadth; mericarps usually cohering and attached to a slender pedicel from 2 to 12 mm. in length; summit with a ring-like disk and 2 projecting, diverging styles; externally grayish or greenish-gray, seldom grayish-brown, slightly pubescent; each with five light brown filiform ridges and in cross-section with from 15 to 45 vitellae. Odor and taste agreeable and aromatic. Under
the microscope transverse sections of Anise show an epidermal layer with numerous papillae and short, one-celled, non-glandular hairs having very thick papillose walls; primary ribs each with a small fibro-vascular bundle, surrounded by a few sclerenchymatous fibers; vittae or oil-tubes from 15 to 45 in number, extending as a more or less interrupted circle in the tissues of the mesocarp on the dorsal side of each mericarp; 2 large vittae on the commissural surface, each separated from the other tissues of the mericarp by a large cavity due to shrinkage of the seed-coat; inner epidermis of pericarp consisting of a layer of narrow, tangentially elongated cells closely united with the 1-layered seed-coat, the inner walls of which are yellowish-brown and considerably thickened; endosperm of polygonal, thick-walled cells filled with spherical or ellipsoidal aleurone grains, each containing a small rosette aggregate of calcium oxalate; the aleurone grains surrounded with an oily protoplasm, the oil of which is liberated upon mounting sections in hydrated chloral T.S., in the form of small globules; epidermal layer near the middle of the commissural surface composed of 2 or 3 rows of cells with thick porous walls, and beneath which occur small groups of thick-walled cells resembling stone cells. The powder is yellowish-brown; consisting of numerous irregular fragments of pericarp showing portions of the yellowish vittae, fragments with tracheae and sclerenchymatous fibers of carpo-phore; cells of endosperm filled with aleurone grains about 0.006 mm. in diameter, each usually enclosing a rosette aggregate crystal of calcium oxalate about 0.002 mm. in diameter; non-glandular hairs 1-celled, from 0.025 to 0.2 mm, in length, either straight or curved and with numerous, slight, centrifugal projections on the outer surface. Heat 1 Gm. of the whole drug or powdered drug with 10 mils of potassium hydroxide T.S.; no mouse-like odor develops (fruits of Conium maculatum Linne). Anise yields not more than 9 per cent. of ash."

"Ovoid, somewhat compressed laterally; about five millimetres long and two millimetres broad. Mericarps usually united and attached to the pedicel. Rough from the presence of short, bristly hairs. Greenish-grey or greyish-brown; primary ridges pale, slender and entire. In transverse section, numerous vittae in each mericarp; commissural surface of the endosperm not deeply grooved. Agreeably aromatic odor; taste aromatic and sweet. Ash not more than 11 per cent." Br.

Their odor and taste, which depend upon a peculiar volatile oil existing to the extent of from 1.5 to 3.5 per cent., are imparted sparingly to
boiling water, but freely to alcohol. (See Oleum Anisi.) The endosperm of the fruit contains a bland fixed oil. By expression, a greenish oil is obtained, which is a mixture of the two. The fruits are sometimes adulterated with fine gravel and small fragments of an argillaceous earth which resembles them in color. This accounts for the fact that the amount of ash may run as high as 30 per cent., greatly exceeding the official requirements. Their aromatic qualities are occasionally impaired by a slight fermentation, which they are apt to undergo in the mass, when collected before maturity. Russian anise is sometimes admixed with as much as 30 per cent. of coriander. Anise is also contaminated with weed seeds and stems of the anise plant.

The Italian anise not infrequently is admixed with from 2 to 10 per cent. or even 50 per cent. of the fruits of conium. A case of poisoning is on record from the accidental admixture of the fruits of Conium maculatum, which latter may be distinguished by their crenate or notched ridges and the absence of oil tubes; by their mericarps being-smooth, grooved upon the face, and having crenate or notched ridges with wrinkles between them. The conium fruits are, moreover, broader in proportion to their length, and are generally separated into half fruits (or single mericarps), while those of anise are whole (double mericarps).

Star aniseed, the Cardamomum Siberienae or Annis de Siberie of the seventeenth century and the badiane of the French writers, is the product of Illicium verum Hook. f., Gaertn., and is fully described under the heading Illicium. They contain about 4 per cent. of a volatile oil very closely resembling that of anise. There are no known chemical differences between these oils, although dealers distinguish them by their odor and taste.

Ruschenberger, U. S. N., has shown that oil of anise has a remarkable power of masking the odor of potassium sulphide; a drop of the oil having entirely deprived of offensive odor a drachm of lard with which five grains of the sulphide had been incorporated. (Am. J. M. S., N. S., xlviii, 419.)

Uses.—Anise, a grateful aromatic carminative, may be used in flatulent colic, and as a corrigent of griping or unpleasant medicines.

Dose, eight to fifteen grains (0.5-1.0 Gm.); of the oil, which should
always be preferred, three to eight minims (0.2-0.5 mil).

**Off. Prep.**—Aqua Anisi, U. S. (from Oil of Anise), Br.; Species Laxativae, N. F.; Species Pectorales, N. F.; Tinctura Rhei Dulcis, N. F.

**Anisodus.** Anisodus luridus Link and Otto. (Scopolia lurida Dun.)—This is a Himalayan solanaceous plant in which Siebert has found atropine and hyoscyamme. (A. Pharm., Feb., 1890; P. J., March, 1890.)

**Anatto.** Orleana. Annotta. Arnotta. Terre de la Nouvelle-Orleans, Fr. Orellana, Orlean, G.—The coloring substance called annatto, arnotta or roucou, is the reddish pulp surrounding the seeds in the fruit of Bixa orellana L. (Fam. Bixaceae), a medium-sized tree native to Northern South America, but widely cultivated in tropical Asia and Africa. The pulp is separated by bruising the fruit, mixing it with water, then straining through a sieve, and allowing the liquid to settle. The mass which remains is dried and formed into flat cakes or cylindrical rolls. Another mode is to bruise the seeds, mix them with water, and allow the mixture to ferment. The coloring matter is deposited during the fermentation, after which it is removed and dried. In commerce there are two kinds of annatto, the Spanish or Brazilian, and the French, the former coming in baskets from Brazil, the latter in casks from French Guiana. The French, which is also called flag annatto, has a disagreeable odor, probably from having been prepared by the fermenting process in which urine is sometimes used; but is superior, as a dye stuff, to the Spanish, which is without any disagreeable odor. Annatto is of a brownish-red color, usually rather soft, but hard and brittle when dry, of a dull fracture, of a sweetish peculiar odor, and a disagreeable, saline, bitterish taste. It is inflammable, but does not melt with heat. It softens in water, to which it imparts a yellow color, but does not dissolve. Alcohol, ether, the oils, and alkaline solutions dissolve the greater part of it. The South American Indians are said to produce directly from the annatto seeds, without fermentation, a color similar to and almost as brilliant as carmine. (P. J., April, 1903.) For a proximate analysis of the leaves see Ap. Ztg., 1899, p. 35. It contains a peculiar coloring principle, to which Preissier, its discoverer, gave the name of bixin. This has the formula $C_{28}H_{34}O_{5}$, and when pure is a dark, red, somewhat crystalline substance. According to Van Hasselt, bixin has the composition $C_{29}H_{34}O_{5}$, but Heiduschka and Eiffart believe that the correct formula is $C_{29}H_{34}O_{5}$. (A. Pharm., 1911, No. 1, 39.) It is accompanied by a yellow coloring matter, orellin. A coloring matter found in the root of Escobedia scabrifolia, a plant growing in tropical America, is used by the Mexicans in coloring fats and butter yellow. (S. W. P., 1912, No. 18, 260.) The chief uses to which annatto is applied are for dyeing silk and cotton orange-yellow, and for coloring cheese and butter. The color, however, which it imparts to cloth is fugitive. It has been given internally as a medicine; but is not now used, and probably exercises little influence upon the system. In pharmacy it is employed to color ointments and plasters, and has occasionally been substituted for saffron. It is frequently adulterated with red ochre, powdered bricks, colcothar, farinaceous substances, chalk, calcium sulphate, turmeric, etc. The mineral substances, if present, will be left behind when the annatto is burned. Tincture of annatto is made by extracting 100 parts of annatto with 100 parts of
water containing $1\frac{1}{2}$ per cent. of potassium carbonate, and evaporating to 60 parts, mixing with 12 parts of alcohol and filtering.

**Anona.**—The seeds of A. squamosa, L., Sugar Apple or Sweet Sop of the West and East Indies, are said to be poisonous and to be used to kill lice, while the bark is a drastic cathartic. The seeds of A. muricata, L., A. palustris, L., and A. spinescens. Mart., are employed to poison fish and to exterminate destructive insects. (Ph. Rev; Oct., 1896.)

**ANTHEMIDIS FLORES. Br.**

**CHAMOMILE FLOWERS [Chamomile, English Chamomile, Roman Chamomile]**

"Chamomile Flowers are the expanded flower-heads of Anthemis nobilis, Linn., collected from cultivated plants, and dried." Br.

Anthemis, U. S. VIII; Flores Chamomillae Romanae, P. G.; Roman, Low, Garden, White or English Chamomile, Chamomile Flowers, Camil, Camovyne, Whig-plant; Camomille Romaine, Fr.; Romische Kamille, G.; Camomilla Romana, Camomilla Ingleses, It.; Manzanilla (Flor de), Manzanilla Romana, Sp.

Chamomile flowers were formerly recognized by the U. S. Pharmacopoeia. They still receive official recognition in the British, Austrian and Swiss Pharmacopoeias.

Several species of anthemis have been employed in medicine. A. nobilis, which is the subject of the present article, is by far the most important. A. Cotula L., Dog Fennel, or mayweed, was formerly recognized by the U. S. Pharmacopoeia. A. arvensis L. (corn chamomile), a native of Europe, naturalized in this country, bears flowers which have an acrid bitter taste and possess medicinal properties analogous though much inferior to those of common chamomile. They may be distinguished by their want of odor. A. tinctoria L. is occasionally employed as a tonic and vermifuge in Europe. Matricaria suaveolens is said to yield the chamomile of the Indian bazaars.

Anthemis nobilis is an herbaceous plant with a perennial root. The stems are from six inches to a foot long, round, slender, downy, trailing, and divided into branches, which turn upward at their extremities. The leaves are bipinnate, the leaflets small, thread-like, somewhat pubescent, acute, and generally divided into three segments. The
flowers are solitary, with a yellow convex disk, and white rays. The involucre is of a hemispherical form, and composed of several small imbricated hairy scales. The receptacle is convex, prominent, and furnished with rigid bristle-like paleae. The ray florets are numerous, narrow and terminated with three small teeth. The whole herb has a peculiar fragrant odor, and a bitter aromatic taste.

This plant is a native of Europe, and grows wild in all the temperate parts of that continent. It is also largely cultivated for medicinal purposes. In France, Germany, and Italy, it is generally known by the name of Roman chamomile. By cultivation the yellow disk florets are often converted into the white ray florets. Thus altered, the flowers are said to be double, while those which remain unchanged are called single; but, as the conversion may be more or less complete, it generally happens that with each of the varieties there are intermingled some flowers of the other kind, or in different stages of the change. The double flowers are generally preferred; though, as the sensible properties are found in the greatest degree in the disk florets, the single flower heads are the more powerful. It is rather, however, in aromatic flavor than in bitterness that the radial florets are surpassed by those of the disk. If not well and quickly dried, the flowers lose their beautiful white color, and are less efficient. The flowers which are largest, most double, and whitest should be preferred. They are thus described: "Flower-heads hemispherical, from about twelve to twenty millimetres in diameter, white or pale buff in color. Involucre composed of several rows of oblong bracts with membranous margins; receptable solid, conical, and densely covered with concave, blunt, narrow, scaly bracts; florets mostly ligulate and white, the ligula possessing four veins and terminating in three teeth. Strong aromatic odor; taste bitter." Br.

The seeds yield by expression a fixed oil, which is said to be applied in Europe to various economical uses.

Though not a native of America, chamomile grows wild in some parts of this country, and is occasionally cultivated in our gardens for family use, the whole herb being employed. The medicine, as found in commerce, consists chiefly of the double flowers, and is imported from Germany and England. From the former country the flowers of Matricaria Chamomilla are also occasionally imported, under the name of chamomile. (See Matricaria.) In Europe the flowers of A. arvensis L., corn chamomile, are sometimes substituted for the official drug. In
France corn chamomile flowers are sold in commerce indiscriminately with those of Anthemis nobilis, of Chrysanthemum Parthenium Bernli. (Pyrethrum Parthenium Smith), or of Anthemis parthenoides De Cand. (Matricaria parthenoides De Cand.). (J. P. C., May, 1859, p. 347.) For the peculiar character by which these two flowers may be distinguished from the chamomile, see Pyrethrum parthenium.

**Properties.**—Chamomile flowers, as usually found in commerce, are large, almost spherical, of a dull white color, a fragrant odor, and a warmish, bitter, aromatic taste. When fresh, their odor is much stronger, and was fancied by the ancients to resemble that of the apple. Hence the name *chamaemelum*; and it is somewhat singular that the Spanish name *manzanilla* (a little apple) has a similar derivation. The flowers impart their odor and taste to water and alcohol, the former of which, at the boiling temperature, extracts only one-fourth of their weight. The investigations of several chemists made in 1878-1879, in Fittig's laboratory at Strassburg, have shown the oil of chamomile to contain the following constituents: a fraction distilling at 147° to 148° C. (296.6°-298.4° F.) consisting of isobutyl esters and hydrocarbons; isobutyl angelicate at 177° C. (350.5° F.); isoamyl angelicate at 200° to 201° C. (392°-394° F.); isoamyl tiglinate at 204° to 205° C. (399°-401° F.) (both of these esters answering to the formula C₅H₁₁C₅H₇O₂). In the residual portion, hexylic alcohol, C₆H₁₃OH, and an alcohol of the formula C₁₀H₁₆O isomeric with camphor, to which the name of anthemol has been given (see Chem. Cb., 1903 (1), 1226), are met with, both probably occurring in the form of esters. By decomposing the angelicates and the tiglinate with potassium hydroxide, angelic acid, C₅H₈O₂, and tiglinic acid (or methyl-crotonic), isomeric with the former, are obtained to the extent of about 30 or more per cent. of the crude oil. In the oil examined by Fittig, angelic acid prevailed; from another specimen E. Schmitt (1879) obtained but very little of it, tiglinic acid prevailing. Naudin (Bull. Soc. Chim., 1884, 41, 483) extracted also a solid paraffin, C₁₈H₃₆, to which the name of anthemene was given; Klopp obtained another body, anthesterin, from chamomile. (P. J., 1903, 458.) Umney states that pure oil of chamomile has the sp. gr. 0.905 to 0.912 at 15° C. (59° F.) (P. J., 1895, p. 949). The oil from Anthemis Cotula closely resembles that from A. nobilis, see A. J. P., 1885, pp. 376, 381. E. Amerman (A. J. P., 1889, p. 69) obtained a wax which was nearly white, bitter, and crystalline, melting at about 130° C. (266° F.), and a crystalline substance distinctly acid and of a glucosidal nature.
There was no evidence of the presence of an alkaloid. (See Oleum Anthemidis, Br., and Extractum Anthemidis, Br. Pharm., 1898.)

Uses.—Chamomile is a mild tonic, in small doses acceptable and corroborant to the stomach, in large doses capable of acting as an emetic. In cold infusion it is often advantageously used in cases of enfeebled digestion in convalescence, of general debility, with languid appetite, which often attends convalescence from infectious fevers. The flowers are sometimes applied externally in the form of fomentation, in cases of irritation or inflammation of the abdominal viscera, and as a gentle incitant in flabby, ill-conditioned ulcers. The infusion is usually preferred. The decoction or extract cannot exert the full influence of the medicine, as the volatile oil is driven off.

Dose, of the powder as a tonic, from half a drachm to a drachm (2.0-3.9 Gm.) three or four times a day, or more frequently.

Anthriscus. Anthriscus cerefolium (L.) Hoffm. (Chaerophyllum sativum Lam. Scandix cerefolium, L.), Chervil.—An annual European plant of the Fam. Umbelliferae, cultivated in gardens as a pot-herb, and naturalized in Eastern and Southern Pennsylvania. It has a strong agreeable odor, and a pungent, slightly bitterish taste. It contains a volatile oil of very feeble medicinal power, but it has been used as an emmenagogue and diuretic.

Aphloia theaeformis Benn. (Fam. Bixaceae).—This plant is a native of Madagascar and is claimed to possess marked alterative properties and beneficial effects upon hemoglobin. It is administered as an infusion of the leaves, 30 Gm. of the plant being used to make 1 liter of infusion.

Apocynum. N. F. IV (U. S. P. VIII). Canadian Hemp. Black Indian, Hemp. Dogsbane. Chanvre du Canada, Fr. Canadische Banfwurzel, G.—"The dried rhizome and roots of Apocynum cannabinum Linne (Fam. Apocynaceae), without the presence of more than 5 per cent. of stems or other foreign matter." N. F. IV. Although latterly apocynum has fallen into disuse, some physicians have insisted that the A. cannabinum is a valuable remedy and that its unfavorable reputation has arisen from the use of other species. The drug of commerce in recent years has consisted of several species of Apocynum. A number of physicians in the United States have come to the conclusion that the absorption of Apocynum in the gastro-intestinal tract is uncertain and irregular, which led to its being deleted from the Pharmacopoeia. It has been admitted into the N. F.

There are several indigenous species of this genus of very similar general aspect, the rhizome and roots of two of them being collected, viz.: Apocynum cannabinum, L., and A. androsaemifolium, L. Both plants abound in a milky juice, and have a tough, fibrous bark, which, by maceration, affords a substitute for hemp; hence the common
name. It is used by the Indians of California for making all manner of cordage and for weaving.

In *A. cannabinum* the stems and branches are upright or ascending, terminated by erect and close, many-flowered cymes, which are usually shorter than the nearly sessile leaves, and the corolla has nearly erect lobes, with the tube not longer than the lanceolate divisions of the calyx. In *A. androsaemifolium* the branches are divergently forked, the leaves are slender petioled, the cymes loose and spreading, the open bell-shaped corolla with revolute lobes and a tube much longer than the ovate-pointed divisions of the calyx. *A. cannabinum*, of which there are a number of well recognized varieties, grows in gravelly or sandy soil mostly near streams, while *A. androsaemifolium* grows in dry thickets and open woods. According to E. A. Manheimer, the root of the latter is distinguished from *A. cannabinum* by the thick-walled stone cells, which are arranged in an interrupted circle near the middle of the bark. (A. J. P., Nov., 1881. See also A. J. P., 1888.) Holm has contributed an article on the structure of *A. cannabinum*. (Merck's Rep., 1910, p. 277.)

It is described in the N. F. as: "Cylindrical, somewhat branched, of varying length, from 3 to 10 mm. in thickness; externally reddish-brown to grayish-brown, longitudinally wrinkled and occasionally with transverse fissures having vertical sides extending through the bark; fracture short; internally, bark light brown, from 1.5 to 3 mm. in thickness, wood faintly radiate and with large tracheae, a small pith occurring in pieces of the rhizome. Almost inodorous; taste starchy, afterwards becoming bitter and somewhat acrid. Under the microscope sections of *Apocynum* show numerous laticiferous vessels in both the bark and pith. The stems of *Apocynum* have a comparatively thin fibrous bark, a light brown porous wood and a large, hollow pith. The powder is light brown, starch grains numerous, from 0.003 to 0.015 mm. in diameter, spherical, ellipsoidal, ovate, pyriform, or more or less irregular, sometimes more or less altered, swollen, and with a hyaline central cleft; numerous fragments of strongly lignified wood fibers, associated with tracheae mostly having bordered pores, occasionally with spiral thickenings; fragments of cork layer few, the walls being of a reddish-brown color; an occasional fragment with laticiferous tissues; stone cells few or absent (*Apocynum androsaemifolium* Linne). *Apocynum* yields not more than 5 per cent. of ash." N. F. IV. The fresh root, when wounded, emits a milky juice, which concretes into a substance resembling caoutchouc. The stems of *Apocynum* have a comparatively thin, fibrous bark, a light brown porous wood and a large, hollow pith. In the dried state, the rhizome and roots are brittle and readily pulverized, affording a powder which is light brown, containing numerous starch grains which are from 0.003 to 0.015 mm. in diameter, spherical, ellipsoidal, ovate, pyriform, or more or less irregular, sometimes more or less altered, swollen, and with a hyaline central cleft. It also contains numerous fragments of strongly lignified wood fibers which are associated with tracheae having bordered pores or occasionally with spiral thickenings, a few fragments of cork, the walls being of a reddish-brown color, and an occasional fragment with laticiferous tissues. Stone cells are not present in *A. cannabinum*, but are common in *A. androsaemifolium*.

The nature of the active principle of *Apocynum* is as yet somewhat uncertain. Finnemore, in 1908, obtained from the *A. cannabinum* a crystalline substance to
which the name of cynotoxin was applied. The following year Moore (J. Chem. Soc., 1909, xcv) separated from the A. androsaemifolium a glucoside having the formula C\textsubscript{14}H\textsubscript{18}O\textsubscript{3}, to which he applied the name of apocynamarin. These two principles which appear to be identical, possess the characteristic physiological effects of the crude drug. Taub and Fickewirth (A. G. P., cliii, p. 239) believe that neither of these principles is chemically pure and that the activity of the plant is due to an intensely bitter principle which is not of glucosidal nature and to which they apply the name of cymarin. This latter substance has been studied pharmacologically by Impens and has also been used practically by Allard (D. M. W., 1913, xxxix, p. 783) and others, and appears to exert the characteristic effects of the drug. Cymarin is given in oral single dose of one two-hundredth of a grain (0.003 Gm.) ; daily dose, one-sixtieth to one-thirtieth of a grain (0.001-0.002 Gm.) intravenous or intramuscular dose, one one-hundred and twenty-eighth to one sixty-fourth of a grain (0.0005-0.001 Gm.).

Von Oefele (Journ. Pharm. Elsass-Lothr., 1891, 325) described apocynteine, an alkaloid obtained from A. venetum; it is said to be a cardiac sedative.

Apocynum belongs physiologically to the digitalis group of cardiac tonics. Like digitalis it slows the pulse by stimulating cardiac inhibition, increases the vigor and tone of the heart muscle, and in overdose causes systolic spasm of the frog's heart, increases vasomotor tone and the activity of the kidney. It differs from digitalis only in the relative degree of its different effects. It appears to be the most powerful of the whole group in its effect upon inhibition, the slowing of the pulse being so extreme that despite marked constriction of the blood vessels the pressure is often lowered instead of elevated. According to Dale and Laidlaw (Proceedings of the Royal Society of Medicine, Dec., 1909), its action upon the vasomotor system is also relatively strong. It appears to be more irritant to mucous membranes than either digitalis or strophanthus, and therefore is prone to cause nausea and catharsis. Perhaps this local stimulant effect is also the explanation of its very powerful diuretic action, although Dale and Laidlaw believe that the effect upon the kidneys is due chiefly to a relative dilatation of the renal arteries.

Apocynum is useful in medicine as a diuretic and as a cardiac tonic. For the former purpose it is especially of service in dropsies due to heart failure, but has been also highly recommended in the ascites of hepatic cirrhosis; indeed, so powerful are its hydragogue properties that it has been dubbed the "vegetable trocar." As a tonic to the heart it is useful in the same classes of chronic heart disease in which digitalis is of service. The N. F., however, adds the following caution: "It has been stated that the absorption of Apocynum in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." Its irritant action upon the intestinal tract also militates strongly against its clinical usefulness; many patients are quite unable to take the drug because of the occurrence of emesis or purgation. Dose, five to fifteen grains (0.32-1.0 Gm.).

Aplopappus. Aplopappus (Haplopappus) Baylahuen Remy.—This composite herb is a native of Chili, where it is said to be relied upon as a stimulant in flatulent...
dyspepsia, and chronic inflammation with hemorrhage of the lower bowels. It has been analyzed by H. H. Rushy (A. J. P., 1890, 488), and later by H. Kahn (A. J. P., 1891, 377). The former found a volatile oil, a fatty oil which had the specific odor of the plant, a brown acid resin of sharp taste, and tannin. The latter determined the percentage of volatile oil as 6.65, and of resin as 21.15. He also considers that this resin is a mixture of four different resins. G. Baille asserts (B. G. T., Feb., 1889) that the remedy is valuable not only in dysentery, but in genito-urinary catarrhs, and also as a stimulating expectorant. Dose, one-half to one tablespoonful (7.5-15 mils) of a strong decoction, one part to five, may be given every two hours; or the fluid-extract, from five to twenty minims (0.3-1.3 mils). It has also been used in tincture form as an application to slowly healing sores and ulcers.

**AQUA AMYGDALAE AMARAE. U. S.**

**BITTER ALMOND WATER Aq. Amygd. Amar.**

Eau d'Amandes ameres, Fr.; Aqua Amygdalarum Amararum, P. G.; Bittermandelwasser, G.; Acqua distillata di mandorle amare, It.; Agua de almendras amargas, Sp.

"Oil of Bitter Almond, one mil [or 16 minims] ; Distilled Water, recently boiled, nine hundred and ninety-nine mils [or 33 fluidounces, 6 fluiddrachms, 14 minims], to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Dissolve the oil of bitter almond in the recently boiled distilled water by agitation, and filter. Note: Bitter Almond Water contains a mere trace of hydrocyanic acid and differs from the preparation of the same name, recommended by the International Protocol, 1906, which contains 0.1 per cent. of hydrocyanic acid." U. S.

Owing to the universal employment at this time of artificial oil of bitter almond (or benzaldehyde), which is free from hydrocyanic acid (such oil being much cheaper than that made from bitter almond), the bitter almond water of pharmacy cannot be relied upon as a medicinal agent, but is used mainly as a pleasant vehicle, but the requirements of the U.S. P. IX are that the oil of bitter almond shall contain not less than 85 per cent. of benzaldehyde, and not less than 2 per cent. nor more than 4 per cent. of hydrocyanic acid, hence the use of benzaldehyde (see Benzaldehyde) is no longer permissible and care must be exercised not to prescribe a larger dose of the water to begin with than two teaspoonfuls (7.5 mils). Its principal use in this country is as a vehicle, many physicians prescribing it not for its medicinal virtues, but on account of its agreeable taste and powers of masking the taste of saline substances. The process for Aqua amygdalarum amararum of the
German Pharmacopoeia directs that 12 parts of bruised bitter almonds shall be expressed without heat, so as to remove as much fixed oil as possible; the press-cake is powdered, mixed thoroughly with 20 parts of water, and 9 parts distilled off into a receiver containing 3 parts of alcohol; the distillate is assayed to determine the percentage of hydrocyanic acid, and then diluted with a mixture of 1 part of alcohol and 3 parts of water, so that 1000 parts of the final product shall contain 1. part of hydrocyanic acid.

Under the name of chloral hydrocyanate a substance has been introduced for making cherry-laurel or bitter almond water extemporaneously. It occurs in white, translucent, rhombic prisms, soluble in water, alcohol, and ether. It has the odor of hydrocyanic acid and chloral, and is said to be a very stable compound. A solution of 6.5 grains of the salt in 1000 grains of distilled water corresponds with the official bitter almond water of the German Pharmacopoeia, which is 1 to 1000. (Merck's Bulletin.)

Dose, one fluidrachm (3.75 mils).

**AQUA ANETHI. Br.**

**DILL WATER**

_Eau d'Aneth_, Fr.; _Dillwasser_, G.

“Dill Fruit, 100 grammes; Water, 2000 millilitres. Distil one thousand millilitres. In preparing this and other similar aqueous liquids by distillation, only good natural potable water must be employed, as directed for ‘Distilled Water’” Br.

“This Water may be prepared by triturating the oil of dill with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in placed of the corresponding Water of the text of the British Pharmacopoeia.” Br.

This water, which is frequently prescribed in Great Britain, is occasionally used here; it closely resembles caraway water, over which it has no advantages. It is used only as a vehicle.
AQUA ANISI. U. S., Br.

ANISE WATER Aq. Anisi

Eau d’Anis, Fr.; Aniswasser, G.; Acqua distillata di anice, It.; Agua de anis, Sp.

"Oil of Anise, two mils [or 32 minims]; Purified Talc, fifteen grammes [or 231 grains]; Distilled Water, recently boiled, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]. Triturate the Oil of Anise with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Anise Water is perfectly clear." U. S. See also Aquae Aromaticae.

"Anise Fruit, 100 grammes; Water, 2000 millilitres. Distil one thousand millilitres." Br.

"This water may be prepared by triturating the oil of anise with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopoeia." Br.

Anise water is rarely made by distillation, although the product thus secured has a more delicate flavor than the U. S. preparation. It is used solely as a vehicle.

AQUA AURANTII FLORUM. U. S. (Br.)

ORANGE FLOWER WATER Aq. Aurant. Flor.

Aqua Aurantii Floris, Br., Aqua Florum Naphae; Eau distillee (Hydrolat) de Fleura d'Oranger, Fr. Cod.; Eau de Naphe, Fr.; Orangenbluthenwasser, G.; Acqua distillata di arancio. It.; Agua destilada de azahar, Sp.

"Stronger Orange Flower Water, Distilled Water, recently boiled, each, one volume. Mix them immediately before use. Orange Flower Water complies with the tests for identity and purity given under Aqua Aurantii Florum Fortior." U. S. "Orange-flower Water is the orange-
flower water of commerce, prepared by distillation from the flowers of the Bitter Orange tree, Citrus Aurantium, var. Bigaradia, Hook., f., diluted, immediately before use, with twice its volume of Distilled Water." Br.

The U. S. Pharmacopoeia, 1890, and the U. S. P. VIII and IX introduced "Stronger Orange Flower Water," providing for its dilution with an equal volume of distilled water to make "orange flower water." This plan enables American pharmacists to employ the imported "triple" water, as it is known in commerce. This retains its fragrance longer than a weaker water; moreover, economy is effected through saving customs duty and freight, and a fresh, delicate water can be dispensed.

"Colorless or with a slight yellowish tint; odor very fragrant. Yields no reactions for lead or copper. The orange-flower water of commerce is a saturated solution of the volatile oil of the fresh flowers." Br.

This preparation is also considered by the British Pharmacopoeia as an object of importation. According to this authority, it is obtained from the flowers of the bitter orange tree; this is concurred in by our own official standard. In Italy and France, where it is largely made, the flowers of the bitter orange have long been preferred, as yielding the most fragrant product. It may be prepared in the most southern districts of our country from the fresh flowers; and these may be brought to the North for the same purpose, if previously incorporated with one-third or one-fourth of their weight of common salt. The proper method is to arrange the flowers and salt in successive layers in jars of stoneware or glass. They may also be preserved by means of glycerin. Notwithstanding, however, the facility of preparing this water here, it is generally imported from the south of France, whence it usually comes in cans of tinned copper.

L. Malenfant observed that fresh orange flowers, mixed with cold water, yield, on distillation over the naked fire, a milky water, possessing a somewhat empyreumatic odor and a strong, somewhat acrid taste. Kept for twelve or eighteen months in glass vessels covered with parchment, it loses its empyreuma, and after filtering has an agreeable odor and taste. If the flowers be mixed with boiling water and immediately distilled, the water is limpid, and gradually separates some thick oil of a brownish color; the water has the odor and taste of the flowers, but complicated with an odor of the still, which it loses after long keeping; it
seems to alter less rapidly than that obtained by the former process. Distilled by steam, limpid water of a pure odor and taste it at once obtained, free from empyreuma; it may be at once used, and keeps better in the light than when obtained by the two former processes. (A. J. P., June, 1874.) Hesse and Zeitsehel (J. Pr. Chem., 1901, 525) found by exhausting with ether the orange flower water obtained in the distillation of the orange blossoms that the quantity of oil dissolved in the water represented about one-third of the total amount of oil from the blossoms. A distilled water of the leaves is also prepared, and sometimes a mixture of the leaves and flowers is employed. But this is a fraud, as the distilled water of the leaves never has the sweet perfume of that of the flowers. (J. P. G., 4e ser., iii, 249.) Orange flower water is used exclusively on account of its agreeable odor as a flavoring agent.

Orange flower water is stored in large glass vessels or carboys in cool cellars by the manufacturers in Grasse, France, care being taken not to stopper them tightly, but simply cover the orifice with a piece of paper or coarse cloth.

Nitric, sulphuric, or hydrochloric acid produces a red coloration with orange flower water, particularly if the water be shaken with ether to take up the oil, and the acid added to the ethereal solution. (P. J., 1878, 248.) It is used as a vehicle, and to flavor syrups and elixirs.

Off. Prep.—Syrupus Aurantii Florum, U. S.

AQUA AURANTII FLORUM FORTIOR. U. S. (Br.)

STRONGER ORANGE FLOWER WATER Aq. Aurant. Flor. Fort. [Triple Orange Flower Water]

"The saturated aqueous distillate prepared by distilling the fresh flowers of Citrus Aurantium amara Linne (Fam. Rutaceae) with water. Preserve it in bottles stoppered with a pledget of purified cotton and in a dark, cool place." U. S. The orange flower water of commerce is a saturated solution of the essential oil of the fresh flowers, and the British Pharmacopoeia uses this in several preparations, terming it "Orange-flower water of commerce, undiluted." (See Aqua Aurantii Florum)

Orange flower water is nearly colorless, though often of a pale yellowish tint. "Stronger Orange Flower Water is colorless and clear or only faintly
opalescent, and possesses a strong and pleasant odor and taste of orange blossoms, and must be free from empyreuma, mustiness, or mucoid growths. It is neutral or only slightly acid to litmus, and 100 mils, when evaporated to dryness on a water bath and the residue subsequently dried in an oven to constant weight at 100° C. (212° F.), yields not more than 0.001 Gm. of residue. It gives no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (metallic impurities).” U. S. From being kept in tinned copper cans, it sometimes contains metallic impurity, which is said to be chiefly lead carbonate, derived from the lead used as a solder in making the cans. The means of detecting metallic impurity is also mentioned under the general observations on distilled water. Much color, offensive odor, or mouldiness indicates impurity derived from the flowers in distillation.

**AQUA CARVI. Br.**

**CARAWAY WATER**

*Aqua Carvi;* Eau Distillee de Carvi, Fr.; Kummelwasser, G.

"This Water may be prepared by triturating the oil of caraway with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopoeia." Br.

“Caraway Fruit, 100 grammes; Water, 2000 millilitres. Distil one thousand millilitres." Br.

Distilled Caraway Water has the flavor of the fruit or seeds, but is seldom used in the United States. The water made from the volatile oil (16 minims in a pint), in the same manner as is cinnamon water, is largely employed. It is used only as a vehicle.
AQUA CINNAMOMI. U. S., Br.

CINNAMON WATER Aq. Cinnam.

"Oil of Cinnamon, two mils [or 32 minims]; Purified Talc, fifteen grammes [or 231 grains]; Distilled Water, recently boiled, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 6¹/₂ fluidrachms]. Triturate the Oil of Cinnamon with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Cinnamon Water is perfectly clear." U. S.

"Cinnamon Bark, bruised, 100 grammes; Water, 2000 millilitres. Distil one thousand millilitres." Br. "This Water may be prepared by triturating the oil of cinnamon with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopoeia." Br.

Of these processes, that of the U. S. Pharmacopoeia is the easier, though the second, the British, may yield a sweeter product. On standing, cinnamon water, made from oil of Ceylon cinnamon, is apt to precipitate, owing to the gradual oxidation and formation of cinnamic acid, which is comparatively insoluble in water: this can be prevented, according to E. Backhaus, by passing a stream of carbon dioxide through the fresh water for a few minutes. We have never seen the precipitation successfully prevented, notwithstanding the application of numerous so-called preventives; these usually delay the precipitation, but in a few weeks’ time the cloudiness due to the formation of minute crystals of cinnamic acid invariably appears. When oil of cinnamon (Oleum Cassia) is used as directed in the U. S. P. IX process precipitation rarely occurs. E. Holmes recommends glycerin as an excellent intermedium between the oil of cinnamon and water. Ten drops of glycerin will effect the solution of a drop of the oil in a fluidounce of water.
Cinnamon water is much used as a vehicle for other less agreeable medicines, but should be given cautiously in inflammatory affections. For ordinary purposes the U. S. preparation is sufficiently strong when diluted with an equal measure of water.

**AQUA FOENICULI. U. S., Br.**

**FENNEL WATER Aq. Foenic.**

Eau de Fenouil, Fr.; Aqua Foeniculi, P. G.; Fenchelwasser, G; Acqua distillata di finocchio, It; Agua de hinojo, Sp.

"Oil of Fennel, two mils [or 32 minims]; Purified Talc, fifteen grammes [or 231 grains]; Distilled Water, recently boiled, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 6⅛ fluidrachms]. Triturate the Oil of Fennel with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Fennel Water is perfectly clear." U. S.

"Fennel Fruit, 100 grammes; Water, 2000 millilitres. Distil one thousand millilitres." Br.

"This Water may be prepared by triturating the oil of fennel fruit with twice its weight of calcium phosphate and five hundred times its volume of distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopoeia." Br.

**Uses.**—Fennel water is a pleasant vehicle for other medicines, and useful when a mild aromatic is indicated. The distillation process of the British Pharmacopoeia, although more troublesome, furnishes a more delicate and agreeable water than does that of the U. S. Pharmacopoeia.
AQUA HAMAMELIDIS. U. S. (Br.)

HAMAMELIS WATER Aq. Hamam. [Witch Hazel Water Distilled Extract of Witch Hazel]

Liquor Hamamelidis, Br.; Solution of Hamamelis, Witch-hazel extract; Eau distillée de hamamelis, Fr.; Hamamelis-wasser, G.

“A saturated aqueous liquid obtained by distilling with steam or water the bark, twigs, smaller stems or the entire shrub of Hamamelis virginiana Linne (Fam. Hamamelidaceae) collected in the autumn, and adding one hundred and fifty mils [or 5 fluidounces, 35 minims] of alcohol to each eight hundred and fifty mils [or 28 fluidounces, 356 minims] of distillate. Preserve it in tightly-closed containers in a cool place." U. S. "Fresh Hamamelis Leaves, 1000 grammes; Distilled Water, 2000 millilitres; Alcohol (90 per cent.), 160 millilitres. Macerate for twenty-four hours; then distil one thousand millilitres." Br.

The U. S. P. VIII directed that this water be made from Hamamelis Bark, the Br. Pharm. (1914) directs fresh Hamamelis leaves; the U. S. P. IX uses the bark, twigs, smaller stems, or the entire shrub of Hamamelis.

Hamamelis Water or, as it is popularly called, "Distilled Extract of Witch Hazel," has been found on the market containing very little alcohol, formaldehyde being used as a preservative. Methyl alcohol has also been found in place of ethyl alcohol in many samples. The U. S. Pharmacopoeia IX describes Hamamelis Water as "a clear and colorless, or not more than faintly opalescent or slightly yellowish liquid having a characteristic odor and taste. It is neutral or only faintly acid to litmus. Specific gravity: 0.979 to! 0.982 at 25° C. (77° F.). It must be free from mucoid or fungous growths and must not have an acetous odor. It gives no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (metallic impurities). Evaporate 100 mils of Hamamelis Water to dryness on a water bath; not more than 0.025 Gm. of residue remains (dissolved impurities). It contains not less than 14 per cent. of absolute alcohol, by volume, when estimated as directed under Determination of alcohol in official preparations (see Part III, Test No. 14). Add 8 drops of an aqueous solution of resoreinol (1 in 200) to 5 mils of Hamamelis Water and then carefully pour this upon 5 mils of sulphuric acid, contained in a test tube, in such a manner that the two liquids do not
mix. After standing for three minutes a rose-red ring does not appear at
the line of contact of the liquids nor does a distinct, white layer appear
above this zone (formaldehyde). Ten mils of Hamamelis Water gives no
reaction for methyl alcohol when tested as directed under Alcohol for the
detection of methyl alcohol." U. S.

**Uses.**—This water was probably introduced into the British
Pharmacopoeia and U. S. Pharmacopoeia IX on account of the large
demand for it which has grown out of the wide advertisements of a
certain proprietary medicine, and the universally recognized need in
American families for an embrocation which appeals to the psychic
influence of faith. As the tannic acid of hamamelis bark does not come
over into the distillate the water is therapeutically a mixture of water
and alcohol, the volatile oil being found in too minute a proportion to
possess any therapeutic value.

**AQUA LAUROCERASI. Br.**

**CHERRY LAUREL WATER**

Eau distillee de Laurier-cerise, Fr. Cod.; Kirschchlorbeer-wasser, G; Agua
destilada de laurel-cerezo, Sp.

"Cherry-Laurel Leaves, crushed, 800 grammes; Water, 2500 millilitres.
Distil one thousand millilitres; shake the product; filter, if necessary;
adjust the strength of the finished product either by adding hydrocyanic
acid or Distilled Water, so that, when tested as described under 'Acidum
Hydrocyanicum Dilutum' it contains 0.1 per cent. by weight of
hydrocyanic acid, HCN." Br.

The International Protocol (1906) fixed the strength of Cherry-Laurel
Water at 0.1 per cent. of hydrocyanic acid which corresponds with the
strength of the Br. Pharm, 1898 and 1914.

It is greatly to be regretted that this uncertain, dangerous, and
troublesome preparation should retain a place in European
pharmacopoeias, inasmuch as it could easily be replaced by a flavored
water containing a definite amount of a soluble cyanide. See S. W. P.,
1909, No. 10, 147, and 1909, No. 36, 542.

As the cherry-laurel is little cultivated in the United States, the water is
not official; but from several experiments by William Procter there is little or no room to doubt that a preparation identical in its effects might be made from the leaves of our common wild cherry, Prunus serotina. The imported cherry-laurel water, as found in commerce, is generally impaired by age, and not to be relied on.

Cherry-laurel leaves contain 65 per cent. of water, sufficient to provoke the reaction which results in the formation of a volatile oil and hydrocyanic acid. Water is very prone to hasten the conversion of the benzaldehyde, contained in the volatile oil, into benzoic acid by oxidation, and it has been found by C. Umney (P. J., x, 467) and by Moore (Ibid., 604) that the water distilled without previous maceration is somewhat stronger in hydrocyanic acid and decidedly stronger in oil (Umney) than the official product. The strength of cherry-laurel water was formerly very variable, but the present Pharmacopoeias require 0.1 per cent. of hydrocyanic acid. The proportion of hydrocyanic acid in the water diminishes with time. It has been ascertained by Deschamps that if a drop of sulphuric acid be added to a pint of the preparation it will keep unchanged for at least a year. It is best preserved by the entire exclusion of air and light. Lepage found that, preserved in full and perfectly air-tight bottles, both this and bitter almond water remained unchanged at the end of a year; while if freely exposed to the air, they lost all their hydrocyanic acid and essential oil in two or three months. (J. P. C., xvi, 346.) For Deniges's method of assaying the water, see Proc. A. Ph. A., 1894* 556.

Uses.—Cherry-laurel water is employed in, Europe as a sedative narcotic, identical in its properties with a diluted solution of hydrocyanic acid; but it is of uncertain strength, and should not be allowed to supersede the preparation of the acid now in use.

Dose, twenty minims to a fluidrachm (1.3-3.75 mils).

AQUA MENTHE PIPERITAE. U. S., Br.

PEPPERMINT WATER Aq. Menth. Pip.

“Oil of Peppermint, two mils [or 32 minims]; Purified Talc, fifteen
grammes [or 231 grains]; Distilled Water, recently boiled, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]. Triturate the Oil of Peppermint with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Peppermint Water is perfectly clear." U. S. "Oil of Peppermint, 1 millilitre; Water, 1500 millilitres. Distil one thousand millilitres." Br.

"This Water may be prepared by triturating the oil of peppermint with twice its weight of calcium phosphate and five hundred times its volume of distilled water, and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopoeia." Br.

**Uses.**—Peppermint water is one of the most popular of the aqueous vehicles. It is especially useful as an ingredient in mouth washes because the menthol content produces a pleasant and cool sensation on mucous membranes.

**Off. Prep.**—Liquor Sodaet Menthse (Alternative with Spearmint), N. F.

**AQUA MENTHE VIRIDIS. U. S., Br.**

**SPEARMINT WATER Aq. Menth. Vir.**

Eau de Menthe verte, Fr.; Romisch-Minzwasser, G.; Agua de yerba buena, Sp.

"Oil of Spearmint, two mils [or 32 minims]; Purified Talc, fifteen grammes [or 231 grains]; Distilled Water, recently boiled, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]. Triturate the Oil of Spearmint with the Purified Talc, add the recently boiled Distilled Water gradually with continued trituration, filter, and pass the filtrate through the filter repeatedly until the Spearmint Water is perfectly clear." U. S.

"Oil of Spearmint, 1 millilitre; Water, 1500 millilitres. Distil one thousand millilitres." Br.

"This Water may be prepared by triturating oil of spearmint with twice its weight of calcium phosphate and five hundred times its volume of...
distilled water and filtering the mixture. In tropical and subtropical parts of the Empire this Water may be used in place of the corresponding Water of the text of the British Pharmacopoeia." Br.

There would seem to be no good reason for distilling the mint waters from their respective volatile oils, as directed in the British processes. If the fresh plants were available, a good source for a distilled water could be provided; but if a volatile oil must be used with its uncertainty of freshness always present, the quicker process of the U. S. P. is greatly preferable.

Uses.—Spearmint water is used solely as a vehicle. Its flavor to most persons is inferior to that of peppermint, and it lacks the characteristic cooling effect of the menthol which is found in peppermint.

Off. Prep.—Liquor Sodae et Menthae, N. F.

AQUA ROSAE. U. S., Br.

ROSE WATER Aq. Ros.

Eau distillée de Rose, Fr. Cod.; Aqua Rosse, P. G.; Roaen-wasser, G.; Acqua diatillata di Rose, It; Agua destilada de rosas, Sp.

"Stronger Rose Water, Distilled Water, recently boiled, one volume [or 1 pint]. Mix them immediately before use." U. S. "Rose Water is the rose water of commerce, prepared by distillation from the flowers of Rosa damascena, Linn., diluted, immediately before use, with twice it; volume of Distilled Water. The rose water of commerce is a saturated solution of the volatile oil of the fresh rose flowers." Br.

"Rose Water complies with the tests for identity and purity described under Aqua Rosae Fortior." U. S.

The British Pharmacopoeia of 1898 abandoned the former process of distilling the petals and followed the method adopted by the U. S. Pharmacopoeia of diluting the so-called triple rose water of commerce with distilled water. This, however, does not make rose water identical in strength in these authorities, the U. S. preparation being the stronger.
Although domestic rose water of fair quality may be made by distilling fresh rose petals, it does not possess the strength or delicacy of the by-product obtained from abroad, as officially described under Aqua Rosae Fortior; hence the above process of diluting this stronger rose water. The process of distilling the fresh petals of the hundred-leaved rose is sometimes practised. These are usually preferred in the recent state; but it is said that, when preserved by being incorporated with one-third of their weight of common salt, they retain their odor, and afford a water equally fragrant with that prepared from the fresh flowers. Indeed, Haselden prefers the salted roses, believing that the water prepared from them is less mucilaginous, less apt to become sour, and keeps its odor better than that prepared from the fresh flowers. (P. J., xvi, 15.) It is not uncommon to employ the whole flower, including the calyx; but the product is less fragrant than when the petals only are used, as officially directed. A. Monthus states that the petals of the hundred-leaved rose are more odorous the nearer they are to the center of the flower, and, contrary to what is said in the text, thinks that the calyx should not be rejected in preparing the distilled water. He maintains that so far from injuring the product it in fact contributes to its preservation, and that the water obtained from the whole flower is less liable to that mucosity which is the commencement of decomposition. This effect he ascribes to the astringent matter of the calyx, coagulating the mucilaginous matter of the petals, and preventing it from passing over in the distillation. (J. P. C., 1863, p. 497.) Rose water is sometimes made by distilling together water and the oil of rose. This is best performed by dropping 10 drops of oil of rose on a sponge and adjusting it in the upper part of a still in the body of which a gallon of water is placed; the steam from the boiling water will carry over portions of the oil, and the distillate will thus be impregnated. Alpers (Am. Drug., 1896, 384) prepares rose water by dropping 10 drops of oil of rose into a liter of hot distilled water, agitating and filtering. Rauschenberger improves the flavor by adding a trace of oil of cloves; 2.5 Gm. of oil of rose, 0.25 Gm. of oil of cloves are added to sufficient alcohol to make 100 mils; then 10 mils of this solution is added to 1000 mils of boiling water and the liquid cooled and filtered.

Rose water when properly prepared, has the perfume of the rose in great perfection. It is most successfully made on a large scale. Like the other distilled waters, it is liable to spoil when kept; and the alcohol which is sometimes added to preserve it is incompatible with some of the purposes to which the water is applied, and is even said to render it sour.
through acetous fermentation. It is best, therefore, to avoid this addition, and to substitute a second distillation. It may be kept in a bottle stoppered with a plug of absorbent cotton. This distilled water is chiefly employed, on account of its agreeable odor, in collyria and other lotions. It is wholly destitute of irritating properties, unless it contain alcohol.

**AQUA ROSAE FORTIOR. U. S. (Br.)**

**STRONGER ROSE WATER Aq. Ros. Fort.**

"The saturated aqueous distillate prepared by distilling the fresh flowers of *Rosa centifolia* Linne (Fam. Rosaceæ) with water. Preserve it in bottles stoppered with a pledget of purified cotton, in a cool, dark place." U. S.

This has been introduced for the purpose of making rose water. (See the preceding article.)

"Stronger Rose Water is colorless and clear, and possesses a strong and pleasant odor, and a taste of fresh rose blossoms, and must be free from empyreuma, mustiness, or mueoid growths. It is neutral or only slightly acid to litmus, and 100 mils, when evaporated to dryness on a water bath and the residue subsequently dried in an oven to constant weight at 100° C. (212° F.), yields not more than 0.001 Gm. of residue. It gives no reaction with hydrogen sulphide T.S. or with sodium sulphide T.S. (metallic impurities); U.S.

**Aquilegia.** Aquilegia vulgaris, L. Columbine. —A perennial herbaceous plant of the Fam. Ranunculaceæ, indigenous to Europe, but cultivated in our gardens. At one time considered diuretic and diaphoretic, columbine is not at present used in practical medicine. For further information concerning this drug, see U. S. D., 19th ed., p. 1394.
**Aralia.** N. F. IV. American Spikenard. Spignet.—Aralia of the N. F. is "the dried rhizome and roots of Aralia racemosa Linne (Fam. Arali-aceae), without the presence of more than 5 per cent. of adhering stem bases, or other foreign matter. Rhizome of oblique growth, about 12 cm. in length and 5 cm. in thickness, somewhat flattened, tortuous, externally pale brown, somewhat annulately roughened, frequently cut longitudinally, whitish internally; nodes approximate, each with a prominent stem scar about 3 cm. in breadth; fracture fibrous; roots numerous, of varying length, from 5 to 25 mm. in thickness, usually cut longitudinally and furrowed, sometimes with transverse ridges and corky patches; light brown or purplish-brown externally, whitish and spongy or porous internally; fracture of the cortex short, of the wood short and fibrous. Odor aromatic; taste mucilaginous, pungent and slightly acrid. A transverse section of the root shows a thick bark with several zones of secretion reservoirs containing oil, a well-developed cork with one or more hypodermal layers of lignified cells, and a more or less distinctly radiate wood. Examined microscopically, the powdered drug shows spherical or angular, single or two- or more compound starch grains, from 0.005 to 0.02 mm. in diameter, rosette aggregates of calcium oxalate from 0.03 to 0.07 mm. in diameter, tracheae with scalariform or reticulate thickenings and simple or bordered pores, characteristic lignified cells from the hypodermis about 0.04 to 0.1 mm. in length and about one-half as broad, their walls showing simple pore (distinction from Aralia nudicaulis). Aralia yields not more than 10 per cent. of ash."

Aralia nudicaulis L. False Sarsaparilla. Wild Sarsaparilla. Shotbush. Small Spikenard. Wild Licorice. Racined’arali niee, Petitnard, Fr. Nackte Aralienwurzel, G.—This plant is an indigenous perennial. It grows from Canada to the Carolinas, inhabiting shady and rocky woods, being common in rich soil. The rhizome is horizontal, creeping, sometimes several feet in length, and 5 to 15 mm. in thickness, more or less twisted, of a yellowish-brown color externally, of a fragrant odor, and a warm, aromatic, sweetish taste. Alpers and Murray (Proc. A. Ph. A., 1897, 182) found in it 3.05 per cent. of resin, 0.33 per cent. of oil, tannin, an acid, albumen, mucilage, and cellulose.

The roots of Aralia racemosa and A. nudicaulis have been used especially in domestic practice for their gently stimulant diaphoretic and alterative action, chiefly in rheumatic, syphilitic, and cutaneous affections, in the same manner and dose as genuine Sarsaparilla. W. R. Monroe (A. J. P., Oct., 1898) found in the rhizome of the Aralia californica S. Wats. a small amount of a pale yellow, very aromatic, volatile oil, but failed to detect saponin. Danzel found a glucoside aralin in the fresh leaves of Aralia japonica. (See J. P. C., 1912, 530.)

Aralia spinosa, L. Angelica-tree. Hercules club. Toothache-tree. Prickly Elder. Prickly Ash.—The name "prickly ash" should be dropped, as it belongs properly to a species of Xanthoxylum. Angelica tree is an arborescent shrub which grows in Southeastern North America. The bark, root, and berries are used as alteratives.
Archidendron. Archidendron Vaillantii.—The bark and black beans of this leguminous plant of New South Wales are said to be an active paralyzant to the motor side of the spinal cord. (Bancroft, Proc. Roy. Soc. N. S. W., 1886.)

Areca Nut Semen Arecae. Betel Nut. Noix d’Arece, Fr. Arekanuse, Betelnuse, G.—The Areca Catechu, L., is an East India palm. The fruit, which is ovoid and from 2 to 3 cm. in diameter, and of an orange-yellow color, contains the nut embedded in a fibrous, fleshy envelope, and invested with a brittle shell which adheres to the exterior flesh. The kernel, the betel nut of commerce, is of a roundish-conical shape, rather larger than a chestnut, externally of a deep brown, diversified with a fawn color, so as to present a reticulate appearance, internally brownish-red with whitish veins, very hard, of a feeble odor when broken, and of an astringent, somewhat acid taste. It abounds in tannin, and contains also gallic acid, a fixed oil, gum, a little volatile oil, lignin and various saline substances. It yields its astringency to water, and in some parts of Hindustan an extract is prepared from it having the appearance and properties of catechu. A red coloring matter known as Areca red is extracted, probably resulting from the decomposition of a tannin. It is insoluble in cold water and ether, soluble in boiling water and alkaline liquids, out of which it is precipitated by acids. E. Jahns (Ber. d. Chem. Ges., 1888, 3404) has found three alkaloids in areca nut:

1. Arecoline, \( C_8H_{13}NO_2 \), identical with the arekane of Bombalon.

2. Arecaaine \( C_7H_{11}NO_2 + H_2O \), which occurs in permanent, colorless crystals, soluble in water, insoluble in absolute alcohol, ether, chloroform, and benzene.

3. An alkaloid which exists in such small quantities that sufficient was not obtainable for close examination. On heating arecoline with strong hydrochloric acid to 150° C. (302° F.) it is decomposed into methyl chloride, \( CH_3Cl \), and arecaidine, \( C_7H_{11}NO_2 \). This latter base forms colorless plates, stable in the air, fusing at from 223° to 224° C. (433.4°-435.2° F.), easily soluble in water, difficultly soluble in strong alcohol, and insoluble in ether and chloroform. Arecaidine has been shown to be methyltetrahydronicotinic acid, and has been made synthetically from nicotinic acid. The third alkaloid of Jahns is probably guvacine, \( C_6H_9NO_2 \), of which the methyl derivative is the base arecaidine before mentioned.

Immense quantities of areca nut are consumed in the East, mixed with the leaves of the Betel pepper (Piper Betle, L., Chavica Betle (L.) Miq.) and with lime, forming the masticatory so well known by the name of Betel. The red color which this mixture imparts to the saliva and the excrements is owing to the areca nut, which is also powerfully astringent, and, by its internal use, tends to counteract the relaxation of bowels to which the heat of the climate so strongly predisposes. (See N. R., 1876, 71.) Arecoline resembles pilocarpine in its effects on the system. (Patz, Z. E. P. T., 1910, vii.) According to Jahns (B. G. T., 1889) arecaaine is the active principle of the areca nut, and a powerful taenicide, and is an active poison with an action of the type of muscarine and pilocarpine. Locally applied, or when given internally, it contracts the pupils.
In India the areca nut has long been used as a vermifuge, the dose being a teaspoonful of the freshly grated nut, and its value against the tape worm has been confirmed by various European and American practitioners. The usual dose is from one to two drachms (3.9-7.7 Gm.). In this country the nut has also been used for the making of a hard charcoal, employed as a basis of tooth-powder.

**Argemone.** Argemone mexicana, L. Prickly Poppy. Argemone Fr. Stachelmohn, G.—An annual plant, belonging to the Papaveraceae, growing in our Southern and Western States, Mexico, the West Indies, Brazil and in many parts of Africa and Southern Asia. For an illustrated paper on the structure of the seed of this plant by Schlotterbeck and Eckler, see Proc. A. Ph. A., 1906, 467. The whole plant abounds in a milky, acrid juice, which becomes yellow on exposure, and has been used as a local application in obstinate cutaneous diseases, especially that affection known in Upper India as dhad, and also in cases of warts and even chancre. The alleged presence of morphine in Argemone mexicana has been disproven by J. O. Schlotterbeck (Proc. A. Ph. A., 1901, p. 247), who finds that the plant contains berberine, besides an alkaloid, protopine (argemonine of Peckoldt). The seeds of the plant have been used in colic, 8 grains (0.5 Gm.), given in emulsion, and repeated if necessary every half hour until three doses have been taken. (P. J., xiii, 642.) For further information concerning this drug, see U. S. D., 19th ed., p. 1395.

**Aristolochia.**—There are several species of the genus Aristolochia which are found in the herbalists' stores of India but do not enter commerce. Of these A. bracteata Retz is employed as an emmenagogue. Aristolochia of the Br. Add. was the dried stem and root of Aristolochia indica L. As sold in commerce this drug consists chiefly of stems with attached roots and is employed for the cure of snake bite and to produce abortion. The possession by it of any distinct medicinal properties is very doubtful. Later investigation has shown A. rotunda L. to contain aristolochine, C$_{32}$H$_{22}$N$_2$O$_{13}$, which has been used in Europe as a general tonic in febrile debility. The Br. Add. recognized the concentrated liquor (1 in 2 of 20 per cent. alcohol) (Liquor Aristolochiae Concentratus, Br. Add.), dose, one-half to two fluidrachms (1.8-7.5 mils); the tincture (1 in 5 of 70 per cent. alcohol) (Tinctura Aristolochiae, Br. Add.), dose, one-half to one fluidrachm (1.8-3.75 mils). Among the other species of Aristolochia, which have been used medicinally A. Clematitis L., A. longa L., A. rotunda L., are still retained in official catalogues of the continent of Europe, where they are indigenous. A. Pistolochia- L. of Southern Europe appears to have been the aristolochia of Pliny and is still used under the name of Pistolochia. The rhizome of A. Clematitis is very long, cylindrical, about 5 mm. in diameter, as a goose-quill or thicker, variously contorted, beset with the remains of the stems and roots, of a grayish-brown color, a strong, peculiar odor, and an acid, bitter taste; that of A. longa L. is spindle-shaped, from 5 cm. to 3 dm. in length, about 2 cm. in thickness, fleshy, very brittle, grayish externally, brownish-yellow within, bitter, and of a strong, disagreeable odor when fresh; that of A. rotunda L. is tuberous, roundish, heavy, fleshy, brownish on the exterior, grayish-yellow internally, and similar to the preceding in odor and taste; that of A. Pistolochia L. consists of numerous slender yellowish or brownish rootlets, attached to a common head, and possessed of an agreeable aromatic odor, with a
taste bitter and somewhat acrid.

Many species of aristolochia, growing in the West Indies and Southern America, have been used medicinally. A. cymbifera Martius, known, in Brazil as milhommen, jarra, jarrinha, and in Mexico as guaco, is said to have medicinal properties similar to those of the official species, but Butte affirms that it is depressant to the sensory nerve centers and is useful in neuralgia and pruritus. In the Argentine Republic the root of A. argentina is used as a diuretic and diaphoretic, especially in rheumatism. In the East Indies A. indica L. is employed for similar purposes with the European and American species, and the Arabians are said by Forskhal to use the leaves of A. sempervirens as a counter-poison. A. foetida Kunth, of Mexico, or Yerba del Indio, is used as a local stimulant to foul ulcers. A number of species of aristolochia are employed as a remedy for snake-bites in various parts of the world, as A. Serpentaria L., in North America; A. maxima L. (the rhizome of which is called Guaco or Contra Capitano), in South America; A. anguicida L., in the Antilles; A. brasiliensis Mart. et Zucc.; A. cymbifera Mart. et Zucc.; A. macroura Gom.; A. trilobata L., etc. There is no sufficient reason for supposing that any one of them is effective.

Armeria. Armeria vulgaris Willd. (Statice Armeria, L.) Maiden Pink. (Fam. Plumbaginaceae).—This plant, found in Europe, Asia, and Western North America, is said to be an active diuretic. (Ph. Post, May, 1890.)

ARMORACIAE RADIX. Br.

HORSERADISH ROOT

"Horseradish Root is the fresh root of Cochlearia Armoracia, Linn., collected from cultivated plants." Br.

Armoracia, Br. 1864; Raifort sauvage, Moutarde des Moines, Radis de Cheval, Cran de Bretegce, G.; Meerrettig, G.; Rabano rusticano (Raiz de), g.

Cochlearia Armoracia L. (also known as Roripa Armoracia (L.) Hitch, and Radicula Armoracia (L.) Robinson) is a native of the marshy districts of Great Britain. It is cultivated very largely for its roots which are used as a condiment, being considered stimulating to the digestive organs. It has escaped from our gardens, growing in moist grounds, especially along streams. The root of this plant is perennial, sending up numerous very large radical leaves from the midst of which r-, round, smooth, erect, branching stem rises two or three feet in height. The radical leaves are lance-shaped, waved, scollopied on the edges, sometimes pinna-tifid, and stand upon strong footstalks. Those of the stem are much smaller, without footstalks, sometimes divided at the edges, sometimes almost entire. The flowers are numerous, white, pe-
duncled, and form thick terminal clusters.

The root, which is official in its fresh state, is long, conical at top, then nearly cylindrical for some inches, at last tapering, whitish externally, very white internally, fleshy, of a Strong pungent odor when scraped or bruised, and of a hot, biting, somewhat sweetish, and sometimes bitterish taste. "Nearly cylindrical, except at the crown, where it is somewhat enlarged, and marked with closely approximated semi-amplexicaul leaf-scar. Diameter from twelve to twenty-five millimetres, length commonly thirty centimetres or more; pale yellowish-white or brownish-white externally, whitish within. Inodorous when unbroken, but yielding a characteristic pungent odor when scraped or bruised; taste very pungent." Br. Its virtues are imparted to water and alcohol. They depend upon a volatile oil, which is dissipated by drying, the root becoming at first sweetish, and ultimately insipid and quite inert. Its acrimony is also destroyed by boiling. The oil may be obtained by distillation with water. It is colorless or pale yellow, heavier than water, very volatile, excessively pungent, acrid, and corrosive, exciting inflammation and even vesication when applied to the skin. Hubatka considers it as identical with the volatile oil of mustard. He combined it with ammonia and obtained crystals of thiosinamin, NH₂CS.N(C₃H₅)H, which agreed with that produced from mustard oil. (J. P. C; 3e ser., v, 42.) According to Gutret, only six parts of it are obtained from 10,000 of the root. Besides this principle, the fresh root contains, according to the same chemist, a bitter resin in minute quantity, sugar, extractive, gum, starch, albumen, acetic acid, calcium sulphate and acetate, water, and lignin. A. Hilger found in the ashes of the root of horseradish the following: calcium, magnesium, potassium, a trace of sodium and iron in combination with sulphuric, hydrochloric, carbonic, phosphoric, and silicic acids. (Chem. Cb., p. 597, 1878; A. J. P., 1879, p. 21.) From observations made by F. L. Winekler, it may be inferred that myronic acid exists in the root combined with potassium, and that it is from the reaction between this potassium myronate, myrosine, an enzyme, also existing in the root, and water, that the volatile oil is produced, in the same manner as oil of mustard from mustard seed. (See Sinapis.) Horseradish when distilled with alcohol yields none of the oil. Buried in cool sand the root may be kept for some time without material injury.

It is said that if to the powder of the dried root which has become apparently inert, the emulsion of white mustard seed containing myrosin be added, it reacquires its original irritant properties; so that it
is the myrosin and not the potassium myronate which is injured by drying. Hence the powdered root may be added with advantage to mustard in preparing cataplasms, pediluvia, etc. (J. P. C., xxvii, 268.)

The French Codex contains a formula for compound syrup of Horseradish under the name of Sirop de Raifort Compose. It was formerly called Sirop Antiscorbutique.

Uses.—Horseradish is highly stimulant, exciting the stomach when swallowed, and promoting the secretions, especially that of urine. Externally it is rubefacient. Its chief use is as a condiment to promote appetite and invigorate digestion.

Dose, fifteen to thirty grains (1-2 Gm.) or more, grated or cut into small pieces.

Off. Prep.—Spiritus Armoraciaa Compositus, Br.

ARNICA. U. S. (Br.)

ARNICA Arnic. [Arnicae Flores, U. S. 1890 Arnica Flowers]

"The dried flower-heads of Arnica montana Linne (Fam. Compositae)." U. S. "Arnica Flowers are the dried flower-heads of Arnica montana, Linn." Br.

Arnicae Flores, Br.; Leopard's Bane, Wolf's Bane, Mountain Tobacco; Fleurs d'Arnique, Fr.; Flores Arnicas P. G.; Wohlverleihbluthen, Arnicabluthen, Arnika, Blutblume, Gemsblume, Fallkraut, G.; Fiori di arnica, It.; Flor de arnica, Sp.

Arnica montana is a perennial herbaceous plant, having a woody, brownish, horizontal rhizome, from 2 to 10 cm. long, and 0.5 to 5 mm. thick, ending abruptly, and sending forth numerous slender fibers of the same color. The stem is about 3 dm. high, cylindrical, striated, hairy, and terminating in one, two, or three peduncles, each bearing a flower. The radical leaves are ovate, entire, ciliated, and obtuse; those of the stem, which usually consist of two opposite pairs, are lance-shaped. Both are bright green, and somewhat pubescent on their upper surface. The flowers are yellow.
This plant is a native of the mountainous districts of western and central Europe, and is found, according to Nuttall, in the northern regions of this country, west of the Mississippi. It has been introduced into England, and might no doubt be cultivated in the United States. The flowers, leaves, and root are employed; but the flowers only are official in the U.S.P. (9th Rev.). In the Swiss and German Pharmacopoeia the definition of arnica flowers is restricted to the flowers separated from the receptacles, this being done as the latter contain the larvae of Trypeta arnicivora. On the other hand the Austrian Pharmacopoeia permits the use of the entire flower heads, but the receptacles containing larvae must be removed.

**Properties.**—The whole plant, when fresh, has a strong, disagreeable odor, which is apt to excite sneezing, and is diminished by drying. The taste is acrid, bitterish, and durable. Water extracts its virtues. The U.S. Pharmacopoeia thus describes the flowers: "Consisting chiefly of the tubular and ligulate flowers, occasionally with the involucre and receptacle present; in-volucral bracts narrowly lanceolate, about 1 cm. in length, dark green and pubescent; receptacle slightly convex, deeply pitted and densely short-hairy; ray flowers bright yellow, the ligulate portion 2 cm. in length, more or less folded lengthwise, 3-toothed, 7- to 12-veined, pistillate; tubular flowers perfect, reddish-yellow, stamens without a tail-like appendage (distinguished from anthers in flowers of *Inula* Helenium Linne, which have two bristles or long tails at the base); the achenes spindle-shaped, from 5 to 7 mm. in length, dark brown, finely striate, glandular-pubescent and surmounted by a pappus a little longer than the achene and composed of a single circle of nearly white barbelleate bristles; odor characteristic and agreeable; taste bitter and acrid. The powder is yellowish-brown; pollen grains numerous, from 0.025 to 0.035 mm. in diameter, spherical, triangular in section and spinose; non-glandular hairs of three kinds, either unicellular, 4- to 6-celled, or consisting of a pair of unicellular hairs with numerous pores on the dividing wall; glandular hairs of three kinds, either with a large unicellular stalk and a unicellular, glandular head, or with a 4-celled stalk and a unicellular, glandular head, or a stalk of a double row of 5 cells and a 2-celled, glandular head; pappus consisting of a multicellular axis with unicellular branches. Arnica yields not more than 9 per cent. of ash." U.S..

"Receptacle nearly flat, bristly, with two rows of dark-green, linear-lanceolate, acute, hairy bracts. Each ray-floret possesses a much
shriveled dark yellow ligulate corolla which, after expansion in water, exhibits from eight to twelve veins and three terminal teeth. Disc-florets numerous, yellow. Fruits slender, shriveled, with numerous appressed hairs, and crowned with a single row of stiff, whitish, barbed bristles. Slight aromatic odor; taste 'bitter and acrid." Br.

Arnica flowers of commerce are not infrequently admixed with and substituted by other composite flowers. Farwell states that the heads of Lapachis columnaris T. et G.-, a western composite, have been offered in large quantities for arnica. Hartwich has recently found a sample of arnica adulterated with the flowers of the common dandelion. Beilstein reported having found in one lot approximately 90 per cent. of the flowers of Inula. The following flowers also have been used: Anthemis tinctoria L., Calendula officinalis L., Doronicum Pardalianches L., Inula britannica L., and Scorzonera Jiumilis L. The first three of these are distinguished by the fact that the achenes do not have any pappus. In Inula the receptacle is naked and the Ungulate flowers are four-nerved. In Scorzonera the flowers are all ligulate and the pappus is feather-shaped.

The rhizome which was formerly official in both the British and U. S. Pharmacopoeias was described by the latter as follows:

"Rhizome about 5 Cm. long, and 3 or 4 Mm. thick; externally brown, rough from leaf-sears; internally whitish, with a rather thick bark, containing a circle of resin-cells, surrounding the short, yellowish wood-wedges, and large, spongy pith. The roots numerous, thin, fragile, grayish-brown, with a thick bark containing a circle of resin-cells. Odor somewhat aromatic; taste pungently aromatic and bitter." U. S., 1890.

Arnica rhizome is at the present time officially recognized only by the Austrian Pharmacopoeia. It is frequently substituted by or admixed with the rhizomes of other plants. Of these the following are easily recognized because of their absence of balsam canals: Achyrophorus maculatus Scop., Hieracium murorum L., Fragaria vesca L., and Betonica officinalis L. The rhizomes of Eupatorìa cannabinum L. are completely surrounded with small roots. The rhizome of Solidago Virgaurea L. has a thicker and yellowish rhizome, the taste being very faintly aromatic. The rhizome of Geum urbanuim L. has an odor resembling cloves.
Bastick (P. J., x, 389) separated what he believed to be an alkaloid from the flowers, to which he gave the name of arnicine. The arnicin of Walz (N. Jahrb. Pharm., xiii), extracted from both the root and the flowers, is a different substance; it is an amorphous yellow mass of acrid taste, slightly soluble in water, freely in alcohol or ether, and dissolving also in alkaline solutions. It is precipitable from its alcholic solution by tannic acid or by water. Walz assigns to arnicin the formula \( \text{C}_{20}\text{H}_{30}\text{O}_{4} \); other chemists that of \( \text{C}_{35}\text{H}_{45}\text{O}_{7} \). Arnicin has not been proved to be a glucoside, although it is decomposed by diluted acids. Sigel (1873) obtained from dried arnica root about \( \frac{1}{2} \) per cent. of essential oil, and 1 per cent. from the fresh; the oil of the latter had a sp. gr. of 0.999 at 18° C. (64.4° F.). The oil was found to be a mixture of various bodies, the principal being the dimethyl ether of thymohydroquinone, 
\[
\text{C}_{10}\text{H}_{12} \quad \{ \text{OCH}_{3} \}_{2}, \text{ boiling at about 235° C. (455° F.)},
\]
and with this, phloryl isobutyrate to the extent of one-fifth of the oil, and the methyl ether of a phlorol. (Pflanzenstoffe, 2d ed., p. 1530.) Kondakow (1910) confirmed the results of Sigel's investigations. (J. P. Chem., ii, 79.) (See also Gildemeister and Hoffmann, Die Aetherische Oele, p. 900.) The water from which the oil separates contains isobutyric acid, probably also a little angelic and formic acids, but neither capronic nor caprylic acid, which had been pointed out by Walz. Arnica root contains inulin, which Dragendorff extracted from it to the extent of about 10 per cent. (Pharmacographia, 2d edition, p. 391.) Kloebb reported the presence in arnica flowers of a colorless, crystalline body which he at first named arnisterin, but in 1905 he changed its name to arnidiol. (Ph. Ztg., 1905, xl, p. 846.)

**Uses.**—Arnica is an active irritant, which is capable when taken in overdose of producing symptoms of violent toxic gastro-enteritis, with great nervous disturbance, reduction or increase of the pulse rate, and collapse. In a number of cases of severe or even fatal poisoning by it, the symptoms have been burning pains in the stomach, vomiting, choleraic diarrhea, giddiness, intense muscular weakness, dilated pupils, finally complete insensibility and collapse. In some cases the disturbances of the gastro-intestinal canal have been absent, and the symptoms have chiefly been of cerebral origin. An ounce of the tincture (L. L., Nov., 1864) has produced serious but finally not fatal symptoms.

Arnica has been used in Germany in the treatment of palsies and
various other diseases, but we have very little positive knowledge concerning its action upon the system, and there is no sufficient reason for believing that it is valuable in the treatment of internal diseases. It is largely employed externally in the treatment of bruises and sprains, generally in the form of the tincture.

The powdered flowers and leaves are employed as a sternutatory; and the inhabitants of Savoy and the Vosges are said to substitute them for tobacco. They may be given in substance or infusion. The dose of the powder is from five to twenty grains (0.32-1.3 Gm.), frequently repeated. The infusion may be prepared by digesting an ounce of the flowers in a pint of water, of which from half a fluid-ounce to a fluidounce (15-30 mils) may be given every three hours. It should always be strained through linen, in order to separate the fine fibers, which might irritate the throat. A tincture of the root was official in the British Pharmacopoeia 1898, this would be preferable for internal use. (See Tinctura Arnicae.)

Dose, of the flowers, fifteen grains (1 Gm.).

**Off. Prep.**—Tinctura Arnicae, U. S. (Br.) (from flowers); Fluidextractum Arnicae, N. F.

**Artabotrys.** Artabotrys odoratissima, (Roxb.), R. Br. (Fam. Anonaceae) and Anona undinata Blanco. Ilag-ilag de China, Sp.-Fil. Alag-ilag Sonson, Tag.—A decoction of the leaves of these plants is used in the Philippine Islands in the treatment of cholera; the overdose is said to be capable of producing abortion.

**Artar Root.**—This is a drug coming from the west coast of Africa, possibly the product of Fagara Xanthoxyloides Lam. (Fam. Rutaceae), the leaves of which have been found in commercial specimens. Two alkaloids have been discovered in it by Giacosa and Nionari, one of which is said to resemble somewhat in its action veratrine, but to be a stimulant to the heart. (Ph. Centralh., 1887, No. xxv.)

**Artemisia frigida** Willd. Sierra Salvia. Colorado Mountain, Sage (Fam. Compositae)—This Rocky Mountain plant, which is found growing in immense quantities from the Saskatchewan to Western Texas, and westward, is said to be much used in that region as a diaphoretic, antiperiodic, and mild cathartic. F. A. Weiss (A. J. P., 1890) found indications of a glucoside. One or two drachms (3.9 or 7.7 Gm.) of the powdered leaves, or one or two fluidrachms (3.75 or 7.5, mils) of the fluidextract, may be administered in hot infusion every half hour until perspiration has set in. The Artemisia nana, one of the North American sage brushes, is reported to yield a volatile oil, which is rich in camphor. (P. J., 1910, xxxiv, 237.)
Arum.—The root or corm of *Arum maculatum* L. (Fam. Araceae), is occasionally used as a medicine in Europe. Its properties closely resemble those of *Arisaema triphyllum*. Its constituents, according to Enz, are a neutral acrid volatile principle soluble in ether, starch, gum, mucilage, sugar, lignin, albumen, saponin, fixed oil, resin, and calcium phosphate, the fresh corm containing 58.4 per cent. of water, 5.2 of lignin, and 27.2 of starch. (A. J. P., xxxi.)

*Arisaema triphyllum* (L.) Schott. Gouët a trois feuilles, Fr. Dreiblädtriger Aron, G. (Fam. Araceae). Dragon-root, Pepper Turnip, Indian Turnip, Jack-in-the-pulpit, Wake-robin.—This plant is common in all parts of the United States, growing in moist shady places. The corm was formerly official. It is roundish, flattened, an inch or two in diameter, covered with a brown, loose, wrinkled epidermis, and internally white, fleshy, and solid. In the recent state it has a peculiar odor, and is violently acrid. It was found by D. S. Jones to contain, besides the acrid principle and from 10 to 17 per cent. of starch, albumen, gum, sugar, extractive, lignin, and salts of potassium and calcium. (A. J. P., xv, 83.) The acridity has been ascribed to the raphides of calcium oxalate by R. A. Weber (J. Am. C. S., 1891, p. 215). This has been denied, Schneegans proving that *A. maculatum* contains saponin and Spica and Biscaro ascribe the acridity to the same principle. (Ph. Centralh., 1895, p. 731.) The Indian turnip may be preserved fresh for a year, if buried in sand.

From both *Arum maculatum*, L., and *Arum italicum* Mill., Herbert and Heim (P. J., July 31, 1897) separated a saponin, also a brownish, oily, liquid alkaloid closely resembling coniine in its properties, but less active. They also found a saponin in the arum tubers.

Both the European and American arum are, in their fresh state, violent irritants to the mucous membranes, producing when chewed insupportable burning in the mouth and throat. Taken internally, this plant causes violent gastro-enteritis, which may end in death. The fresh, partially dried root has been used internally as a stimulant to the secretions, especially in asthma, whooping cough, chronic catarrh, and rheumatism. Dose, ten grains (0.65 Gm.), two or three times a day, increased to half a drachm (2 Gm.). The perfectly fresh root should not be used, and the fully dried root is inactive.

The corm of the European arum contains much starch, and a farina is prepared from it, in small quantities, in the Isle of Portland, on the south coast of England, and called Portland arrow root, or Portland sago. The root of *A. esculentum*, L. (more correctly *Colocasia antiquorum* Schott.), which abounds in starch, is much used by the natives of the Hawaiian and other islands of the Pacific as an article of food, having been previously deprived of its acridity by heat.

Asarabacca.—*Asarum europaeum* L., is an acrid, herbaceous perennial plant, of the Fam. Aristolochiaceae, growing in woods and shady places in Europe, Siberia and the Caucasus. The rhizome is from 2 to 3 inches in thickness, of a grayish color, quadrangular, knotted and twisted, and sometimes furnished with rootlets at each joint. It has an odor similar to that of pepper, and acrid taste, and affords a grayish
powder. The leaves, which have long petioles, are kidney-shaped, entire, somewhat hairy, of a shining deep green color when fresh, nearly inodorous, with a taste slightly aromatic, bitter, acrid, and nauseous. According to Feneulle and Lassaigne, the root contains a concrete volatile oil (see Asarum), a very acrid fixed oil, a yellow substance analogous to cystin, starch, albumen, mucilage, citric acid, and saline matters. The root and leaves of asarabacca are powerfully emetic and cathartic, in doses of from thirty grains to a drachm (2.0-3.9 Gm.), but are used almost exclusively as an errhine in headache, and rheumatic affections of the face, mouth, and throat. One or two grains (0.065-0.13 Gm.), snuffed up the nostrils, produce much irritation, and a copious, persistent flow of mucus. For further information concerning this drug, see U. S. D., 19th ed., p. 1400.

Asarum. N. F. IV. Wild Ginger, Canada Snake-root. Asaret du Canada, Fr. Canadische Haselwurzel, G.—"The dried rhizome and roots of Asarum canadense Linne (Fam. Aristolochiaceae), with only an occasional leaf or flower present, and without the presence of more than 5 per cent. of other foreign matter." N. F. The plant has in all its parts an aromatic odor and an aromatic, slightly bitter taste, which it imparts to alcohol and hot water. "Of horizontal growth, occasionally branched, two-edged when young, quadrangular when older, finely striate, usually more or less twisted, from 5 to 17 cm. in length and from 2 to 4 mm. in thickness; nodes enlarged with irregular scars from petioles and remains of pedicels; internodes with annular scars from scales; dark purplish-brown externally; fracture short, internally whitish, starchy or resinous; attached roots few, from 5 to 7 cm. in length and not over 1 nun. in thickness, having from four to six radial fibro-vascular bundles. Odor aromatic, non-irritating upon heating; taste pungent and slightly bitter. In transverse section the rhizome shows a thick bark with numerous oil cells, a wood with about twelve fibro-vascular bundles And a large pith. Examined microscopically, the powdered drug shows simple and two-to four-compound starch grains, the individual grains being from 0.004 to 0.02 mm. in diameter, and tracheae with scalariform or reticulate thick-enings, a few spiral. Asarum yields not more than 12 per cent. of ash." N. F. The chief constituent is the volatile oil, at one time largely used in perfumery. According to Petersen, the oils of Asarum Europaeum and Asarum canadense are composed in the main of one compound, which is identical with the methyl ether of eugenol, C₆H₃(OCH₃)₂C₃H₅, a compound which has been made synthetically but not previously found in nature. Under the trade name Asaron a camphor derivative of Asarum Europaeum is recommended as an antiseptic and tonic. It is given the formula (CH₃)₃C₆H₂(CH)₂CH₂OH₂, and occurs as a whitish-yellow crystalline powder or fragments possessing a faint biting taste. According to the researches of Power and Lees (Trans. Chem. Soc., 1902) the oil of Asarum canadense contains the following substances: a phenol, C₉H₁₂O₂; pinene, apparently a mixture of the d- and l- forms; d-linalool, l-borneol, l-terpineol, geraniol, eugenol-methyl-ether, a blue oil, of undetermined composition, consisting of oxygenated substances of alcoholic nature; a lactone, C₁₄H₂₀O₂, palmitic acid, acetic acid, and a mixture of fatty acids intermediate between acetic and palmitic acids. For formulas for fluidextract, syrup, and oleoresin, see A. J. P., 1876, 155. F. P. Streeper (A. J. P., 1888, 6) proved that strong alcohol was the proper menstruum for the fluidextract. The medicinal properties of this drug are those of a feeble aromatic. From a half to
one drachm (2-3.9 Gm.) may be used. It is employed as an aromatic adjuvant to tonic mixtures and infusions. From Asarum arifolium Michx., E. K. Miller obtained from 7 to 10 per cent. of volatile oil having a sassafras odor, sp. gr. 1.0585 (P. J., lxix); see also Schim. Rep; 1902, p. 12; also Proc. Alabama Pharm. Assoc., 1910, 56-58.

**ASAFOETIDA. U. S. (Br.)**

**ASAFOETIDA Asafoet. [Gum Asafetida]**

"The gum-resin obtained by incising the rhizomes and roots of Ferula Asafoetida Linne and Ferula foetida Regel and of some other species of Ferula (Fam. Umbelliferae), indigenous to Persia and adjacent countries, and yielding not less than 60 per cent. (or if powdered 50 per cent.) of alcohol-soluble constituents." U. S. "Asafetida is an oleo-gum-resin obtained by incision from the root of Ferula foetida, Regel, and probably other species of Ferula." Br.

**Asafoetida, Br.; Stercus Diaboli, Cibus Deorum; Gummi resina Asafoetida; Asa foetida, Asse-fetide, Aasafoetida, Fr.; Asa foetida, P. G.; Asant, Stinkasant, Teufelsdreck, G.; Assa fetida, It.; Asafetida, Sp.; Ungoozeh, Pers.; Hildeet, Arab.; Hing, India; Angusa-kema, Afgh.**

Ferula Asafoetida was first described from actual observation by H. Falconer, who found it near Kashmir, and has long been successfully cultivated in the Edinburgh Botanical Gardens. It is distinguished by the greater height of the stem (6 to 10 feet), and by the numerous stem leaves furnished with wide sheathing petioles. The flowers are pale yellow, and the oval fruit thin, flat, foliaceous, and reddish brown, with pronounced vittae. It yields a milky juice having a powerful odor of asafetida.

Ferula foetida is a coarse umbelliferous plant, growing from five to seven feet high, with a large fleshy root, the crown of which is covered with coarse bristly fibers, and gives origin to large bipinnate radical leaves and a nearly naked stem which has only a few bipinnate leaves without wide sheathing petioles, and ends at the top in very numerous umbels. The flat-winged fruit have the vittae almost obsolete. This plant was first discovered in the sandy desert near the sea of Aral, by Lehmann, in 1844. Bunge found it in Persia about twenty years later. It would seem to be native all through Afghanistan.

It is possible that asafetida is obtained from various species of Ferula,
yet the bulk of the drug probably comes from the official plants. Among the other plants yielding asafetida is Ferula Narthex Boiss. While this is disputed by Aitchison yet it appears that it is the source of the gum-resin obtained from certain portions of Afghanistan. Tschirch describes this plant with illustrations in S. W. P., 1910, p. 289. E. M. Holmes's discussion of the asafetida plants (P. J., ser. iii, xix, 1888-1889) still remains one of our chief sources of information on the subject. (See also article on the sources of the fetid gum-resins by James Small, P. J., 1913, vol. xc, p. 287.) Ferula Jaeschkeana Vatke, which has been believed to be the source of asafetida, according to E. M. Holmes, has, at least in its dried state, not the slightest odor of asafetida, and yields a strongly celery-scented juice. (P. J., 1894, xxv.)

The asafetida plants are indigenous to Western Afghanistan and Eastern Persia. In 1687 the collection of asafetida was witnessed by Kaempfer, whose description of the method is very similar to that given by H. W. Bellew in 1872, and by J. E. T. Aitchison in 1884. According to Aitchison, the high plains of Afghanistan, two to four thousand feet above the sea, are arid and bare in winter, but in the early summer are covered with a thick growth of Ferula foetida, Dorema ammoniacum, and Ferula glabaniflua. The great cabbage-like heads of the asafetida plant, representing the primary stage of the flower heads covered over by the stipules of its leaves, are eaten raw by the natives as a sort of green. In June the asafetida is obtained. The root stock is first laid bare to the depth of a couple of inches, those plants only which have not reached their flower-bearing stage being selected. A slice is then taken from the top of the root stock, which is immediately covered with twigs and clay, forming a sort of dome, with an opening towards the north, so that the sun cannot get at the exposed root. About five or six weeks later, a thick, gummy, not milky, reddish substance found upon the exposed surface of the root in more or less irregular lumps is scraped off with a piece of iron hoop or removed with a slice of the root and at once placed in a leather bag. The asafetida is conveyed to Herat, where it is adulterated with red clay before being sent into commerce. It is brought to this country directly from India, whither it is conveyed from Bushire and down the Indus, or it is shipped first to London and then to America. It sometimes comes in mats, but more frequently in cases, the former containing eighty or ninety pounds, the latter from two hundred to four hundred pounds. Asafetida is sometimes also imported in casks.

The fruit of the asafetida is said to be sent to India, where it is highly
esteemed as a medicine.

Properties.—As usually found in commerce, asafetida is in irregular masses, soft when not long exposed, of a yellowish or reddish-brown color externally, exhibiting when broken an irregular, whitish, somewhat shining surface, which soon becomes red on exposure, and ultimately passes into a dull yellowish-brown. This change of color is characteristic of asafetida, and is ascribed to the influence of air and light upon its resinous ingredient. The masses appear as it composed of distinct portions agglutinated together, sometimes of white, almost pearly tears, embedded in a darker, softer, and more fetid paste. Occasionally the tears are separate, though rarely in the commerce of this country. They are roundish, oval, or irregular, and generally flattened, from the size of a pea to that of a large almond, sometimes larger, yellowish or brownish externally and white within, and not unlike ammoniac tears, for which they might be mistaken except for their odor, which, however, is weaker than that of the masses. A very fine variety of asafetida is spoken of by Bellew as being procured from the leaf bud in the center of the root. It does not come into European commerce, but is the Kandaharéé Hing of the Indian bazaars. (P. J., viii, 103.) It occurs in moist flaky pieces and tears, yielding a reddish-yellow oil on pressure, and mostly mixed with the remains of leaf buds. The ordinary asafetida of the Indian bazaars is known in the superior grade as Hing, in the inferior grade as Hingra. The odor of asafetida is alliaceous, fetid, and tenacious; the taste, bitter, acrid, and persistent. The effect of time and exposure is to render it more hard and brittle, and to diminish the intensity of its odor and taste, particularly the former. Kaempfer assures us that one drachm of the fresh juice diffuses a more powerful odor through a close room than one hundred pounds of the drug as usually kept in the stores. The color, which is at first white, becomes pink, and finally the well known brown, on exposure. Asafetida softens by heat without melting, and is difficult of pulverization. Its sp. gr. is 1.327. (Berzelius.) It is inflammable, burning with a clear, lively flame. It yields all its virtues to alcohol, and forms a clear tincture, which becomes milky on the addition of water.

The description in the U. S. P. IX has been considerably enlarged and is as follows: "In a soft mass, sometimes almost semi-liquid, or in irregular, more or less pliable masses composed of agglutinated tears of variable size imbedded in a yellowish-brown or dark brown matrix, or in loose ovoid tears, from 1 to 5 cm. in diameter, the surface sometimes
containing streaks of violet, yellowish-red or brownish-red and with a few vegetable fragments; when fresh the mass is either soft or tough, becoming hard and occasionally even brittle on drying; the surface of the freshly fractured tears is milky-white and opaque, changing gradually on exposure to a pinkish or reddish-purple or even reddish-brown; on moistening with water, the tears become milky-white; odor persistent, alliaceous; taste bitter, alliaceous and acrid. Triturate one part of Asafetida with three parts of water; it forms a milk-white emulsion which becomes yellowish on the addition of alkalies. Heat a fragment of one of the tears of Asafetida with sulphuric acid; a reddish-brown solution is formed; greatly dilute the latter with water, filter, and add an excess of any of the alkalies; the solution acquires a blue fluorescence, which becomes more pronounced upon the addition of a slight excess of ammonia water. An alcoholic solution of Asafetida, on the addition of a few drops of phloroglucinol T.S. and a few drops of hydrochloric acid, acquires a cherry-red color. Add a few drops of ferric chloride T.S. to a portion of the alcoholic solution of Asafetida, obtained in the assay process given below; an olive-green color is produced (most foreign resins). Add hydrochloric acid to another portion of the same alcoholic solution of Asafetida until a faint turbidity results; a bluish-green color is developed, which fades on standing (galbanum). Evaporate a quantity of the same alcoholic solution, representing 5 Gm. of Asafetida, to 25 mils, mix it with 25 mils of petroleum benzin, in a separatory funnel, and afterwards add to it twice its volume of water and agitate. The petroleum benzin layer, after washing with water and subsequent separation, exhibits no green color when shaken with 30 mils of a freshly made aqueous solution of copper acetate (1 in 20) (rosin). Mix 2 mils of emulsion, prepared as directed under Emulsum Asafoetida, with 5 mils of water and add 5 mils of sodium hypobromite T.S., so as to form a separate layer; a red color is not produced (ammoniac). The yield of ash of the gum-resin does not exceed 15 per cent. The powder is prepared by drying the gum-resin over freshly-burnt lime or by exposure to currents of warm air until it ceases to lose weight and then reducing it to a powder at a low temperature. Diluents of starch or magnesium carbonate may be added in order to maintain the powdered form. The color of po'vdered Asafetida is light brown. The yield of ash of powdered Asafetida does not exceed 30 per cent.

"Assay."—Introduce about 10 Gm. of Asafetida into a tared, 250 mil Erienmeyer flask, determine the exact weight of the drug, add 100 mils of alcohol, and having connected the flask with an upright condenser,
boil the mixture in the flask during one hour or until the drug is completely disintegrated. Then transfer the contents of the flask to two counterpoised, plainly folded filters one within the other, so that the triple fold of the inner filter is laid against the single side of the outer, and wash the flask and filter with consecutive, small portions of boiling alcohol until the washings no longer produce a cloudiness when dropped into water. Collect and reserve the mixed alcoholic solutions, for the qualitative tests given above. Dry the filters and flask to a constant weight at a temperature of about 115° C. (239° F.). Now determine the weight of the residue on the filter and in the flask and calculate its percentage from the amount of Asafetida originally taken. This percentage of alcohol-insoluble material, when subtracted from 100, gives the percentage of alcohol-soluble constituents contained in the Asafetida." U. S.

"Rounded or flattened tears from twelve to twenty-five millimetres in diameter, or masses containing tears, greyish-white to dull yellow, darkening on keeping. Fresh tears usually tough at ordinary temperatures, hard when cold. Internally yellowish and translucent, or milk-white and opaque; freshly exposed surfaces often slowly become pink, then red, and finally reddish-brown. Odor strong, alliaceous and persistent; taste bitter, acrid and alliaceous. When triturated with water Asafetida forms a white emulsion. When the freshly fractured surface of a tear is touched with sulphuric acid, a bright red or brownish-red color is produced. The tincture obtained by macerating 0.5 gramme of Asafetida with 10 millilitres of alcohol (90 per cent.), filtered, made alkaline with strong solution of ammonia, and then largely diluted with alcohol (90 per cent.), does not exhibit a blue fluorescence (distinction from and absence of galbanum). Contains not more than 50 per cent. of matter insoluble in alcohol (90 per cent.). Ash not more than 15 per cent." Br.

Much commercial asafetida of prime appearance fails to come up to the requirements of the U. S. Pharmacopoeia. Large quantities are said to be returned from the United States ports to Europe on account of their failure to contain the proper percentage of material soluble in alcohol, and in reducing the requirements from 60 to 50 per cent. the revisers of the U. S. P. VIII yielded to a slight extent to the necessities of the situation, but the U. S. P. IX raised the percentage of alcohol-soluble constituents to 60 per cent. for asafetida and to 50 per cent. of powdered asafetida. Macerated in water it produces a turbid red solution, and
triturated with that fluid it gives a white or pinkish milky emulsion of considerable permanence. Touched with nitric acid (sp. gr. 1.2) the tear becomes of an evanescent green color. In 100 parts, Pelletier found 65 parts of resin, 19.44 of gum, 11.66 of bassorin, 3.60 of volatile oil, with traces of acid calcium malate. J. Polasek examined the pure tears of *Asafoetida amygdaloides*, finding the following constituents: 61.40 per cent. of resin soluble in ether, which is regarded by him to be the ferulaic acid ester of asaresino-tannol; 0.60 per cent. of resin insoluble in ether, regarded to be free asaresino-tannol; 25.10 per cent. of gum; 6.70 per cent. of volatile oil; 0.06 per cent. of vanillin; 1.28 per cent. of free ferulaic acid; 2.36 per cent. moisture; 2.50 per cent. impurities. Asaresino-tannol has the composition corresponding to the formula C$_{24}$H$_{35}$O$_5$. The author has prepared a benzoyl derivative, C$_{24}$H$_{33}$O$_5$.C$_6$H$_5$CO, and an acetyl derivative, C$_{24}$H$_{33}$O$_5$.CH$_6$CO, which prove it to contain a hydroxyl group—viz., C$_{24}$H$_{33}$O$_4$.OH. Umbelliferone was obtained as a secondary product of hydrolysis with sulphuric acid from asaresino-tannol, and was also obtained from ferulaic acid synthetically, guaiacol being produced at the same time. By nitrification of asaresino-tannol, picric acid is produced. (A. Pharm., 1897, ccxxxv, 125, 132.) The odor of the gum-resin depends on the volatile oil, which may be procured by distillation with water or alcohol, and amounts to from 6 to 9 per cent., according to Fluckiger. It is lighter than water, colorless when first distilled, but becomes yellow with age, of an exceedingly offensive odor, and of a taste at first flat, but afterwards bitter and acrid. Hiasiwetz (Ann. Ch. Ph., Ixxi, 23) considers it a mixture, in variable proportions, of the sulphide and disulphide of a compound radical consisting of carbon and hydrogen (C$_6$H$_{11}$). Allyl persulphide, which is sublimed when oil of mustard is heated with potassium persulphide, is said by Wertheim to have an extremely intense odor of asafetida, a fact which justifies the supposition that it may be identical with the oil of that gum-resin. (Gmelin, ix, 377.) Semmler, in a later study (Ber. d. Chem. Ges., 23, p. 3530, and 24, p. 78), states that it contains pinene and a second terpene in smaller amount, and in the higher boiling fractions, a disulphide, C$_7$H$_{14}$S$_2$; a disulphide, C$_{11}$H$_{20}$S$_2$; a body (C$_{10}$H$_{16}$O)n; a disulphide, C$_8$H$_{18}$S$_2$; and C$_{10}$H$_{18}$S$_2$.

The resin is, according to Hiasiwetz and Barth (Ann. Ch. Ph., cxxviii, 61), a mixture containing ferulaic acid, C$_{10}$H$_{10}$O$_4$, crystallizing in
iridescent needles, and obtained by precipitating the alcoholic solution with lead acetate, washing the precipitate, and decomposing it with diluted sulphuric acid. Submitted to dry distillation, the resin yields umbelliferone, \( \text{C}_9\text{H}_6\text{O}_2 \), and blue-colored oils. Fused with potassium hydroxide, ferulaic acid yields oxalic acid and carbon dioxide, several acids of the fatty series, and protocatechuic acid. The resin itself treated in like manner, after it has been freed from gum, yields resorcinol. Tsehirch (Harze und Harzebehalter, 1900, p. 234) states that the resin is the ferulaic ester of asaresino-tannol containing some free ferulaic acid, and some vanillin, which latter is a product of the oxidation of the ferulaic acid.

**Impurities and Adulterations.**—Asafetida is often purposely adulterated; it frequently comes of inferior quality, and mixed with various impurities, such as sand and stones. It is generally conceded to be the worst adulterated drug upon the market, the chief adulterant being gypsum. Portions which are very soft, dark brown, or blackish, with few or no tears, and indisposed to assume a red color when freshly broken, should be rejected. We have been informed that a case seldom comes without more or less of this inferior asafetida, and of many it forms the larger portion. It is sold chiefly for horses. A factitious substance, made of garlic juice and white pitch with a little asafetida, has occurred in commerce. Asafetida is said to be sometimes mixed with wheat or barley flour or with earthy matters at the place of its production, the impurities sometimes exceeding 30 per cent. The gum-resin imported from the Persian Gulf and Bombay is largely adulterated with sand and other gum-resins. Hingra of the Bombay bazaars is a very stony variety, composed largely of earthy matter. Gaul has recently reported having met with an asafetida containing 45 per cent. of sand. Patch (Proc. A. Ph. A., 1905, p. 183) has found asafetida on the market which yielded 62, 62.5 and 73.3, respectively, of material insoluble in alcohol. The Belgian inspectors reported in 1905 finding as high as 75 per cent. of ash in some commercial samples. In spite of these figures Gehe & Co. report that the quality of the available asafetida has materially improved.

J. U. Lloyd, after examining a large number of samples of commercial asafetida, was convinced that it is impracticable to obtain the crude drug of the official standard, gypsum, carbonates, and other insoluble matters being present in large amounts. He did not find white turpentine or rosin in any of the samples; exhausting asafetida with
alcohol and evaporating the alcohol carefully, he obtained an extract for which he proposed the name of Purified Asafetida. (Ph. Rev., 1896.) H. William Jones (Y. B. P., 1900, 503) purifies asafetida by pouring a concentrated alcoholic solution into water slightly acidulated with hydrochloric acid, collecting the precipitate, washing and drying it.

A few years ago a new method was proposed for the detection of adulteration in asafetida which depended upon the combining power of the purified resins with the lead in a standard solution of lead acetate. This method, the details of which will be found in J. A. C., vol. ii, p. 86, is called the lead number and has hardly been in use long enough to warrant its adoption as an official method. Some observers, including Rippetoe (A. J. P., 1913, p. 199) find it to be subject to fluctuations as yet unexplained. Harrison and Self (Ph. J., 1912, 205) present what they term a preliminary report on the investigation of this drug for the purpose of suggesting an improved method of standardization. They claim that there is good reason to believe that the virtues of asafetida are due not only to the volatile oil, but to the sulphur containing constituents of the volatile oil. They give abundant analytical data in support of their views and as showing how adulterations with other gum-resins may be readily detected. They state that if a gum-resin contains not less than 1.5 per cent. of sulphur it may unhesitatingly be pronounced as genuine asafetida. Bernegau and E’we propose a method for estimating asafetida in commercial tablets, pills, etc., depending upon extractions with hot chloroform under specified conditions. (Proc. P. P. A., 1912, p.305.)

Asafetida is sometimes kept in a powdered state, but this is objectionable, as the drug is thus necessarily weakened by the loss of volatile oil, and is more liable to adulteration. Powdered asafetida is best prepared by exposing the gum-resin to a low temperature for several hours or several days.

Uses.—Asafetida appears to have been used in the East from the earliest times of which we have any record and notwithstanding its repulsive odor is at present much used in India and Persia as a condiment. It is by some believed to have been imported into Europe as far back as the second century, but the earliest undoubted reference to it in European medical literature is in the twelfth century. Although it is without doubt capable of being absorbed from the intestinal tract in greater or lesser quantities there is no convincing evidence that after its
absorption it exercises any distinct effect upon the system. Pidoux took a half an ounce at one dose without perceptible effects not ascribable to its local action. It has in the past been supposed to exercise a stimulant action upon the cerebral centers. The evidence in favor of this view is based upon the beneficial effects which have followed its administration in hysteria and conditions of nervous exhaustion. Its effects in these conditions, however, is entirely explicable on the grounds of the psychical impression made by taking a drug of so powerful odor and taste. On the other hand as a local stimulant to the mucous membranes, especially of the alimentary tract, it is a remedy of much value, thus it is a favorite carminative in the treatment of flatulent colic; it is often useful as an addition to laxative drugs in various types of constipation. There is evidence that after its absorption the volatile oil of asafetida is eliminated through the lungs and consequently it has been used as a stimulating expectorant in various forms of bronchitis, in whooping cough, and in asthma.

When used internally in adults it is generally preferable to administer it in the form of a pill on account of its disagreeable taste. In colic, especially in infants, it is often administered per rectum. For this purpose the emulsion of asafetida in the proportion of from one-half to one fluidounce to a pint of water may be employed.

Asafetida may be given in pill or emulsion. The tincture is official, and is much used. It may also sometimes be conveniently used in the form of a suppository, or plaster. (See Emplastrum Asafostidae, 18th ed. U. S. D., p. 238.) A syrup has been recommended in which the fetid odor of the drug is disguised by the use of the infusion of wild cherry bark. (See A. J. P., 1871, p. 397.)

J. W. Wood prepared syrup of asafetida by dissolving 256 grains of asafetida in two fluid-ounces of glycerin by the aid of a gentle heat and straining. He then dissolved 15 drops of oil of wintergreen, 5 drops of oil of cinnamon and 1 drop of oil of bitter almond in 3 fluidrachms of 95 per cent. alcohol, and added to it the above, together with enough syrup to make one pint. Each teaspoonful represents two grains of asafetida. (A. J. P., 1874.)

Dose, of asafetida, five to ten grains (0.32-0.65 Gm.).

Off. Prep.—Emulsum Asafoetidae, U. S.; Pilula Aloes et Asafoetidae,
Asclepias. N. F. IV. Butterfly weed. Pleurisy root.—This is described in the N. F. as "the dried roots of Asclepias tuberosa Linne (Fam. Asclepiadaceae), without the presence of more than 6 per cent. of foreign matter. Usually cut or broken pieces, of variable size, of an irregularly fusiform root, which, when entire is from 10 to 20 cm. in length and from 0.5 to 5 cm. in thickness; occasionally branched; externally pale orange-brown, becoming grayish-brown, annulate above, the surface roughened by numerous fine intersecting grooves; bark thin; fracture tough, the broken surface granular and white, with inconspicuous pale yellow wood bundles and large white medullary rays. Odor slight; taste bitterish and disagreeable, somewhat acrid. The powdered drug is yellowish-brown and, when examined with the microscope, shows numerous simple or two- to four-compound starch grains, the individual grains up to 0.015 mm. in diameter, somewhat spherical in shape, or truncate and often with a sleft at center; calcium oxalate crystals in rosette aggregates up to 0.04 mm. in diameter; strongly lignified thick-walled stone cells up to 0.075 mm. in diameter and with simple or branching pores; tracheae with reticulate markings, occasionally bordered porea; spindle-shaped sclerenchyma fibers few, lignified and mostly with simple pores. Asclepias yields not more than 9 per cent. of ash." N. F. It grows from Ontario to Minnesota, most abundantly southward and southwestward. It contains a glucosidal principle, Asclepiadin, which occurs as an amorphous body, is soluble in ether, alcohol and hot water. It also contains several resins and a trace of volatile oil. Besides the American species Asclepias tuberosa, A. syriaca, and A. incarnata, which were formerly recognized by the U. S. Pharmacopoeia, various other species of the genus have been used medicinally.

To the root of the A. tuberosa, have been ascribed diaphoretic, expectorant, and cathartic properties. In the Southern United States the drug has been given in pulmonic catarrhs in doses of from twenty grains to a drachm (1.3-3.9 Gm.) in a powder or in the form of a decoction; as a diaphoretic, a tea cupful of the decoction (1 in 30) every hour until some effect is produced. For additional information concerning Asclepias species, see U. S. D., 19th ed., p. 1400.

Asimina. Asimina triloba, (L.) Dunal. (Fam. Anonaceae.)—J. U. and C. G. Lloyd have found in the common pawpaw an alkaloid, asiminine, besides a volatile oil. (A. J. P., 1886.) T. M. Fletcher failed to find an alkaloid, but gives the principal constituents as fixed oil, 3.53 per cent.; resin, 343 per cent.; resin insoluble in ether, 9.5 per cent.; glucose and extractive, 8 per cent. (A. J. P., 1891, 476.)

Asparagus. Asparagus officinalis, L. Asperge, Fr. Spargel, G. Esparaguera, Sp. (Fam. Convallariaceae)—This well-known garden vegetable is a native of Europe. It is perennial and herbaceous. The root, which is inodorous, and of a weak, sweetish taste, is used in France as a diuretic and aperient in the form of decoction, made in the proportion of one or two ounces of the root to a quart of water. Hayne asserts that, in the dried state, it is wholly inert. In the berries H. Reinsch has found a large
proportion of glucose and a yellowish-red coloring matter, spargin. (A. J. P., xlii, 371.)
From the juice of the young shoots Robiquet and Vauquelin obtained a peculiar crystallizable principle, called asparagin, \( \text{C}_4\text{H}_8\text{N}_2\text{O}_3 \), which has since been found in a number of plants. (See Althaea.)

There is at present no sufficient reason for believing that asparagus is of value in practical medicine. The peculiar heavy odor which it imparts to the urine has been the chief foundation for the belief in its diuretic properties; but Nencki (Provincial Med. Journ., March, 1891) appears to have demonstrated that this odor is due to the presence in the urine of methyl-mercaptan, a gas which is frequently produced in minute quantities in the intestines by the decomposition of proteids. According to Justin D. Lyie (N. Y. M. J., July, 1892), eating asparagus causes the urine to answer Trommer's, Fehling's, and Bottger's glycosuria tests, although sugar is not present. Tanret found two carbohydrates, asparago-se and pseudo-asparago-se, in the roots and green berries of asparagus. (P. J. Tr., 1909, 205.) Certain physiologists have claimed that asparagin has an effect on metabolism, but this view is probably incorrect. (See Z. B., 1892, x.) Asparagus may be administered internally in the form of the syrup produced from the fresh juice or from the tincture. For further information concerning Asparagus, see U. S. D., 19th ed., p. 1401-1402.

**ASPIDIUM. U. S. (Br.)**

**ASPIDIUM [Male Fern]**

"The rhizome and stipes of Dryopteris Filix-mas (Linne) Schott, or of Dryopteris marginalis (Linne) Asa Gray (Fam. Polypodiaceae), collected in the autumn, freed from the roots and dead portions of rhizome and stipes and dried at a temperature not exceeding 70° C. (158° F.). Preserve Aspidium in tightly-closed containers and protect from light." U. S. "Male Fern is the rhizome of Dryopteris Filix-mas, Schott. Collected late in the autumn, divested of its roots, leaves, and dead portions, and carefully dried. Should not be kept more than a year." Br.

As the term Dryopteris was first used by Amman in 1739, and applied in 1763 by Adamson, as the name of the genus to which the Aspidium was applied in 1800 by Swartz the use of the generic term Dryopteris would seem to be necessitated by the ordinary laws of botanic nomenclature. The synonyms of the male fern are extraordinarily numerous. We append some of them: Aspidium Filix-mas, of many
authors; Polypodium Filix-mas Linn.; Polystichum Filix-mas Roth.; Nephrodium Filix-mas Rich.; Lastrea Filix-mas PresL; Tectarea Filix-mas Cavan.; Dryopteris Filix-mas (L.) Schott; Lophodium Filix-mas Newm.; Polypodium memorale Salisb.; Polystichum durum et induratum Schur.; Polystichum abbreviatum De Candolle; Aspidium mildemii Goppert; Dryopteris affinis; Polypodium heliopteris. Under the name of inkomankomo or uncomocomo, the rhizome of Aspidium athamanticum (Hook.) Kuntze, has long been used by the South African Kaffirs, and has entered European commerce as pannum.

The male fern has a perennial, horizontal rhizome, from which numerous annual fronds or leaves arise, forming tufts from a foot to four feet in height. The stipe, or footstalk, and midrib are thickly beset with brown, tough, transparent scales; the frond itself is ovate-oblong in outline, the pinnae being lanceolate, acuminate, slightly broadest above the base (D. marginalis), or lancedolate, the pinnae being linear-lanceolate, tapering from base to apex (D. Filix-mas). The fructification is in small dots on the back of each lobe, occurring close to the margin in D. marginalis and nearer the midvein than the margin in D. Filix-mas. The latter is a native of Europe, Asia, and the north of Africa. It is also found in some of the Polynesian islands, and grows in British America, following the Rocky Mountain chain through Mexico, Venezuela, etc., as far south as Peru.

D. marginalis is common in the Eastern United States, especially northward, on rocky hillsides and in the woods.

It is probable that most species of the genus, if not of the family, are medicinally active. J. L. Patterson (A. J. P., 1875) found that the D. marginalis contained all of the active principles of D. Filix-mas, and Chas. H. Cressler has demonstrated the activity of its oleoresin. (Ibid., 1878.) According to Rosendahl (P. J., 1911, lxxxvii, p. 35) the Dryopteris dilatata is indeed four times as active a poison to the tapeworm as the true aspidium. According to V. Penndorf (Ap. Ztg., 1903), in Germany the rhizomes of D. spinulosum and Athyrium Filix-fosmina are frequently found mixed with those of the true male fern, in quantities varying from five to ninety per cent. The rhizomes of D. Filix-faemina are readily recognized by having only two large dumb-bell-shaped steles. The rhizomes of D. spinulosum closely resemble those of the genuine drug, but it is stated that they can be distinguished by the numerous small glands found on the margin of their scales, the scales of
D. Filix-mas having only two upon each. On account of this substitution, many of the German extracts of the male fern are said to contain aspidin, a yellow crystalline substance having a melting point of 124° to 125° C. (255.2°-257° F.), which is found only in D. spinulosum. (Ap. Ztg., 1903.) Lauren of Helsingsfors states that the extract of A. spinulosum is a very active tenicide, and is less apt to produce disagreeable sensations in the patient than is the official drug. He gives the dose as sixty grains (3.9 G-m.), followed by a laxative, and states that some Finnish apothecaries are especially noted for their fern extracts, because they use only the rhizome of A. spinulosum. (Ap. Ztg., 1903.) Under the name of filicone there is used what is asserted to be the active principle of Aspidium spinulosum. The dose is thirty grains. On the Pacific slope the indigenous A. rigida Underw. is locally used against the tapeworm, and W. J. Bowman has found in it filicic acid and resin. Popular belief has long ascribed tenicidal virtues to our native Asplenium Filix-femina, commonly known as Lady Fern. It occurs in conical pieces from 8 to 13 cm. long, 2 to 5 cm. in diameter, of a reddish-brown color, covered with root fibers and leaf scars. According to R. Kiirsten (P. J., xxii, 1891), its active principle is closely allied to filicic acid, differing in being especially soluble in strong alcohol, in subliming at 80° C. (176° F.), and is not yielding iso-butyric acid when heated in a sealed tube with water. Pannic acid crystallizes in thin, shining, light yellow, rectangular prisms, melting at 187° C. (368.6° F.).

Heffter (A. E. P. P., 1897, 458) finds three well characterized and crystallized principles in pannum: flavopannin, $C_{21}H_{26}O_7$, crystallizing in citron-yellow prisms, melting at 151° C. (303.8° F.), and soluble in ether, benzene, acetic ether, acetone, and boiling methyl and ethyl alcohols, insoluble in petroleum, ether and water; albopannin, $C_{21}H_{24}O_7$, crystallizing in silky-white needles, which melt at 147° C. (296.6° F.); and pannol (pannic acid of Kursten), $C_{11}H_{14}O_4$, fusing at 192° C. (377.6 °F.), which is easily soluble in hot glacial acetic acid and acetone, more difficultly soluble in alcohol and ether, and very slightly soluble in petroleum benzin, benzene, and water. The alcoholic solution is colored intensely dark green with ferric chloride. Heffter compares these three compounds with the three obtained from D. Filix-mas, and finds a close chemical and therapeutic correspondence between aspidin and flavopannin, between albaspidin and albopannin, and between aspidinol and pannol. According to the experiments of A. Heffter, both flavopannin and albopannin are powerful muscle poisons, directly
affecting the heart. (A. E. P. P., Bd. xxxviii.)

Aspidium deteriorates rapidly when kept, and in about two years becomes entirely inert. The rhizomes of other species of fern are frequently substituted for the official, and in the dried state it is difficult to distinguish them. The varying results reported by physicians when using this drug, can undoubtedly be ascribed to the employment of spurious male fern, or old brownish rhizomes which should have been thrown away.

Properties.—As taken from the ground, the rhizome consists of a long cylindrical caudex, around which are closely arranged, overlapping each other like the shingles of a roof, the remains of the leafstalks or stipes, which are 2 to 5 cm. in length, from 3 to 8 mm. thick, somewhat curved and directed upwards, angular, brown, shining, and surrounded near their origin from the rhizome with thin silky scales of a light brown color. From between these remains of the footstalks emerge numerous small radical fibers. The whole rhizome, thus constituted, presents a somewhat flexible, cylindrical mass, 2.5 to 5 cm. thick, and from 7 cm. to 4 dm. in length. In this form, however, it is not usually found in commerce. The whole is ordinarily broken up into fragments, consisting of the separated remains of the leafstalks before described, with a small portion of the substance of the rhizome attached to their base, where they are surrounded by the silky scales. These fragments, as seen in commerce, often appear as if long kept, and are probably, in general, much deteriorated by time. The official description is as follows:

"Usually with the blackish-brown outer layers removed; rhizome 1 to 3 cm. in thickness, cylindraceous and nearly straight, or curved and tapering toward one end, usually split longitudinally, roughly scarred with remains of the stipe-bases, or bearing several coarse longitudinal ridges and grooves; stipes cylindrical, 3 to 5 cm. in length, about 6 mm. in thickness, nearly straight or somewhat curved, tapering toward one end, and with occasional elongated patches of the still-adhering, blackish-brown outer layers; fracture short, pale green in the inner half, the texture rather spongy, and exhibiting, in an interrupted circle, from 6 to 12 vascular bundles, each surrounded with an endodermis; odor slight; taste sweetish, astringent, bitter, acrid. Use only such portions as have retained their green color. Aspidium yields not more than 3 per cent. of ash." U. S.
"From seven to fifteen centimetres or more in length; the rhizome itself about two centimetres in diameter. Entirely covered with the hard, persistent, curved, angular, dark brown bases of the petioles, which bear numerous brown membranous scales. Petioles green internally and exhibiting in transverse section about eight pale yellow fibrovascular bundles arranged in a diffuse circle (distinction from the petioles of Athyrium Filix foemina, Roth.). Rhizomes brown externally, green internally. In transverse section, stalked secreting glands in intercellular spaces. Margins of the membranous scales with two-celled projections but no glands; at the base two minute glands (distinction from the rhizomes of certain other ferns). Feeble but disagreeable odor; taste sweetish and astringent at first, but subsequently bitter and nauseous." Br.

In collecting male fern, all the black discolored portions should be cut away, the fibers and scales separated, and only the sound green parts preserved. These should be immediately but carefully dried, and then pulverized; and the powder should be kept in small well-stoppered glass bottles. Powdered althsea leaves are sometimes used as an adulterant of powdered aspidium, giving the desirable light-green tint indicative of a good quality of drug. At other times the powder is said to consist entirely of the chaff and other inert material which the Pharmacopoeia directs should be rejected.

Kraemer has reported that much of the aspidium in the American market consists of the large rhizomes of Osmunda Claytonia. For distinction see Proc. A. Ph. A., 1906, p. 345. Capelle discusses the characteristics of genuine aspidium and the differentiation of related species. (Ap. Ztg., 1907, p. 433.)

Microscopic examination shows that aspidium is composed of polyhedral parenchyma and vascular bundles containing sealariform ducts; in D. Filix-mas ten of these bundles are arranged in an interrupted circle near to the surface; while in D. marginalis there are only six bundles in the circle. It has been analyzed by H. Bock, who gives as its constituents volatile oil, fixed oil, resin, starch, vegetable jelly, albumen, gum, sugar, tannic and gallic acids, pectin, lignin, and various salts. (See A. J. P., xxiv, 64.) Peschier ascertained that its active properties reside in the ethereal extract, which is the fixed oil in an impure state, containing volatile oil, resin, coloring matter, etc. It is a thick dark liquid, with the odor of the fern, and a nauseous, bitterish, somewhat acrid taste. E.
Luck found in it a peculiar acid, which he denominated filicic acid. Daccomo gives to filicic acid the formula \( C_{14}H_{16}O_5 \), and finds in addition a white waxy substance, melting at 80° C. (176° F.), with the formula \( (C_{13}H_{26}O)n \), glucose, tannin, a red coloring matter (filix red), a green oil which he separated into several fractions, and two resins, one brick-red, melting at 85° to 93° C. (185°-199.4° F.), the other black and plastic. He considers that filicic acid is probably an iso-butyrlic acid derivative of hydroxynaphthaquinone. Poulson (A. E. P. P., 1891) states that, when pure, crystalline, inactive filicic acid is dissolved in alkalies and reprecipitated by an acid, the amorphous precipitate possesses the active properties of the extract. He thinks that the inactive crystalline body is an anhydride or lactone of the amorphous filicic acid, and should be called filicin. Bohm announced three additional substances which he named flavaspidic acid, albaspidin and aspidinol. Kraft (Ph. Ztg., 1903, p. 275) confirms this and finds in addition, flavaspidin, and an amorphous acid which he names filmaron, which pharmacological examination has proven conclusively to be the true anthelmintic constituent of male fern. Filmaron is a bright yellowish-brown powder, insoluble in water, difficultly soluble in cold alcohol, but very soluble in other general solvents. The rhizome contains about 5 per cent. of filmaron. Its formula is \( C_{47}H_{54}O_{16} \). The other different constituents seem to be largely decomposition products of filmaron. For an assay method for male fern extract, see Am. Drug., 1897, 73.

**Uses.**—Male fern was used by the ancients, and is mentioned as a vermifuge in the works of Dioscorides, Theophrastus, Galen and Pliny, and by some of the earlier modern writers. But it does not appear to have been generally known till about the year 1775, when the King of France purchased from Madame Nouffer, the widow of a Swiss surgeon, a secret remedy for tapeworm, which proved to be the powdered root of the male fern. As was first demonstrated by Straub (A. E. P. P., 1902, xlviii, p. 1) the principles of aspidium paralyze the voluntary muscles of the higher animals as well as the analogous contractile tissue of the invertebrates. In smaller quantities these principles are stimulant to the central nervous system and may cause even tetanic convulsions.

Aspidium is used in medicine almost solely for the purpose of getting rid of various intestinal parasites, especially the tapeworm. As to its value in other forms of helminthiasis there is difference of opinion. Schultz (J. A. M. A., 1911, Ivii) reports 75 per cent. of cures in cases of hookworm
infection, but Patterson (T. G., 1908, xxxii), on the other hand, states that it has been found absolutely without value in this infection. Its action appears not to be so much to kill the parasite as to paralyze it so that it can be washed out of the alimentary canal with an active purge. For the latter purpose castor oil is often employed, but there is little doubt that its use increases the absorbability of the drug and hence adds to the danger of poisoning. For this reason calomel is generally to be preferred.

Besides as a vermifuge aspidium has been recommended by La Nara (J. des Pract., 1910) as a local application in eczema and acne.

Aspidium is a violent poison, the relative rarity of serious symptoms from its use being due to its non-absorbability. Under certain conditions, probably when there is a large amount of fatty matter in the bowel, it may be absorbed with unexpected readiness and give rise to serious and even fatal poisoning. Six drachms of it have caused death. (L. L., 1882.) The common symptoms have been vomiting, diarrhea, vertigo, headache, tremors, cold sweats, dyspnea, cyanosis, convulsions and mental disturbances. In nearly half of the cases there was disturbance of vision and even blindness, which in a few instances remained permanently. According to Harnack (M. M. W., 1912, lix, 1941) the blindness is due to spasm of the retinal vessels and subsequent optic atrophy. Prevost and Binet have found that in the lower animals, given hypodermically, the oleoresin produces violent dyspnea and death from arrest of the heart in systole, and Frohner has found parenchymatous nephritis in animals fatally poisoned by it.

Dose, sixty to one hundred and twenty grains (3.9-7.7 Gm.). Filmaron has been used clinically in doses of fifteen to twenty grains (1.0-1.3 Gm.).

Off. Prep.—Oleoresina Aspidii, U. S. (Br.).

**ASPIDOSPERMA. U. S.**

**ASPIDOSPERMA Aspidosp. [Quebracho]**

"The dried bark of Aspidosperma Quebracho blanco Schlechtendal (Fam. Apocynaceae), without the presence or admixture of more than 2 per cent. of wood or other foreign matter." U. S.
Aspidosperma Quebracho. Quebracho Bark. Quebracho Blanco.

Quebracho is an evergreen tree which sometimes reaches the height of one hundred feet, and is remarkable for its erect stem and its wide-spreading crown reaching out over the cacti and lower bushes among which it grows. The tree is indigenous to the western provinces of Argentine and is also found growing in Chili, Bolivia and Southern Brazil. The bark has been used for a long time in South America as a febrifuge and was not introduced into Europe until about 1878. The name quebracho is derived from the two Spanish words, quebrar and hacha, signifying "The axe breaks." The wood of the quebracho tree is not met with in commerce, but is said to be very hard, distinctly marked with rings of growth, and of a bright chocolate-brown color, except the very young wood, which is yellowish or reddish. According to Hesse and Penzoldt, the wood contains no alkaloids; it is used for tanning. In addition to Aspidosperma quebracho blanco there are two other plants which are known as quebracho. (1) The wood and bark of Schinopsis Lorentzii (Grisebach) Engl. (Fam. Anacardiaceae) are extensively used in tanning. The plant was formerly known as Aspidosperma quebracho Colorado and the wood is sold in commerce as "quebracho wood." Under the name of "quebracho flojo," the wood and bark of Iodina rhombifolia Hook. et Am. (Fam. Santalaceae) are substituted and sold for quebracho Colorado in Southern Brazil to Argentina and Uruguay.

Properties.—Quebracho bark is remarkable for the extreme thickness of the corky layer which often constitutes more than half of its entire substance, and is separated from the lower layer by a more or less sharply defined outline. The corky layer is usually externally dirty gray, or where it has been rubbed appears yellowish-red. "In irregular chips or in longitudinal pieces attaining a length of 14 cm. and a thickness of 35 mm.; outer corky layer from 3 to 25 mm. in thickness, brownish-gray or reddish-brown and deeply furrowed, frequently somewhat reticulate with longitudinal and shallow transverse fissures, the crevices being occasionally lined with the mycelia of a grayish mold; outer surface of bark, from which the cork has been separated, light brown or reddish-brown and usually more or less roughened; inner surface occasionally with adhering wood, otherwise light yellowish-brown to light reddish-brown, longitudinally finely striate and finely porous; fracture short-fibrous with projecting bast-fibers; nearly inodorous, taste bitter and slightly aromatic. Under the microscope, transverse sections of
Aspidosperma show a number of successive layers of cork separated by
large groups of stone cells, isolated bast-fibers and parenchyma; inner
bark with starch-bearing medullary rays 1 to 5 cells in width, separatin
narrow wedges composed of large prominent groups of stone
cells in which are occasionally included one or more thick-walled bast-
fibers; bast-fibers usually single, very thick-walled, strongly lignified
and surrounded with crystal fibers and starch-bearing parenchyma.
The powder is reddish-brown; bast-fibers single, very long and
surrounded by crystal fibers, the crystals being in prisms frequently
terminated by pyramids and from 0.008 to 0.03 mm. in length; stone
cells in large thick groups composed of numerous more or less tabular
cells; cork cells more or less polygonal in outline with thick, slightly
lignified walls; starch grains single or 2- to 4-compound, the individual
gains spherical, ovoid or more or less plano-convex, from 0.003 to 0.025
mm. in diameter."

In 1878, Fraude (Ber. d. Chem. Ges., 1878, p. 2189; 1879, p. 1560)
discovered in the quebracho blanco an alkaloid, aspidospermine,
C_{22}H_{29}N_{2}O, but Hesse has found five other alkaloids, aspidospermatine,
C_{22}H_{28}N_{2}O_{2}, and isomeric with it aspidosamine, C_{22}H_{28}N_{2}O_{2}, que-
bachine, C_{22}H_{26}N_{2}O_{3}, and isomeric with this hypoquebrachine,
C_{21}H_{26}N_{2}O_{2}, and quebrachamine, quebrachol, C_{20}H_{34}O + H_{2}O,
quebrachit, C_{6}H_{11}(OCH_{3})O_{5}. (Ber. d. Chem. Ges., xiii, 2308.)

Aspidospermine is a brownish-yellow amorphous powder or needle-
shaped crystals, fusing at 205° to 206° C. (401°-403° F.), is soluble in
about 6000 parts of water at 15° C. (59° F.), the solution having a
decidedly bitter taste, soluble in about 48 parts of absolute alcohol, in
106 parts of ether, insoluble in glycerin; it dissolves readily in fats and
fixed oils, cod liver oil dissolving a larger proportion than it does of
quinine. Its sulphate and hydrochloride are very soluble in water. The
citrate is crystallizable, and very soluble. The yield of aspidospermine is
small, 0.33 per cent. of the bark. Aspidospermatine is crystalline, and
fuses at 162° C. (323.6° F.); aspidosamine is amorphous, and fuses at
100° C. (212° F.); quebrachine in colorless crystals fuses at 214° to 216°
C. (417.2°-420.8° F.); hypoquebrachine is a yellowish mass resembling
albumin, and fuses at 80° C. (176° F.); quebrachamine forms colorless
silky needles, only slightly soluble in alcohol, ether, chloroform, and
benzin, and fuses at 142° C. (287.6° F.). Two new sugars have also been
extracted by Tanret, quebrachite and laevogyrate inosite. Tannin and
starch have also been found in the bark. According to H. C. Wood, J r.,
the most important principle is quebrachine. (U. P. M. B., 1910, xxiii.)

**Uses.**—When a preparation of aspidosperma is injected into the circulation it causes an enormous increase in the rate and depth of the respiration with some fall in the blood pressure. Pentzold, who first described the effects of this drug on the respiration, believed that the breathing was dyspneic in type and that the drug acted by preventing the red corpuscles from giving up their oxygen. He based his belief on the fact that after death from the poison the blood had the same color in both arteries and veins, but Wood and Hoyt (U. P. M. B., Sept., 1903) showed that the blood retained its normal oxidizing powers after aspidospermin and believed that the arterial hue in the veins was due to the violence of the respiration. The fall of blood pressure is due primarily to weakness of the heart, although larger doses also cause dilatation of the blood vessels— according to Cow (J. P. Ex. T., 1914, v, p. 341), by a depressant action on the medullary centers. The increase in the respiration which is the most marked effect of aspidosperma appears to be due to a direct action upon the respiratory center as H. C. Wood, Jr. (U. P. M. B., 1910, xxiii), has shown that it does not affect the circulation in the lungs, and Cow that it does not affect the bronchioles.

All of the alkaloids of aspidosperma as far as they have been studied are possessed of similar physiological properties, although to different degree. Both Wood and Cow agree that quebrachine is the most active alkaloid in the drug.

Aspidosperma is used in medicine for the relief of various types of dyspnea, especially in emphysema and asthma. In the latter condition it is not generally useful to interrupt the paroxysm, but in many cases if used continuously will greatly reduce the frequency and severity of attacks.

Under the name of amorphous aspidospermine there has entered in commerce a mixture of the various alkaloids of this drug. Dose of this preparation is from a quarter to one grain (0.016-0.065 Gm.); that of the crystalline aspidospermine is from one-fortieth to one-twentieth of a grain (0.0016-0.003 Gm.).

Dose, of aspidosperma, fifteen grains (1 Gm.); it is not, however, used in the crude state.
Off. Prep.—Fluidextractum Aspidospermatis, U. S.

Asplenium. Asplenium Filix-foemina (L.) Bern. Female Fern.—The rhizome of the female fern has been supposed to possess similar vermifuge properties to that of the male fern. At present, however, it is not used. The vulgar name of female fern is also given to the Pteris aquilina, or common brake, which is further said by some authors to have the property of destroying the tape worm. The leaves of two species of Asplenium, A. Trichomanes, L., or common spleenwort, and A. Adiantum-nigrum, L., or black spleenwort, are mucilaginous, and have been used as substitutes for maidenhair (Adiantum Capillus-Veneris L., and A. pedatum. L.) as pectorals, though destitute of their aromatic flavor.

Aster. Aster puniceus, L. (Fam. Compositae.)—The aromatic astringent rootlets of this indigenous plant have been employed as a stimulating diaphoretic in rheumatic and catarrhal affections.

Asteracantha. Asteracantha longifolia Nees. Ik Kirit. (Fam. Acanthaceae)—This Indian plant is said by A. Jayesingba to be an energetic hydragogue diuretic. (Ph. Z. R., Sept., 1887.)

Atherosperma. Atherosperma moschatum Labill. Australian Sassafras. (Fam. Monimiaceae.)—The bark of this tree, a native of Southern Australia, is said to have been long used by the aborigines, and later by the settlers, in rheumatism and in secondary syphilis, and has been highly commended by Grooves (L. L., 1862) in acute bronchitis. It has been stated that both the bark and the volatile oil are powerful poisons, and Zeyer (Vierteljahrschr. f. Pract. Pharm., x, 504) obtained from the drug an alkaloid, atherospermine (C\textsubscript{30}H\textsubscript{20}NO\textsubscript{5}); see also Wittstein's Organic Constituents of Plants, 20. The abundant volatile oil is light yellow, and has a pleasant aromatic odor and taste, resembling those of oil of sassafras. Scott obtained from the leaves 1.7 to 2.65 per cent. of volatile oil. (J. Chem. S., 101, 1912, 1612.) Ralph Stockman (Lab. Rep. Royal Coll. Phys., vi, 1897) found it to resemble in its physiological action oil of sassafras and other allied volatile oils. He took repeatedly ten minims (0.6 mil) without any pronounced effect, and one fluidrachm (3.75 mils) given to a rabbit caused only temporary stupor, with slowing of the respiration, but not of the pulse. Three fluidrachms (11.25 mils) caused in the rabbit marked depression of the heart and of the respiration, coma, and death in twelve hours by asphyxia.

**AURANTII AMARI CORTEX. U. S. (Br.)**

**BITTER ORANGE PEEL Aur. Amar. Cort.**

"The dried rind of the fruit of Citrus Aurantium amara Linne (Fam. Rutaceae)." U. S. "Dried Bitter-Orange Peel is the dried outer part of the pericarp of Citrus Aurantium, var. Bigaradia, Hook. f." Br.
**Aurantii Cortex Siccatus**, Br.; Aurantii Pericarpium; Cortex Aurantiorum, Cortex Pomorum Aurantii; Seville Orange Peel, Wild Orange Peel; Ecorce (Zeetes) d’Oranges amères, Ecorce de Bigarade, Fr.; Cortex Aurantii Fructus, P. G.; Pomeran-Eenschale, G.; Corteccia di arancio amaro, It; Corteza de naranja amarga, Sp.

Bitter Orange Peel of the U. S. P. IX is the dried rind. In the Br. Pharm., 1914, both the dried and the fresh rind are official, while under the name of Aurantii Cortex Indicus, Indian Orange Peel, the British Pharmacopoeia, 1914, recognizes the bitter orange peel obtained from varieties of the *Citrus Aurantium*, grown in India and Ceylon. For description and properties, see under *Aurantii Dulcis Cortex*.

**AURANTII CORTEX INDICUS.** Br.

**INDIAN ORANGE PEEL**

"Indian Orange Peel is the fresh and the dried outer part of the pericarp of varieties of *Citrus Aurantium*, Linn., grown in India and Ceylon." Br.

It is thus described: "Possesses the pleasant aromatic odor and bitter taste characteristic of Bitter-Orange Peel derived from *Citrus Aurantium*, var. Bigaradia, Hook, f. Inner surface retains not more than a very small amount of the white spongy part of the pericarp." Br.

In India and the Eastern divisions of the Empire, Indian Orange Peel, fresh or dried, may be employed in making the official preparations for which Fresh or Dried Bitter-Orange Peel is directed to be used.

**AURANTII CORTEX RECENS.** Br.

**FRESH BITTER-ORANGE PEEL**

"Fresh Bitter-Orange Peel is the fresh outer part of the pericarp of *Citrus Aurantium*, var. Bigaradia, Hook. f." Br.

It is thus described: "Outer surface red or deep orange-red in color, and generally rough. Inner surface retains not more than a very small
amount of the white spongy part of the pericarp; in transverse section numerous large oil-glands below the epidermis. Pleasant aromatic odor; taste aromatic, bitter." Br.

**AURANTII DULCIS CORTEX. U. S.**

**SWEET ORANGE PEEL Aurant. Dulc. Cort.**

"The outer rind of the fresh, ripe fruit of Citrus Aurantium sinensis Gallesi (Fam. Rutaceae)." U.S.

Cortex Aurantiiorum Dulci; Ecorce (Zestee) d'Orangea douces, Fr.; Apfelainenschalen, G.; Scorze del frutto dell' arancio, It.; Corteza de naraja dulce, Sp.

The U. S. Pharmacopoeia includes two kinds of orange peel, bitter and sweet, the former dried and the latter fresh. On the other hand, the British Pharmacopoeia recognizes bitter orange peel in three forms, the fresh and the dried, under the respective names of Aurantii Cortex Recens, fresh bitter orange peel, Aurantii Cortex Siccatus, dried bitter orange peel, and Indian Orange Peel; but the orange peel which is called sweet by the U. S. Pharmacopoeia—i.e., Citrus Aurantium—is termed C. Aurantium var. Bigaradia, bitter orange peel, by the British authority.

The orange tree grows to the height of about thirty feet. Its stem is rounded, much branched, and covered with a smooth, shining, greenish-brown bark. In the wild state, and before inoculation, it is often furnished with axillary spines. The leaves are ovate, pointed, entire, smooth, and of a shining pale green color. When held between the eye and the light, they exhibit numerous small transparent vesicles, filled with volatile oil, and when rubbed between the fingers, are highly fragrant. Their footstalks are about an inch long, and have wing's or lateral appendages. The flowers, which have a delightful odor, are large, white, and attached by short peduncles, singly or in clusters, to the smallest branches. The calyx is saucer-shaped, with pointed teeth. The petals are oblong, concave, white, and beset with numerous small glands. The filaments are united at their base in three or more distinct groups, and support yellow anthers. The ovary is roundish, and bears a cylindrical style, terminated by a globular stigma. The fruit is a spherical berry, often somewhat flattened at its base and apex, rough, of a yellow or orange color, and divided internally into a number of
vertical loculi, each containing from two to four seeds, surrounded by a pulp. The rind of the fruit consists of a thin exterior layer, abounding in schizolysigenous cavities filled with a fragrant volatile oil, and of an interior one, which is thick, white, spongy, insipid, and inodorous.

According to Lloyd, the orange was unknown to the ancient Greeks and Romans and was probably introduced into Europe by the Arabians. (Bull. Lloyd Libr., 1911, p. 7.) According to Tschirch, the word orange is derived from the Sanscrit, Nagaranga or Naranga. (J. P. C., 1910, p. 2.)

There are two varieties of C. Aurantium, considered by some as distinct species. They differ chiefly in the fruit, which in one is sweet, in the other is sour and bitterish and often has a darker and rougher rind. The sweet is officially recognized as Citrus Aurantium sinensis L., and the bitter or Seville variety as Citrus Aurantium amara L. The latter is ascribed by the British authority to Citrus Aurantium var. Bigaradia Hook, f., which is the Mandarin Orange. This is probably a native of China, but cultivated in Sicily, the south of Italy, and Florida, bears a fruit much smaller than the common orange, round, but flattened above and below, with a smooth, thin, delicate rind, and a very sweet delicious pulp. A volatile oil is obtained from the rind by expression, of a yellow color, a very bland agreeable odor, different from that of the orange or lemon, and a not unpleasant taste, like that of the rind. When freed from coloring matter by distillation, it was found by M. S. de Luca to be a pure hydrocarbon, with the formula doHis. (J. P. C., 3e ser. xxxii, 52.) This constituent is now recognized as d-limonene.

The orange tree is a beautiful evergreen, in which the fruit is mingled, in every stage of its growth, with the blossoms and foliage and has been applied to numerous purposes of utility and ornament. A native of China and India, it was introduced into Europe at a very early period, was transplanted to America soon after its first settlement, and is now found in every civilized country where the climate is favorable. The fruit is brought to us chiefly from California, Florida, Southern Europe, and the West Indies. The Florida and Havana oranges are the sweetest. A seedless variety termed the navel orange is rapidly replacing all others in cultivation.

Various parts of the plant are used medicinally. The leaves, which are bitter and aromatic, are employed in some places in the form of infusion as a gently stimulant diaphoretic. They yield by distillation with water a
volatile oil, which is said to be often mixed by the distillers with the oils obtained from the flowers and unripe fruit. In regard to polarized light it has a rotary power to the left, which is considerably weakened by the prolonged action of heat. (Chautard, J. P. C; 3e ser. xlv, 28.) The fresh flowers may be kept for some time by mixing them well with half their weight of sodium chloride, pressing the mixture in a suitable jar, and keeping it well closed in a cool place. They were formerly recognized by the U. S. P. under the name of Aurantii Flores, and were officially described as "about half an inch (12 mm.) long; calyx small, cup-shaped, five-toothed; petals five, oblong, obtuse, rather fleshy, white and glandular-punctate; stamens numerous, in three or more sets; ovary globular, upon a small disk, with a cylindrical style, and a globular stigma; odor very fragrant; taste aromatic and somewhat bitter." U. S., 1880. The dried flowers are used on the continent of Europe as a gentle nervous stimulant, in the form of infusion, two drachms to the pint of boiling water, taken in the dose of a teacupful. The flowers should be dried in the shade, at a temperature between 24° C. (75° F.) and 35° C. (95° F.).

An oil is obtained also from the flowers by distillation, which is called oil of neroli, and is much used in perfumery, and in the composition of liqueurs. It is an ingredient of the famous Cologne water. That obtained from the flowers of the Seville or bitter orange is deemed the sweetest. It was introduced into the Edinburgh Pharmacopoeia, with the title of Aurantii Oleum, to serve for the preparation of orange flower water. Soubeiran considers this oil rather as a product of the distillation than as pre-existing in the flowers. The fact may thus be explained that orange flower water made by dissolving even the finest neroli oil in water has not the precise odor of that procured by distillation from the flowers.

The fruit is applied to several purposes. Small unripe oranges, about the size of a cherry or less, previously dried, and rendered smooth by a turning-lathe, were sometimes employed to maintain the discharge from issues. They were preferred to peas on account of their agreeable odor, and by some were thought to swell less with the moisture; but this was denied by others, and it was asserted that they required to be renewed at the end of twenty-four hours. These fruits are sometimes found in commerce under the name of orange berries. They are sub-globular, 5 to 20 mm. in diameter, of a grayish or greenish-brown color, fragrant odor, and bitter taste, and are said to be used for flavoring cordials. A volatile
oil is obtained from them by distillation, known to the French by the
name of essence de petit grain, and employed for similar purposes with
that of the flowers. The oil, however, which now goes by this name is
said to be distilled from the leaves, and those of the bitter orange yield
the best. The oils from the unripe and the ripe fruit have a rotating
power to the right, the latter much greater than the former; and this
property might serve to distinguish them from the oil of the leaves.
Several of the oils from the Rutaceae deposit a crystalline substance,
differing from camphor. (Chautard.) The juice of the Seville orange is
sour and bitterish, and forms with water a refreshing and grateful
drink in febrile diseases. It is employed in the same manner as lemon
juice, which it resembles in containing citric acid, though in much
smaller proportion. The sweet orange is more pleasant to the taste, and
is extensively used as a light refrigerant article of diet in inflammatory
diseases, care being taken to reject the membranous portion. The best
mode of separating the outer rind, when its desiccation and preservation
are desired, is to pare it from the orange in narrow strips with a sharp
knife, as we pare an apple. When the object is to use the fresh rind for
certain pharmaceutical purposes, as for the preparation of the
confection of orange peel, it is best separated by a grater, carefully
avoiding the grating of the white portion which contains the bitter
principle. The dried peel sold in the shops is usually that of the Seville
orange, and is brought chiefly from countries adjacent to the
Mediterranean.

Properties.—Bitter orange peel has a grateful aromatic odor, which
depends upon the volatile oil contained in its schizo-lysigenous cavities,
and a warm, bitter taste. Bitter orange peel occurs "in narrow, thin
bands (ribbons), or more often elliptical, flattened, more or less curved,
pieces (quarters), varying from 3 to 6 cm. in length; outer surface
convex, varying from reddish- or yellowish-brown (ribbons) to greenish-
brown (quarters), coarsely reticulate and with the edges recurved; inner
surface concave, whitish, with numerous conical projections and
yellowish-white, linear, more or less anastomosing fibro-vascular
bundles; fracture hard; transverse section light brown, somewhat
spongy, outer layer with 1 or 2 rows of oil reservoirs; odor fragrant;
taste aromatic and bitter. The powder is yellowish-white or light brown;
fragments of parenchyma cells numerous, the walls from 0.004 to 0.012
mm. in thickness; few fragments of tracheae with close spiral markings
or simple pores; occasional membrane crystals of calcium oxalate in
monoclinic prisms, from 0.02 to 0.035 mm. in diameter. Powdered Bitter
Orange Peel is colored yellowish upon the addition of potassium hydroxide T.S. Bitter Orange Peel yields not more than 7 per cent. of ash." U. S.

"In thin strips. Outer surface deep orange-red and rough. Inner surface retains not more than a very small amount of the white spongy part of the pericarp; in transverse section numerous large oil-glands below the epidermis. Pleasant aromatic odor; taste aromatic, bitter." Br.

The Br. Pharmacopoeia requires that the outer surface both of the fresh and of the dried bitter orange peel shall be of a deep orange-red color, and rough and glandular.

The sweet peel is described officially as having "the outer, orange-yellow layer recently separated by grating or paring and consisting of epidermal cells, parenchyma cells of the sarco-carp with chromoplastids, oil reservoirs and globules of volatile oil; odor highly fragrant; taste pungently aromatic." U. S.

For the preparation of powdered bitter orange peel the German Pharmacopoeia directs that the drug should be previously dried over freshly burnt lime. For histological study of orange fruit, see Winton and Moeller, "The Microscopy of Vegetable Foods." Bitter orange peel is sometimes adulterated with sweet orange peel. The latter is less aromatic and bitter. The following test which is distinctive for bitter orange peel is recognized by the Netherland Pharmacopoeia: the section of the fruit is mounted in a solution of potassium bichromate slightly heated when the tissues become colored brown. This reaction does not take place with sweet orange peel. A distinctive test for the latter is the use of fuming nitric acid (containing 55 per cent. N₂O₅) which gives a dark green color distinguishing it from bitter orange peel which is colored brown.

Both orange peels yield their sensible properties to water and alcohol. The bitter principle, hesperidin C₁₆H₁₄O₆, was discovered by Le-breton in 1828, but its character as a glucoside was first established by Hilger and Hoffmann. (Ber. d. Chem. Ges., 9, 26, 685.) Treated with diluted acids it yields hesperedin, C₁₆H₁₄O₆, and glucose. It is crystalline (fusing point 250° to 251° C. (482°-483.8° F.), and may be prepared by Patemo and Briosi's process, as follows: The cut and bruised oranges are covered
with diluted alcohol, solution of potassium hydroxide added in excess, the liquor filtered after two days, and impure hesperidin precipitated by hydrochloric acid; the precipitate is boiled with acetic acid for ten minutes, and, after cooling, filtered from the resinous mass left. The hesperidin gradually separates from the filtrate upon standing, in white fine needles. From 4000 oranges about 6 ounces av. of the principle were obtained. (Ber. d. Chem. Ges., 1876, 250-252.) Tanret found in the rind of the bitter orange,

(1) a crystalline acid, $C_{44}H_{28}O_{14}$;
(2) a non-crystalline resinous body;
(3) hesperidin;
(4) isohesperidin, a crystalline glucoside isomer of hesperidin;
(5) aurantiamarin, another glucoside to which, in part, the bitterness of the peel is due. (P. J., 1886, 839.)

Orange peel contains also albumen, gum, resin, a trace of fixed oil, volatile oil, and a principle resembling tannin in its action on salts of iron. The bitter principles are much more abundant in the white spongy inner portion of the peel than in the outer yellowish layer. The volatile oil, Oleum Aurantii, U. S., may be obtained by expression from the fresh grated rind, or by distillation with water. It is imported into the United States in tinned copper cans. It has properties resembling those of the oil of lemons, but spoils more rapidly on exposure to the air, acquiring a terebinthinate odor. The perfumers use it in the preparation of Cologne water, and for other purposes; and it is also employed by the confectioners. According to Imbert-Gourbeyre, persons who are much exposed to the inhalation of the oil of bitter oranges are apt to be affected with cutaneous eruptions, and various nervous disorders, as headache, tinnitus aurium, oppression of the chest, gastralgia, want of sleep, and even muscular spasm. (Ph. Cb., Feb., 1854, 128.)

**Uses.**—Bitter orange peel is a mild tonic, carminative, and stomachic; the sweet is simply aromatic; but neither is much used alone. They are chiefly employed to communicate a pleasant flavor to other medicines, to correct their nauseating properties, and to assist their stimulant impression upon the stomach. They are a frequent and useful addition to bitter infusions and decoctions, such as those of gentian, quassia, calumba, and Peruvian bark. It is obviously improper to subject orange peel to the action of heat, as the volatile oil is thus driven off. Violent colics, convulsions, and even death have been caused in children by
eating large quantities of the rind. When orange peel is used simply for its agreeable flavor, the rind of the sweet orange is preferable; as a tonic, that of the Seville orange.

Dose, from half a drachm to a drachm (2.0-3.9 Gm.).

**Off. Prep.**—Syrupus Aurantii, U. S., Br. (from Tincture); Tinctura Aurantii Dulcis, U. S.; Vinum Aurantii (from Fresh Peel), Br.

**Azadirachta.** Azedarach, U. S. 1880. Pride of India. Pride of China. Ecorce d’Asedarach, Ecorce de Margousier, Fr. Zedrachrinde, G.— The U. S. P. formerly recognized the bark of the root of *Melia Azedarach* L. (Fam. Meliaceae), a beautiful tree, thirty or forty feet high, with a trunk fifteen or twenty inches in diameter. This species of *Melia* is a native of Syria, Persia, and the north of India, and is widely cultivated. It is abundant in our Southern States. North of Virginia it does not flourish. "The bark [root] is in curved pieces or quills of variable size and thickness; outer surface red-brown, with irregular, blackish, longitudinal ridges; inner surface whitish or brownish, longitudinally striate; fracture more or less fibrous; upon transverse section tangentially striate, with yellowish bast fibers; inodorous, sweetish, afterwards bitter and nauseous. If collected from old roots, the bark should be freed from the thick, rust-brown, nearly tasteless, corky layer." U. S., 1880. The bark of the trunk is "externally of a rusty-gray color, internally yellowish, and much foliated; coarsely fibrous; inodorous, bitter and slightly astringent, structure and thickness varying according to age." Br. Add. (For a description of the leaves and root bark, see Ph. Rev., 1896, p. 231.)

Oil of Azedarach is found of two kinds in Eastern Asia where it is used. One is employed for burning, the other medicinally. The latter oil, according to Lewkowitch (Oils, Fats, Waxes, vol. ii, p. 426), is known as Veepa Oil, Veppam Fat and Neem Oil, and has a specific gravity of 0.914, a saponification value of 196.9, and iodine value of 69.6, a Reichert-Meissel value of 1.1 and a butyro-refractometer reading of 52° at 25° C. (77° F.).

Azadirachta indica Br. Add. Neem Bark, Margosa Bark. Under this name was recognized the bark of the stem of *Melia Azadirachta* L., or Indian Lilac Tree—This contains, according to Broughton (P. J., 1873, 992), a bitter amorphous resin, and a crystallizable principle, melting at
175° C. (347° F.). (See also Ph. Rev., 1896, 231.) Cornish (Ind. Ann. Med. Sci., 4, 104) had previously announced the presence of a bitter alkaloid, to which he gave the name margosine.

The decoction of azedarach is affirmed to be cathartic and emetic, and in large doses narcotic; but in a number of experiments made by H. C. Wood with extracts from the dried bark and fruit, it was found impossible to poison frogs or rabbits. Robins eating of the sweetish fruit, of which they are very fond, are often rendered so far insensible as to be picked up under the tree; though they usually recover in a few hours. Children are said to eat the fruit without inconvenience, and possibly the robins simply choke themselves with the large berries. The bark is considered, in the Southern States, an efficient anthelmintic. The form of decoction is usually preferred. A quart of water is boiled with four ounces of the fresh bark to a pint, of which the dose for a child is a tablespoonful every two or three hours, until it affects the stomach or bowels. Another plan is to give a dose morning and evening for several successive days, and then to administer an active cathartic. The fresh bark and the fruit are said to be superior as vermifuges. The Br. Add. recognized an infusion (Infusum Azadirachtae Indicae, Br. Add.), eighty-eight grains in a pint of cold water, dose, one-half to one fluidounce (15-30 mils); also a tincture (Tinctura Azadirachtae Indicae, Br. Add.), two ounces in a pint of 45 per cent. alcohol, dose, one-half to one fluidrachm (1.8-3.75 mils).
[This was the last era in pharmacy when plant drugs were widely prepared, both for Regular School, Eclectic and Irregular physicians, and the Dispensatories were the major reference works used by pharmacists to prepare these products. Official plant drugs and preparations are in larger case, unofficial plant drugs and preparations are in smaller case. I have extracted all plant drugs and preparations, excluded non botanicals and those most reasonably used only by physicians...Opium, Digitalis, etc. Michael Moore]

**Baccharis.** Baccharis cordifolia DC. Mio Mio. —This composite plant of Southeastern South America ia notorious for its deadly effect upon sheep and cattle. Pedro N. Arata has isolated from it an alkaloid baccharine. (P. J., x, 6.)

**Balanites.** Agialida. Balanites Roxburghii Planch. (Fam, Zygophyllaceae) —The fruit of this plant is used medicinally in India. It contains a principle closely resembling saponin. The ripe seed yield about 50 per cent. of a fixed oil (zachun oil), which is used for burning. (See P. J., 1913, 905.) The unripe fruit is anthelmintic and purgative.

**Balata.** Gum Chicle. Chicle. Tuno Gum. Leche de Popa, Fr. Zapota Gum.—This is the dried milky juice of the Bully Tree, Mimusops Balata Gartn. (Sapota Muelleri Linden) of the Fam. Sapotaceae, a native of Northern South America from Mexico to Guiana. It is an oxidized hydrocarbon, both physically and chemically closely related to caoutchouc and gutta-percha, of a grayish-white color, with dark spots and veins; specific gravity 1.05; tasteless, but emitting an agreeable odor when warmed. It has the general properties of gutta-percha, differing, however, in being but slightly extensible, a property which specially fits it for the manufacture of transmission belts. Solid and somewhat crumbling at ordinary temperature, it softens at 49° C. (120.2° F.), and can be molded like gutta-percha. The chemical constituents of chicle have been investigated by Tschirch and Schereschewski who found so-called resins, two of them being crystallizable a-balatan and b-balaban and a yellow substance, balafluavil. (A. Pharm., 243, No. 5, 1905, 358; see also Bosz and Cohen's investigations, A. Pharm., 250, 1912, No. 1, 52; also P. J. Tr., 1910, 609.) It is used as a substitute for gutta-percha, but more especially in the manufacture of chewing gum, for which purpose it is imported in large amounts from Mexico. It ia sometimes adulterated with paraffin wax. It is not used in medicine.

**Balm of Gilead.** Balsam of Gilead. Mecca Balsam. Balsamum Meccae v. Judiacum. Balsamum Oileadense. Baume de la Mecque, Fr.—The genuine balm of Gilead ia the resinous juice of Commiphora Opobalsamum (L.) Engl. (Fam. Burseraceae), a small evergreen tree, growing on the Asiatic and African shores of the Red Sea. It was in high repute with the ancients, and is still esteemed by the Eastern nations as a medicine and cosmetic. In Western Europe and in this country it is seldom found in a
state of purity, and its use has been entirely abandoned. It is described as a turbid, whitish, thick, gray, odorous liquid, becoming solid by exposure. It possesses no medicinal properties not existing in other balsamic or terebinthinate juices. It was formerly known as opobalsamum, while the dried twigs of the tree were called xylobalsamum, and the dried fruit, carpobalsamum. In this country Poplar buds are often, incorrectly, called Balm of Gilead Buds.

**Balsam of Cativo.** Cativo Balsam.—This substance appeared in the London market in 1902 as a substitute for copaiba. It is a balsamic resin, opaque, of a dirty light brown color and slightly bitter taste, and having an extremely adhesive quality. According to Umney, it ia not soluble in 90 per cent. alcohol, but is soluble in ether and consists chiefly of acid resins with the addition of an oily substance. According to Weigel's analysis it consists of 80 per cent. of resin acids and 2 per cent. of volatile oil. It is supposed to be a product of Prioria copaifera Gris. (Fam. Leguminosae), a large tree indigenous to Panama and Jamaica. (See P. J., vol.Ixix; and Ph. Centralh., March, 1903.)

**Balsam of Cebur or Tagulaway.** Cebur or Tagulaway Balsam is prepared in the Philippine islands by boiling the root and twigs of Parameria vulneraria Radl. (Fam. Apocynaceae), in cocoa-nut oil, so as to form a yellowish-white, oily liquid, which is used with asserted excellent results for skin diseases and wounds. (A. Pharm., Nov., 1885.)

**Balsam of Lagam.** Lagam Balsam.—A thick, yellowish, fluorescent liquid, of a peculiar aromatic odor, and bitterish, acrid taste, resembling copaiba. (A. J. P., 1883, p. 368.)

**Balsam of Riga.** Riga Balsam. Balsamum Carpaticum. Balsamum Libam.—This is the product of Pinus Cembra, L. (Fam. Pinaceae), a large tree growing in the mountainous regions and northern latitudes of Europe and Siberia. The juice exudes from the extremities of the young twigs, and ia collected in flasks suspended from them. It is a thin, white fluid, having an odor analogous to that of the juniper, and possessing the ordinary terebinthinate properties. In this country it is very rare; but it is occasionally brought from Riga or Kronstadt in bottles. Keller, of Darmstadt, affirms that Riga Balsam is the product of the ordinary Pinus palustris Mill. A similar product, called Hungarian balsam, is obtained in the same manner from Pinus Pumilio Haenke, growing on the mountains of Switzerland, Austria and Hungary.

**Balsam of St. Thome.** Pan Olaeo. Belam Pu. A balsam obtained from Santirriopsis balsamifera (Oliv.) Engl. (Fam. Burseraceae). It is a resinous juice obtained by incisions in the trunk of the tree. It is used as a vulnerary and in diseases of the bladder and bronchi. (Ap. Ztg., 1898.)

**Balsam Wood.** Palo Balsamo.—This is a South American wood, derived from an unknown tree, which is believed to contain guaiacin, and which yields to distillation nearly six parts of a thick viscous aromatic oil. This contains as its chief constituent a crystalline solid of alcoholic character, melting at 91° C. (195.8° F.) and
corresponding closely to the formula $C_{14}H_{24}O$. It has found employment in perfumery. (Sohim. Rep., April and Oct., 1892.)

**Balsamorhizæ.** Balsamorhiza terebinthinacea Nutt. (Fam. Compositæ.) —The root of this plant, obtained from Idaho and Oregon, has a strong, terebinthinate odor, and is used medicinally in the Western States. It contains volatile oil, fixed oil, resin, organic acid, and sugar (Herman T. Kelly, D. C., 1897, 32).

**BALSAMUM PERUVIANUM. U. S., Br.**

**BALSAM OF PERU Bals. Peruv. [Peru Balsam]**

“A balsam obtained from Toluifera Pereiræ (Royle) Baillon (Fam. Leguminosæ).” U. S. “Balsam of Peru is a viscid balsam exuded from the trunk of Myroxylon Pereiræ, Klotzsch, after the bark has been beaten and scorched.” Br.

Balsamum Peruvianum Nigrum, Balsamum Indicum; Baume des Indes, Baume de Perou noir, Baume de Sonsonate, Fr.; Balsamum peruvianium, P. G.; Peruvianischer Balsam, Indischer Balsam, Perubalsam, G.; Balsamo peruviano, Balsamo del Peru, It.; Balsamo del Peru liquido, Balsamo de San Salvador, Balsamo negro, Sp.

The origin of Peru balsam has been the subject of considerable investigation (see U. S. D., 19th ed.), and while the U. S. Pharmacopoeia in conjunction with the Swiss Pharmacopoeia ascribes it to Toluifera Pereirae, the British authority ascribes it to Myroxylon Pereiræ. Tschirch, who has given a great deal of attention to the origin of Peru balsam, has come to the conclusion that it is merely a physiological variety of the same tree that yields Balsam of Tolu, and has designated it as Toluifera Balsamum, L., var. phys. Peréiræ.

Toluifera Pereiræ is a handsome tree, with a straight, round, lofty stem, a smooth ash-colored bark, and spreading branches at the top. The leaves are alternate, petiolate, and unequally pinnate. The leaflets are from five to eleven, shortly petiolate, oblong, oval-oblong, or ovate, about three inches long by somewhat less than an inch and a half in breadth, rounded at the base, and contracting abruptly at top into an emarginate point. When held up to the light they exhibit, in lines parallel with the primary veins, beautiful rounded and linear pellucid spots. The common and partial petioles and midribs are smooth to the naked eye, but when examined with a microscope are found to be furnished with short hairs. The fruit, including the winged footstalks,
varies from two to four inches in length. At its peduncular extremity it is rounded or slightly tapering; at the top enlarged, rounded, and swollen, with a small point at the side. The mesocarp, or main investment of the fruit, is fibrous, and contains in distinct receptacles a balsamic juice, which is most abundant in two long receptacles or vittae, one upon each side. The yellowish-white beans yielded to Rother (P. J. xv, 244) two per cent. of coumarin; the husks, a brown, extremely bitter, somewhat acrid resin. A gum-resin exudes in small quantities from the trunk of the tree, which, though containing, besides gum and resin, a small proportion of volatile oil, is distinct from the proper balsam, and yields no cinnamic acid. (Attfield, P. J., Dec., 1863.) The valuable wood of the tree resembles mahogany.

This tree grows in Central America, in the State of San Salvador, upon the Pacific coast. It is found in the wild forests, singly or in groups, but the trees are owned by individuals. Charles Dorat states that it is never found at a greater height on the mountains than one thousand feet, that it begins to be productive after five years, and continues to yield for thirty years or more, and that the aroma of its flower is perceived at the distance of one hundred yards. (A. J. P., xxxii.) The balsam is collected by the aborigines, on lands reserved to them, within a small district denominated the Balsam Coast, extending from Acajutia to La Libertad. Early in November or December the bark is beaten on four sides of the trunk, so as to separate it from the wood without breaking it, intermediate strips being left sound, in order not to destroy the life of the tree. The bruised bark soon splits, or cuts are made in it. Five or six days after the beating the injured surface is set on fire, and about a week later the bark, if it has not fallen off spontaneously, is removed. The juice now begins to exude freely from the exposed wood, which the natives cover with rags. The latter, when saturated, are boiled in water in large jars, and the liquid allowed to stand, whereupon the water rises to the top, and is poured off, leaving the balsam, which is put into calabashes or bladders. Seven to ten days later a second flow of balsam occurs, and is secured as before. Subsequently the exposed parts are scraped or otherwise wounded, and a third balsam is obtained. These three grades of balsam are said to be known respectively as Tagauzonte, balsam, de trapo, balsamo de contrapique. The balsam is then taken for sale to the neighboring towns, where it is purified by subsidence and straining and put into jars or metallic drums for exportation. The destroyed bark is said to renew itself in two years, so that by care a tree can be worked for a long time; two pounds is stated to be the average
yearly yield. In 1861 the tree was introduced in Ceylon with complete success.

The term Balsam of Peru is a survival of the times when the products of the Spanish colonial coast were assembled at Callao, Peru, for shipment to Europe. This fact has caused Gane and Webster to assert that Balsam of Peru is mis-branded under the Foods and Drugs Act in that it does not come from Peru. (Drug Topics, 1910, p. 4.) It is estimated that the Republic of Salvador exports annually about 130,000 pounds of Balsam of Peru. In spite of this there is a good deal of factitious balsam on the market which consists chiefly of synthetic cinnamcin which is often added to exhausted tolu. Riedel reports having found a sample of balsam on the market, which was apparently derived from Myroxylon punctatum Klotzsch, and which contained none of the active principles of Balsam of Peru.

A substance called white balsam (Balsamo blanco) is procured from the fruit. This has been confounded with the balsam of Tolu, but is wholly distinct. It is of a semi-fluid or soft-fluid consistence, somewhat granular, and, on standing, separate's into white, resinous crystalline deposit, and a superior, translucent more fluid portion. The odor, though quite distinct from that of the balsams of Tolu and Peru, is not disagreeable. Stenhouse has obtained from it a peculiar resinous body, readily crystallizable, and remarkably indifferent in its chemical affinities, which he denominated myroxocarpin. (P. J., x, 290.) Tschirch (Harze und Harsbehalter, 1900, p. 166) gives the compound the name myroxoresene, and the formula, C_{7}H_{10}O. Dorat, however, denies that the white balsam is produced by the same tree, or in the same vicinity.

Another substance obtained from the same tree, and much used in Central America, is a tincture of the fruit made by digesting it in rum. It is called balsamito by the inhabitants, and is said to be stimulant, anthelmintic, and diuretic. It is also used as an external application to gangrenous or indolent ulcers, and as a wash to the face to remove freckles. According to Dorat, the balsamito is not the tincture, but an alcoholic extract of the young fruit. Neither this nor the white balsam reaches the markets of this country.

Balsam of Peru was named from its place of exportation, and it was long thought to be a product of Peru. It is now shipped partly from the Pacific coast, and partly from the Balize or other Atlantic ports, whether it is
brought across the country. It was Guibourt who first made known the fact of its exclusive production in Central America. As imported, it is usually in tin canisters, with a whitish scum on its surface, and more or less deposit, which is dissolved with the aid of heat.

Besides the official species, there are others of the genus which possess medicinal virtues, and have been more or less employed. (See 14th ed., U. S. D.) The pod of M. frutescens Jacq., growing in Trinidad, is popularly used in that island as a carminative, and externally, in the form of a tincture, as a lotion in rheumatic pains, and by incisions in the stem a small quantity of balsamic juice is obtained not distinguishable from balsam of Tolu. (P. J., Sept., 1862, p. 108.) Another species is known in Paraguay under the name of quino-quino, the bark of which is used, in powder and decoction, as a remedy in wounds and ulcers, and from the trunk of which a juice is obtained which in its concrete state closely resembles dried balsam of Peru. (P. J., Oct., 1862, p. 183.) A product of T. peruiferum, sometimes known as Brazilian balsam or as Oleo-balsam has been offered for sale as genuine Peru balsam. In bulk it is of a dark brown color, but in thin layers it is dark red. Its odor is smoky, feebly fragrant; its taste slightly pungent, leaving a choking, disagreeable, persistent feeling. It is entirely soluble in ether and in rectified spirits. It also mixes with castor oil in all proportions, and forms with carbon disulphide a clear light brown solution with residue, also a deposit, in its chloroform solution, which becomes a powdery precipitate upon standing. At 17° C. (62.6°F.) its specific gravity is 1.031. Its general constitution is very similar to that of balsam of Peru, containing volatile oil, myroxylin, cinnamic and tannic acids, and resin. (P. J., 3d ser. xi, 818.) It is especially to be distinguished from Peru balsam by its behavior with sulphuric acid. When Peru balsam is treated with sulphuric acid, and cold water poured upon it, a beautiful violet color is imparted to the surface, and the whole mass has a bright shade. The same procedure yields with the oleo-balsam a gray mass. For further information, see P. J., xv, 771.

Properties.—"Balsam of Peru is a viscid liquid of a dark brown color; free from stringiness or stickiness; transparent and reddish-brown in thin layers; of an agreeable, vanilla-like odor and a bitter, acrid taste, with a persistent after-taste. When swallowed it leaves a burning sensation in the throat. It does not harden on exposure to the air. It is soluble in alcohol, chloroform, and glacial acetic acid with not more than a slight opalescence; only partly soluble in ether or petroleum benzin.

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - B - Page 6
The Southwest School of Botanical Medicine http://www.swsbm.com
Water, when agitated with the Balsam, is acid to litmus. Specific gravity: 1.130 to 1.160 at 25° C. (77° F.). One Gm. of the Balsam forms a clear solution when shaken with a solution of 3 Gm. of hydrated chloral in 2 mils of distilled water (fixed oils). Shake about 1 Gm. of the Balsam with 5 mils of purified petroleum benzin, and warm the mixture on a water bath for 10 minutes, adding a sufficient quantity of the solvent to replace the loss by evaporation. On evaporating 2 mils of the benzin solution, no odor of turpentine is noticeable, and when the residue is treated with a few drops of nitric acid, no green or bluish color is produced (turpentine or rosin). Weigh accurately about 1 Gm. of the Balsam and dissolve it in 100 mils of alcohol, add 1 mil of phenolphthalein T.S. and titrate the solution with half-normal potassium hydroxide V.S. The acid number thus obtained is not less than 56 nor more than 84. Mix about 3 Gm. of the Balsam, accurately weighed, with 30 mils of sodium hydroxide T.S. and shake the mixture for a few minutes with 60 mils of ether. Then add about 3 Gm. of powdered tragacanth, filter and transfer 50 mils of the ethereal filtrate (representing five-sixths of the weight of the Balsam taken) into a tared, conical flask. Evaporate the ether and dry the residue to constant weight at 100° C. (212° F.). The weight of the residue of cinnamein so obtained is not less than 50 per cent. nor more than 56 per cent. of the weight of the Balsam represented by the 50 mils of ethereal solution taken. Dissolve this residue in 25 mils of alcohol, add 25 mils of half-normal alcoholic potassium hydroxide V.S. and heat the mixture carefully in a flask provided with a reflux condenser, during half an hour on a water bath. Then add 1 mil of phenolphthalein T.S. and titrate the excess of alkali with half-normal hydrochloric acid V.S. The amount of half-normal alcoholic potassium hydroxide V.S. consumed corresponds to a saponification value for the cinnamein of from 235 to 238 (see Part III, Test No. 10)." U.S.

"A viscid liquid, in bulk nearly black but in thin layers deep orange-brown or reddish-brown and transparent. Agreeable balsamic odor, taste acrid, leaving when swallowed a burning sensation in the throat. Insoluble in water; soluble in chloroform. 1 volume is soluble in 1 volume of alcohol (90 per cent.), but on the further addition of 2 or more volumes of the alcohol the mixture becomes turbid. Specific gravity between 1.140 and 1.158. Does not diminish in volume when shaken with an equal bulk of water (absence of ethylic alcohol). When tested by the following method it yields not less than 57 per cent. of cinnamein, the saponification value of which is not less than 235:—Dissolve 1
gramme of the Balsam in 30 millilitres of ether and shake in a separating funnel with two successive quantities of 20 and 10 millilitres of N/2 solution of sodium hydroxide. Separate the alkaline solutions, mix and shake with 10 millilitres of ether. Draw off and reject the alkaline solution. Add the second ethereal solution to that previously obtained. Wash the mixed ethereal solutions with two successive quantities of 5 millilitres of water. Transfer the ethereal solution thus washed to a tared wide-mouthed flask, evaporate at a gentle heat until the odor of ether has disappeared, add 1 millilitre of absolute alcohol, dry at 100° C. (212° F.) for half an hour, and weigh. The weight of the cinnamenein thus obtained is not less than 0.57 gramme. To this residue add 20 millilitres of N/2 alcoholic solution of potassium hydroxide and 20 millilitres of alcohol (90 per cent.). Attach a reflux condenser, boil for half an hour, and titrate back with N/2 solution of sulphuric acid, solution of phenolphthalein being used as indicator. Each gramme of the residue thus treated requires not less than 8.4 millilitres of the alkaline solution for complete saponification (corresponding to a saponification value of not less than 235)." Br.

Boiling water extracts the acid. The oily liquid which separates on agitating Peru balsam with potassium or sodium hydroxide, called Peru balsam oil by Stoize, and cinnamenein by Fremy, may be separated by fractional distillation into three portions, viz., benzyl alcohol, \( \text{C}_7\text{H}_8\text{O} \), passing over at about 200° C. (392° F.); benzyl benzoate, \( \text{C}_7\text{H}_5\text{O}_2\text{C}_7\text{H}_7 \), the principal portion boiling at 303° to 304° C. (577.5°-5790 F.); and benzyl cinnamate, \( \text{C}_9\text{H}_7\text{O}_2\text{C}_7\text{H}_7 \), passing over at about the boiling point of mercury. The crude oil likewise contains small quantities of free cinnamic and benzoic acids, resulting from the decomposition of the benzylic ether by the alkali used in separating it. According to Kraut (Ann. Ch. Ph., diii, p. 129), the benzyl cinnamate constitutes nearly 60 per cent. of the balsam; but Trog (A. Pharm., 1894, 70-98) states that it is the benzyl benzoate which makes up the bulk of the oily portion and amounts to from 63 to 64 per cent. Tschirch (loc. cit.) states that in the sample of Peru balsam investigated by him benzyl benzoate was the main constituent, but small amounts of benzyl cinnamate were also present, and he considers that the relative proportions of the two esters may vary greatly in different samples of the balsam. The odor of the balsam Tschirch considers to be due to the peruviol, \( \text{C}_{13}\text{H}_{22}\text{O} \), discovered by Thoms.
Peru balsam appears to contain only a single resin, yielding, by analysis, 66.3 to 67.25 per cent. of carbon, and 6.22 to 6.32 per cent. of hydrogen. (Kraut, loc. cit.) This resin separated from the alkaline solution of the balsam by hydrochloric acid is brown, has a faint odor of vanilla, and when fused with potash yields protocatechuic acid, together with a little benzoic acid. Tsehirch has studied this resin and finds it to be the cinnamic ester of an alcoholic body called peru-resino-tannol, with the formula $C_6H_5.CH.COOC_{18}H_{19}O_4$. The tree also exudes a gum-resin, which, according to Attfield (P. J., 1864, p. 248), contains 77.4 per cent. of a resin, and is non-aromatic, devoid of cinnamic acid, and entirely distinct from balsam of Peru. The leaves of the tree contain a fragrant oil. Like benzoin, balsam of Peru appears to be a pathological product.

The balsam is said to be adulterated in Europe (especially at Bremen) with castor oil, copaiba, Canada turpentine, etc. (P. J., xii, 549), and a factitious substance has been sold in this country for the genuine balsam, prepared by dissolving balsam of Tolu in alcohol. This may be distinguished by its taking fire readily and burning with a blue flame, but a skillfully prepared product known commercially as Perugen is furnished, of which K. Enz (1913) states that the only constants of the German Pharmacopoeia available for detection are the acid number, iodine number, isolated cinnamene nitric acid reaction, and behavior in contact with benzoin; the other pharmacopoeial constants are of no value. "Synthetic Balsam of Peru" (Ph. Ztg., No. 79, 828), is defended by Dr. F. Evers on the ground that it is equivalent to the natural balsam therapeutically and in some respects superior. Caesar and Soretz state that the characteristic odor and taste of the natural balsam are absent in the substitute.

For additional tests, see Proc. A. Ph. A., 1894, 903; also 1895, 866, and D. C., 1898, 60. A method of detecting castor oil, proposed by Wagner, is to expose a small portion of the suspected balsam to distillation until somewhat more than one-half has passed, shake the distillate with baryta water, remove by means of a pipette the layer of oil floating on the surface, and shake this with a concentrated solution of sodium bisulphite. If castor oil be present, the liquid will immediately become a crystalline mass. (A. J. P., xxx, 570.)

A color test to distinguish true Peru Balsam from the factitious variety is as follows: One drop of Peru Balsam is shaken with 5 mils of petroleum
benzin, and to 2.5 mils of this liquid 5 mils of ether is added. Sulphuric acid is then added, drop by drop, until from 10 to 15 drops have been added. Genuine Peru Balsam gives a beautiful violet to cornflower blue color in the lower layer, while the artificial products give either no color or very different shades.

Fluckiger relied upon the specific gravity, which should be between 1.140 and 1.145, and the limetest, in which 10 drops of the balsam are shaken with 6 grains (0.4 Gm.) of slaked lime, forming, if there be no adulteration, a soft mixture, which does not harden. Grote's test consists in shaking 3 drops of balsam with 2 mils of official ammonia water; if, after standing, the mixture solidifies, rosin or other adulterant is present; benzoin, storax, and certain other substances cannot be detected by this test. (A. J. P., 1881, 302, 361.)

As stated by Trog and others, the percentage of cinnamcin should approximate 60. The saponification number should be between 235 and 238.

Uses.—Balsam of Peru is useful internally as a stimulating expectorant in asthma and chronic bronchitis, especially when of tuberculous origin. Although not so agreeable as balsam of Tolu it is much more active. Externally it affords a valuable stimulating dressing in indolent ulcers and local tuberculosis of the skin, bone, larynx, etc. It has also been highly lauded by Malannik (M. M. W; 1912) as a first dressing for military wounds. He asserts that it is not only bactericidal of itself but that it stimulates the local resistance of the tissues and that it exercises a valuable protective action. Extensive erythema has followed its local application. (Hazen, J. A. M. A., 1910, liv.) Internally it is best administered suspended in water by the yolk of egg or acacia.

Dose, from five to fifteen minims (0.3-0.9 mil).

Off. Prep.—Mistura Oleo-Balsamica, N. F.

BALSAMUM TOLUTANUM. U. S., Br.

BALSAM OF TOLU Bals. Tolu. [Tolu Balsam]

"A balsam obtained from Toluifera Balsamum Linne (Fam. Leguminosae)." U. S. "Balsam of Tolu is a solid balsam obtained from
incisions made in the trunk of Myroxylon toluiferum, H. B. and K.” Br.

Balsamum Americanum; Baume de Tolu, Baume de Carthagene, Fr.; Balsamum Tolutanum, P. G.; Tolubalsam, G.; Balsamo Tolutano, Balsamo del Tolu, It.; Balsamo de Tolu, Sp.

This balsam like balsam of Peru, has been the subject of much controversy. This is not only seen in the distinct sources above given by the U. S. and British Pharmacopoeias, but is rendered more confusing by the fact that the German Pharmacopoeia prescribes "the air hardened balsam of Myroxylon balsamum (L.) Harms var. genuinum Baillon." In addition to this Tschirch regards the tree yielding balsam of Tolu like that of the tree yielding balsam of Peru, merely physiological varieties of Toluifera Balsamum L. Schaer has recently reported on Myrocarpus Balsam (Cabureiba Balsam, of Piso; Baume du Perou en coques, of Guibourt), and concludes that it has intermediate properties between balsam of Tolu and balsam of Peru. It did not contain cinnamic acid an the benzoic acid which he obtained had a melting point from 3° to 4° higher than normal benzoic acid. (Arch. d. Pharm., 1909, p. 176.)

The balsam is said to be produced normally in the tree only in young growing tissues such as the young twigs and leaves, and to be formed in the older tissues only as the result of injuries received. It is procured by making V-shaped incisions in the trunk quite through the bark. The juice is received in small calabash cups, which are inserted in slight excavations beneath the point of the two vertical incisions meeting at the lower end; and Weir has seen as many as twenty cups at a time on one tree. The collectors go from tree to tree, emptying the cups into flasks of raw-hide. In these skin vessels the juice is taken to the different ports on the river, where it is transferred to tin cans. It is brought from Carthagena in calabashes or baked earthen jars, or in tin or glass vessels.

Properties.—As first imported, balsam of Tolu has a soft tenacious consistence, which varies considerably with the temperature. By age it becomes hard and brittle like rosin. It is shining, translucent, of a reddish or yellowish-brown color, a highly fragrant odor, and a warm, somewhat sweetish and pungent, but not disagreeable taste. Exposed to heat, it melts, inflames, and diffuses an agreeable odor while burning. It is entirely soluble in volatile oils. The official description is as follows: "Balsam of Tolu is a yellowish-brown, or brown, plastic solid, becoming brittle when old, dried, or exposed to cold. It is transparent in thin
layers, has a pleasant, aromatic odor, resembling that of vanilla, and a mild aromatic taste. Balsam of Tolu is nearly insoluble in water and in petroleum benzine. It is soluble in alcohol, chloroform, and ether. It is dissolved by solutions of the fixed alkalies, usually leaving an insoluble residue. An alcoholic solution of the Balsam (1 in 20) is acid to litmus. Shake about 1 Gm. of the Balsam with 25 mils of carbon disulphide, allow it to stand for thirty minutes, filter the liquid and evaporate 15 mils of the nitrate to dryness. The residue thus obtained, when dissolved in glacial acetic acid, does not show a green color on the addition of a few drops of sulphuric acid (rosin). The remaining portion of the filtrate, when shaken with an equal volume of an aqueous solution of copper acetate (1 in 1000), does not acquire a green color (rosin or copaiba). Dissolve about 1 Gm. of the Balsam, accurately weighed, in 50 mils of alcohol, add 1 mil of phenolphthalein T.S. and titrate the solution with half-normal alcoholic potassium hydroxide V.S. The acid number thus obtained is not less than 112 nor more than 168. Now add sufficient half-normal alcoholic potassium hydroxide V.S. to the neutralized liquid to make the total amount of the volumetric alkali solution exactly 20 mils; heat the liquid on a water bath for half an hour, under a reflux condenser, and allow it to cool. Mix this liquid with 200 mils of distilled water, or more if necessary, and titrate the excess of potassium hydroxide with half-normal sulphuric acid V.S.; the total amount of half-normal potassium hydroxide V.S. consumed corresponds to a saponification value of not less than 154 nor more than 220 (see Part III, Test No. 10)." U. S.

"A soft, tenacious solid when first imported, becoming harder and finally brittle. Transparent and yellowish-brown in thin films. Pressed between pieces of glass with the aid of heat, and examined with a lens, it exhibits crystals of cinnamic acid. Odor fragrant, especially when warmed; taste aromatic and slightly acid. Soluble in alcohol (90 per cent.), the solution being acid to litmus. Acid value 107.4 to 147.2; saponification value 170 to 202. If 5 grammes are gently warmed with three successive portions of 25, 15, and 10 millilitres of carbon disulphide, the solution yields, when evaporated to dryness, a distinctly crystalline residue, which, when tested as described under ‘Styrax Praeparatus’ yields not less than 1.25 grammes of balsamic acids." Br.

The carbon disulphide test is based upon Braithwaite's researches upon spurious balsams of Tolu. (See P. J., 1895,145; also 1897, 307.)
Boiling water extracts its acid. Distilled with water it affords a small proportion of volatile oil, and, if the heat be continued, an acid matter sublimes. Hatchett states that when dissolved in the smallest quantity of solution of potassium hydroxide it loses its own characteristic odor and acquires that of the clove pink. G. L. Ulex gives as a test of the purity of the balsam, that if heated in sulphuric acid it dissolves without disengagement of sulphurous acid, and yields a cherry-red liquid. (A. Pharm. Jan., 1853.) A modification of this test is that of R. A. Cripps (P. J., xix, 1888), who states that by a comparative test of the suspected balsam with a pure specimen 1 per cent. of storax or other resinous adulterant can be detected. Thirty grammes of the sample are digested in carbon disulphide for fifteen minutes with gentle warmth, the clear liquid decanted, evaporated to dryness, and dissolved in sulphuric acid. A bright red rose color is produced, remaining rose for a length of time if the balsam be pure, rapidly becoming brown if the balsam has been adulterated. The balsam is a mixture of volatile oil, free acid, and resin. The volatile oil is obtained by distilling the balsam with water, and may amount to a little over 1 per cent. This oil is chiefly tolene, C_{10}H_{16}, boiling at 170° C. (338° F.), and rapidly hardening by absorption of oxygen from the air. The free acid, according to Deville and Scharling, consists of benzoic and cinnamic acids, which statement has been confirmed by Fluckiger. (Pharmacographia, 2d ed., 204.) Buse (Ber. d. Chem. Ges., 1876, 833) has shown that the benzylic esters of these two acids are present in the balsam, the benzyl cinnamate in larger amount.

Tschirch (Harze und Harzbehalter, 1900, p. 173) found that the ester mixture in Tolu balsam amounted to 7.5 per cent. against 62 to 64 per cent. in Peru balsam. Trommsdorff obtained 88 per cent. of resin, 12 of acid, and only 0.2 of volatile oil. According to Heaver, the balsam yields by distillation about one-eighth of its weight of pure cinnamic acid. The acid distills over in the form of a heavy oil, which condenses into a white crystalline mass. It may be freed from empyreumatic oil by pressure in bibulous paper, and subsequent solution in boiling water, which deposits it in minute colorless crystals upon cooling. (A. J. P., xv, 77.) A later investigation by Tschirch and Oberlander shows that the resinous portion of the balsam consists of tolu-resino-tannol in combination with cinnamic and benzoic acids, the latter in small proportions only. It contains, in addition, 7.5 per cent. of an aromatic, acid, oily liquid, composed mainly of benzyl benzoate, with a little benzyl cinnamate and...
a trace of vanillin. (A. Pharm., 1894, 599.) A factitious balsam described by R. V. Mattison (A. J. P., 1876, 51) contained 63 per cent. of storax.

Tolu balsam is sometimes adulterated with rosin and pine resins, both of which are readily detected, as they are soluble in carbon disulphide and benzol. The Balsam of Tolu of commerce is sometimes deficient in alcohol-soluble contents. Occasionally, the cans of shipment of tolu contain large pieces of red brick with enough melted balsam poured in to completely cover the bricks and fill the cans.

**Uses.**—Balsam of Tolu is a feeble stimulant expectorant; the syrup of Tolu is much used, on account of its agreeable flavor, as the basis of cough mixtures. Old and obstinate catarrhs are said to be sometimes greatly relieved by the inhalation of the vapor proceeding from an ethereal solution of this balsam. The best form of administration is that of emulsion, made by triturating the balsam with mucilage and loaf sugar, and afterwards with water.

Dose, ten to thirty grains (0.65-2.0 Gm.).

**Baptisia.** N. F. IV. Wild Indigo. Indigo sauvage. Fr. Baptisie, G.—"The dried roots of Baptisia tinctoria (Linne) R. Brown (Fam. Leguminosae), without the presence of more than 10 per cent. of the crown and stem or other foreign matter." N. F. This is an indigenous perennial plant, abundant throughout the Eastern United States, in woods and dry barren uplands. The roots are "fleshy, from 0.5 to 4 cm. in thickness, usually cut into elongated cylindrical pieces; the crown from 5 to 8 cm. in thickness, more or less warty and marked by stem scars; outer surface dark-brown; usually longitudinally wrinkled, transversely warty, or the thicker pieces covered with a soft and friable corky layer, bearing few branching rootlets; fracture tough, the fractured surface whitish; bark section radially striate, wood-section inconspicuously radiate, porous. Nearly odorless; the bark bitter and acrid, the wood nearly tasteless. The powdered drug is light-grayish and, when examined with the microscope, shows numerous, rounded, simple, or two-to-four-compound starch grains up to 0.016 mm. ia diameter, the larger grains sometimes with a cleft through the center; tracheae with bordered pores up to 0.085 mm. in diameter; numerous sclerenchyma cells, long, thick-walled, non-porous, more or less lignified and up to 0.024 mm. in width; fragments of medullary-ray tissue composed of cells with lignified walls and numerous simple pores; groups of parenchyma, many of the cells filled with starch; few epidermal and cork cells with brownish walls. Baptisia yields not more than 5 per cent. of ash." N. F. It contains a glucoside, baptism, an alkaloid, baptitoxine, and a coloring principle which has been used as a substitute for indigo, but which is greatly
inferior. It is not often used in medicine. For further information concerning this drug, see U. S. D., 19th ed., p. 1406 and A. Pharm., 245, 1907, No. 8, 561-572.

**Barbados Nuts.** Purging Nuts. Physic Nuts. Semen Ricini Majoris. Pignon d'Inde (des Barbados), Sentences du Médecin, Fr. Purgirnuss, SchwarseBrechnuss, G.—These are the seeds of Jatropha Curcas, L. (Fam. Euphorbiaceae), growing in Brazil, the West Indies, and cultivated extensively in all tropical countries. The fruit is a three-locular capsule, containing one seed in each locule, and is about the size of a walnut. The seeds are blackish, oval, 1.5 to 2 cm. long, flat on one side, convex on the other, and the two sides present a slight longitudinal prominence. They yield a fixed oil, an acrid resin, sugar, gum, a fatty acid, glutin, a free acid, and salts. A. Siegel (Bot. Centralb., xlvi, 120) found in the seeds a poisonous principle, curcin, which he states is analogous to ricin, and places in the class of toxalbumins. The oil, sometimes called jatropha oil, may be separated by hot expression, the yield being about 40 per cent. When fresh it is without odor or color, but becomes yellowish and slightly odorous by time. Alcohol does not readily dissolve it. It is colorless, odorless, of sp. gr. 0.91 at 19° C. (66.2° F.), solidifies to buttery consistence at -8° C. (17.6° F.). Bouis believed it to be the glyceride of a peculiar acid, isocetic acid, but it is now considered to be a mixture of palmitin and myristin. From three to five of the seeds, slightly roasted and deprived of their envelopes, operate actively as a cathartic, and not infrequently produce nausea and vomiting, with a sense of burning in the stomach. The oil purges in the dose of five to ten minims (0.3-0.6 mil), and is analogous in its action to croton oil, though less powerful. The cake left after the expression of the oil is an acrid emetocathartic, operating in the dose of a few grains. Either of these substances may produce serious consequences in overdoses. The leaves of the plants are rubefacient, and the juice is said to have been usefully employed as a local remedy in piles. (A. J. P., 1893, 335.) The seeds of Curcas multifidus (L.) Encl. (Jatropha multifida Linn.) have similar properties, and yield a similar oil. This species also grows in Brazil and the West Indies. (See Peckoldt, A. Pharm., 1887, 415.)

Jatropha gossypifolia Linn., of South America, is used as a local application in leprosy and to indolent ulcers, and probably has similar physiological influence to curcas. Jatrophaurens, L., must be excessively poisonous, as accidental contact of the wrist of a gardener in Kew with a young plant produced such symptoms that for five minutes the man was thought to be dead. (P. J., April, 1872, 863.)

The roots of the Jatropha cardiophylla Muell. Arg. are largely employed in Southern Arizona and Mexico for tanning purposes. According to the analysis of Josiah C. Peacock, they contain, when thoroughly dried, over 5 per cent. of tannic acid. (A. J. P., 1900, 432.)

**Barringtonia.** Barringtonia speciosa.—The large Indo-Malayan tree, Barringtonia speciosa Forst. (Fam. Myrtaceae) contains, according to Maresuw, 3.3 per cent. of barringtonin, a colorless, amorphous glucoside, having the formula C_{18}H_{28}O_{10}, and belonging to the saponin group. It is said to be an active cardiac poison. (S. W. P., xli, 1903, pp. 423, 435.)
**Bassialongfolia** L. (Fam. Sapotaceae.)—In this Indian plant, known as mowrah by the natives, there has been found a glucoside which was named mowrin by its discoverers, Moore, Baker, Young and Sawton. According to these investigators, mowrin has a digitalis-like action upon the heart and a saponin-like effect of destroying red blood cells.

**Bassora Galls** are cultivated in Persia and Asia Minor, and are exported by way of Smyrna for tanning purposes. They come into commerce ground and pressed into the form of bricks. They contain, on an average, 27 per cent. of tannin.

**Bassora Gum.** Caramania Gum. Hog Gum. India Gum. False Tragacanth. Kutera Gum.—This substance came into commerce originally from the neighborhood of Bassora, on the Gulf of Persia; but is often found mixed with gum brought from other countries, and is said to be the product of the almond and plum trees. It is in irregular pieces, about the same size as tragacanth, brown or yellow, intermediate in the degree of its transparency between gum arabic and tragacanth, inodorous, tasteless, and possessed of the property of yielding a slight sound when broken under the teeth. Only a small portion of it is soluble in water, whether hot or cold. The remainder swells up considerably, though less than tragacanth, and does not, like that substance, form a gelatinous mass, as it consists of independent granules which have little cohesion. The soluble portion is pure gum or arabin, and, according to Guerin, constitutes 11.2 per cent. The insoluble portion consists of bassorin, associated with a small proportion of saline substances, which yield, when the gum is burnt, 5.6 per cent. of ash. The gum is employed to adulterate tragacanth, and for this purpose is sometimes whitened by means of white lead, which can readily be detected, however. It is frequently used as a filler and thickener in the manufacture of certain food products, as cheap ice creams.

**Batiator Root.**—The root of the Vernonia nigritiana Oliver and Hiern. (Fam. Compositae), a widely distributed plant of West Africa, is said to be largely used in Senegal as a febrifuge, emetic, and anti-dysenteric, resembling ipecac somewhat in its therapeutic application. The plant is a composite which climbs to the height of a foot and a half, and yields a root composed of numerous fibers from twenty to thirty centimeters long, slender and grayish-yellow externally, a number of which are united to form an irregular knotty rhizome, unequally spherical at the neck or crown, and covered at this point with silky hairs. The active constituent is a glucoside, vernonin, C_{10}H_{24}O_{7}. (Heckel and Schlagden-hauffen, A. de P., Aug., 1888; see also Zét. An. Chem., 1893, p. 364.) This is a hygroscopic whitish powder, forming a pale yellow solution with water, and only slightly soluble in ether and in chloroform. By the absorption of 2 molecules of water it is split into a resinous body and glucose. Physiological experiments made upon frogs show vernonin to be a cardiac poison of the digitalis group; it is also said to act as a paralyzant to the motor nerve trunks. (P. J., June 30, 1888.)

**Baycuru Root.**—This is the root of a Brazilian plant, probably the Statice brasiliensis Boiss. (Fam. Plumbaginaceae), which is used by the natives as a discutient in glandular swellings and as an astringent gargle. F. A. Daipe (A. J. P., xiv,
believed that he has found in it an alkaloid, baycurine, besides volatile oil, gum glucose, etc. 0. Symes found in it 12.5 per cent. of tannic acid. (Newer Mat. Med., 51.)

**Bdellium.**—Under this name have been included various gum resins having little or nothing in common. The commercial Bdelliums are naturally divided into the Indian and the African, but E. M. Holmes, in an elaborate study (P. J., lxi), recognizes five commercial varieties of African Bdellium—namely, 1. Perfumed Bdellium, which is believed to be collected in Northeastern Africa; 2. African Bdellium; 3. Opaque Bdellium; 4. Hotai Bdellium from the Somaliland, and 5. A non-aromatic acrid gum resin. Perfumed Bdellium, or Babaghadi, closely resembles in appearance Somali myrrh, but has a less bitter, more acrid and peculiar taste which distinguishes it at once from myrrh. African Bdellium, proper, occurs in hard, roundish pieces, of a pale to dark grayish-brown color with a resinous unstreaked fracture, dotted with glistening points. The odor is said to recall that of cedar wood; the taste is slightly acrid but not bitter. Opaque Bdellium is of a pale brown color and has a bitter, slightly acrid taste and cedar-like odor; it occurs in tough, roundish pieces about an inch to an inch and a half in diameter. Hotai Resin resembles opaque bdellium, but is distinguished by its lack of odor, its slightly soapy taste, and its brittleness. These four bdelliums of Holmes are for the most part collected in Somaliland. They are the product of different species of Commiphora, small trees or large shrubs which suggest in appearance the English hawthorn. The species are by Holmes divided into four groups. (See P. J., lxxii.) According to A. Engler, the resin of Commiphora roxburghiana (Stocks) Engl. is the commercial Gugul, or India Bdellium, which is employed in the East Indies as a remedy for leprosy, rheumatism, and syphilis. Bdellium sometimes cornea mixed with gum arabic and gum Senegal. It is either in small roundish pieces, of a reddish color, semi-transparent, and brittle, with a wax-like fracture, or in large irregular lumps, of a dark brownish-red color, less transparent, somewhat tenacious, and adhering to the teeth when chewed. It has an odor and taste like that of myrrh, but weaker. It is infusible and inflammable, diffusing while it burns a balsamic odor. According to Pelletier, it consists of 59 per cent. of resin, 9.2 of gum, 30.6 of bassorin, and 1.2 of volatile oil, including loss. In medicinal properties it is analogous to myrrh, and was formerly used for the same purposes. In Europe it is still occasionally employed in plasters. The dose is from ten to forty grains (0.65-2.6 Gm.).

**Bebeeru Bark.**—Nectandrae Cortex, Br. 1885, is the dried bark of Nectandra Rodiaei Hook. (Fam. Lauraceae). The beteëru, bibiru or sipiri, as it has been variously named, is a tree sixty feet or more in height, growing in British Guiana and the neighboring regions of South America, and yielding the wood known as greenheart.

The bark occurs in large, flat, heavy pieces, from 30 to 60 cm. long, from 10 to 15 cm. broad, and about 6 mm. thick, with a short, granular fracture, of a grayish-brown color on its outer surface and a dark cinnamon color on the inner. It has an intensely bitter, somewhat astringent taste. On microscopical examination it is seen to be composed chiefly of very thick-walled parenchymatous cells. The inner bark contains peculiar short, sharp-pointed, undulate bast fibers. Within the cells dark brown masses (colored greenish-black by ferrous sulphate) may be seen. Analyzed by Maclagan, of Edinburgh, it was found to contain tannic acid of the kind that
precipitates the salts of iron green, resin, gum, sugar, albumen, fibrin, various salts, and two peculiar alkaloids, named respectively bebeerine, \( \text{C}_{19}\text{H}_{21}\text{O}_{3}\text{N} \), and sipirine, the former soluble and the latter insoluble in ether. In the seeds, besides the foregoing principles, Madagan found 63 per cent. of starch, and a peculiar white, crystalline, volatile acid, which he named bebeeric acid. The alkaloids are extracted together from the bark, in the form of impure sulphate, by a process similar to that for preparing quinine sulphate. This preparation was formerly known as the commercial bebeerine sulphate. The sulphate, hydrochloride and alkaloid are all used in medicine, the dose of either being from one to two grains (0.065-0.13 Gm.). According to Fluckiger (P. J.; xi, 193, 1869), pure bebeerine is a white, amorphous powder, whose concentrated aqueous solution is not precipitated by tartar emetic, but affords abundant white precipitates with sodium phosphate, potassium nitrate, iodide, or iodohydrargyrate, mercuric chloride, potassium platino-cyanide, and nitric or iodic acid. Its acetate yields yellow amorphous precipitates with potassium ferrocyanide, potassium ferricyanide, potassium chromate, potassium dichromate, or platinum dichloride. D. B. Dott has confirmed the results of Fluckiger’s examination, although he found a larger percentage of alkaloids than the latter did. Owing to the difficulty of obtaining the alkaloids in crystals, it was almost impossible to ascertain the quantity present. (Y. B. P., 1881, 442; 1885, 420.) Bebeerine was asserted by Walz, in 1860, to be identical with buxine, obtained from Buxus sempervirens. This statement was confirmed by Flickiger, who proved that pelosine was identical with both of the above principles. (P. J., xi, 1870, 192.) (Palen gives \( \text{C}_{19}\text{H}_{21}\text{NO}_{3} \) as the formula.)

By treating the mixed alkaloids obtained from the wood with chloroform, Douglas Madagan and Arthur Gamgee have separated an alkaloid, nectandrine. It is a white powder, amorphous, and intensely bitter. It differs from bebeerine in being much less soluble in ether, and, when treated with strong sulphuric acid and manganese dioxide, in giving rise to a magnificent green, slowly passing into a beautiful violet, and, lastly, in having a higher molecular weight, its formula being \( \text{C}_{20}\text{H}_{23}\text{N}_{4} \). After separating nectandrine from the mixed bases, the authors succeeded in extracting another alkaloid, different from bebeerine, much more soluble in water than nectandrine, but insoluble in chloroform. (A. J. P., 1869, 453.)

Nectandra is reputed to resemble cinchona in its virtues, although much inferior. It has generally been employed in the form of the impure bebeerine sulphate. In some cases of intermittent and remittent fevers it has apparently exercised a curative effect but it often fails, and cannot be relied on as a substitute for quinine. Bebeerine sulphate has been given in dysmenorrhea, menorrhagia, and leucorrhæa. The dose is from two to five grains (0.13-0.32 Gm.). In malaria from ten to thirty grains (0.66-0.9 Gm.) may be given, in divided doses, between the paroxysms.

**Bedeguar.** Fungus Rosarum.—An excrescence upon the sweetbrier or eglantine, Rosa rubiginosa, and other species of Rosa, produced by the puncture of insects, especially by one or more species of Cynips. It is of irregular shape, usually roundish, about an inch in diameter, with numerous cells containing larvae. It is nearly odorless, of slightly astringent taste, and was formerly considered a diuretic and anthelmintic. Dose from ten to forty grains (0.65-2.6 Gm.).
BELAE FRUCTUS. Br.

BAEL FRUIT

"Bael Fruit is the fresh half-ripe fruit of Aegle Marmelos, Correa.," Br.

Fructus Bael, Bela; Bael fruit, Indian Bael, Bengal Quince; Marmelos de Benguala, Cirifole, Beli; Indische Quitten, Marmelosbeeren, Marmelösfruchte, G.

The so-called Bengal quince is a rather large tree (fam. Rutaceææ extensively cultivated in India, with an erect stem, few and irregular branches, an ash-colored bark, strong, very sharp, axillary thorns, single or in pairs, leaves and large white flowers, temate. The fruit is a berry of delicious flavor, of about the size of a large orange, with a hard smooth shell, and from ten to fifteen loculi containing besides the compressed, woolly seeds a large quantity of exceedingly tenacious mucilage, which when dried is hard and transparent. I' Fruit about 7 or 8 cm. in diameter, globular, ovoid or pyriform, greyish or yellowish-brown. Outer surface hard, nearly smooth. Eind about three millimetres in diameter, and adherent to a pale-reddish juicy pulp in which are ten to fifteen cells, each containing several woolly seeds. Faint aromatic odor; taste mucilaginous, acidulous, and slightly astringent. Br. The mucilage about the seeds is applied to various purposes in the arts, on account of its viscid properties. The rind is used in dyeing. The flowers are deemed refrigerant by the native physicians. The fresh leaves yield by expression a bitterish and somewhat pungent juice, which, diluted with water, is occasionally used in the early stage of catarrhal and other fevers. The bark of the stem and root is thought to possess febrifuge properties.

The fruit yields its virtues to water by maceration or decoction. Pollock found in it traces of tannic acid, an essential oil, and a vegetable acid. (M. T. G., Feb., 1864.) It also contains mucilage, pectin, sugar and a bitter principle. (Badakow, Apoth. Zeit., 1894, p. 773.)

The difficulty of obtaining bael in England is said to have led to the substitution for it of mangosteen, the fruit of Garcinia Mangostana L. This is in irregular fragments of the rind, without adhering pulp. The pieces are convex, three or four lines or more in thickness, externally covered with a smooth, deep reddish-brown, easily separable coating,
and internally pale reddish-brown or reddish-yellow, smooth, with projecting vertical lines. (P. J., May, 1867.)

**Uses.**—Bael fruit has been used in India in the treatment of diarrhoea and dysentery for many years. It is also asserted to have laxative properties. Whether it has any real therapeutic activity is, at present, very doubtful. The decoction, two ounces of dried fruit in a pint of water boiled down to four fluidounces, is used in doses of one to two fluidounces (30-60 mils) every two to six hours; or the Liquid Extract of Bael, Br., may be given in doses of 1 to 2 fluidrachms (3.75-7.5 mils).

**Off. Prep.**—Extractum Belae Liquidum, Br.

**BENZOINUM. U. S., Br.**

**BENZOIN Benzoin. [Gum Benjamin]**

"A balsamic resin obtained from Styrax Benzoin Dryander and some other species of Styrax (Fam. Styracaceae) growing in the East Indies and known in commerce as Sumatra Benzoin and Siam Benzoin."

"Benzoin is a resinous solidified balsam obtained from the incised stem of Styrax Benzoin, Dryand. Known in commerce as Sumatra benzoin."

Br.

Resina Benzoe, Asa Dulcis; Gum Benjamin; Benjoin, Fr.; Benzoc, P. G.; Benzoeharz, G.; Benzoino, It.; Benjui, Sp.

It is generally believed that Siam Benzoin is obtained from Styrax Benzoin Dryander. It appears to closely resemble the tree growing in Sumatra, which yields a balsamic resin bearing this name. Tschirch considers that the trees yielding Siam and Sumatra Benzoin are physiological varieties of the same species. (Tschirch, "Harze," II. Aufl., p. 195.) Strueff presents a careful morphological paper on the trees of Styrax Benzoin, growing in Siam, Sumatra and Java, in Arch. d. Pharm., 1911, p. 10.

Styrax Benzoin, or Benjamin Tree, is a tall tree of quick growth, sending off many strong round branches, covered with a whitish downy bark. Its leaves are alternate, entire, oblong, pointed, smooth above and downy beneath. The flowers are in compound, axillary clusters, nearly as long as the leaves, and usually hang, all on the same side, upon short
slender pedicels. The tree is a native of Sumatra, Java, Borneo, and other islands in the vicinity. By wounding the bark near the origin of the lower branches, a juice exudes, which hardens upon exposure and forms the Sumatra benzoin of commerce. According to the researches of A. Tschirch (Journ. Roy. Microscop. Soc., 1890), the exudation is purely the result of pathological processes, the plant containing no resin receptacles. The trees, which are either wild or cultivated, are deemed of a proper age to be wounded at six years, when the trunks are usually about seven or eight inches in diameter. The operation is performed annually, and the product on each occasion from one tree never exceeds three pounds. The juice which first flows is the purest, and affords the whitest and most fragrant benzoin.

The tree which yields the Siam benzoin is stated to grow in an extremely circumscribed locality, on the bank of the river Mekong, occurring on high ground in clusters of from fifty to sixty trees. According to E. M. Holmes, its leaves are thinner and less distinctly venated than are those of the true Styrax Benzoin. In July and August the Siam trees are notched, and from these notches three months later the hardened benzoin is picked out. According to later studies (Kew Bulletin, 1912, p. 391) the Siam benzoin is derived from a new species, Styrax benzoides Craib. This view is also held by Hartwich. The benzoin of farther India is probably derived from Styrax tonkimensis.

Siam benzoin is usually imported in cubical blocks, which take their form from the wooden boxes in which the soft resin has been packed. It is brittle, with a peculiar, vanilla-like fragrance, but bitter taste. It may be a compact mass, containing more or less numerous opaque white tears embedded in a rich amber-colored translucent resin, mixed to a greater or less extent with bits of bark, wood, etc. In some specimens these tears are exceedingly small, in others almost wanting. The finest variety is composed almost entirely of these tears, loosely agglutinated together. Sumatra benzoin is sent into commerce chiefly from Acheen in Sumatra. It differs from the Siam varieties in having a much grayer color; the resin is grayish-brown, the tears are usually fewer than in the finer variety, and the bits of wood, etc., more abundant. The odor differs from, and is less agreeable than, that of Siam benzoin. Palembang benzoin resembles Sumatra benzoin, but is somewhat more transparent, and is stated to yield a larger percentage of benzoic acid. It is also asserted that it can be distinguished by its tincture, when dropped into water, not producing milkiness, but a flocculent deposit.
benzoin also resembles Sumatra benzoin, but has an odor which is more like that of storax, and it is probably yielded by the Styrax Benzoin; possibly it is the product of one of the Sumatran species, S. subdenticulata Mig. For an account of the cultivation and collection of benzoin in Sumatra, by L. M. Vonck, see C. D., 1891, 486-488; also D. C., 1891, 258. Ludy made an investigation of the bark and wood of a benzoin tree which was brought from Java by Tschirch. He reached the conclusion that benzoin balsam was produced from the tannin of the bark. (A. Pharm., 1893, 43, 95.) A variety of benzoin known as Estoraque or Benjui, is produced in Bolivia from the Styrax Pearcei Perk. var. bolivianus. This has been shown by Wichmann (S. W. P., 1912, p. 237) to be of similar composition to the Asiatic resin. According to this author resins are also collected from a number of other species of styrax in South America.

**Properties.**—Benzoin has a fragrant odor, with very little taste, but when chewed for some time leaves a sense of irritation in the mouth and fauces. It breaks with a resinous fracture, and presents a mottled surface of white and brown or reddish-brown; the white spots being smooth and shining, while the remainder, though sometimes shining and even translucent, is usually more or less rough and porous, and often exhibits impurities. In the inferior kinds the white spots are very few, or entirely wanting. Benzoin is easily pulverized, and, in the process of being powdered, is apt to excite sneezing. Its sp. gr. is from 1.063 to 1.092. The U. S. Pharmacopoeia recognizes both Sumatra and Siam benzoins. The official descriptions of these follow:

"**Sumatra Benzoin.**—In blocks or lumps of varying size, made up of tears, compacted together with a reddish-brown, reddish-gray, or grayish-brown resinous mass; tears externally yellowish or rusty-brown, milky-white on fresh fracture; hard and brittle at ordinary temperatures, but softened by heat and becoming gritty on chewing; odor aromatic and upon digesting with boiling water suggesting the odor of cinnamic acid or storax; taste aromatic and slightly acrid. Heat a few fragments of Sumatra Benzoin in a test tube; a sublimate is formed consisting of plates and small, rod-like crystals that strongly polarize light. Add carefully an ethereal solution of Sumatra Benzoin to a small Quantity of sulphuric acid contained in a porcelain dish; the solution is colored a brownish-red. Not less than 75 per cent. of Sumatra Benzoin dissolves in alcohol; the alcoholic solution, upon the addition of water, becomes milky and is acid to litmus. Sumatra Benzoin does not yield
more than 2.5 per cent. of ash.

"Siam Benzoin."—In pebble-like tears of variable size, compressed, yellowish-brown to rusty-brown externally, milky-white on fracture, separate or very slightly agglutinated; hard and brittle at ordinary
temperatures, but softened by heat and becoming plastic on chewing;
odor agreeable, balsamic, vanilla-like; taste slightly acrid. Heat a few
fragments of Siam Benzoin in a test tube; a sublimate is formed directly
above the melted mass consisting of numerous long, rod-shaped crystals,
which do not strongly polarize light. Add carefully an ethereal solution
of Siam Benzoin to a small quantity of sulphuric acid contained in a
porcelain dish; the solution is colored purplish-red. Not less than 90 per
cent. of Siam Benzoin dissolves in alcohol; the alcoholic solution upon
the addition of water becomes milky and is acid to litmus. Siam Benzoin
does not yield more than 2 per cent. of ash. The tests which follow apply
to Sumatra and Siam Benzoin: Heat gently 1 to 2 Gm. of Benzoin with
15 mls of purified petroleum benzin, and, after cooling, transfer the
supernatant liquid to a separatory funnel, wash once with 10 mls of
saturated sodium bicarbonate solution and then with water until free
from bicarbonate; on the addition of 20 mls of a copper acetate solution
(1 in 200) and vigorously shaking the mixture, no green color is
noticeable in the petroleum benzin layer (rosin and foreign resins).
Treat about 1 Gm. of powdered Benzoin with 15 mls of warm carbon
disulphide, filter the solution, wash the filter with an additional 5 mls
of carbon disulphide and allow the mixed liquids to evaporate
spontaneously; not less than 12.5 per cent. of residue remains, which
corresponds to the tests for identity under Acidum Benzoicum." U. S.

"Hard brittle masses consisting of numerous whitish tears embedded in
a greyish-brown trans-Yncen'L -matrix. O^or agreeable, similar to that
of storax; taste slightly acrid. When cautiously heated in a dry test-tube
it melts and evolves whitish fumes with an irritating odor. When 0.5
gramme is slowly heated to about 40° C. (104° F.) with 10 millilitres of
solution of potassium permanganate an odor of benzaldehyde is evolved
(distinction from Siam benzoin). Not more than 15 per cent. insoluble in
alcohol (90 per cent.). Ash not more than 5 per cent.

When heated it melts, and emits thick, white, pungent fumes, which
excite coughing when inhaled, and consist chiefly of benzoic acid. It is
wholly soluble, with the exception of impurities, in alcohol, and is
precipitated by water from the solution, rendering the liquid milky. It
yields to boiling water a notable proportion of benzole acid. Lime water and the alkaline solutions partially dissolve it, forming benzoates, from which the acid may be precipitated by the addition of other acids. Its chief constituents are resin and benzoic acid, and it therefore belongs to the balsams. The white tears and the brownish connecting medium are said by Stoize to contain nearly the same proportion of acid, which, according to Bucholz, is 12.5 per cent., to Stoize, 19.8 per cent. In a more recent examination by Kopp, the white tears were found to contain from 8 to 10 per cent. of acid, and the brown 15 per cent. (J. P. C., 3e ser., iv, 46.) The resin is of three kinds, one extracted with the benzoic acid by a boiling solution of potassium carbonate in excess, another dissolved by ether from the residue, and the third affected by neither of these solvents. Besides benzoic acid and resin, the balsam contains a little extractive and traces of volatile oil. Benzoin retards the oxidation of fatty matters, and thus tends to prevent rancidity.

The percentage of soluble matter required to be present by the U. S. Pharm. in benzoin is very high, and if rigidly enforced by the customs would exclude Sumatra benzoin in all but its very finest varieties. Robt. C. Pursel and Willard Graham obtained from five commercial varieties of Sumatra benzoin, in the American market, an average of 86 per cent. of soluble matter. (Proc. Pennsylvania Pharm. Assoc., 1902.) John Barclay, in England, found the average of ten samples to be 69.9 per cent. (P. J., Jan., 1903.)

It appears from various researches that benzoin, besides its own characteristic acid, often contains also cinnamic acid, which is found more especially in the white tears. Indeed, Hermann Aschoff obtained from some benzoin of Sumatra a pure cinnamic acid, without any benzoic; and Kolbe and Lautermann, upon examining a specimen of the tears, discovered what they at first supposed to be a peculiar acid, but which on further investigation proved to be a mixture of cinnamic and benzole acids. H. Beckurts and W. Brueche confirm the statement that Siam benzoin contains no cinnamic acid, which is usually present in Sumatra benzoin. They found the specific gravity from 1.120 to 1.171; ash from 0.05 to 2.38 per cent.; portion insoluble in alcohol from 2.1 to 9 per cent. On the other hand, Tschirch and Ludy (A. Pharm., 1893, 500) extracted benzoic acid from Siam benzoin by the wet process. They found Sumatra benzoin to contain esters which yielded by saponification 32.9 per cent. of cinnamic acid, the proportion of esters being benzoësinol cinnamate, 7.4 per cent., and resinotannol...
cinnamate, 92.6 per cent., at least 75 per cent. of Sumatra benzoin consisting of cinnamates yielding from 20 to 24 per cent. of cinnamic acid. (See also A. Pharm., 1893, 461; A. J. P., 1893, 223; and J. P. C., 1894, 172.) In a later research they found that Siam benzoin did not contain cinnamic acid, either free or in combination as ester. Besides some free benzoic acid and vanillin it contains only esters of benzoic acid. These, on saponification, yielded 38.2 per cent. of benzoic acid, 56.7 per cent. of isoresinotannol, and 5.1 per cent. of benzoresinol. (Tschirch, Harze und Harsbehalter, 1900, p. 155.) Benzoin may be rapidly tested for cinnamic acid by heating a small quantity with a little soda and water and warming the filtrate with potassium permanganate, when the odor of bitter almond will be developed. (A. Pharm., 1892,ccxxx.)

Aschoff recommends the following method of detecting cinnamic acid. Boil the benzoin with milk of lime, filter, decompose with hydrochloric acid, and add either potassium dichromate with sulphuric acid, or potassium permanganate, when, if cinnamic acid be present, the odor of oil of bitter almond will be perceived.

According to T. T. Cocking and J. D. Kettle (Tr. Br. Ph. Conf., 1914, 357), the important analytical data to be considered in valuing benzoin are (1) the percentage soluble in 90 per cent. alcohol, and (2) the quantity of aromatic acids present, both free and combined. Methods of obtaining these factors are given in detail and also tables giving the results of such examinations of a number of commercial samples. Reinitzer (A. Pharm., cdl) has made an exhaustive study of Siam benzoin, in which he contradicts some of the previously published statements of Tschireh and Ludy. He claims that the resinotannol of these authors does not exist in the drug, but is an oxidation product created during the analysis.

Rump (1878) treated Siam benzoin with caustic lime, precipitated the benzoic acid with hydrochloric acid, and agitated the liquid with ether. The latter on evaporating afforded a mixture of benzoic acid and vanillin, C₈H₈O₃. Subjected to dry distillation, benzoin affords as the chief product benzoic acid, together with empyreumatic products, among which Berthelot has proved the presence (in Siam benzoin) of styrol, C₈H₈. The latter was also obtained in 1874 by Theegarten from Sumatra benzoin by distilling it with water. (Ber. d. Chem. Ges., 1874, p. 727.)
Sumatra benzoin is sometimes heavily adulterated with stony debris, sand and bark. Schneider reports finding as much as 75 per cent. of bark in a commercial article.

**Uses.**—Benzoin is stimulant and expectorant, and was formerly employed in pectoral affections, but, except as an ingredient of the compound tincture of benzoin, it has fallen into disuse. Trousseau and Pidoux recommend strongly its inhalation in chronic laryngitis. Either the air of the chamber may be impregnated with its vapor by placing a small portion upon some live coals, or the patient may inhale the vapor of boiling water to which the balsam has been added. It is occasionally employed in pharmacy for the preparation of benzoic acid; the milky liquor resulting from the addition of water to its alcoholic solution is sometimes used as a cosmetic, under the impression that it renders the skin soft. A tincture has been strongly recommended in anal fissure. In the East Indies, the balsam is burnt by the Hindus as a perfume in their temples of worship.

Dose, fifteen to thirty grains (1-2 G-m.).

**BERBERIS. Br.**

**BERBERIS**

"Berberis is the dried stem of Berberis aris-tata, DC." Br. "The rhizome and roots or species of the section Odostemon Rafinesque of the genus Berberis Linne (Fam. Berberidaceae), without the presence of more than 5 per cent. of the overground parts of the plant or other foreign matter. Berberis without the bark should be rejected." N. F.

Oregon grape root; Nepaul Barberry, Barberry; Epine-vinette, Vinettier, Ecorce de Racine de Berberides, Fr.; Fauerach, Gemeiner Sauerdorn, Berberitze, Berberitzen-(Saurach-) Wurzelrinde, G.; Berbero, It., Sp.

The genus Berberis (Fam. Berberidaceae) is a large one, comprising shrubs or trees which are widely distributed throughout temperate regions and in the mountains of the tropics. There are three well-defined medicinal groups:
(1) The Rocky Mountain group, including Berberis Aquifolium, which yields the Oregon Grape Root.

(2) The Asiatic group, which includes B. aristata DC., a shrub indigenous to India and Ceylon, and is recognized by the British Pharmacopoeia.

(3) The European group, which includes the common Barberry (B. vulgaris L.), which is naturalized in New England. According to Dragendorff (Die Heilpflanzen), about forty different species of berberis have been used in medicine.

Berberis aristata, which furnishes the Berberis of the British Pharmacopoeia, is a shrub indigenous to the temperate Himalayas, extending from Bhutan to Kanawar, the Nilgiri Hills, Ceylon. It is erect and branching, the leaves being evergreen, obovate or oblong entire, sometimes possessing spinose teeth. The flowers are yellow and occur in compound, often corymbose racemes. The stigmas are distinguished by being small and subglobose. The berries are few-seeded and taper into a short style. Several varieties of this species are recognized, viz., floribunda and micrantha. The type B. aristata closely resembles B. asiatica Roxb., B. Lycium Royle and B. vulgaris L., and consequently are mistaken throughout India. The same vernacular names are frequently applied to each of these plants and the same medicinal properties attributed to all.

The berberis of the British Pharmacopoeia occurs "in undulating pieces from two and a half to five centimetres in diameter. Cork orange-brown, removed in places showing the subjacent darker brown cortex; marked with slightly wavy longitudinal striae and occasional shallow transverse depressions. Transverse section shows a narrow brown cork; a broad, dark brown bast traversed by conspicuous yellow medullary rays; a bright yellow wood composed of numerous narrow vascular rays, containing many vessels, separated by narrow paler medullary rays. Slight odor; taste bitter." Br.

For a description of the bark of B. aristata DC., by Hartwick, see Ph. Rev., 1896, 232.

"Cylindrical, more or less knotty, strongly branched, usually cut into
pieces of varying length and up to 45 mm. in diameter; externally light yellowish-brown, longitudinally wrinkled and short scaly; fracture hard and tough; bark 1 mm. in thickness, easily separable into layers; wood yellow, the color more pronounced upon wetting, distinctly radiate, and showing rings of growth; pith of rhizome small, sometimes ex-central. Slightly odorous; taste distinctive, very bitter; on chewing it tingles the saliva yellow. The powder is yellowish-brown; composed chiefly of fragments of wood fibers associated with a few tracheae and medullary rays; wood fibers yellowish, scarcely giving any reaction with phloroglucinol T.S. and hydrochloric acid, and with large, simple, transverse pores; trachea chiefly with bordered pores, occasionally reticulate; medullary rays one to twelve cells wide, and in very long rows; starch grains simple or two- to three-compound, the individual grains being irregularly spherical, from 0.003 to 0.01 mm. in diameter, and occasionally larger. Berberis yields not more than 5 per cent. of ash.

The N. F. IV recognizes, under the title Berberis, "the rhizome and roots of species of the section Odostemon Rafinesque, of the genus Berberis." This section corresponds to the genus Mahonia of Nuttall, and includes B. Aquifolium and B. Nervosa.

The Oregon grape is a tall shrub, about six to seven feet high, with evergreen, coriaceous, bright and shining leaves, and having numerous small, yellowish-green flowers in the early Spring, and later clusters of purple berries containing an acid pulp. It is a native in woods from Colorado to the Pacific Ocean, especially abundant in Oregon and Northern California. The root, which was formerly official, occurs in pieces about a foot long, one-fourth of an inch thick, of a brownish exterior, but yellowish within, yielding a bright lemon-colored bitter powder. The rhizome was officially described as in mere or less knotty irregular pieces of varying length and from 3 to 20 Mm. in diameter; bark from ½ to 2 Mm. thick; wood yellowish, distinctly radiate with narrow medullary rays, hard and tough; rhizome with a small pith; odor distinct; taste strongly bitter. Pieces without the bark should be rejected." U. S. VIII.
Rusby believes that a large part of the ber-beris collected in Oregon is obtained from B. Nervosa. (Ph. Era, 1909, p. 633.)

Nepaul Barberry—Berberis vulgaris L. (Barberry). B. vulgaris is a native of Europe, but grows wild in waste ground in the eastern parts of New England, and is sometimes cultivated in gardens on account of its berries. It is a spreading shrub, from four to six feet or more in height, with thorny branches, a light gray bark and a fine yellow wood.

The berries of B. vulgaris, which grow in loose bunches, are oblong and of a red color, have a grateful, sour, astringent taste, and contain malic and citric acids. They are refrigerant, astringent, and antiscorbutic, and are used in Europe, in the form of drink, in febrile diseases and diarrheas. An agreeable syrup is prepared from the juice, and the berries are sometimes preserved for the table.

The bark of the root of B. vulgaris L. was formerly included in the secondary list of the U. S. Pharmacopoeia, under the name of Berberis. The root and inner bark have been used for dyeing yellow. The bark of the root is grayish on the outside, yellow within, very bitter, and stains the saliva when chewed. Brandes found in 100 parts of the root 6.63 of bitter, yellow extractive (impure berberine), 1.55 of brown coloring matter, 0.35 of gum, 0.20 of starch, 0.10 of cerin, 0.07 of stearin, 0.03 of chlorophyll, 0.55 of a sub-resin, 55.40 of lignin, and 35.00 of water.

Lycium of the ancients, highly valued as a local application in affections of the eye and eyelids, and used for various other purposes, is supposed to be the medicine still used in India for the same affections, under the name of rusot or ruswut. According to Royle, extracts from various species of berberis enter into this substance, which, combined with opium and alum, was much used in ophthalmia. (P. J. , Dec., 1865.)

Algerita Root, which has been used by Mexicans and old settlers in Western Texas, is derived from Berberis trifoliatus Moricand [Odostemon trifoliatus (Moric.) Heller]. The shrub grows in Western Texas and New Mexico and extends into Mexico. The root contains, according to Hart (A. J. P., 1916, p. 301) 1.3 per cent. of berberine and 0.1 per cent. of associated alkaloids. Hydrastine is absent. Infusions of algerita root are used for eye sores, while chewing the roots is considered reliable as a corrective for sore mouths. Injections of an infusion have been used for gonorrhea.
Hesse found in berberis root four alkaloids besides berberine (see Hydrastis), the mother liquor from berberine hydrochloride when precipitated with sodium hydroxide yielded to ether three alkaloids, a fourth, which is amorphous, remaining undissolved. One of the alkaloids in the ethereal solution crystallized from alcohol in small tabular crystals, and is named by the author berbamine. It has the composition C₁₈H₁₉NO₃+2H₂O. (Ber. d. Chem. Ges., 19, 3190.) To a second alkaloid the name of oxyacanthine has been applied.

For additional information concerning the constituents of berberis berries and root, see U. S. D., 19th ed., p. 1412.

B. aquifolium contains the alkaloids berberine, C₂₀H₁₇NO₄; oxyacanthine, C₁₈H₁₉NO₃; and berbamine, C₁₈H₁₉NO₃, together with phytosterin, gum, fat, resin and wax. Berberine and oxyacanthine were isolated by H. B. Parsons (N. R., 1882, 83), the percentage of the former is said to be 2.35 and of the latter 2.82. Jungk and Stubbe investigated the alkaloids from berberis, and found that the three alkaloids in B. aquifolium are identical with those found in B. vulgaris. Rudel examined and described these alkaloids. (J. C. S., 1892, 641.) Gordin and Merrell (Proc. A. Ph. A., 1901, 228) objected to the method of Gaze (Chem. Ch., 1890, 590) for making berberine from acetone-berberine.

**Uses.**—The various species of Berberis appear to have similar medical properties. The alkaloid berberine is physiologically very feeble. (See Hydrastis.) Antiperiodic properties have been attributed to it, and T. Lascarato (La Grece medicate, 1899, No. 2) affirms that it has a specific action upon the spleen which renders it very valuable in the treatment of malarial splenic enlargement, and that it is so powerful in producing contraction that when the spleen is softened large doses may produce splenic rupture, with fatal hemorrhage. The crude drug probably has no real medicinal effect, except that of a bitter tonic and mild laxative. It is by some believed to have an especial tendency towards the liver and hence is used in jaundice and chronic hepatitis. It is also stated to have alterative powers and has been employed in syphilis and scrofula.

**Off. Prep.**—Tinctura Berberidis, Br.; Fluid-extractum Berberidis, N. F.
BETEL. Br.

BETEL

"Betel consists of the dried leaves of Piper Betle, Linn." Br.

Betel, Betle, Pawn, or Pinang are popular Oriental names for Piper Betle L. and P. Siriboa L., the leaves of which are used by the Malays as a masticatory. The leaves are usually admixed with scrapings of the Areca nut and shell lime. The Betel plants are indigenous throughout the entire Indian-Malay region and cultivated in Madagascar, Bourbon and West Indies. The plants are climbing shrubs and trained upon trellises and poles in shady but hot places. The leaves are picked while green, pressed together by means of stones and dried. The Betel leaves of the British Pharmacopoeia are described as follows: "About fifteen centimetres long, broadly ovate, acuminate, obliquely cordate at base; thin and brittle, upper surface glossy, five or seven conspicuous lateral veins. Mesophyll contains abundant oil-cells filled with brown oleo-resin. Taste warm, aromatic, bitter. As found in commerce the leaves are frequently tied up or stitched together into packets." Br.

The warm aromatic taste of the betel leaves is due to an essential oil known as betel oil. This is of a color varying from clear yellow to dark brown and of aromatic, somewhat creosote-like, odor and burning sharp taste. The specific gravity ranges from 0.958 to 1.044, the lighter oil being that obtained from the fresh leaves. The alcoholic solution of the oil gives a greenish to bluish-green color with ferric chloride.

The betel oil from Siam contains cadinene and a characteristic phenol named betelphenol, iso-meric with eugenol; the oil from Java contains in addition to the betelphenol, chavicol and a sesquiterpene; while the Manila oil contains betelphenol as the sole phenolic constituent. (Gildemeister and Hoffmann, Die Aetherische Oele, Berlin, 1899.)

Uses.—The essential oil of betel is an active local stimulant and has been used in doses of one to two minims (0.06-0.12 mil) in the treatment of various respiratory catarrhs, and as a local application, either by gargle or inhalation, in diphtheria. It is said that the juice of four leaves is equivalent in power to one drop of the oil. In India betel leaves are used locally to a considerable extent for the purpose of counter-irritation and applied to the mammary glands for the purpose of suppressing the
secretion of milk in mammary abscesses. The essential oil has been given internally in doses of from one to two minims (0.06-0.12 mil).

**Betonica.** Beto<noindent>onica officinalis, L. Wood Betony. —A perennial European labiate herb, feebly aromatic and astringent. Its root has been considered emetic and purgative.

**Betula.** Betula alba L. Paper, Canoe or European White Birch. Bouleau, Fr. Birke, G. (Fam. Betulaceae) —Various parts of this tree have been applied to medicinal uses. The young shoots and leaves secrete a resinous substance, having acid properties, which, combined with alkalies, is said to produce the effects of a tonic laxative. (J. P. C., xxvi, 208.) The inner bark, which is bitterish and astringent, has been employed in intermittent fever. The epidermis is separable into thin layers, which may be employed as a substitute for oiled paper, and applied to various economical uses. The bark contains betulin, or betula camphor, which Hausemann (Ann. Ch. Ph., 182, 368) has shown to be a diatomic alcohol, as it forms a diacetate. Its formula is C<sub>36</sub>H<sub>60</sub>O<sub>3</sub>, fusing point 258° C. (496.4° F.). When oxidized it yields betulinic acid, C<sub>36</sub>H<sub>54</sub>O<sub>6</sub>, and betulinamic acid, C<sub>36</sub>H<sub>52</sub>O<sub>16</sub>. When the bark is distilled, it yields an empyreumatic oil known variously as dagget, oleum rusci, oleum betulinum, oleum muscovicum, oleum fagi, and oil of birch tar. This is a thick, brownish-black liquid, sp. gr. 0.955, having the odor of Russia leather, in the preparation of which it is employed. This oil has been found very useful as a local application in chronic eczema and other skin diseases in strengths varying between 1 and 20 per cent. Its medicinal properties closely resemble, if they be not identical with, those of oil of cade. (See Oleum Cadini, Part I.) Dutch and German oil of birch are quite different from the Russian oil. (See P. J.; xv, 769.) The National Formulary IV has introduced a rectified oil of birch. See Oil of Birch Tar. The leaves of birch, which have a peculiar, aromatic, agreeable odor, and a bitter taste, have been employed, in the form of infusion, in gout, rheumatism, and dropsy. Active diuretic properties are claimed for birch leaves and attributed to the betulorentinic acid in them. An alcoholic extract has been used in daily doses of from twenty-five to fifty grains (1.6-3.2 Gm.). When the stem of the tree is wounded a saccharine juice flows out which is considered useful in complaints of the kidneys and bladder, and is susceptible, with yeast, of the vinous fermentation. A beer, wine, spirit, and vinegar are prepared from it in some parts of Europe. Tinctura Rusci is made, according to Hager, as follows: Ol. Rusci 10, Alcohol, Aether, of each 15, Ol. Lavandulae, Ol. Rosmarini, Ol. Rutae, of each 0.4 part; filter. (A. J. P., 1881.)

**Bichetia.** Bichetia officinalis. Murere juice is extracted in Brazil from the incised bark of this plant; it is a thick reddish liquid, sp. gr. 1.100, and is said to contain an alkaloid and to be useful in rheumatism and syphilis. The dose of the juice is one fluidrachm (3.75 mils) in water; in large doses it is drastic.

**Bidens.** Bidens bipinnata, L. Spanish Needles. —An indigenous composite plant, of which the root and seeds are popularly used as emmenagogues, and by the eclectics in laryngeal and bronchial diseases.

**Bistort.** Snakeweeds. Bistorte, Couleuvrine, Fr. Weissenknoterich, Natterwurz,
G.—This is the rhizome of Polygonum Bistorta, L. (Fam. Polygonaceae), a perennial herbaceous plant, growing in Europe and the north of Asia. The rhizome is cylindrical, somewhat flattened, about 1 to 2 cm. in thickness, marked with annular or transverse wrinkles, furnished with numerous rootlets, and folded or bent upon itself, so as to give it the tortuous appearance from which its name was derived. Externally it is dark purplish or blackish-brown. The fracture is nearly smooth, reddish or purple, the taste being astringent. It contains much tannin, some gallic acid and gum, and a large proportion of starch. H. K. Bowman found 21 per cent. of tannin in bistort root. (A. J. P., 1869, 193.) Its medicinal properties are like those of kino, but it is less efficient. It may be employed in powder, decoction, or extract. The dose of the powder is twenty or thirty grains (1.3-2.0 Gm.).

Besides the bistort, some other plants belonging to the genus Polygonum have been used as medicines. Among these are P. aviculare, L., or knot weed, a mild astringent, formerly employed as a vulnerary and styptic; P. Persicaria, L., or lady's thumb, of a feebly astringent saline taste, and at one time considered antiseptic; and P. Hydropiper, L., common smartweed, or water-pepper, the leaves of which have a burning and biting taste, inflame the skin when rubbed upon it, and are esteemed diuretic, and have been used with asserted success in amenorrhea and other uterine disorders. Its irritant and also medicinal properties are due to an acid, polygonic acid, discovered by C. J. Rademaker. Polygonum Hydropiper has been used by Krawkoff (Russki Vratch, 1912) in the treatment of internal hemorrhages, especially of the uterus. He administered from thirty to forty drops of a fluidextract of the leaves. (A. J. P., xliii, 490.) The water-pepper or smartweed of this country—P. acre H. B. K.—which grows abundantly in moist places, possesses properties similar to those of the European water-pepper, and is occasionally used as a detergent in chronic ulcers, and internally in gravel. B. Woodward found that the dried plant contains 18 per cent. of tannin, and used a saturated tincture with great advantage in diarrhea and dysentery, in doses of from twenty to sixty minims (1.3-3.75 mils). Aughey finds that P. amphibium, L., is readily cultivated, with a yield of from three to six tons to the acre, that the roots contain 21.75 per cent., the stems 17.1 per cent, of tannic acid, and urges the growth of it for tanning purposes. (N. R., 1876, 75.)

Fagopyrum esculentum Moench is common buckwheat. The leaves of this plant have been found by E. Schunck to contain a crystallizable coloring principle, identical with the rutin or rutic acid previously discovered by Weiss in the leaves of the common rue, and probably, with the ilixanthin of Moldenhaus, existing in the leaves of Ilex Aquifolium L., or the common holly. Buckwheat leaves yielded to Schunck somewhat more than one part of rutin in a thousand. (Chem. Gaz., No. 399, 201.)

From P. cuspidatum L. has been separated a glucoside, polygonin, and also emodin. (P. J., Feb., 1895.) The bark of the rhizome has been recommenced by Goris and Crete (Bull. Sci. Pharmacol., 1907) as a laxative. The leaves of the P. dumetorum are, according to Tunmann (Ph. Centralh., 1906), also practically useful as a laxative.

Various species of the genus Polygonum are used for the production of dye-stuffs; thus, indigo is obtained largely in China, Japan, and in some parts of Russia, from the leaves of P. tinctorium Ait., and is said also to be yielded by those of P. aviculare and
P. barbatum, L.; while in India, China, and Japan the roots of the P. cuspidatum are employed for making a yellow dye. (J. Chem. S., Dec., 1895.)

**Blepharis.** Blepharis capensis. (Fam. Acanthaceae)—This plant is said to be physiologically very active and useful in the treatment of anthrax. (P. J., lx, p. 140.)

**Blue Flag.** N. F. IV. (U. S. P. 1890.) Iris Versicolor.—"The dried rhizome of Iris versicolor Linne (Fam. Iridaceae), without the presence of more than 5 per cent. of the roots and leaf bases." y. F. In all the species belonging to this genus, so far examined, the roots are more or less acrid, and possessed of cathartic and emetic properties. In Europe, Iris foetidissima L., I. florentina L., I. germanica L., I. pseudoacorus L., and I. tuberosa L. have at various times been admitted into use, and the unpeeled roots of I. germanica are still sold in the Indian bazaars under the name of Irisia. Iris versicolor L., or blue flag, is found in all parts of the United States, flourishing in low wet places in meadows. The flowers afford a fine blue infusion, which serves as a test for acids and alkalies. The recent root is without odor, and has a nauseous, acrid taste, which is imparted to water by decoction, and still more perfectly to alcohol, the acrimony as well as medicinal activity is impaired by age. If cut, when fresh, into slices, dried at the temperature of about 37.8 ° G. (100° F.), then powdered and kept in bottles excluded from the air, the root retains its virtues unimpaired for a considerable time (Andrews). It is described as follows in the National Formulary IV:

"Rhizome frequently branched, up to 10 cm. in length and 2 cm. in thickness, usually cut into longitudinal pieces; outer surface grayish-brown to purplish-brown, somewhat annulate, the upper surface with markings of leaf bases, the lower with numerous root scars and remnants; fracture short, the broken surface pale purplish-brown and exhibiting a central stele with whitish fibro-vascular bundles distributed throughout, a distinct endodermis, and cortex. Odor slight, not distinctive; taste acrid, nauseous. The powder is light purplish-brown and, when examined under the microscope, exhibits numerous resin cells filled with yellow to brown resin; starch grains few, or, in some specimens, abundant, simple, or two-to four-compound, the simple grains being spherical or elliptical, up to 0.022 mm. in diameter; calcium oxalate in prisms, up to 0.35 mm. in length; tracheae with spiral or reticulate markings or with bordered pores; sclerenchymatous fibers few, lignified and with oblique pores. Blue flag yields not more than 7 per cent. of ash." N. F.

D. W. Cressler found in this plant starch, gum, tannin, sugar, and acid resin, fixed oil, and indications of an alkaloid. (A. J. P., 1881, p. 602.)

Blue flag is a cathartic and emetic, said to have been used by the Southern Indians, and may be given in doses of from ten to twenty grains (0.65-1.3 Gm.). Iridin, or irisin, of the eclectics, is an oleoresin obtained by precipitating a tincture of the root with water, and mixing the precipitate with an equal weight of some absorbent powder. Wm. E. Jenks (A. J. P., 1881, p. 601) prepares the oleoresin of iris by exhausting the root with alcohol, sp. gr. 0.835, and distilling off the alcohol. (See also a paper on the constituents of the oleoresin by W. L. Cliffe, A. J. P., 1884, p. 616.) The so-called irisin is undoubtedly purgative and is generally believed to have a very decided action upon
the liver. Power and Salvay (A. J. P., 1911, 14) isolated isophthalic acid, 
\[ C_6K_4(CO_2H)_2 \]. It may be given in pill in the dose of from three to four grains (0.20-0.26 Gm.).

The Pharmacopoeia formerly recognized a solid extract (Extractum Iridis), made by the following process: "Iris, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity. Moisten the powder with four hundred mils [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until three thousand mils [or 101 fluidounces, 31/2 fluidrachms] of tincture are obtained, or the Iris is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." U. S., 1890. The dose of the extract of iris is one to two grains (0.065-0.13 Gm.).

A fluidextract is official in the N. F. (see Part III).

**Blumea.** Blumea racera DC. (Fam. Compositae)—From this plant, which is used in India as an insect powder, Dymock has obtained a light yellow volatile oil. It has a sp. gr. of 0.9144 at 26.7° C. (80° F.), and an extraordinary rotating power, 1 mm. turning the ray 66° to the left.

**Bocconia.**—It is probable that various species of this papaveraceous genus have active medicinal properties. B. arborea Watson, of Mexico, has been found by Elliott to contain two alkaloids, one of which is probably sanguinarine, and the leaves of other species are used in South America as an abortifacient and purgative. (See Rusby, Bull. Pharm., 1891.) Murrill and Schlotterbeck (Proc. A. Ph. A., 1900, p. 128) examined all parts of Bocconia cordata, and isolated protopine, homo-chelidonine, chelerythrine and sanguinarine.

**Boldo.** N F. IV. Boldo Leaves.—It is described by the N. F. as "the leaves of Boldu Boldus (Molina) Lyons (Fam. Monimiaceae), without the presence of more than 2 per cent. of stems or other foreign matter. Broadly ovate or oval, from 3 to 7 cm. in length and from 1 to 4 cm. in breadth, the base varying from rounded to very slightly indented, the summit rounded or slightly notched, the margin entire and sharply revolute; thick, coriaceous, rigid and brittle, from pale-green to brownish-green, papillose, roughened on both surfaces, the principal veins coarsely reticulate, impressed above, sharply prominent underneath; the petiole stout and rigid, from 1 to 5 mm. in length, reticate. Odor peculiar; when crushed very strong, disagreeable, and somewhat like that of oil of chenopodium; taste bitter, warm and pungent, camphoraceous and slightly terebinthinate. Under the microscope a transverse section shows a well-marked hypodermis from which develop papilla-like excrescences, each crowned, with a group of radiating, one-celled, thick-walled hairs; on the lower surface stomata numerous and hairs somewhat smaller, mesophyll with numerous oil secretion cells. Boldo yields not more than 10 per cent. of ash."
plant is an evergreen shrub, frequenting the meadows of the Andes in Chili, where its yellowish-green fruit is eaten, its bark used in tanning, and its wood is employed in charcoal making. The leaves contain an aromatic, volatile oil, of which they yield, on distillation, about 2 per cent. The oil boils between 175° and 250° C. (347° and 482° F.) and gives a green coloration with ferric chloride; it contains terpene and oxygenated bodies which have not as yet been investigated. For chemistry of the Oil of Boldo, see Schim. Rep., Oct., 1907, p. 19. They have found that the oil is chemically related to the Oil of Chenopodium. A peculiar alkaloid, boldine, has been found in them by Bourgoin and Verne (J. P. C., 4e ser., xvi, 191), and a glucoside, boldo-glucin, C_{30}H_{52}O_{8}, a thick syrupy liquid, by P. Chapoteaut. (C. R. A. S., xviii, 1052.) According to Sigismond Pascaletti (Terapia Moderna, 1891), boldine when injected hypodermically paralyzes both the motor and sensory nerves, and also attacks the muscle fibers. When given internally in toxic dose it produces great excitement, with exaggeration of the reflexes and of the respiratory movements, increased diuresis, cramps, disorder of coordination, convulsions, and finally death from centric respiratory paralysis, the heart continuing to beat long after the arrest of respiration, finally stopping in diastole. Boldine has in recent years come into wide use in veterinary medicine as a remedy for jaundice. It has also been used in man in the treatment of hepatic affections, given in doses of one one-hundredth to one-twentieth of a grain (0.0006-0.003 Gm.) in conjunction with calomel. Boldogluicin is said to act on the lower animals as a narcotic, and has been given by Rene Juranviller in doses of one to three grains (0.06-0.2 Gm.) in diseases of the liver. Fifteen minims (0.9 mil) of the oil of boldo cause in man some warmth in the epigastrium; thirty minims (1.8 mils), much gastric irritation, with pain and vomiting, and passage of urine smelling strongly of the oil. Dujardin-Beaumetz finds the oil useful in genito-urinary inflammations in doses of five drops (0.25 mil) [B. G. T., March, 1875], in diseases of which character the drug has long been employed in South America. (Ibid., Ixxxvi, 165.) In France boldo has been employed as a tonic in chronic hepatic torpor and in hepatitis, and Fedeli (Il Policlinico, 1907) reports favorable results in the treatment of cholelithiasis. Eight minims (0.5 mil) of a 20 per cent. tincture or four minims (0.25 mil) of the N. F. fluidextract may be considered as the commencing dose, increased pro re nato. Large doses are apt to vomit and purge.

According to A. T. De Rochebrune (Toxicol. Africaine, i, 1897), the tree Monimia rotundifolia, of Australia, contains an abundant volatile oil, an alkaloid, and a glucoside, which are very similar to, if they are not identical with, those obtained from the Boldo, and may be substituted for the latter in therapeutics.

**Bolduc Seeds.**—These are seeds derived from several species of the genus Caesalpinia (Fam. Leguminosae), which are used in India as febrifuges, tonics, and antiperiodics. Heckel and Schlagdenhauffen have discovered in them a bitter principle (C. R. A. S., ciii, 89), probably identical with that previously isolated by Fliickiger. (Pharmacographia, 2d ed., 212.)

**Borago.** Borago officinalis, L. Borage Bourrache, Fr. Borasch, Boretsch, G. (Fam. Boraginaceae)—This European annual abounds in mucilage, and the stems and leaves contain potassium nitrate with other salts. To these constituents the plant contains...
owes its feeble medicinal properties. An infusion of the leaves and flowers is employed as a demulcent, refrigerant, and gently diaphoretic drink. The expressed juice of the stems and leaves is also given in the dose of from two to four nuidounces (60-120 mls).

**Bowdichia.** Bowdichia virgiliodides H. B. K. (Fam. Leguminosae)—Under the name of Sucupira, the hard, yellow, very bitter bark yielded by this tree is employed in Venezuela and Brazil in fevers and rheumatism. Petit has found it in a mydriatic alkaloid. (P. J., June, 1885.)

**Bragantia.** Bragantia Wallichii. (Fam. Aristolochiaceae)—The roots of this shrub of India contain an alkaloid allied to aristolochine, a soft resin, a resinous acid, and a substance related to dulcite. (P. J., 1894, 231.)

**Brassica.**—In China the oil of Brassica sinensis, or petsai, is used for lighting, and is said also to be purgative, and useful in skin diseases, while the Japanese employ the yellow oil of B. Campestris, L., under the name of aburana, for culinary and lighting purposes. (A. J. P., June, 1885.)

**Brazil Nuts.** Cream Nuts. Butter Nuts (not to be confused with the nuts similarly named and obtained from Juglans cinera L.). Para Nuts. Chataigne du Bresil, Fr. Paranuss, G.—These are edible nuts imported from Brazil, and sometimes employed in making cream syrups for giving flavor to carbonic acid water. In Brazil an expressed oil is obtained from them, which is said to be used for burning, making ointments, and adulterating copaiba. The nuts are the product of Bertholletia excelsa Humb. et Bpl. and B. nobilis Miers, a large and beautiful tree of the Fam. Myrtaceae, growing over extensive regions in South America. Cornwinder has found in the kernel of the nut 65.00 per cent. of oil, and 15.31 per cent. of nitrogenous matter. (P. J., Aug., 1873.) Hugo Kuhl obtained from the seeds an average fat-content of 62.73 per cent., with 2.59 per cent. of nitrogen, corresponding to 16.20 per cent. of proteins. (P. Zeit., 1909, No. 6, 58.)

**Brazil Wood.**—A red dye-wood, the product of different species of Caesalpinia, growing in the West Indies and South America. Two varieties are known in commerce—1, the proper Brazil wood, said to be derived from Caesalpinia echinata Lam., and sometimes called Pernambuco or Fernambuco wood, from the province of Brazil, where it is collected; 2, the brasiletto, produced by C. brasiliensis, L., and C. Crista, L., which grow in Jamaica and other parts of the West Indies. The former is the most highly valued. The Nicaragua or peach wood is also analogous to the brasiletto, and is said by Bancroft to be derived from a species of Ceesalpinia. It is produced in the East Indies. Brazil wood is nearly inodorous, has a slightly sweetish taste, stains the saliva red, and imparts its coloring matter to water. It was formerly used in medicine, but has been abandoned as inert. In pharmacy it serves to color tinctures, etc., but its chief use is in dyeing. A red lake is prepared from it, and it is an ingredient in a red ink. Its dyeing properties are due to a cry stallizable coloring principle, named brazilin or brasilin, $C_{16}H_{14}O_{5}$. This, as usually obtained, is of a sulphur-yellow color, which it preserves in the dark, but in the sunlight, to which it is
remarkably sensitive, changes to a reddish hue after a few minutes' exposure, and
also more slowly in diffused daylight. The principle should, therefore, be kept in
perfectly opaque vessels. It is now stated that when absolutely pure it is colorless,
and becomes red on exposure to the air. The change is due to the formation of
brasilen, $C_{16}H_{22}O_5$, which can be prepared from the brasilen by a variety of methods,
such as oxidation by nitrous acid, by alcoholic iodine solution, etc. Brasilen is sparingly
soluble in water, yielding a sweet and almost colorless solution which is not changed
by acids, but is deeply reddened by alkalies. In alcohol and ether it is somewhat more
soluble than in water, giving a light yellow solution. Brasilen and hematoxylin (from
logwood) are now recognized as related, each being derived from the pyrone nucleus
$C_5H_4O_2$, from which the two groups, the xanthone group and the flavone group, are
also taken. The coloring principles of most dye-woods are now referred to this source.
(Kupe, Die Chemie der naturalien Farbstoffe, Braunschweig, 1900.)

Brea Gum.—This substance, which has been proposed as a substitute for gum
arabic, is believed to be derived from Caesalpinia praecox, a Brazilian tree. It occurs
in stalactitic pieces or oval reddish-yellow tears, isolated or agglomerated. It forms
with water a viscous, pale reddish-yellow mucilage, of acid reaction, which may be
partially decolorized by heating with a few drops of hydrochloric acid. It is said to
contain 77 per cent. of arabin.

Bryonia. N. F. IV. Bryony.—The N. F. describes it as "the dried root of Bryonia alba,
Linne or of Bryonia dioica Jacquin (Fam. Cucurbitaceae), without the presence of
more than 5 per cent. of foreign matter. Usually in circular or elliptical slices,
obtained by cutting the root more or less transversely, from 1.5 to 10 cm. in breadth
and from 3 to 15 mm. in thickness; the edges light gray or yellowish, rough and.
striate, the cut surface white or faintly yellow, showing a thin cortex and a wood with
numerous projecting, collateral fibro-vascular bundles arranged in concentric zones;
fracture short and mealy, whitish internally. Odor faint but distinct and
characteristic; taste bitter and nauseous. The powdered drug is of a light yellow color
and, when examined under the microscope, shows simple, rounded, or two- or more
compound, starch grains from 0.004 to 0.024 mm. in diameter, frequently with a
central cleft, tracheae from 0.035 to 0.25 mm. in width, reticulate or with bordered
pores, and large yellow cork cells. Add sulphuric acid to the powdered drug; it becomes
reddish-brown and then brownish-purple. Bryonia yields not more than 8 per cent. of
ash."

The peasants are said sometimes to hollow out the top of the root, and to employ the
juice which collects in the cavity as a drastic purge. (Merat and De Lens.) The berries
are also purgative, and are used in dyeing. B. americana Lam. and B. africana
Thumb, are respectively used in the West Indies and Africa as hydragogue cathartics
in dropsy. The berries of the European black bryony (Tamus communis L.) are said to
be an irritant poison, and Coutagne has found that their tincture causes in animals
paralysis and convulsions. (See Rep. de Pharm., Nov., 1884; also P. J., Jan., 1903.)

Bryonia contains a glucoside, bryonin, $C_{48}H_{80}O_{19}$, and a peculiar resin called
bryoresin. According to Power and Moore (Tr. Chem. Soc., 1911, xciv), bryonin is a
mixture of a glucoside and an alkaloid, neither of which is physiologically active. The activity of the plant resides in its resin. Bryonin occurs as a brownish-yellow amorphous powder of bitter taste, soluble in water and alcohol. It is used as a cathartic in hepatic congestion and in conditions following acute infectious diseases. Dose one-sixtieth of a grain (0.001 Gm.) every two hours.

Bryonia is an active irritant hydragogue cathartic. In a number of cases it has produced serious or even fatal poisoning. Vomiting and purging have been commonly present, but in some cases there has been no diarrhea. Giddiness, delirium, and dilated pupils, coupled with fall of the bodily temperature, imperceptible pulse, cold perspiration, and other manifestations of collapse, are the usual symptoms. Eighty minims (5 mils) of the homeopathic tincture caused very serious but not fatal poisoning. (For cases, see P. J., 1858, p. 542; L. L., May 9, 1868; B. M. J., 1883, ii, 1067; T. G., ii, 35; also Woodman and Tidy.) The fresh root is highly irritant, and is said, when bruised and applied to the skin, to be capable of producing vesication. The medicine was well known to the ancients, and has been employed as a hydragogue cathartic in dropsy. Dose ten to thirty grains (0.65-2.0 Gm.). The tincture is official in the N. F. (see Part III).

BUCHU. U. S. (Br.)

BUCHU

"The dried leaves of Barosma betulina (Thunberg) Bartling and Wendland, known in commerce as Short Buchu; or of Barosma serratifolia (Curtis) Willdenow, known in commerce as Long Buchu (Fam. Rutaceae), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." U. S. " Buchu Leaves are the dried leaves of Barosma betulina, Bart. and Wendl." Br.

Buchu Folia, Br.; Folia Bucco, Folia Diosmsae s. Barosmae; Feuilles de Bucco (Booko, Buchu), Fr.; Buckublatter, Bucco-blatter, G.

The leaves of the official and other Barosmas and of some Agathosmas, are collected by the Hottentots, who value them on account of their odor, and under the name of bookoo or buchu, rub them, in the state of powder, upon their greased bodies.

Buchu leaves are not recognized except in the U. S. and British Pharmacopoeias. The definitions for this drug do not show any great stability, at one time the "short" buchu being official and then again both the "short" and the "long" buchus are included in one definition. This latter is a mistake as the oils in the several buchus are quite distinct. The drug was exploited in the 70's in the United States by
Helmbold who was one of the most eccentric and fantastic exploiters of proprietary medicines. (See A. J. P., 1916, p. 23.) The medicinal species of Barosma are all erect, slender shrubs with opposite leaves, dotted with conspicuous pellucid oil glands, smooth, angular, purplish branches, often of a purplish color, "white flowers, and a fruit of five erect carpels. They are chiefly distinguished by their leaves.

Barosma betulina is a small shrubby plant indigenous to Cape Colony. The leaves are collected while the plant is in flower and fruit, then dried and shipped to London. B. serratifolia is a well-developed shrub growing in the mountains of the Southwest of Cape Colony. The leaves usually command a higher price and are only employed when the supplies of short buchu are reduced. The exports of buchu from South America in 1908 were 243,742 pounds, in 1912, 223,000 pounds, in 1913, 163,000 pounds, and in 1914 about 75,000 pounds. According to Schimmel and Co., the buchu plant thrives best in a very sandy soil, but it is rather difficult to cultivate as the cuttings do not root readily. The buchu of commerce always contains more or less foreign material, such as stems, twigs and old worthless leaves, and the U. S. Pharmacopoeia has wisely limited the amount of such admixture to 10 per cent.

The non-official species, which have been seen in European markets occasionally, are said to be used in South Africa as substitutes for the official buchu; they are:

Barosma crenulata (L.) Hook.—The leaves are opposite, ovate or obovate, acute, serrated and glandular at the edge, coriaceous, and full of small pellucid dots on the under surface. The flowers are white or of a reddish tint, and, stand solitary at the end of short, lateral leafy shoots. C. J. S. Thompson has found that the leaves of B. serratifolia yield only 3.45 per cent. of resin and 1 per cent. of volatile oil, while those of B. crenulata yield 3.75 per cent. of resin and 1.6 per cent. of volatile oil, and those of B. betulina give 4.25 per cent. of resin and 1.45 per cent. of volatile oil; so that B. serratifolia would seem to be the least active of the species. (P. J., xxi, 1890.)

Barosma Eckloniana Barth., a plant which has been considered to be only a variety of B. crenulata, has leaves which are rounded at the base, shorter and proportionately wider than those of B. crenulata, and also grow upon pubescent shoots.
The leaves of Barosma venusta which are said to have appeared in the London markets, are readily distinguished by their being very much smaller than those of B. betulina, which they otherwise resemble.

Barosma pulchellum (L.) Bartl. and Wendl.— The leaves closely resemble those of the B. betulina, being ovate instead of obovate, that is, they are wider at the base. Their odor is quite different, strongly recalling that of citronella, and Schimmel and Company have demonstrated the presence in them of citronellal.

Under the name of Karoo buchu, in 1904 the leaves of the Diosma succulenta L., var. Bergiana H. and S., appeared in London; they are small and heath-like, thick, obtuse, and slightly recurved, and yielded to C. E. Sage (C. D., lxxv, 506, 787) a small semi-solid volatile oil having the odor of peppermint. Recently a new buchu has appeared on the marker, the leaves resembling very closely those of Barosma scoparia E. and Z. (Perf. & Ess. Oil Rec., 1914, p. 375.)

Buchu is subject to many adulterations both by the leaves of other species of the genus as well as more distantly related leaves. The most important of these adulterations are as follows: Psoralea obliqua E. Mey, or P. bracteata (P. J.; 1910, pp. 69 and 464), and Empleurum serrulatum Ait. The leaves of the latter are lanceolate or narrowly linear, about 4 cm. in length, yellowish-green and very acute at the summit. They furthermore do not contain any oil canals at the base of the teeth. (For description of many other adulterants, see Holmes, P. J., 1910, lxxxv, p. 464.)

Properties.—Buchu leaves are officially described as follows:

"Short Buchu.—Rhomboidally oval or obovate; from 9 to 25 mm. in length and from 4 to 13 mm. in breadth; summit obtuse, and recurved; margin somewhat serrate or finely dentate with an oil gland at the base of each tooth; the base more or less wedge-shaped; color varying from vivid green to yellowish-green, occasionally a few olive-gray leaves; glandular-punctate; both surfaces papillose; under surface longitudinally striate; texture coriaceous; petiole 1 mm. in length; odor and taste characteristic, aromatic and mint-like.

"Long Buchu.—Linear-lanceolate, from 2.5 to 4 cm. in length and from 4 to 6 mm. in breadth; summit somewhat rounded or truncate with an
oil gland at the apex; margin sharply serrate and glandular; otherwise resembling Short Buchu.

"Stems in both Short and Long Buchu about 1 mm. in diameter, yellowish-green or brownish-red, cylindrical, longitudinally furrowed, with prominent leaf-scars nearly opposite to each other giving the stems a jointed character. The yield of ash does not exceed 4 per cent." U. S.

"From twelve to twenty millimetres long, rhomboid-obovate, dull yellowish-green, rigid, cartilaginous when slightly moist. Surface glabrous, bearing small scattered prominences; margin usually sharply denticulate, apex blunt and recurved. Oil glands visible in the leaf, especially near the margin. Transverse section exhibits in epidermis cells containing yellow sphere-crystals; inner walls of these cells thick and rich in mucilage. Odor and taste strong and characteristic." Br.

The leaves of B. crenulata constitute the short buchu or round buchu, while those of B. serratifolia are the long buchu of commerce. The leaves of B. crenulata are at present comparatively infrequent in commerce, the parcels usually consisting of those of one of the other species almost unmixed. The species can be recognized by the characters already given. The leaves of the Empleurum serrulatum sometimes occur mixed with buchu leaves occasionally constituting the bulk of the parcel. They are to be distinguished by their acrid taste and peculiar odor and by being longer and narrower than any buchu leaf, with a sharp-pointed apex, parallel sides, and coarse denticulation. Further, according to Holmes, when the leaf of a Barosma is held up to the light the lateral veins appear straighter, longer, and more strongly developed than in the leaves of the Empleurum. John C. Umney (P. J., March, 1895) finds that the leaves of the latter contain 0.64 per cent. of a peculiar volatile oil. There is no reason to believe that they possess the therapeutical properties of buchu. Holmes enumerated a number of plants used in South Africa as substitutes. (See P. J ; 1900, 70.)

Fluckiger obtained from B. betulina 1.56 per cent. of volatile oil, which had the odor of peppermint rather than of buchu, and deviated the plane of polarization considerably to the left. On exposure to cold it furnished a camphor, which, after resolution in alcohol, crystallized in needle-shaped forms. After repeated purification in this manner, the crystals of Barosma camphor, or diosphenol, C_{10}H_{16}O_{2}, have a peppermint odor; they fuse at 85° C. (185° F.) and begin to sublime at
110° C. (230° F.). After fusion they again solidify only at 50° C. (122° F.). Barosma camphor is abundantly soluble in carbon disulphide. The crude oil from which the camphor had been separated had a boiling point of about 200° C. (392° F.), quickly rising to 210° C. (410° F.), or even higher. The oil which distilled between these temperatures, rectified over sodium, gave approximately the formula $C_{10}H_{16}O$.

(PHARMACOGRAPHIA, 2d ed., p. 109.) Spica examined B. crenulata and found the volatile oil to differ from that obtained by Fluckiger from B. betulina; the solid body was similar to diosphenol, but upon analysis gave the figures $C_{10}H_{16}O_2$, and hence is regarded by Spica as an oxycamphor. The liquid portion was a greenish-yellow oil, having a pleasant odor and a pungent, peppermint-like taste; by fractioning, it was separated into a portion isomeric with borneol, resembling thymol in odor and taste, to which the name of dioscamphor was given. A substance extracted by alcohol from the residue after the removal of the oil Spica named diosmin. (P. J., 1885, p. 106.) The results of Spica were confirmed by Shimoyama (A. J. P., 1888, p. 624), who made several simple derivatives of diosphenol and then prepared from it, by prolonged digestion with alcoholic potash, coolie acid, $C_{10}H_{18}O_3 + H_2O$, forming white crystalline needles, melting at 96° to 97° C. (204.8°-206.6° F.), and a compound to which he gave the name dialcohol. Wayne's experiments (A. J. P., 1876, p. 19) appear to indicate that the oil also contains a substance capable of being converted into salicylic acid. J. M. Maisch believed that buchu leaves do not contain salicylic acid, although the stearopten of the oil gives a blackish color with ferric chloride. (A. J. P., July, 1881.) The yield of ash varies, according to the researches of H. W. Jones (P. J., ix, 673), from 4.69 to 4.40 in B. betulina, 4.32 to 5.39 in B. crenulata, 5.03 to 5.22 in B. serratifolia; the ash itself was remarkable as containing a great deal of manganese. The short leaved buchu was found by P. W. Bedford to yield an average of 1.21 per cent. of volatile oil; while the long leaved, though more highly valued in the market, gave only 0.66 per cent., showing its great inferiority in strength. (Proc. A. Ph. A., 1863, p. 211.)

**Uses.**—Buchu, originally employed by the Hottentots, has long since come into general use. Its activity depends upon the volatile oil, which is eliminated by the kidneys. Under its action there is no marked increase in the amount of the urine, hence the remedy is of no value in dropsies, but the oil affects very decidedly the mucous membrane of the genito-urinary tract. The remedy is useful in diseases of the urinary organs,
such as gravel, chronic catarrh of the bladder, morbid irritation of the bladder and urethra; diseases of the prostate, and retention or incontinence of urine from a loss of tone in the parts concerned in its evacuation. It should be given when the inflammation is not severe, but when it is in that condition of chronicity requiring oil of turpentine, tincture of cantharides, or other stimulant diuretics. An infusion (one ounce in a pint of boiling water) may be given in the dose of one to two fluid-ounces (30-60 mils), but the best preparation is the fluidextract.

Dose, one-half to one drachm (2.0-3.9 Gm.).

**Burgundy Pitch.** Pix Burgundica. Poix de Bourgogne, Poix des Vosges, Poix jaune, Fr. Cod. Poix blanche, Fr. Burgundisches Pech, BurgunderHars, Wasserhars, G. Pecedi Borgogna, It. Pez de Borgona, Sp.—Under the name of Pix Burgundica was formerly recognized both by the British (1898) and by the U. S. (1890) Pharmacopoeias, "the resinous exudation obtained from the stem of the *Picea excelsa* Link., melted and strained." Br., 1898.

*Picea abies* (L.) Karst. or *P. excelsa* Link. (Fam. Pinaceae), commonly known as Norway spruce, is a lofty tree, rising sometimes one hundred and fifty feet in height, with a trunk from three to five feet in diameter. The leaves, standing thickly upon the branches, are short, obscurely four-cornered, often curved, of a dusky green color, and shining on the upper surface. The male aments are purple and axillary, the female of the same color, but usually terminal. The fruit is in pendent, purple, nearly cylindrical strobiles, the scales of which are oval, pointed, and ragged at the edges. This tree is a native of Europe and Northern Asia, and is cultivated in the United States as a shade tree. Commercially Burgundy pitch is derived not only from the Norway spruce, but also from the *Abies picea* or European silver fir tree. To obtain the pitch, portions of the bark are removed so as to lay bare the wood, or perpendicular grooved channels are cut, and the flakes of concrete resinous matter which form upon the surface of the wound, having been detached by iron instruments, are melted with water in large boilers, and then strained through coarse cloths. It is called Burgundy pitch from the province of that name in the east of France, although whether it was ever produced in that province is uncertain. It is chiefly collected in Finland, the Schwarzwald, Austria, and the Bernese Alps. A factitious Burgundy pitch is made by melting together common pitch, rosin, and turpentine, and agitating the mixture with water, which gives it the requisite yellow color. Its odor is different from that of the genuine. Hanbury gives as a test of true Burgundy pitch that it is almost entirely soluble in twice its weight of glacial acetic acid while the factitious article similarly treated...
forms a turbid mixture quickly separating into a thick oily liquid above and a bright solution below.

The resinous exudation from Pinus sylvestris is sometimes offered as Burgundy pitch, but Hirsch-sohn (Ph. Z. R., xxiv) states that it is possible to distinguish the resin of Picea excelsa by its being only partially soluble in ether, chloroform, and solutions of salts of ammonium, sodium carbonate, and borax, which dissolve completely the resin of Pinus sylvestris. The resin of Picea excelsa is also precipitated by the addition of water from its sulphuric acid solution in red violet flakes, while Pinus sylvestris resin precipitates white.

As brought to this country, Burgundy pitch is generally mixed with impurities, which require that it should be melted and strained before being used. In its pure state, according to the U. S. P., 1890, it is "hard, yet gradually taking the form of the vessel in which it is kept; brittle, with a shining, conchoidal fracture, opaque or translucent, reddish-brown or yellowish-brown, odor agreeably terebinthinate; taste aromatic, sweetish, not bitter. It is almost entirely soluble in glacial acetic acid, or in boiling alcohol, and partly soluble in cold alcohol." U. S., 1890. It is very fusible, and at the heat of the body softens and becomes adhesive. It differs from turpentine in containing a smaller proportion of volatile oil. Instead of the sylvic acid of ordinary rosin, it contains an isomeric acid, which has been called pinwric acid, melting at 148° to 149° C. (298.4°-300.2° F.), difficultly soluble in cold but readily soluble in boiling alcohol, and also soluble in ether. According to Perrenoud, its formula is C₄₀H₅₄O₄, but Vesterberg (Ber. d. Ghent. Ges., 1885, p. 3331) showed it to be a mixture, and has since (Ibid., 1886, p. 2167, and 1887, p. 3248) prepared from it two isomeric crystalline acids, a dextropimaric acid and a laevopimaric acid, both of the formula C₂₀H₃₀O₂; with these is mixed a varying amount of an amorphous resin acid known as pinic acid.

Applied to the skin, in the shape of a plaster, Burgundy pitch acts as a gentle rubifacient, producing a slight inflammation without separating the cuticle. Sometimes it excites a papillary or vesicular eruption, and we have known it to act as a violent irritant, giving rise to severe pain, swelling, and redness, followed by vesication and even ulceration. It is used chiefly in chronic rheumatic pains, and in chronic affections of the chest or abdomen, which call for a gentle but long-continued revulsion of the skin.

**Burra Gookeroo** or Burra Gokhroo.—Under this name, in India, the fruit and sometimes the whole plant of the Tribulusterrestris L. (Fam. Zygophyllaceae) is used as a diuretic and aphrodisiac. The carpels have been commended in London as a remedy in nocturnal emissions; dose of fluidextract, from twenty minims to one fluidrachm (1.3-3.75 mils).

**BUTEAE GUMMI. Br.**

**BUTEA CUM [Bengal Kino]**
"Butea Gum is the inspissated juice obtained from incisions in the stem of Butea frondosa, Roxb." Br.

For description and uses, see under butea seeds.

**BUTEAE SEMINA. Br.**

**BUTEA SEEDS**

"Butea Seeds are the seeds of Butea frondosa, Koxb." Br.

The Sacred Tree, Butea frondosa (Fam. Leguminosae), enters largely into the religious rites of the Hindoos. Its red flowers are offered at the bloody sacrifice of the goddess Kali. Its leaf with three spreading leaflets is supposed to represent the Hindoo deity, and furnishes platters used when the Hindoo boy becomes of age.

Butea gum, which has sometimes been mistaken for African kino, is the concrete juice of the Butea frondosa Roxb., or Dhak-tree of Hindostan, and also to some extent of B. superba. The juice flows from natural fissures, and from wounds made in the bark of the tree, and quickly hardens. It is in small elongated tears, or irregular angular masses, less in size than a grain of barley, apparently black and opaque, but translucent and of a ruby-red color when examined in small fragments by transmitted light; in some specimens the tears are much paler than described, and of a very beautiful ruby tint. Many of the tears have small portions of bark adhering to them. They are very brittle, and readily pulverizable, yielding a reddish powder. They are very astringent to the taste, do not adhere to the teeth when chewed, and tinge the saliva red. The solubilities and reactions of this product to water, alcohol, and other chemical reagents are nearly the same as those of ordinary kino. When freed from impurities, consisting of from 15 to 25 per cent. of wood, bark, and sand, etc., it contains, according to E. Solly, 73.26 per cent. of tannin, 5.05 of soluble extractive, and 21.67 of gum and other soluble substances. It is used in the arts in India, and might undoubtedly be employed as kino in medicine. It is, however, very seldom imported into England, and never, at present, into this country. Pereira found a quantity in an old drug store in London, and sent a portion to Guibourt, from which that writer drew up his description of African kino. It is possible that the kino which formerly reached us, full
of small pieces of wood, bark, etc., may have been the Butea gum.

Butea gum occurs in "small irregular shining fragments, very dark ruby color, thinnest flakes transparent when examined by transmitted light. Partially soluble in water; about 40 per cent. soluble in hot alcohol (90 per cent.), the solution being scarcely colored. No odor; taste astringent. Free from corky or woody particles. On keeping, the fragments may become dull and blackish." Br.

It is said (Hanbury) to yield 1.8 per cent. of ash and 13.5 per cent. of water, and to be composed of about equal parts of kino-tannic acid and a soluble mucilaginous substance. On dry distillation it yields pyrocatechin, which, according to Eisafel, does not preexist in it. "In India and the Eastern Divisions of the Empire, Butea Gum may be employed in making the official preparations for which kino (distinguished in commerce as East Indian, Malabar, Madras, or Cochin kino) is directed to be used." Br.

The British Pharmacopoeia describes the seeds as "flat, reniform, from twenty-five to thirty-eight millimetres long, sixteen to twenty-five millimetres wide, and one and a half to two millimetres thick. Testa thin, glossy, veined, wrinkled, dark reddish-brown. Cotyledons large, leafy, yellow. Faint odor; taste slightly acrid." Br.

For a description of the seeds of B. frondosa, see Ph. Rev., 1896, 232.

**Uses.**—Butea Gum is used for the same purposes and in the same doses as kino. The seeds have been used by the native practitioners in India as vermifuges against both the tape worm and the round worm. According to the Pharmacographica Indica, the infusion of three seeds exercises a laxative effect. Before being used, the seeds should be soaked in water and the integument carefully removed. The powdered dried kernels may be given in doses of ten to twenty grains (0.65-1.3 Gm.).

**Off. Prep.**—Pulvis Butea Seminum, Br.

**Buxus.** Buxus sempervirens L. Evergreen Box. (Fam. Buxaceae).—This evergreen shrub is too well known to require description. Though much cultivated in this country as an ornamental plant, it is a native of Europe and Western Asia.

The wood is considered diaphoretic in its native countries, and is used in decoction in rheumatism, secondary syphilis, etc. The leaves, which have a peculiar odor and a
bitter and disagreeable taste, are said to be purgative in the dose of a drachm. A volatile oil distilled from the wood has been given in epilepsy. A tincture formerly enjoyed some reputation as an antiperiodic. (Merat and De Lens.) The alkaloid buxine, which has been discovered in the leaves of this tree, is identical with the bebeerine of nectandra bark. (See p. 1274; also P. J., Oct., 1869, 194.) Pavia obtained a second alkaloid from Buxus sempervirens, which was investigated by Pavesi and Rotondi. (Jahres-berichte, 1874, 903.) They named it parabuxine, and ascribed to it the formula C\(_{22}\)H\(_{48}\)N\(_2\)O. Bar-baglia (A. J. P., 1885, 145) described still another alkaloid, parabuxinidine. It crystallizes in thin, colorless prisms, is insoluble in water, soluble in ether, freely soluble in alcohol, and colors turmeric paper deep red.
Cabbage-Tree Bark. Ecorce de Geoffre, Fr. Kohlbaumrinde, Wurmrinde, G.—The bark of Vouacapoua inermis, Swz. (Andira inermis H. B. K.) This is a leguminous tree, with a stem rising to a considerable height, branched towards the top, and covered with a smooth gray bark. The tree is a native of Jamaica, and other West India islands. The bark, which is the part used, is in long pieces, thick, fibrous, externally of a brown-ish-ash color, scaly, and covered with lichens, internally yellowish, of a resinous fracture, a disagreeable odor, and a sweetish, mucilaginous bitterish taste. Huttenschmidt obtained from it a crystallizable, bitter alkaloid and named it jamaicine. Two grains (0.13 Gm.) of it produced violent purging in pigeons.

On the continent of Europe the bark of Vouacapoua retusa Poir, which grows in Surinam, has also been used. It is considered more powerfully vermifuge and less liable to produce injurious effects. It has a grayish epidermis, beneath which it is reddish-brown, laminated, compact, and very tenacious, and, when cut transversely, exhibits a shining and variegated surface. In the dried state it is inodorous, but has an austere bitter taste. The powder is of a pale cinnamon color.

Cabbage-tree bark is cathartic, and, in large doses, prone to occasion vomiting, fever, and delirium. It is said that these effects are more liable to result if cold water be drunk during its operation, and may be relieved by the use of warm water, castor oil, or a vegetable acid. In the West Indies it is esteemed a powerful vermifuge, and is much employed for expelling lumbrici; but it is dangerous if incautiously administered, and instances of death from its use have occurred. It is almost unknown in this country. The usual form of administration is that of decoction, though the medicine is also given in powder, syrup, and extract. The dose of the powder is from twenty to thirty grains (1.3-2.0 Gm.) ; of the extract three grains (0.2 Gm.).

Theodore Peckoldt says of the wood of an allied species, Vouacoupoua Anthelmia (Veil.) O. Ktze, that the workmen engaged in sawing it are prone to be affected with inflammation of the eyes, constriction of the throat, excessive thirst, a bitter, burning taste, a troublesome itching over the body, and sometimes eruptions on the skin. By treating a concentrated decoction of the wood with calcium hydroxide, then filtering after forty-eight hours, evaporating to the consistence of syrup, and exhausting the residue with alcohol, Peckoldt obtained a yellowish-brown coloring matter which he called andirin. (This name has also been given to a glucoside said to have been found
Cactus Grandiflorus. N. F. IV. Night Blooming Cereus.—Cardiac stimulant properties have been attributed to two Cacti—namely, Cereus Bonplandii Parm. and Cereus grandiflorus Miller (Cactus grandiflorus L. Night-blooming Cereus. Cierge a grandes fleurs, Fr. Konigin der Nacht, G.). Of these the latter only is now used in practical medicine. It is a native of tropical America, often cultivated in hot houses for the interest in its very fragrant night-opening white flowers. The N. F. drug is "the fresh succulent stems of the wild growing Cactus grandiflorus Linne (Cereus grandiflorus Miller) (Fam. Cactaceae). As found in commerce, Cactus Grandiflorus is usually preserved in alcohol and the amount of alcohol present should be stated on the label. It occurs in pieces of varying length, from 1.5 to 4 cm. in diameter, and from five to seven angled. On the angles at intervals of about 2 cm. are tufts of from nine to twelve spines, each about 2 mm. in length, and three slender flexuous spines about 1 cm. in length; at irregular intervals are branched roots. It has a strong, herby odor; taste acidulous and mucilaginous. The transverse section shows a central cylinder about 3 mm. in diameter and a spongy parenchyma containing large crystals and raphides of calcium oxalate." N. F. IV. Due to the difficulty in obtaining this drug commercially the larger drug houses arrange for its collection and preservation for their own manufacturing. F. W. Sultan (A. J. P., 1891, 424) believed that he had found in it an alkaloid, cactine, but the existence of this alkaloid is extremely doubtful.

It has long been used in tropical America in the treatment of dropsy. It was first brought into notice as a cardiac remedy by Eubini, of Naples. According to Myers (N. Y. M. J., June, 1891), it elevates the arterial tension by increasing the muscular energy of the heart, and by contracting the arterioles through the vasomotor centers. Considerable clinical testimony has been given to the value of cactus as a cardiac regulator in functional disorders of the heart connected with neurasthenia, Graves's disease, tobacco toxemia, and allied affections. On the other hand, Hatcher and Bailey (J. A. M. A., 1911, lvi, p. 26), experimenting with carefully identified specimens of the Cactus grandiflorus, as well as commercial preparations purporting to be of this drug, were unable to recognize any action upon the circulation, even when given in enormous doses.

Sharp could obtain from the drug only resins which were inactive, and concludes that it is inert. (Pract., Sept., 1894.) The usual dose of the fluid extract is from five to ten minims (0.3-0.6 mil).

From Cereus Caespitosus Engl. and A. Gray, Heyl separated an alkaloid, pectenine, which, according to Heffter (A. Pharm., 1901, cxxxix, s. 462), produced both in cold and warm blooded animals tetanic convulsions with heightened reflexes. According to the experiments of Mogilewa, the alkaloid acts upon the isolated frog's heart as a
depressant.

From *Cereus pilocereus* (?), Heyl separated the alkaloid *pilocereine*, which Hefftner found to produce in frogs central paralysis with great cardiac depression, and in warm blooded animals to kill by cardiac arrest.

Anthelmintic properties have been ascribed to *Cereus flagelliformis* Miller and to *C. divaricatus* (Lam.) DC.

**Cacur.**—This is a small gourd which, while still unripe, is used by the Kaffirs as an emetic, and which, according to Oliver, is yielded by the *Cucumis myriocarpus* Naud. (Fam. Cucurbitaceae) G. A. Atkinson (A. J. P., 1887) obtained from it a neutral resinous body, *myriocarpin*, and found that twenty grains (1.3 Gm.) of the fresh pulp produced in man nausea and slight purgation. (Ed. M. J., July, 1886.)

**Cahinca.** David's Root. Radix Caincae. Cainga, Fr. Kainkawurse, G.—This medicine attracted at one time considerable attention. The name of Cahinca or cainca was adopted from the language of the Brazilian Indians. The Portuguese of Brazil call the medicineraiz pretta, or black root. When first noticed in Europe, it was supposed to be derived from the *Chiococca racemosa* (Fam. Rubiaceae), which was known to botanists as an inhabitant of the West Indies. But Martins, in his work on *Materia Medica Brasiliensis*, describes two other species of *Chiococca*, *C. anguifuga* Mart. and *C. densifolia* Mart., both of which are now known as *C. brachiata* Ruiz and Pav., which afford roots having the properties of the root ascribed to *C. racemosa*. A. Richard, however, received from Brazil specimens of *C. racemosa* as the Cahinca plant.

A specimen brought to Philadelphia consisted of cylindrical pieces, from 1 to 2 cm. thick somewhat bent or contorted, slightly wrinkled longitudinally, and more or less roughened, internally ligneous, externally covered with a thin, brittle, reddish-brown bark, having a light brown or brownish ash-colored epidermis. The cortical portion, which was of a resinous character, had a bitter disagreeable, somewhat acrid and astringent taste; the ligneous part was quite tasteless. The virtues of the root reside almost exclusively in its bark. They are extracted by water and alcohol. Four distinct principles were discovered in it by Pelletier and Caventou—

(1) a crystallizable, bitter substance, believed to be the active principle, and called cahincaic acid, C_{40}H_{64}O_{18} (also called caincic acid and caincin);
(2) a green, fatty matter of a nauseous odor;
(3) a yellow coloring matter; and
(4) a colored viscid substance. Rochleder and Hiasiwetz found also caffe-tannic acid. Cahincaic acid is white, without odor, of a taste at first scarcely perceptible, but afterwards extremely bitter and slightly astringent, slightly soluble in water, but readily soluble in alcohol, permanent in the air, and unaltered at 100° C. (212° F.). It reddens vegetable blues, and unites with the alkalis, but does not form crystallizable salts. It is thought to exist in the root as calcium subcahinate. When treated with diluted hydrochloric acid it is decomposed into glucose and other products, of which is
obtained at first chiocecaic acid, $C_{28}H_{42}O_7$ (thought by some to be identical with quinovic acid), and later, by boiling with alcoholic hydrochloric acid, caincetin, $C_{22}H_{34}O_3$.

Cahinca is tonic, diuretic, purgative, emetic, and is capable of producing serious gastro-intestinal irritation. In Brazil it has long been used by the natives as a remedy for the bites of serpents, also in rheumatism and in dropsy. Dose, of the powdered bark, from twenty grains to a drachm (1.3-3.9 Gm.); of the aqueous or spirituous extract, from ten to twenty grains (0.65-1.3 Gm.).

**Calamus.** U. S. VIII. Sweet Flag. Radix Calami Aromatic'1. Radix Acori. Sweet Sedge {Cane, Rush, Root or Myrtle}. Myrtle-flag (Grass or Sedge). AcoreVrai, Fr. Cod. Acore Odorant, Fr. Rhizoma Calami, P. G. Kalmus, Kalmus-wursel, G. Calamo aromatico, It., Sp.—" The un-peeled, dried rhizome of Acorus Calamus Linne (Fam. Araceae)." U. S. VIII. The sweet flag, or Calamus, has a perennial, horizontal, jointed, somewhat compressed rhizome, from half an inch to an inch thick, sometimes several feet in length, sending off numerous round and yellowish or whitish roots from its lower surface, and groups of brown fibers resembling coarse hair from its joints, internally white and spongy, externally whitish with a tinge of green, variegated with triangular leaf scars of light brown and rose color. The leaves are all radical, sheathing at the base, very long and sword-shaped. The scape or flower stem resembles the leaves, but is longer, and from one side, near the middle of its length, sends out a cylindrical spadix, tapering at each end, about two inches in length, and crowded with greenish-yellow flowers. The fruit is an oblong capsule, divided into three locules, and containing numerous oval seeds.

This plant grows abundantly in the wet places throughout the United States, Europe, Western and Southern Asia. The leaves as well as the rhizome have an aromatic odor; but the rhizome only is employed. It should be collected late in the autumn, or in the spring. After removal from the ground, the rhizomes are washed, freed from their roots, and dried with a moderate heat. Most of the commercial article has the outer portions of the cortex removed. By drying they lose nearly one-half their diameter, but are improved in odor and taste.

Calamus was officially described as follows: "Rhizome 1 to 2 cm. thick, usually in longitudinally split pieces of various lengths; when entire, cylindraceous and somewhat vertically flattened, externally reddish-brown, somewhat annulate from remnants of leaf-sheaths; upper surface with triangular leaf-scar, the lower surface with circular pitted scars of roots; fracture short, showing numerous oil cells and scattered fibro-vascular bundles, the latter crowded within the endodermis; odor aromatic; taste pungent and bitter." U. S. VIII.

The odor of Calamus is strong and fragrant; its taste warm, bitterish, pungent, and aromatic. Its active principles are taken up by boiling water. From 100 parts of the fresh root of the European plant, Trommsdorf obtained 0.1 of volatile oil. The volatile oil is contained in all portions of the plant, the leaves yielding to distillation, according to the analysis of Schimmel & Co., 0.2 per cent., the fresh root 1.5 to 3.5 per cent.,
the dried German root 0.8, and the Japan root as much as 5 per cent.

The oil is at first yellow, but ultimately becomes red, and has the odor and taste of Calamus. Kurbatow (Ann. Ch. Ph., vol. 173, p. 4) examined oil of Calamus, and found that the portion boiling below 170° C. (338° F.) yielded, after treatment with sodium, a terpene, C\textsubscript{10}H\textsubscript{16}, having a sp. gr. .8793 at 0° C. (32° P.), and having a boiling point of 158° C. (316.4° F.). The extractive matter has an acrid and sweetish taste. H. Thomas (A. Pharm., 1886, p. 465; P. J., 1886, p. 1085) obtained from Calamus rhizomes a bitter glucoside, acorin, in the form of a clear, thick, yellow liquid, having a neutral reaction and having the formula C\textsubscript{36}H\textsubscript{60}O\textsubscript{6}, splitting into oil of Calamus and sugar. By oxidation acoretin, a neutral resin, is formed, and from the extract remaining after the acorin is removed Thomas obtained an alkaloid which he named calamine. Calamus is sometimes attacked by worms, and deteriorates on keeping.

Uses.—Calamus is a feeble aromatic and as such is used, especially in domestic practice, in India and to some extent in other portions of the world. The volatile oil is largely used in perfumery, and the powdered root itself is esteemed in Ceylon and India as a vermifuge and an insecticide. Dose in substance, fifteen to thirty grains (0.9-1.9 Gm.); of infusion (an ounce to one pint of boiling water), one to two wineglassfuls (60-120 mils).

The fluidextract, which was formerly official, Fluidextractum Calami U. S. VIII, was made as follows: "Calamus, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each a sufficient quantity, to make onethousand mils [or 33 fluidounces, 6\frac{1}{2} fluiddrachms]. Mix seven hundred and fifty mils [or 25 fluidounces, 173 minims] of alcohol with two hundred and fifty mils [or 8 fluidounces, 218 minims] of water, and, having moistened the powder with three hundred and fifty mils [or 11 fluid-ounces, 401 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close to the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the. Calamus is exhausted. Reserve the first ninehundred mils [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the fluidextract measure one thousand mils [or 33 fluidounces, 6\frac{1}{2} fluiddrachms]." U. S. VIII. Dose, from fifteen to thirty minims (0.9-1.9 mils).

Calendula. N. F. IV. (U. S. VIII.) Marigold. Mary-bud. Holligold. Fleurs de Tous les mois, Souci, Fr. Ringelbume, Todtenblowne. Gold-blumen, G. Calendula, Sp.—"The dried ligulate florets of Calendula officinalis Linne (Fam. Compositae), without the presence of more than 2 per cent. of other parts of the plant or other foreign matter." N. F.

The N. F. drug is described as in "florets from 15 to 25 mm. in length, yellow- or orange-colored, one to three-toothed, four- to five-veined, margin nearly entire, the
short hairy tube occasionally enclosing the remnants of a filiform style and bifid stigma. Odor slight, somewhat heavy; taste slightly bitter, faintly saline. The powdered drug is light yellow to orange-yellow and, when examined under the microscope, exhibits a few characteristic, non-glandular hairs, consisting of a double row of thin-walled, more or less collapsed cells, with a one- or two-celled summit, and up to about 0.8 mm. in length; elongated epidermal cells with thin, somewhat wavy walls, a striated surface, and containing irregular chro-mo-plasts and oil-like globules, the latter coalescing when mounted in hydrated chloral T.S.; pollen grains, more or less spherical, with numerous spiniae projections, three pored, and up to 0.04 mm. in diameter; tracheae about 0.009 mm. in width with spiral and annular markings; prisms or rosette aggregates of calcium oxalate from 0.002 to 0.004 mm. in diameter. Calendula yields not more than 11 per cent. of ash. N. F.

The odor is much stronger in the fresh than in the dry flowers, and on exposure to light, the orange-red or yellow color fades. Among its constituents are a bitter principle, and an amorphous substance called calendulin (discovered by Geiger most abundantly in the flowers), considered by Berzelius as analogous to bassorin, though soluble in alcohol. French or African marigold, so called, is very frequently substituted for the official drug. It is the Tagetes patula L., and T. erecta Linn., both of Mexico. The flowers are readily distinguished by the scales of the involucre being united to form a tube, and by the slender, flattish achenes being crowned with a few chaffy or awned scales. The broadly strap-shaped ray-florets are toothed, and of a light or deep orange color sometimes striped with red. Latour and Magnier de la Source isolated from African marigold a yellow crystalline substance, quercetagetin, which Perkin examined and gave the composition $C_{15}H_{10}O_8$. (P. J., 1902, 294.)

In the days of therapeutic darkness calendula was thought to be medicinally active, but it has no virtues beyond that of a feeble aromatic. Both the leaves and the flowers were used; but the latter were preferred, and were usually administered in the recent state in the form of tea. Dose, from fifteen to sixty grains (0.9-3.9 Gm.) See Tinctura. Calendulae, N. F. (Part III).

Cali Nuts.—These nuts, which come from the west coast of Africa, are the seeds of a papilionaceous plant, either a species of Mucuna or Dioclea, and have a more circular shape than Calabar beans, but otherwise agree with the latter in essential external characters. They contain an alkaloid which is said to be chemically and physiologically closely allied to physostigmine. (Merck, Chem. Cb., 1887.)

Calliandrein.—A glucoside (probably a saponin) obtained from Calliandra grandiflora Benth. (Fam. Leguminosae), a Mexican shrub. It is a white, odorless powder soluble in water, the solution forming a heavy froth on shaking. It possesses antipyretic properties, having been administered with asserted good results in intermittent fever. Dose, one grain (0.065 Gm.).

Calotropis. Br. Add. Mudar.—The dried root-bark of Calotropis procera R. Brown (Asclepias procera L.) and of Calotropis gigantea R. Brown freed from the outer corky layer. These asclepiadaceous plants are natives of Hindostan, but have become widely naturalized in various parts of the East and West Indies. Their milky juice is a
violent local irritant, which, when taken internally, acts as an emeto-cathartic and may produce a fatal gastro-enteritis. In India it has long been used not only for suicidal purposes but to kill newly-born female infants, and is also applied to the womb to cause abortion.

The root-bark occurs in short, more or less quilled pieces having a thickness of from one-tenth to one-fifth of an inch (two to five millimeters) and a width of not more than one and a half inches (thirty-seven millimeters). It is covered with a soft, grayish-buff, strongly furrowed and reticulated, easily separated periderm. The fracture is short and mealy; the taste bitter and acrid. According to C. J. H. Warden and L. A. Waddel, calotropis contains an acid resin, a crystalline, colorless substance, madaralban, an amber-colored viscid body, madarfluavil, and caoutchouc. (P. J., 1885, 165.) Lewin (A. E. P. P., 1913, lxxi, 142) has found a neutral principle (calotropin) which is a very active poison of the digitalis type.

Calotropis has been very largely used as a local remedy in Hindostan in elephantiasis and leprosy, and is asserted by John Morton (Indian Medical Record, viii, 1895) to act with extraordinary efficiency upon chronic eczema. It has also been employed internally as a remedy in diarrhea and dysentery; also with less probability of usefulness in syphilis and rheumatism. Dose, of powder, from three to twelve grains (0.2-0.78 Gm.), three times a day, gradually increased until it affects the system.

Tincture of Calotropis. Tinctura Calotropis, Br. Add., two ounces to a pint (alcohol 6 per cent.), is given in doses of one-half to one nui-drachm (1.8-3.75 mils).

**Calycanthus.** Calycanthus floridus L.—This is a shrub of the fam. Calycanthaceae, from six to eight feet high, which inhabits the low, shady woods along the mountains of Georgia and North Carolina, and also Tennessee, where it is known as sweetshrub or Carolina allspice. The whole plant is aromatic, having, when crushed, the odor of strawberries. According to R. G. Eccles, the seeds contain a fixed oil, and an alkaloid, calycanthine. H. W. Wiley (A. J. P., 1890, 96) found in the seeds over 47 per cent. of oil and 4.25 per cent. of alkaloid. H. M. Gordin made an extensive investigation of calycanthine and its salts. (Proc. A. Ph. A., 1905, 224.) According to Cushny (A. I. P. T., 1905, xv, p. 487) calycanthine has the empiric formula of \( C_{11}H_{14}N_2 \). When injected into the lower animals it causes muscular weakness, by an action upon the peripheral motor nerves, associated with increased reflexes, and, in the higher mammals, with convulsions similar to those seen in picrotoxin poisoning. The alkaloid also exercises a powerfully depressant action upon the heart muscle. More recently, a second alkaloid, isocaly-canthine, has been described by Gordin. (Proc. A. Ph. A., 1908 and 1909, 889.) This alkaloid, according to the experiments of MacGuigan and Hess (J. P. Ex. T., 1912, iii), is very similar in its physiological properties to calycanthine. It is asserted that the shrub is important as a source of poisoning to cattle and sheep. Calycanthus has been used as an antiperiodic. The dose of the fluidextract is thirty to sixty minims (1.9-3.75 mils).
CALUMBA. U. S. (Br.)

CALUMBA Calumb, [Columbo, Columbia, Colombo]

“The dried root of Jateorhiza palmata (Lamarck) Miers (Fam. Menispermaceae).” U.S. “Calumba Root is the root of Jateorhiza Columba, Miers, cut in transverse slices and dried.” Br.

Calumba is official in nearly all pharmacopoeias. The difference in botanical origin as given in the definition in the U. S. and British Pharmacopoeias is merely one of synonymy, as J. palmata (Lamarck) Miers is merely another name for J. Columba Miers. There is considerable confusion in the spelling of both the generic and specific names: Jateorhiza is spelled by most of the European Pharmacopoeias Jatrorrhiza. In the same way the specific name is usually given as Calumb and not Columba.

Jateorrhiza palmata is a dioecious climbing plant, with a perennial root consisting of several fasciculated, fusiform tuberous portions. The stems are twining, cylindrical, hairy and simple in the staminate plant, being branched in the Distillate plant. The leaves, which stand on rounded, glandular, hairy footstalks, are alternate, distant, cordate, with three, five, or seven entire, acuminate, wavy, somewhat hairy lobes, and as many nerves, each running into one of the lobes. The flowers are small and inconspicuous, and arranged in solitary axillary racemes, which in the staminate plant are compound, in the pistillate simple, and in both plants are shorter than the leaves.

The Calumba plant is indigenous to Mozambique, on the southeastern coast of Africa, where it grows wild in great abundance in the thick forests extending from the sea many miles into the interior. It is more particularly abundant in the region between the Zambezi and Rovuma. (Ap. Ztg., 1912, p. 147.) The root is dug up in March, when dry weather prevails. From the base of the root numerous fusiform offsets proceed, less fibrous and woody than the parent stock. These offsets are separated and cut into transverse slices, which are dried in the shade. The old root is rejected.
The plant is said to be cultivated both in Africa and the East Indies for the sake of its root, which under the name of Calumb is used in dyeing.

Calumba is sent from the Portuguese dominions in Southeastern Africa into India, from whence it goes into general commerce. At one time, when thought to be a product of Ceylon, it was supposed to have derived its name from Columbo, a city of that island, but a much more probable derivation is from the African name of the root above given. (See Lloyd's history of Colombo root, West. Drug., 1898, 8.)

Properties.—It is officially described in the U. S. P. as "in circular or oval disks attaining a diameter of 9 cm. and seldom exceeding 2 mm. in thickness, or in longitudinal or in oblique slices attaining a length of 30 cm., a breadth of 35 mm. and a thickness of 16 mm.; externally brown and roughly wrinkled; cut surface varying from yellowish-brown to grayish-yellow, the transverse slices distinctly radiate in the outer portion and with a dark cambium; central portion often depressed; fracture short, mealy; odor slight; taste slightly aromatic, very bitter. The powder is greenish-brown to grayish-yellow; starch grains numerous, mostly single, occasionally 2- to 3-compound, the individual grains from 0.003 to 0.085 mm. in the long diameter, ovoid, ellipsoidal, frequently very irregular, slightly lamellated, with an ex-central linear x-shaped or branching cleft; stone cells few with irregularly thickened, strongly lignified, coarsely porous walls and containing one or more prisms of calcium oxalate from 0.01 to 0.03 mm. in length, or numerous sphenoidal micro-crystals; fragments with trachea? few, the latter with reticulate thickenings or bordered pores, and associated with wood-fibers having long, oblique, slit-like pores. Calumba yields not more than 8 per cent. of ash." U. S.

The drug is described in the British Pharmacopoeia as follows: " Cork thin, brownish and wrinkled; cortex thick, yellowish and separated by a dark line from the greyish wood, in which the parenchymatous tissue is largely developed and the vessels arranged in narrow elongated groups. In the cortex, in transverse section, numerous isolated scler-enchymatous cells, with yellow, irregularly thickened walls enclosing small prismatic crystals of calcium oxalate; in the wood, vessels with yellow reticulated walls. The parenchymatous cells of both wood and cortex filled with starch grains, which are irregularly ovoid in outline, from 20 to 70 microns in length, and exhibit a conspicuous, excentric, radicate or cleft hilum." Br.
Along with the disks are sometimes a few cylindrical pieces an inch or two in length. The cortical portion is thick, of a bright yellow, slightly greenish color internally, but covered with a brownish, wrinkled epidermis. The interior or medullary portion, which is readily distinguishable from the cortical, is light, spongy, yellowish, usually more or less shrunk, so that the pieces are thinnest in the centre; and is often marked with concentric circles and radiating lines. Those pieces are to be preferred which have the brightest color, are most compact and uniform, and least worm eaten.

The odor of calumba is slightly aromatic. The taste is very bitter, that of the cortical much more so than that of the central portion, which is somewhat mucilaginous. The root is easily pulverized. The powder is greenish, becoming browner with age, and deepening when moistened. As it attracts moisture from the air, and is apt to undergo decomposition, it should be prepared in small quantities.

The crude drug, as well as the powder, is liable to be attacked by insects if kept for any length of time. This can be guarded against by thoroughly drying the drug, keeping it in a dry place, and adding either carbon tetrachloride or chloroform. According to the U. S. P. microscopical description, it is inferred that the calcium oxalate crystals occur only in the stone cells. Tunmann (Ph. Zentrblh., 1906, p. 1069) asserts that the crystals are distributed throughout the woody portion of the root as well as in the bark, and outlines a method for readily demonstrating their presence.

**Adulterations.**—Formerly the high price of calumba led to its frequent adulteration, especially, it is said, with the roots of the white bryony, and of Frasera carolinensis or American calumba, and with the stem of Coscinium fenestratum, the columbo wood or false columbo of Ceylon. According to Stoize of Halle, the American calumba can be readily detected by the fact that while the tincture of true calumba is not affected by ferric sulphate or sesqui-chloride, and yields with tincture of galls a dirty precipitate, the tincture of Frasera becomes dark green with the former and is not affected by the latter reagent. Coscinium fenestratum, a bitter tonic used in Ceylon, is at once to be distinguished by its being a stem, not a root, and is said not to have appeared upon the market for many years. At present, owing to its great cheapness, calumba root seems to be very rarely adulterated (see P. J., 1901, 502,
and Dec., 1904), although a specimen of calumba yielded, on incineration, 16 per cent. of ash. Holmes believes that the fictitious drug is the overground portion of *Jateorrhiza palmata*, while Wardleworth believed that the drug is a product of *Tinospora Bakis* (A. Rich.) Miers which is used in Senegal as an anti-periodic.

**Chemistry.**—Planche analyzed calumba in 1811, and found it to contain a nitrogenous substance, probably albumen, in large quantity, a bitter yellow substance not precipitated by metallic salts, and one-third of its weight of starch. He obtained also a small proportion of volatile oil, salts of calcium and potassium, ferric oxide, and silica. Wittstock, of Berlin, afterwards isolated a principle, which he called columbin. This crystallizes in beautiful transparent quadrilateral prisms of the formula $C_{21}H_{22}O_7$, is without odor, and is extremely bitter. It is but very slightly soluble in water, more soluble in alcohol, ether, or chloroform, and imparts to these fluids a strongly bitter taste. It is more soluble in boiling alcohol, which deposits it upon cooling. The best solvent is diluted acetic acid. It is taken up by alkaline solutions, from which it is precipitated by acids. It is obtained by exhausting calumba by means of alcohol of the sp. gr. 0.835, distilling off three-quarters of the alcohol, allowing the residue to stand for some days until crystals are deposited, and lastly treating these crystals with alcohol and animal charcoal. The mother waters still contain a considerable quantity of columbin, which may be separated by evaporating with coarsely powdered glass to dryness, exhausting the residue with ether, distilling off the ether, treating the residue with boiling acetic acid, and evaporating the solution to crystallization.

P. E. Alessandri (L'Orusi, v, 1; P. J., 1882, p. 995) isolated cumbine (which he considers an alkaloid) by the following process: An infusion of calumba is made with a 3 per cent. solution of oxalic acid; the yellow bitter liquid is neutralized with ammonia and evaporated to one-third its bulk; it is, when cooled, treated with ether, separated, and the ethereal solution on evaporation yields pure white calumbine. Allesandri obtained what he called berberine from calumba by neutralizing a cold infusion, made with diluted oxalic acid (3 per cent.), with baryta; the precipitate which is produced is separated. The liquid is heated, allowed to stand for twenty-four hours to allow the barium oxalate to deposit, filtered, and then a current of carbonic acid is passed through to remove barium oxide. It is then treated by shaking the ammoniacal liquid with ether as in Alessandria process for calumbine (see above), and, after the
ethereal layer is separated, the aqueous liquid is evaporated to dryness. Columbic acid may be obtained from the precipitate produced by the addition of barium oxide to the oxalic acid infusion. Bocchiola (Y. B. P., 1891, p. 162) states that the older roots contain more of the active principles than the younger ones. He found that the inner and the outer portions of ealumba also vary in their constituents;

thus in the woody or inner part he found the following percentages: calumbine 1.90, berberine 0.72, ether extract 0.80, alcoholic extract 3.86, diluted alcoholic extract 17.80, ash 6. In the cortical or outer part he found calumbine 1.42, berberine 1.43, ether extract 0.70, alcoholic extract 3.89, diluted alcoholic extract 17.96, ash 5. He assigns to columbin the formula C_{21}H_{24}O_{7}, and to columbic acid C_{21}H_{22}O_{6}. (Zeit. Oest. Apoth. Ver., 1896, No. 1, 8-14.) Gordin questioned the presence of berberine in calumba and Gadamer, Feist and Gunzel proved the absence of berberine and stated that ealumba contains calumbamine, C_{21}H_{22}O_{5}N.OH, jateorrhizine, C_{20}H_{20}O_{5}N.OH, and probably palmatine, C_{22}H_{24}O_{5}N.OH, the last formula not having been positively proved. (A. Pharm., 1907, No. 8, 586.) Haensel (P. J., 1904, 216) obtained from calumba a volatile oil which exists in very small quantities (0.00568 per cent). It has a peculiar odor and bitter taste.

There can be little doubt that both columbin and the alkaloids contribute to the remedial effects of ealumba. The virtues of the root are extracted by boiling water and by alcohol. Precipitates are produced with the infusion and tincture by infusion of galls, and by solutions of lead acetate and subacetate, but the bitterness is not affected.

**Uses.**—Biberfeld (Z. E. P. T., 1909, vii) has shown that all the alkaloids of ealumba root are depressant to the central nervous system and especially to the respiratory center; palmatine indeed exceeds morphine in its respiratory toxicity; calumbamine and jateorrhizine increases intestinal tonus. Despite these findings, however, it is improbable that ealumba has any medical virtue aside from that of a mild bitter, free from astringency. It is useful in functional atonic conditions of the digestive organs, especially with other tonics, aromatics, or cathartics. A favorite remedy of the late George B. Wood for the cure of a disposition to the accumulation of flatus in the bowel was an infusion made with half an ounce of ealumba, half an ounce of ginger, a drachm of senna, and a pint of boiling water, and given in doses of a wine-glassful three
times a day. By the natives of Mozambique it is used in dysentery and various other diseases.

Dose, of the powder, from ten to thirty grains (0.65-2.0 G-m.), which may be repeated three or four times a day.

**Calystegia Solandella.**—This plant—a member of the Convolvulaceous family—has lately come into vogue as a constipation remedy. A compound tincture of solandella has been used with some success, but whether this can be attributed to the calystegia or to other ingredients is not known.

**Cam Wood.**—A red dye-wood, procured from the Baphia nitida Lodd., a leguminous tree, growing on the western coast of Africa. The wood is usually kept in the shops in the ground state. It yields its coloring matter scarcely at all to cold water, slightly to boiling water, and readily to alcohol and alkaline solutions. The coloring matter is thought to be identical with santalin, C₁₅H₁₄O₅.

**CAMBOGIA. U. S.**

**GAMBOGE Cambog. [Pipe Gamboge]**

"A gum-resin obtained from Garcinia Hanburii Hooker filius (Fam. Guttiferae)." U. S.

Cambogia, Br. 1898; Gambogia, U. S. Pharm. 1870; Gummi-resina guttae (s. gutti), Gutta Gamba, Cambodia; Gommegutte, Fr. Cod.; Gutte, Fr.; Gutt, P. G.; Gummigutt, G.; Gumma gottia, It.; Gutagamba, Goma gutta, Sp.

Under the name of Cambogia Indica, Indian Gamboge, the British Addendum formerly recognized a gum-resin obtained from the Garcinia Morella Desrousse. Several plants belonging to the family of Guttiferae, growing in the equatorial regions, yield on incision a yellow opaque juice, which hardens on exposure and bears a close resemblance to gamboge; but it is only from a particular tree, growing in Siam, that the official gum-resin is procured. According to observations of Baildon and Jamie, gamboge is obtained exclusively from the province of Cambodia, the plant not being found in any other part of Siam nor in Cochin China. (J. P. C., Juillet, 1874.) Several years since, Christison received from Singapore specimens of the gamboge plant cultivated in that island, and derived from Siam, which proved to be a Garcinia, differing...
from the G. elliptica of Wallieh chiefly in having its male flowers upon pedicels. Subsequently Hanbury obtained from the same source numerous specimens of the same plant, and was enabled to confirm the statement of Christison; but he also found that the plant approached very near to the Garcinia Morella of Desrousseaux, from which it could be distinguished only by its pedicellate flowers. These specimens were afterwards submitted to the inspection of Thwaites in Ceylon, who is perfectly familiar with the Garciniias of that island, and were pronounced by him to belong to a variety of G. Morella, scarcely differing from the Ceylon plant, except in having pedicellate instead of sessile flowers; for these two varieties the names of G. Morella, var. sessile, and G. Morella, var. pedicellata, were proposed. Sir Joseph Hooker, however, determined (Journ. Linn. Soc., xiv, 485) that the var. pedicellata is a distinct species, differing from G. Morella in having not only its flowers pedicellate, but also its leaves more ovate and much larger, and its fruit larger; he very properly gave it the specific name of Hanburii to commemorate the contributions of the late Mr. Hanbury to pharmaceutical science; and its connection with the history of the present plant. According to the researches of Beckett, G. Hanburii is confined to the islands and sea coast of the Gulf of Siam, where it is known as "Ton Rong," and where it grows to the height of fifty feet, with a diameter of twelve inches.

It is doubtful if all of the Gamboge of commerce is obtained from Garcinia Hanburii. Some of it is probably obtained from G. Morella Desr. and G. Roxburghii Engler, plants growing in Canara; G. Wightii T. Anders, a plant of Southern Farther India; G. tetrandra Wall., G. Gaudichaudii Planch, et Triana growing in Cochin China and G. pictoria (Roxb.) Engl, a plant found in Ceylon and Farther India.

Ceylon gamboge, derived from G. pictoria, Roxb., is procured by incisions, or by cutting away a portion of the bark, and scraping off the juice which exudes. The specimens sent to Christison were in flatfish or round masses, eight or nine inches in diameter, apparently composed of aggregated irregular tears, with cavities which are lined with a grayish and brownish powdery incrustation. It resembled coarse gamboge, and was identical in composition. In Ceylon it is used as a pigment and purgative. (Christison.) New Caledonian Gamboge, derived from Garcinia collina Vieil, is described by Heckel and Schlagdenhauffen as very similar in its appearance and reactions to ordinary gamboge; its color is, however, deep orange. A white crystalline compound, which
when heated beyond 235° C. (455° F.) produced pyrocatechin, was found in it, and marked the point of difference between it and other varieties of gamboge. (Rep. de Pharm., 1893, 193.)

Gamboge is said to be procured in Siam by breaking off the leaves and shoots of the tree; the juice, which is contained in ducts or latex vessels in the bark, issues in drops, and, being received in suitable vessels, gradually thickens, and at length becomes solid. Jamie, of Singapore, states that incising the trunk and larger branches is often practised. The juice is frequently received into the hollow joints of the bamboo, and the water expelled by mild continuous heat. In this way the so-called pipe gamboge is formed, the contraction during drying causing the cylinders to be hollow. According to Beckett, Siam gamboge is obtained only from trees of not less than ten years of age and during the rainy months, from June to October, by cutting long, spiral grooves into the bark and collecting in hollow bamboos the sap which trickles down in a viscous stream. (Kew Bulletin, 1895.)

The name gummi gutta, by which gamboge is generally known on the continent of Europe, probably originated from the circumstance that the juice escapes from the plant by drops. The official title was undoubtedly derived from the province of Cambodia, in which the gum-resin is collected. Gamboge was first brought to Europe by the Dutch, about the middle of the seventeenth century. We import it from Canton and Calcutta, whither it is carried by the native or resident merchants. There is no difference in the appearance or character of the drug as brought from these two ports—an evidence that it is originally derived from the same place.

**Varieties.**—The best gamboge is in cylindrical rolls, from two to five centimeters in diameter, sometimes hollow in the centre, sometimes flattened, often folded double, or agglutinated in masses so that the original form is not always easily distinguishable. The pieces sometimes appear as if rolled, but are in general striated longitudinally from the impression made by the inner surface of the bamboo. They are externally of a dull orange color, which is occasionally displaced by greenish stains, or concealed by the bright yellow powder of the drug, slightly adhering to the surface. In this form the drug is sometimes called pipe gamboge. Another variety is imported under the name of cake or lump gamboge. It is in irregular masses weighing a kilo or more, often mixed with sticks and other impurities, containing many air-cells,
less dense, less uniform in texture, and less brittle than the former
variety, and breaking with a dull and splintery instead of a shining and
conchoidal fracture. The worst specimens of this variety, as well as of
the cylindrical, are sometimes called by the druggists coarse gamboge.
They differ, however, from the preceding only in containing a greater
amount of impurities. Indeed, it would appear from the experiments of
Christison, that all the commercial varieties of this drug have a common
origin, and that cake or lump gamboge differs from the cylindrical only
in the circumstance that the latter is the pure concrete juice, while to the
former, farinaceous matter and other impurities have been added for
the purpose of adulteration. The inferior kinds of gamboge may be
known by their greater hardness and coarser fracture; by the brownish
or grayish color of their broken surface, which is often marked with
black spots; by their obvious impurities, and by the green color which
their decoction, after cooling, gives with tincture of iodine (starch).
When pure, the gum-resin is completely dissolved by the successive
action of ether and water, so that the amount of residue left by any
specimen treated in the manner just spoken of indicates approximately
the measure of the adulteration.

Properties.—The official description is as follows: "In hard, brittle,
cylindrical pieces, usually hollow in the center, from 2 to 5 cm. in
diameter, from 10 to 20 cm in length, externally grayish-orange-brown,
longitudinally striate; fracture conchoidal, smooth, orange-red; odorless;
taste very acrid. When rubbed with water it yields a yellow emulsion
which becomes darker and almost transparent upon the addition of
ammonia water. The emulsion turns green upon the addition of iodine
T.S. (starch). The powder is bright yellow, containing few or no starch
grains. When mounted in hydrated chloral T.S. and examined under the
microscope the particles, for the most part, slowly dissolve, leaving
scattered fragments of vegetable tissues. Not less than 65 per cent. of
Gamboge is soluble in alcohol. Gamboge yields not more than 2 per cent.
of ash." U. S.

From the brilliancy of its color, gamboge is highly esteemed as a
pigment. It has no odor, and little taste, but, after remaining a short
time in the mouth, produces an acrid sensation in the fauces. Its sp. gr.
is 1.221. "When solution of iodine is added to a cooled aqueous
decoction, the color should not become distinctly green (absence of more
than a trace of starch), When incinerated it should not yield more than
3 per cent. of ash." Br. 1898. It is a gum-resin, without volatile oil.
Christison has shown that the proportion of gum and resin varies in different specimens even of the purest drug. In one experiment, out of 100.8 parts he obtained 74.2 of resin, 21.8 of gum, and 4.8 of water. The gum is quite soluble in water, and of the variety denominated arabin. Fluckiger, however, says that the gum is not identical with gum arabic, as its solution does not redden litmus, and is not precipitated by neutral lead acetate, nor by ferric chloride, nor by sodium silicate or bib orate. By fusing purified gamboge resin with potassium hydroxide, Hiasiwetz and Earth (Ann. Ch. Ph., 138, 61) obtained acetic and other acids of the same series, together with phloroglucin, $C_6H_3(OH)_3$, pyrotartaric acid, $C_5H_8O_4$, and isouvitinic acid, $COOH.C_6H_4.CH_2COOH$. Sassarini found gamboge to contain the following constituents: 1. Gum analogous to arabin. 2. Volatile oil, consisting of ter-pene and a camphor. 3. Isouvitinic and acetic acids. 4. A phenol ester. 5. Resin. 6. Methyl alcohol and some higher homologues. 7. A liquid having a fruity odor resembling aldehyde or acetone. He believes phloroglucin found by others to be a decomposition product. (Ann. di Chim. Farm., 1897.) Gamboge is readily and entirely diffusible in water, forming a yellow opaque emulsion, from which the resin is very slowly deposited. It yields its resinous ingredient to alcohol, forming a golden-yellow tincture, which is rendered opaque and bright yellow by the addition of water. Its solution in ammoniated alcohol is not disturbed by water. Ether dissolves about four-fifths of it, taking up only the resin. It is wholly taken up by alkaline solutions, from which it is partially precipitated by the acids. The strong acids dissolve it; the solution when diluted deposits a yellow sediment. The color, acrimony, and medicinal power of gamboge are thought to reside in the resin. Hirschsohn gives a method for detecting gamboge in mixtures in Ph. Z. R., xxiv. (A. J. P., 1885.)

**Uses.**—Gamboge is a powerful, drastic, hydragogue cathartic, so very apt to produce nausea and vomiting and much griping when given in the full dose that it is almost never employed except in combination with other cathartics. In large quantities it is capable of causing fatal effects, and death has resulted from a drachm. The full dose is from two to six grains (0.13-0.4 Gm.), which in cases of tenia has been raised to ten or fifteen grains (0.65-1.0 Gm.). It may be given in pill or emulsion, or dissolved in an alkaline solution. In the dose of five grains (0.32 Gm.) the resin is said to produce copious watery stools, with little or no uneasiness. If this be the case, it is probable that, as it exists in the gum-resin, its purgative property is somewhat modified by the other ingredients.
Dose, two grains (0.13 Gm.).

**Off. Prep.**—Pilulas Catharticae Compositae, U.S.

**Canada Pitch.** Pix Canadensis. U. S. 1880. Hemlock Pitch.—The Tsugacanadensis (L.) Carr, Hemlock or Hemlock Spruce of the United States and Canada, when of full growth, is often seventy or eighty feet high, with a, trunk of two or three feet in diameter, and of nearly uniform dimensions for two-thirds of its length. Its leaves are scattered, short, linear, obtuse, from 8 to 13 mm. in length, whitened beneath and appearing as two-ranked. The strobiles are ovate, little longer than the leaves, terminal and pendulous.

The tree is abundant in Canada, Nova Scotia, and the more northern parts of New England, and is found in the elevated and mountainous regions of the Middle States. Its bark is much used for tanning, an extract being made for the purpose. The tree contains much less juice than some other of the Pinaceae, and very little flows from incisions made into its trunk. But in the trees which have attained their full growth, and are about to, or have begun to, decay, the juice exudes spontaneously, and hardens upon the bark, in consequence of the partial evaporation or oxidation of its volatile oil. The bark thus incrusted is stripped from the tree, broken into pieces, and boiled in water. The pitch melts, rises to the surface, is skimmed off, and is still further purified by a second boiling in water. Hemlock pitch is hard, brittle, quite opaque, of a dark reddish-brown color, becoming still darker by exposure to the air, of a weak peculiar odor, and scarcely any taste. It softens and becomes adhesive with a moderate heat, and even at ordinary temperatures takes the form of the vessel containing it, and melts at 92.2° C. (198° F.).

The constituents of this pitch are resin and a minute proportion of volatile oil. It is sometimes known by the incorrect name of 'hemlock gum. Canada pitch is a gentle rubeufacient, closely analogous to Burgundy pitch in its properties, and employed for precisely the same purposes. It is, however, more readily softened by heat, and is sometimes almost too soft for convenient application at the temperature of the body. A volatile oil obtained from *Tsuga canadensis*, and called oil of spruce or oil of hemlock, has been employed to & considerable extent in veterinary liniments. It has also been used as an abortifacient, with the effect of endangering the life of the woman. (J. S. Paige, N. Y. M. J., viii, 184.)

W. Zinn (M. M. W., Oct., 1902) reports a case of stupor and involuntary evacuation of urine, and collapse with subsequent psychic disturbance, as produced by the inhalation for many hours of the emanations from branches of *Pseudotsugatascifolia* (Lamb.) Britton (P. Douglassi Car.).

The U. S. Pharmacopoeia of 1880 gave the following directions for preparing the Hemlock or Canada Pitch Plaster (Emplastrum, Picis Canadensis, U. S., 1880): "Canada Pitch, ninety parts [or nine ounces av.]; Yellow Wax, ten parts [or one ounce, av.], to make one hundred parts [or ten ounces av.]. Melt them together, strain the
mixture, and stir constantly until it thickens on Cooling." U. S., 1880.

**Canary Seed.** Fructus (Semen) Canariense, SemencedeCanarie, Fr. Kamariensamen, G.—The seeds of Phalaris canariensis L., an annual grass originally from the Canary Islands, but now growing wild in Europe and the United States. The seeds are ovate, somewhat compressed, about 5 mm. long, shining and of a light yellowish-gray color externally, and light within. Their chief constituent is starch, and they are used chiefly as bird seed.

**Canchalagua.**—This plant, Erythraea venusta A. Gray (Fam. Gentianaceae), found on our Pacific coast, is a valuable bitter tonic and stomachic. (Ph. Rec., 1887, 363.) Erythraea australis R. Br. is said to be similarly used in Australia. (P. J., xix.)

**Canella.** N. F. IV.—The N. F. describes it as "the dried inner bark of Canella Winterana (Linne) Gaertner (Fam. Canellaceae). In quills usually from 1 to 3 dm. in length and from 1 to 4 cm. in thickness, occasionally two or three times this size, or in irregular fragments of quills, from 1.5 to 5 mm. in thickness and 2 to 3 cm. in width, the outer periderm mostly removed; outer surface light brownish-yellow or pale orange-brown, more or less scaly, with a very few shallow fissures, often more or less reticulate with slight ridges; inner surface paler, somewhat smooth, but showing coarse, longitudinal striae; fracture short and sharp, pale yellow, with an irregular, slightly darker band just inside of the center. Odor slight (Unless the bark is heated, then aromatic, resembling that of cinnamon; taste aromatic, warm, somewhat bitter and mucilaginous. The powdered drug is light brown to brownish-red and, when examined under the microscope, exhibits numerous, isodiametric, thick-walled stone cells about 0.075 mm. in diameter, the walls with simple or branching pores; calcium oxalate in rosette aggregates up to 0.05 mm. in diameter; starch grains simple or two- to three-compound up to 0.02 mm. in diameter; oil cells with suberized walls numerous. Canella yields not more than 7 per cent. of ash." N. F. It was formerly recognized by the U. S. and Br. Pharmacopoeias. The tree is a native of Florida and the Bahama and West India Islands. The bark of the branches, which is the part employed in medicine, is loosened and deprived of its epidermis by beating. After removal from the tree it is dried in the shade. It enters commerce solely from the Bahamas, where it is known as cinnamon bark, or as white wood bark. At first it was considered to be a variety of cinnamon bark and was at one time confused with Winter's bark. Boiling water extracts nearly one-fourth of its weight; but the infusion, though bitter, has comparatively little of the warmth and pungency of the bark. It yields all its virtues to alcohol, forming a bright yellow tincture, which is rendered milky by the addition of water. Canella bark yields from distillation from 0.75 to 1.25 per cent. of a volatile oil, having an odor resembling that of a mixture of cajeput and clove. It contains benzoyl eugenol; 1-pinene; cineol and caryophyllene. The bark yielded to Fluckiger 0.74 per cent. of oil. According to John P. Prey, it contains volatile oil, 1.28 per cent.; resin, 8.2 per cent.; mannite, 8 per cent.; ash, 8.9 per cent.; also starch, bitter principle, albumen, and cellulose. (A. J. P., 1884, 1.) Canella has been sometimes confounded with Winter's bark, from which, however, it differs widely. (See Wintera.) It is a mild, aromatic tonic, very acceptable to the stomach, and especially as an addition to tonic or purgative medicines. It is scarcely ever prescribed except in
combination. Its best known compound is the famous Pulvis Aloe et Canellae (see Part III), commonly known as Hiera Picra, literally "Sacred Bitters," from the esteem in which it was once held. In the West Indies it is employed by the negroes as a condiment and as an antiscorbutic. Dose, ten to forty grains (0.65-2.6 Gm.).

Cangoura.—An evergreen creeper, Bouea oblongifolia (Fam. Anacardiaceae), from the seeds of which the natives of Salvador are said to produce a paste which is a violent nerve poison, producing in some cases delirium lasting as long as eight days. (Nouv. Rem; April, 1892.)

**CANNABIS. U. S. (Br.)**

**CANNABIS Cannab. [Indian Hemp Cannabis Indica U. S. VIII, Guaza, Ganjah]**

"The dried flowering tops of the pistillate plants of Cannabis sativa Linne, or of the variety indica Lamarck (Fam. Moraceae), freed from the thicker stems and large foliage leaves and without the presence or admixture of more than 10 per cent. of fruits or other foreign matter. Cannabis, made into a fluidextract in which one hundred mils represent one hundred grammes of the drug, when assayed biologically, produces incoordination when administered to dogs in a dose of not more than 0.03 mil of fluidextract per kilogramme of body weight." U. S. "Indian Hemp consists of the dried flowering or fruiting tops of the pistillate plant of Cannabis sativa, Linn., grown in India; from which the resin has not been removed." Br.

**CannabisIndicae, Br.; Hemp, Indian Hemp; Herba Cannabis ludicae; Chanvre, Fr. Cod.; Chanvre de l'Inde, Fr.; Indischer Hanf, G.; Cañamo, Sp.**

For many years the official cannabis was restricted to the drug which was used for centuries in India. The reason for this was that the Indian cannabis was more uniformly active. Recently the Indian Government has placed a high tax on every pound of the drug grown. The result has been that other markets have been sought and the hemp plant has been grown in other parts of Asia, Africa and America. While of course, much of this material is not equal to that grown in India yet the fact that it can be grown, as shown by experiments in the United States (see Hamilton, J. A. Ph. A., 1913, ii; 1915, iv, 389) of a very high quality has caused the framers of the U. S. Pharmacopoeia to permit the use of a cannabis, no matter where it may be grown, provided it comes up to the biological standard as given in the definition. Physiologically active cannabis is obtained at the present time not only from India, but Africa,
Turkey, Turkestan, Asia Minor, Italy, Spain and the United States.

The Cannabis sativa, or hemp plant, is an annual, from four to eight feet or more in height, with an erect, branching, angular stem. The leaves are alternate or opposite, and digitate, with five to seven linear-lanceolate, coarsely serrated segments. The stipules are subulate. The flowers are axillary; the staminate in long, branched, drooping racemes; the pistillate in erect, simple spikes. The stamens are five, with long pendulous anthers; the pistils two, with long, filiform, glandular stigmas. The fruit is ovate and one-seeded. The whole plant is covered with a fine pubescence, scarcely visible to the naked eye, and somewhat viscid to the touch. The hemp plant of India has been considered by some as a distinct species, and named Cannabis indica; but the most observant botanists, upon comparing it without cultivated plant, have been unable to discover any specific difference. It is now, therefore, regarded merely as a variety, and is distinguished by the epithet indica. Pereira states that in the female plant the flowers are somewhat more crowded than in the common hemp, but that the male plants in the two varieties are in all respects the same.

C. sativa is a native of the Caucasus, Persia, and the hilly regions in Northern India. It is cultivated in many parts of Europe and Asia, and largely in our Western States. It is from the Indian variety exclusively that the medicine was formerly obtained, the heat of the climate in Hindostan apparently favoring the development of its active principle. H. C. Wood, many years ago, obtained a parcel of the male plant of C. americana (C. sativa) from Kentucky, made an alcoholic extract of the leaves and tops, and, upon trying it on the system, found it effective in less than a grain, and, having inadvertently taken too large a dose, experienced effects which left no doubt of the powers of the medicine, and of the identity of its influence with that of the Indian plant. (Proc. Am. Philos. Soc., vol. xi, p. 226.) The results obtained by H. C. Wood have been confirmed by a number of observers.

The fruits or "so-called" seeds, though not now official, have been used in medicine. They are from three to five millimeters long and about two millimeters broad, roundish-ovate, somewhat compressed, of a shining ash-gray color, and of a disagreeable, oily, sweetish taste. For a comprehensive monograph on the morphology of cannabis fruits, as well as their history and chemical composition, see Tsehirch, "Handbuch der Pharmakognosie" p. 555. They yield by expression about 20 per cent. of
a fixed oil, "which has the drying property, and is used in the arts. They contain also uncrystalli-zable sugar and albumen, and when rubbed with water form an emulsion, which may be used advantageously in inflammations of the mucous membrane, though without narcotic properties. The seeds are much used as food for birds, as they are fond of them. They are generally believed to be in no degree poisonous; but Michaud relates the case of a child in whom serious symptoms of narcotic poisoning occurred after taking a certain quantity of them. It is probable that some of the fruit eaten by the child was unripe, as in this state it would be more likely to partake of the peculiar qualities of the plant. (Ann. Ther., 1860.)

In Hindostan, Persia, and other parts of the East, hemp has long been habitually employed as an intoxicating agent. The parts are the tops of the plant, and a resinous product obtained from it. Bhang is the selected, dried and powdered leaves. Ganjah or gunjah is the tops of cultivated female plants, cut directly after flowering, and formed into round or flat bundles from two to four feet long by three inches in diameter. It is stated that in the province of Bengal great care is taken to eradicate the male plants from the fields before fertilization of the female, and that thereby the yield and quality of the resin is greatly increased. In Bombay this matter is commonly neglected, so that Bengal ganjah is much superior to Bombay ganjah. It is recognized in India that ganjah rapidly deteriorates on keeping, that which is one year old being not more than one-quarter as potent as the fresh drug, while two-year-old ganjah is practically inert and is required by the Indian government to be burned in the presence of excise officers. It is probable, however, that much old ganjah finds its way into the markets of the world. All importations of ganjah or hemp from India should be made directly after the harvesting of the new crop in April or May, and the extract should be prepared at once and kept in hermetically sealed jars. There is on the surface of the plant a resinous exudation to which it owes its stickiness. According to Hooper (P. J., 1909, Ixxxi, 347) only small amounts of charas are raised in India, that which is being consumed there being mostly imported. The method of collection in Baluchistan is to gently rub the dried plant between carpets. The dust which comes off contains the active principle and is known as "rup." The second shaking produces an inferior variety, known as "tah-galim" and the third shaking is known as "ganja." In Nepal the plant is squeezed between the palms of the hands, and the resin scraped off from the hands. These balls, and also masses formed out of resin
mechanically separated from the hemp plant are called charas or churrus. This is the hashish or hasheesh of the Arabs.

Hashish is also produced in considerable quantities in Persia by rolling and rubbing the flowers, stalks and leaves of hemp on rough woolen carpets and subsequently scraping off with a knife and making into balls or sticks the adherent resinous substance. The carpets are afterwards washed with water and the extract obtained by evaporation sold at a low price. The dose for smoking of the best hashish is said to be one-fourth to one grain (0.016-0.065 Gm.). The fanatics are affirmed to be generally hashish devotees.

The dealing in hashish in India is said to be a Government monopoly, and a very heavy license is required for the right to even purchase it in quantity. The importation of it into Egypt is so strongly interdicted that the mere possession of it is a penal offense; H. C. Wood found it, however, readily procurable. It is said to be brought into the country in pigs' bladders, in the Indo-European steamers, and thrown out at night during the passage into the Suez canal, to be picked up by the boats of confederates. Notwithstanding the Governmental interdiction, it is largely used by smoking in Egypt, as an intoxicant. The statement of W. E. Dixon (B. M. J., Nov., 1899) that the inhalations of hemp smoke produces great exhaliation and causes muscular fatigue to disappear for the time being is undoubtedly correct, but his further belief that the habit is not apt to grow upon the hemp votary is more doubtful.

Momea or mimea is a hemp preparation said to be made in Thibet with human fat. From gunjah the Messrs. Smith, of Edinburgh, obtained a purer resin by the following process: Bruised ganjah is digested, first in successive portions of warm water, until the expressed liquid comes away colorless; and afterwards for two days, with a moderate heat, in a solution of sodium carbonate, containing one part of the salt for two of the dried herb. It is then expressed, washed, dried, and exhausted by percolation with alcohol. The tincture, after being agitated with milk of lime containing one part of the earth for twelve of the gun jah used, is filtered; the lime is precipitated by sulphuric acid; the filtered liquor is agitated with animal charcoal, and again filtered; most of the alcohol is distilled off, and to the residue twice its weight of water is added; the liquor is then allowed to evaporate gradually; and, finally, the resin is washed with fresh water until it ceases to impart a sour or bitter taste to the liquid, and is then dried in thin layers. Thus obtained, it retains the
odor and taste of gunjah, which yields from 6 to 7 per cent. of it.

**Properties.**—Fresh hemp has a peculiar narcotic odor, which is said to be capable of producing vertigo, headache, and a species of intoxication. It is much less in the dried tops, which have a feeble bitterish taste. According to Royle, churrus is, when pure, of a blackish-gray, blackish-green, or dirty olive color, of a fragrant and narcotic odor, and a slightly warm, bitterish, and acrid taste. Cannabis is officially described as "in dark green or greenish-brown and more or less agglutinated fragments, consisting of the short stems with their leaf-like bracts and pistillate flowers, some of the latter being replaced with more or less developed fruits; stems cylindrical, of varying length, not more than 3 mm. in diameter, longitudinally furrowed, light green to light brown, strigose-pubescent; leaves digitately compound; leaflets, when soaked in water and spread out, linear-lanceolate, nearly sessile, margin deeply serrate, bracts ovate, pubescent, each enclosing one or two pistillate flowers, or more or less developed fruits; calyx dark green, pubescent and somewhat folded around the ovary or fruit; styles two, filiform and pubescent; ovary with a single campylotropous ovule; fruit light green to light brown, broadly ellipsoidal, about 3.5 mm. in length, finely wrinkled and slightly reticulated; odor agreeably aromatic; taste characteristic. The powder is dark green, giving a strong effervescence on the addition of dilute hydrochloric acid; numerous sharp pointed fragments of upper portion of non-glandular hairs and fragments of bracts and leaves showing yellowish-brown laticiferous vessels, rosette aggregates of calcium oxalate from 0.005 to 0.025 mm. in diameter; non-glandular hairs unicellular, with a very slender pointed apex and a considerably enlarged base containing, usually in the lumen, some calcium carbonate; glandular hairs of two kinds, one with a short, one-celled stalk and the other with a multicellular, long, tongue-shaped stalk, the glandular portion being globular and consisting of from 8 to 16 cells, fragments of fruits with palisade-like, non-lignified sclerenchymatous cells, walls yellowish-brown, finely porous, the lumina usually containing air; tissues of embryo and endosperm with numerous oil globules and aleurone grains, the latter from 0.005 to 0.01 mm. in diameter and consisting of large crystalloids and globoids. The yield of alcohol extractive is not less than 8 per cent. and the alcoholic solution is of a bright green color. Cannabis yields not more than 15 per cent of ash."

The British Pharmacopoeia describes Indian cannabis as follows:

The British Pharmacopoeia describes Indian cannabis as follows:
"In compressed, rough, dusky-green masses, consisting of the branched upper part of the stem, bearing leaves and pistillate flowers or fruits, matted together by a resinous secretion. Upper leaves simple, alternate, 1-3 partite; lower leaves opposite and digitate, consisting of five to seven linear-lanceolate leaflets with distantly serrate margins. Fruit one-seeded and supported by an ovate-lanceolate bract. Both leaves and bracts bear external oleo-resin glands and one-celled curved hairs, the bases of which are enlarged and contain cystoliths. Strong, characteristic odor; taste slight. When a mixture of 10 grammes of finely powdered Indian Hemp and 100 millilitres of alcohol (90 per cent.) is shaken occasionally during twenty-four hours and then filtered, 20 millilitres of the filtrate, evaporated in a flat-bottomed dish, yield a residue weighing, when dried at 100° C. (212° F.), not less than 0.250 gramme. Ash not more than 15 per cent."

Br.

For a histological description of the leaf by A. R. L. Dohme, see Proc. A. Ph. A., 1897, 569. The Cannabis of the market may consist of fruiting tops and stems and occasionally the staminate tops are admixed with it.

Hooper (P. J., Ixxxii, p. 80) describes a method for the chemical standardization of cannabis indica based upon its iodine value. He finds that the alcoholic extract of old samples has a lower iodine value than that from recent specimens, and there is more or less constancy of relation between the age and the iodine value.

Indian churrus or hasheesh is a hard resinous mass of a greenish-gray color, containing much gritty earth, and, as it occurs in Egypt, of a feeble, hemp-like odor and taste. Schlesinger found in the leaves a bitter substance, chlorophyll, green resinous extractive, coloring matter, gummy extract, extractive, albumen, lignin, and salts. The plant also contains volatile oil in very small proportion, which probably has narcotic properties. The resin obtained by T. & H. Smith of Edinburgh, in 1846, has been thought to be the active principle, and received the name of cannabin. By repeated distillation of the same portion of water from relatively large quantities of hemp renewed at each distillation, M. J. Personne obtained a volatile oil, of a stupefying odor, and an action on the system such as to dispose him to think that it was the active principle of the plant. As the water distilled was strongly alkaline, he supposed that his volatile principle might be a new alkaloid; but the alkaline reaction was found to depend on ammonia; and the liquid
obtained proved to be a volatile oil, lighter than water, of a deep amber color, a strong odor of hemp, and composed of two distinct oils, one colorless, with the formula $C_{18}H_{22}$, the other a hydride of the first, $C_{18}H_{22}$, which was solid, and separates from alcohol in plate-like crystals. For the former Personne proposes the name of cannabene. It is affirmed that when this is inhaled, or taken into the stomach, a singular excitement is felt throughout the system, followed by a depression, sometimes amounting to syncope, with hallucinations which are generally disagreeable, but an action on the whole slighter and more fugitive than that of the resin. The various substances of alkaloidal nature that have been described by different investigators as found in Indian hemp are now recognized as due to decomposition products of choline, which was identified as present by Jahns. (P. J., 1887, xvii, 1049.) Cannabindon, $C_8H_{12}O$, is a dark red syrupy liquid obtained by Kobert (Chem. Ztg., 1894, 741) from Cannabis Indica; it is soluble in alcohol, ether and oils; it is affirmed to be narcotic in doses of from half a grain to two grains (0.032-0.13 Gm.). As a result of a reinvestigation of charras (churrus) from Indian hemp, Wood, Spivey, and Easterfield (J. Chem. S., vol. Ixix, 539) have found the following principles: 1, a terpene, boiling between 150° and 180° C. (302° and 356° F.); 2, a sesquiterpene, boiling at 258° to 259° C. (496.4°-498.2° F.); 3, a crystalline paraffin of probable formula $CsH_{30}$, melting at 63.5° C. (146.3° F.); and 4, a red oil, boiling at 265° to 270° C. (509°-518° F.) under a pressure of 20 mm., to which they give the name cannabinol, and the formula $C_{18}H_{24}O_2$. This latter constituent they consider the only active ingredient. It is probably the same substance as the dark red syrup of Kobert, mentioned above under the name cannabindon. The authors found that cannabinol readily underwent superficial oxidation, at the same time losing its toxic activity. Famulener and Lyons (A. Pharm., 1904) believe that the only reliable preparation of cannabis is a fluidextract made from the fresh drug. I. Roux (A. Pharm., 1887) has experimented upon extracts made by treating purified extract of hemp with petroleum benzin and ether. The ether extract produced insignificant results. The petroleum extract was excitant and convulsant. The alcoholic extract was a feeble narcotic. The resin "cannabin" of which cannabinol is the chief constituent, appears to be active. Frankel (A. E. P. P., 1903, p. 266) claims to have isolated the active principle of hashish as a pure and chemically well defined body. It has the formula $C_{21}H_{30}O_2$, and is a phenol-aldehyde. It is of a pale yellow color and of a thick consistency. When heated it becomes quite
fluid and distils at 215° C. (419° F.), under a pressure of 0.5 mm. It oxidizes in the air, acquiring a brown tint. It responds to Millon's reaction, and can be acetylated, showing thus its phenol character. Frankel proposes that the name cannabinol be given to it and that the term pseudo-cannabinol be given to the inactive substance of Wood, Spivey and Easterfield.

Assay.—"Prepare a fluidextract and proceed as directed below." U. S.

Attempts have been made to apply physiological tests to the standardization of cannabis indica. Up to the present no means have been suggested for determining the relative potency of different samples of cannabis indica, the physiological test simply demonstrating that the drug possesses a certain indefinite amount of physiological action. This test is carried out upon dogs in the following manner: It is advisable to use the same animal for repeated tests, because the individual susceptibility of the dog varies so greatly, and the experimenter gradually learns the degree of reaction to be expected from a certain dog. A tincture of the specimen to be tested is either evaporated into a soft extract and given in the form of a pill or mixed with an inert absorbing powder and enclosed in a capsule; it must not be given hypodermically. The symptoms caused by cannabis indica in the dog recall those of alcoholism in the human being. There is at first a slight loss of control in the hind legs so that the animal staggers as he walks, later the ataxia becomes so marked that the dog is unable to stand up without leaning against some object, and about this time begins to show distinct drowsiness, and may eventually pass into a heavy sleep.

The details of assay as directed by the U.S. are as follows: "The assay of Cannabis and its preparations has been made a requirement and is based upon the fact that this drug produces certain symptoms of muscular incoordination. The method consists of ascertaining the dose of the preparation to be tested which will produce these symptoms of incoordination in dogs and then adjusting its strength by comparison with a standard preparation.

"Dogs.—The animals differ considerably in susceptibility to the drug and therefore it is best to make preliminary tests upon several dogs with average-sized doses and select from among them the animals which react easily to the drug. As a rule, fox terriers serve very-well for the purpose, but any dog may prove satisfactory. It is best to provide at least
two dogs for each assay, but if many samples are to be examined more
dog's will be needed. The dogs should be at least one year old and in
normal health and must be kept under the best sanitary conditions.
They may be used repeatedly for the purpose but not at shorter
intervals than three days. Each series of tests should be conducted by
the same person, who should be perfectly familiar with the peculiarities
of each animal in order that he may recognize more certainly deviations
from the normal. While the tests are being made the animals should be
kept in a perfectly quiet room, free from-disturbance and separated so
that they cannot see each other.

"Preparation of the Drug.—The drug may be given most conveniently in
the form of the fluidextract which is administered in gelatin capsules, or
the extract made into soft pills may be used; but whichever form is
chosen the same should be used for both the standard and the
preparation that is to be tested.

"Before administration the animal should not be fed for twenty-four
hours in order to hasten absorption. The head of the animal being held,
its mouth is opened and the capsule or pill is placed upon the back of the
tongue. Usually the drug is easily swallowed when given in this way,
but this may be facilitated by giving the animal a small amount of
water to drink.

"Assay.—An average dose of the known or standard preparation is given
to one of the dogs and a like dose of the preparation to be standardized
is given the second dog. After one hour both dogs are observed very
carefully for symptoms of muscular incoordination. The incoordination is
manifested differently in different animals, but in small doses it shows
itself most frequently in slight swaying, when the animal is standing
quietly, or in some ataxia when it runs about. The observation should
be made frequently during the second hour following the administration
of the drug.

"The results obtained from the first test should be confirmed after an
interval of not less than three days by repeating the administration, but
reversing the order, that is, giving the known strength drug to the dog
which received that of unknown strength before and vice versa.

"In subsequent tests which are carried out, the dose of the preparation
of unknown strength is modified so as to produce similar symptoms to
those produced by the standard. If the preparation to be tested is below
the standard in strength, its dose must be increased, or if it is above
strength its dose is lessened until equivalent doses of the two are found.
Dogs may be used over long periods of time, even for some years, but
occasionally they have to be discarded, as in some cases they seem to
learn the effects of the drug and so refuse to stand up. A certain degree
of tolerance is sometimes gained which necessitates larger doses.

"Standard.—As there is no chemical substance of definite composition
which can be adopted as a standard, a Fluidextract of Cannabis or an
extract which has been carefully prepared and suitably preserved may
be utilized for this purpose. A standard Fluidextract will produce
incoordination when administered to dogs in the dose of 0.03 mil for
each kilogramme of body weight of dog. When administered in the form
of the Extract a dose of 0.004 Gm. for each kilogramme of body weight
of dog should produce similar symptoms, and the requirement for a
standard tincture is a dose of 0.3 mil for each kilogramme of body
weight of dog." U. S. IX.

Uses.—Aside from a slight local irritant effect the action of cannabis
seems to be limited almost exclusively to the higher nerve centers. In
man this is first manifested by a peculiar delirium which is accompanied
with exaltation of the imaginative function and later by a remarkable
loss of the sense of time. The delirium is often accompanied with motor
weakness and diminished reflexes and generally followed by drowsiness.
In the dog the earliest manifestation of the drug's action is a slight
degree of restlessness which is soon followed by disturbances of
equilibrium and later weakness of the legs and drowsiness.

Cannabis is used in medicine to relieve pain, to encourage sleep, and to
soothe restlessness. Its action upon the nerve centers resembles opium,
although much less certain, but it does not have the deleterious effect
on the secretions. As a somnifacient it is rarely sufficient by itself, but
may at times aid the hypnotic effect of other drugs. For its analgesic
action it is used especially in pains of neuralgic origin, such as migraine,
but is occasionally of service in other types. As a general nerve sedative
it is used in hysteria, mental depression, neurasthenia, and the like. It
has also been used in a number of other conditions, such as tetanus and
uterine hemorrhage, but with less evidence of benefit. One of the great
hindrances to the wider use of this drug is its extreme variability.
Formerly many of the preparations of cannabis were inert before they
left the manufacturers' hands, and the present requirements of the U. S. P. that the drug be tested upon dogs to insure its activity is an important step in the right direction. But even granted an active preparation when manufactured, so rapidly does the drug deteriorate that by the time the drug reaches the patient it has lost a large proportion of its activity. The only way of determining the dose of an individual preparation is to give it in ascending quantities until some effect is produced. The fluid extract is perhaps as useful a preparation as any; one may start with two or three minims of this three times a day, increasing one minim every dose until some effect is produced. According to C. R. Marshall (L. L., 1897, i, also J. A. M. A., Oct., 1898) the deterioration of cannabis is due to the oxidation of cannabinol, which he has found to act upon dogs and cats as the crude drug.

Dose, of cannabis, one to three grains (0.065-0.2 Gm.).

**Off. Prep.**—Extractum Cannabis, U. S. (Br.); Fluidextractum Cannabis, U. S.; Tinctura Cannabis (from Extract), U. S. (Br.); Collodium Salicyli Composita (from Fluidextract), N. F.; Mistura Chlorali et Potassii Bromidi Composita (from Extract), N. F.; Mistura Chloroforma et Morphinae Composita (from Tincture), N. F.

**Capparis.** Capparis spinosa L. Caper-bush. (Fam. Capparidaceae)—A low, trailing shrub, growing in the south of Europe and north of Africa. The buds of unexpanded flowers, treated with salt and vinegar, form a highly esteemed pickle, which has an acrid, burning taste, and is considered useful in scurvy. The dried bark of the root was formerly official. It is in pieces partially or wholly quilled, about one-third of an inch in mean diameter, transversely wrinkled, grayish externally, whitish within, inodorous, and of a bitterish, somewhat acrid, and aromatic taste. It contains rutic acid and a volatile substance of garlic-like odor. It is considered diuretic, and was formerly used in amenorrhea and chronic rheumatism.

**Capsella.** Capsella Bursa-pastoris (L.) Medic. Shepherd's purse. Bourse a Pasteur, Molette, Fr. Hirtentschlein, G. (Fam. Cruciferae)—This very common weed in the United States, naturalized from Europe, is bitter and pungent, yields on distillation a volatile oil identical with oil of mustard, and, according to E. Bombelon, contains an alkaloid, bursine. (See A. J. P., 1888; also Provincial Med. Journ., 1858.) It has been used as an antiscorbutic, also in hematuria, and in other hemorrhages, amenorrhea and dropsy. From two to four fluidounces (60-120 mils) of the fresh expressed juice may be given at a dose or from one-fourth to one-half fluidrachm (0.9-1.8 mils) of the fluidextract of the dried plant.

**Capulincullo.**—This drug, derived from the Rhamnus Humboldtianus Roem. and Schult. (Fam. Rhamnaceae) of Mexico, is said to be a violent poison, acting like curare.
A non-toxic, non-drying fixed oil, tasteless and odorless, is obtained in considerable quantities from the fruit of the tree.

**Cardamine.** Cardamine pratensis L. Cuckoo-flower.—This is a perennial herbaceous plant, of the fam. Cruciferae, with a simple, smooth, erect stem, about a foot in height. The plant grows in Northern Europe and to some extent in wet places and bogs from New Jersey northward to Labrador. Its bitterish and slightly pungent leaves are supposed to be antiscorbutic. The seeds are said to contain myronic acid, and to yield on decomposition by hydrolysis an oil analogous to oil of mustard. Feist investigated C. amara L. and its volatile oil and found thio-urea. Kuntze states that two kinds of crystals were isolated, both being forms of thio-urea. (A. Pharm., 1907, 657.) In Europe they are sometimes added to salads. The flowers formerly possessed the reputation of being diuretic, and of being useful in chorea and asthma.

**CARDAMOMI SEMEN. U. S. (Br.)**

**CARDAMOM SEED Cardam. Sem. [Cardamomum U.S. VIII Cardamom]**

"The dried seeds of Elettaria Cardamomum White et Maton (Fam. Zingiberaceae), recently removed from the capsules." U. S. "Cardamom Seeds are the dried ripe seeds of Elettaria Cardamomum, Maton. The seeds should be kept in their pericarps and separated when required for use." Br.

**Cardamomi Semina, Br.; Cardamomum Minus, Cardamomum Malabaricum; Malabar Cardamoms, Cardamoms; Cardamome du Malabar, Fr. Cod.; Petit Cardamome, Fr.; Fructus Cardamomi, P. G.; Malabar Kardamomen, Carda-momen, Kleine Kardamomen, G; Cardamomo minore. It.; Cardamomo, Cardamomo menor, Sp.; Ebil, Arab.; Kakelah seghar, Pers.; Capalaga, Malay; Gujaratii elachi, Hindost.**

The fruit of cardamom is official in most of the Pharmacopoeias. The U. S. Pharmacopoeia in its definition confines cardamom to the seeds. In this it follows the British Pharmacopoeia which has always limited the drug to the seeds, but specifically states that the fruit should be kept intact and the seeds separated when required for use. This step was probably a wise one as there has always been some confusion by manufacturers as to whether the article designated as cardamom is a formula was restricted to the seeds or not. On the other hand the pericarp contains some oil and forms an excellent surface for the grinding of the seeds. Furthermore, the decorticated seeds are liable to adulteration with seed of wild cardamom and other foreign seeds which are not detected except upon careful examination.
The subject of cardamom has been involved in some confusion and uncertainty, both in its commercial and botanical relations. The name has been applied to the aromatic capsules of various Indian plants belonging to the family of Zingiberaceae. Three varieties have long been designated by the several titles of the lesser, middle, and larger—cardamomum minus, medium, and majus; but these terms have been used differently by different writers, so that their precise signification remains doubtful. To Pereira we are mainly indebted for the clearing up of this confusion. It is well known that the lesser cardamom of most writers is the variety recognized by the Pharmacopoeias and generally kept in the shops. The other varieties, though circulating to some extent in European and Indian commerce, are little known in this country.

Ceylon Cardamom.—This has been denominated variously cardamomum majus and cardamomum longum, and is sometimes termed in English commerce wild cardamom. It is the large cardamom of Guibourt. In the East it is sometimes called grains of Paradise; but it is not the product known with us by that name. (See below.) It is derived from a plant cultivated in Candy, in the Island of Ceylon, and also growing wild in the forests of the interior, which was designated by Sir James Edward Smith Elettaria major, but is now generally acknowledged to be only a variety of the official plant. (Elettaria Cardamomum var. ß-Major Smith.) It is affirmed that the annual product reaches nearly 750,000 pounds. The fruit is a lanceolate-oblong, acutely triangular capsule, somewhat curved, about 3.5 cm. long and 6 to 8 mm. broad, with flat and ribbed sides, tough and coriaceous, brownish or yellow ash-colored, having frequently at one end the long, cylindrical, three-lobed calyx, and at the other the fruit-stalk. It is three-locular, and contains angular, rugged, yellowish-red seeds, of a peculiar fragrant odor and spicy taste. Its effects are analogous to those of the official cardamom.

Round or Siam Cardamom.—This is probably the Αμομον of Dioscorides and the Amomi uva of Pliny, and is believed to be the fruit of Amomum cardamomum, Willd., growing in Sumatra, Java, and other East India islands. The capsules are usually smaller than a cherry, roundish or somewhat ovate, with three convex sides, more or less striated longitudinally, yellowish or brownish-white, and sometimes reddish, with brown, angular, cuneiform, shrivelled seeds, which have a spicy
camphorous flavor. They are sometimes, though rarely, met with connected in their native clusters, constituting the amomum racemosum, or amome en grappe, of the French. They are similar in medicinal properties to the official, but are seldom used except in the southern parts of Europe.

Java Cardamom.—The plant producing this variety is supposed to be the amomum maximum of Roxburgh, growing in Java and other Malay islands in the East. The capsules are oval, or oval-oblong, often somewhat ovate, from 1.5 to 3 cm. long, and from 8 to 15 mm. broad, usually flattened on one side and convex on the other, sometimes curved, three-valved, and occasionally imperfectly three-lobed, of a dirty grayish-brown color, and coarse fibrous appearance. When soaked in water, they exhibit as their distinguishing character from nine to thirteen ragged membranous wings along their whole length. The seeds have a feebly aromatic taste and odor. This variety of cardamom affords but a very small proportion of volatile oil, is altogether of inferior quality, and, when imported into London, is usually sent to the continent.

Madagascar Cardamom.—This is the Cardamomum majus of Geiger and some others, and is thought to be the fruit of Amomum angustifolium, of Sonnerat, growing in marshy grounds in Madagascar. The capsule is ovate, pointed, flattened on one side, striated, with a broad circular scar at the bottom, surrounded by an elevated, notched, corrugated margin. The seeds have an aromatic flavor similar to that of official cardamom.

Bengal or Nepal Cardamom.—The fruit of Amomum subulatum, Boxb., sometimes known by the name of winged Bengal cardamom. Morung elachi, or Buro elachi, is about 2.5 cm. in length, obscurely three-sided, ovoid or somewhat obconic, with nine narrow, jagged ridges or wings (best seen after soaking in water) upon its distal end, which terminates in a truncate bristly nipple. The pericarp is coarsely striated, of a deep brown, splitting into three valves, disclosing a three-lobed mass of seeds, 60 to 80 in number.

Nepal Cardamom is produced by an Amomum of undetermined species, and resembles the Bengal cardamom, except in having a long tubular calyx on its summit, and in being usually attached to a stalk.
Grains of Paradise. Grana Parodisi.—Under this name and that of Guinea grains, and Melegueta or Mallaguetta pepper, are found in commerce small seeds of a round or ovate form, often angular, and somewhat cuneiform, minutely rough, brown externally, white within, of a feebly aromatic odor when rubbed between the fingers, and of a strongly hot and peppery taste. Two kinds of them are known in the English market, one larger, plumper, and more warty, with a short conical projecting tuft of pale fibers on the umbilicus; the other smaller and smoother and without the fibrous tuft. The latter are the more common. It is probable that one of the varieties is produced by Amomum Grana Parodisi of Sir J. E. Smith, and the other by Roscoe’s Amomum Melegueta. (Pereira’s Mat. Med., 3d ed., p. 1134.) W. F. Daniell, who has published (P. J., xiv 312 and 356) an elaborate paper on the Amoma of Western Africa, states that the true Mallaguetta pepper is obtained exclusively from varieties of the same species to which belong the Amomum Granum Parodisii of Afzelius and the A. Melegueta of Roscoe; while the A. Grana Parodisi of Sir J. E. Smith is a different plant, and yields a different product. These grains are imported from Guinea, and other parts of the western coast of Africa. Similar grains are taken to England from Demerara, where they are obtained from a plant cultivated by the negroes, supposed to have been brought from Africa, and believed by Pereira to be the Amomum Melegueto of Roscoe. (P. J., vi, 412.) Their effects on the system are analogous to those of pepper; but they are seldom used except in veterinary practice, and to give artificial strength to spirits, wine, beer, and vinegar. Pereira points out seven distinct Scitamineous fruits to which the name of grains of Paradise has been applied by different authors. J. C. Thresh made a proximate analysis of the seeds, and found volatile oil, resin, tannin, starch, albuminoids, and an active principle in the form of a straw-colored viscid, odorless fluid, pungent, but not so hot as capsaicin. (P. J., 1884, p. 297.) Fred’k Schwartz found in the seeds a reddish-brown acrid resin, and an oil having a burning aromatic taste, upon which the virtues probably depend. (A. J. P., 1886, 118; consult also Hanausek’s researches on grains of Paradise in Chem. Ztg., 1893, 1765.)

Bastard Cardamom, the seeds of Amomum Xanthioides Wall., resembles true cardamom in appearance, but is of a dirty green color, and has a very biting camphor-like taste. B. Niederstadt gives the following as the results of analysis of the true (hulled) seed and of the bastard cardamom:
A cardamom from East Africa, with a flavor resembling that of official cardamom and of the Korarima cardamom, is said to have been seen in the London market, but apparently has not been identified.

The official cardamoms are produced solely in India, chiefly in Malabar, Mysore, and adjacent regions. Malabar cardamoms are rather smaller than Mysore cardamoms.

The cardamom plant has a tuberous horizontal rhizome, sending up from eight to twenty erect, simple, smooth, green and shining, perennial stems, which rise from six to twelve feet in height, and bear alternate elliptical-lanceolate sheathing leaves. The flower-stalk proceeds from the base of the stem, and lies upon the ground, with the flowers arranged in a panicle. The fruit is a three-celled capsule, containing many seeds; during drying it is said to lose three-fourths of its weight.

This valuable plant is a native of the mountains of Indochina, where it springs up spontaneously in the forests after the removal of the undergrowth, and is very extensively cultivated by the natives. Recent reports indicate that the cultivation of cardamom is being discontinued in favor of cinchona and rubber plantations on both the Malabar Coast as well as in Ceylon. For a detailed account of culture, see A. J. P., 1877, 605; also P. J., 1888, and Bull. des Sc. Pharmacol; Paris, 1906, pp. 114 and 584. Cardamoms have also been cultivated to some extent in tropical America. The plant begins to yield fruit at the end of the fourth year, and continues to bear for several years afterwards. The capsules when ripe are picked from the fruit-stems, dried over a gentle fire or by sun-heat, and separated, by rubbing with the hands, from the footstalks and adhering calyces. J. W. Mollison describes the method of washing and curing cardamoms employed in the Bombay Presidency, India. The washing and manipulation is performed by women, and water from special wells is employed. The cardamoms are first washed in earthenware vessels containing a mixture of the well water with pounded soap nut and a species of acacia, in the proportion of two.
pounds of the former to a quarter pound of the latter. About ten pounds
of cardamoms are treated at one time. Two women stir them vigorously
in the mixture for about one minute and then allow them to rest about
an equal length of time, and again stir for another minute. A thick
lather results. This completes the first washing, after which the
cardamoms are baled out by hand into a basket where they are allowed
to drain for a few seconds, and then subjected to a second washing
similar to the first except that the mixture contains less of the soap nut
preparation and an additional quantity of soap solution. They are then
thrown upon a mat and sprinkled with water from the special well at
intervals of a half hour, until the next morning, when they are spread
upon the roof of a house and allowed to dry for four or five hours. After
nipping off the short stalk, an operation performed with a large pair of
shears, the cardamoms are sorted, only the most plump fruits being
prepared for the foreign market. Besides bleaching by this process,
cardamoms are also subjected to starching in India. The starched
product has a whiter appearance than, the bleached cardamoms. The
starch is prepared by pounding together rice, wheat, country soap and
buttermilk. The paste is diluted with water and sprinkled over the
cardamoms as they are nibbed by hand. (B. C. D., 1904, see also Ph.
Era, 1904, 137.) Most of the cardamom is sent to Bombay, from whence
it is shipped to London, about 250,000 pounds being marketed
annually. Thus prepared, they are ovate-oblong, from 10 to 17 mm.
long, from 6 to 8 mm. thick, three-sided with rounded angles, obtusely
pointed at both ends, longitudinally wrinkled, and of a yellowish-white
color. The seeds constitute about 74 parts per cent. by weight. According
to Pereira, three varieties are distinguished in commerce: 1, the shorts,
from 6 to 12 mm. long, from 4 to 6 mm. broad, browner and more
coarsely ribbed and more highly esteemed than the others; 2, the long-
longs, from 14 to 25 mm. in length by 4 to 6 mm. in breadth, elongated,
and somewhat acuminate; and 3, the short-longs, which are somewhat
shorter and less pointed than the second variety. The odor of cardamom
is fragrant, the taste warm, slightly pungent, and highly aromatic.

"Mostly agglutinated in groups of from 2 to 7, the individual seeds,
obleng-ovoid in outline, 3- or irregularly 4-sided, convex on the dorsal
surface, strongly longitudinally grooved on one side, from 3 to 4 mm. in
length; externally reddish-gray-brown, coarsely tuberculated, and with
more or less adhering portions of the membranous aril; in section
showing a thin reddish-brown seed-coat, a large white perisperm and a
central, greenish endosperm enclosing a small straight embryo; odor
aromatic; taste aromatic, pungent. The powder is greenish-brown; consisting chiefly of coarse angular fragments of cells of the reserve layers and seed-coat; cells of endosperm and perisperm filled with compound starch grains, the individual grains from 0.001 to 0.004 mm. in diameter; fragments of seed with dark brown stone cells, which are polygonal in surface view and about 0.02 mm. in diameter; in mounts made with hydrated chloral T.S. single prisms or crystals in rosette aggregates may separate in the cells of the endosperm and perisperm; fragments of spiral tracheae with accompanying slightly lignified bast-fibers relatively few. Cardamom Seed yields not more than 8 per cent. of ash." U.S.

"Fruits from one to two centimetres long, ovoid or oblong, bluntly triangular in section, shortly beaked at the apex, pale buff in color, plump and nearly smooth or with slight longitudinal striations. Seeds dark reddish-brown, about three millimetres in length and the same in breadth and thickness, irregularly angular, transversely wrinkled, and enclosed in a thin, colorless, membranous aril. The powdered Seeds exhibit abundant, minute, angular starch grains, often compacted into masses; but no spiral vessels, sclerenchymatous fibres, or strongly elongated selerenehymatous cells (absence of pericarps). Aromatic odor; taste agreeably warm and aromatic. Ash not more than 6 per cent." Br.

Cardamom yields its virtues to water and alcohol, but more readily to the latter. The seeds contain 4.6 per cent. of volatile oil, 10.4 of fixed oil, 2.5 of a salt of potassium mixed with a coloring principle, 3.0 of starch, 1.8 of nitrogenous mucilage, 0.4 of yellow coloring matter, and 77.3 of ligneous fiber. (Trommsdorff.) The volatile oil is colorless, of an agreeable and very penetrating odor, and of a strong aromatic, burning, camphorous, and bitterish taste. It is dextrogyrate, and consists essentially of a terpene, \(C_{10}H_{16}\), with small quantities of formic and acetic acids. From old specimens of oil Dumas and Peligot claim to have separated crystals of terpene hydrate, \(C_{10}H_{20}O_2 + H_2O\), while Fluckiger has obtained a crystalline deposit from Ceylon oil which he considers identical with common camphor. Weber (Ann. Ch. Ph., cxxxviii., 98) found a small amount of a crystalline non-volatile compound which fuses at 60° to 61° C. (140°-141.8° F.). Schimmel & Co. published in their semi-annual reports for April and October, 1897, some results of investigation of several varieties of cardamom oil. The terpenes of Ceylon oil they state to be terpinene and dipentene; both Ceylon and
Bengal cardamom contain cineol, C_{10}H_{18}O; Malabar cardamom yields terpineol as well as cineol, while Siam cardamom yields a crystalline sediment composed of borneol and camphor in approximately equal proportions. The sp. gr. of the oil is between 0.92 and 0.94. It cannot be kept long without undergoing change, and finally, even though excluded from the air, loses its peculiar odor and taste. If ether be made to percolate through the powdered seeds, and the liquor obtained be deprived of the ether, a light greenish-brown fluid remains, consisting almost exclusively of the volatile and fixed oils. It has the odor of cardamom, and keeps better than the oil obtained by distillation. (A. J. P., xxi, 116.) The oil of cardamom of commerce is often factitious, being composed of several cheap volatile oils, oils of cajuput, nutmeg, and others being used. Schimmel & Co. announced in 1901 that they no longer distilled the oil from the fruit of Elettaria cardamomum, but from the seeds of another species; this oil makes a clear solution with three parts by volume of 70 per cent. alcohol. (Schim. Rep., 1901, 14.) See Oil of Cardamom, N. F. IV., Part II. The seeds should be powdered only when wanted for use, as they retain their aromatic properties best while in the capsule.

Cardamoms are sometimes adulterated; G. W. Kennedy reported nearly 4 per cent. of orange seeds and unroasted grains of coffee admixed with cardamom. Solstein (1892) found that pure powdered cardamom yields 8.36 per cent. of ash; three commercial samples of powdered cardamom that he examined contained sodium carbonate.

Uses.—Cardamom is a grateful aromatic, not strongly heating or stimulating, and useful chiefly as an adjuvant. Throughout the East Indies it is largely consumed as a condiment. It was known to the ancients, and derived its name from the Greek language. In this country it is employed chiefly as an ingredient in compound preparations.

Dose, fifteen to thirty grains (1-2 Gm.).

Carnauba Root.—This root, the product of *Copernicia cerifera* (AT.) Mart. (*Corypha cerifera*}, the Brazilian wax palm, is several feet in length, about three-eighths of an inch thick, with a thick friable cortex of a mixed grayish and reddish-brown color. (A. J. P., 1875, 349.) E. L. Cleaver found in it tannic acid, an acrid resinous body, a red coloring matter, and a minute portion of volatile oil and of an alkaloid (P. J., 1875, 965.) It is said to act like sarsaparilla. Carnauba Wax, with which the young leaves of the palm are coated, is a dark colored, hard, brittle wax, melting at from 83° to 88° C. (181.4°-190.4° F.) and possessing an acid number of 4 to 8, a saponification value of 80 to 95, and an iodine number of 7 to 13. (See under Cera, p. 310.) It is used in church candles to prevent guttering, for the manufacture of phonograph records, in the composition of sealing wax and for other purposes in the arts.

Carota. U. S. 1870. Carotte, Fr. Mohre, Gelbe Rube, G. Daucus Carota L.—The wild carrot (Fam. Umbelliferae) is widely distributed, growing along fences, and in neglected fields. It grows wild also in Europe. The well-known garden carrot is the same plant altered by cultivation. The fruits are very light, of a brownish color, an oval shape, flat on one side and convex on the other, and on their convex surface present four longitudinal ridges, which are beset with stiff, whitish hairs or bristles. They have an aromatic odor, and a warm, pungent, and bitterish taste. By distillation they yield a pale yellow volatile oil, upon which their virtues chiefly depend. Schimmel & Co. found the distilled brownish-yellow oil to possess the odor of carrots only to a slight extent and to yield 1.26 per cent. (Schim. Rep., 1907, 31.) Pictet isolated from the leaves of carrots a liquid alkaloid. (Chem. Ztg; 1905, No. 97.) Subsequently two volatile alkaloids, pyrvalidine and daucine, were reported to be present by Pictet and Court. Carrot seeds are slightly aromatic, moderately excitant and diuretic, and have been employed as a diuretic in chronic renal diseases and in dropsy. An ounce of them may be given in infusion, in a day. The flowers are sometimes substituted for the seeds, and the scraped root has been used as a local stimulant to sloughing or indolent ulcers. For additional information concerning this drug, see U. S. D., 19th ed., p. 1432.

Carthamus. Carthamus tinctorius L. Safflower.—The African, false, American, or dyers' saffron is an annual composite, with a smooth, erect stem, somewhat branched at top, and a foot or two in height. The plant is a native of India, the Levant, and Egypt, and is cultivated in those countries, as well as in various parts of Europe and America. The fruit yields 25.82 per cent. of fixed oil, the separated kernels of the seeds, 50.37 per cent., according to Fendler. (Ap. Ztg., 1904, 121.) The florets are brought to us chiefly from the ports of the Mediterranean. Safflower (Flores Carthami; Flours de carthame, Safran batard, Fr.; Saflor, Gr.; Cartamo, It., Sp.) in mass is of a red color, diversified by the yellow of the styles contained within the floret. It has a peculiar, slightly aromatic odor, and a scarcely perceptible bitterness. It contains a fixed oil; also two coloring substances—one red, insoluble in alkaline liquids, and called carthamin or carthamic acid by Dobereiner, who found it to possess weak acid properties; the other yellow, and soluble in water. Carthamin, C_{14}H_{16}O_{7}, exists at the amount of from 0.3 to 0.6 per cent. only in the safflower, while the samower-yellow, to which Malin gives the formula C_{24}H_{30}O_{15}, is present to the amount of from 24 to 30 per cent. It is the former which renders safflower useful as a dye stuff. Kametaka and Perkins give the formula of carthamin as C_{25}H_{24}O_{12}. (P. J.,
1910, 299.) These flowers are sometimes fraudulently mixed with saffron, whidi they resemble in color, but from which they may be distinguished by their tubular form, and the yellowish style and filaments within they enclose. In large doses carthamus is said to be laxative, and, administered in warm infusion, diaphoretic. It is used in domestic practice, as a substitute for saffron, in measles, scarlatina, and other exanthematous diseases, to promote the eruption. An infusion, two drachms to a pint of boiling water, is usually employed pro re nata.

Caruba di Gulden.—Under this name are largely used, for the relief of asthma, certain gall-like bodies, formed on various species of Pistacia, especially P. Terebinthus L., as the result of the stings of a hemipterous insect. According to Ignaz Hoffman, they are used for smoking and fumigation. For this purpose they are coarsely pulverized and burned in the bowl of a pipe, or in a dish, using a small funnel attached to a rubber tube for inhaling the fumes. Preparations should be made beforehand, so that the smoke may be inhaled at the commencement of the attack. They appear to act by exciting free secretion, probably through the turpentine with which they are saturated. They are said to be useful in chronic bronchitis. (S. Jb., Bd. dill.)

CARUM. U. S. (Br.)

CARAWAY [Carawayseed, Caraway Seed]

"The dried fruit of Carum Carvi Linne (Fam. Umbelliferae). Without the presence or admixture of more than 3 per cent. of other fruits, seeds or foreign matter. Preserve Caraway in tightly-closed containers, adding a few drops of chloroform or carbon tetrachloride, from time to time, to prevent attack by insects." U. S. "Caraway Fruit is the dried ripe fruit of Carum Carvi, Linn." Br.

Carul Fructus. Br.; Caraway Fruit; Carvies, Cumin des Pres, Carvi., Fr. Cod.; Fructus Carvi, P. G.; Gemeiner Kum-ael, Kummel, Garbe, G.

The caraway plant is biennial and umbelliferous, with a spindle-shaped, fleshy, whitish root, and an erect stem, about two feet in height, branching above, and furnished with doubly pinnate, deeply incised leaves, the segments of which are linear and pointed. The flowers are small and white, and in erect terminal umbels, with an involucre, consisting sometimes of three or four bracts, sometimes of one only, and are destitute of partial involucre.

It is a native of Europe, growing wild in meadows and pastures, and cultivated in many places. It has been introduced in many places in this country, especially in the North. The flowers appear in May and June,
and the seeds, which are not perfected until the second year, ripen in August. The root, when improved by culture, resembles the parsnip, and is used as food in Northern Europe. The fruits are the part used in medicine. They are collected by cutting down the plant, and threshing it on a cloth. Our markets are supplied partly from Europe, partly from our own gardens. The American fruits are usually rather smaller than the German. Under the name of Ajowan, the fruits of the Carum Ajowan, Bentham & Hooker (Ammi copticum L.) are largely used in India. (See Ajowan, Part II.) They contain about 4 per cent. of a volatile oil, which has the odor of the oil of thyme, and contains thymol; it may be used as an aromatic carminative. (See B. M. J., June 6, 1885.)

Caraway is officially described as follows: “Mericarps usually separated, crescent-shaped, 3 to 7 mm. in length, 1.5 mm. in diameter; externally dark brown with 5 yellowish filiform ribs; in transverse section nearly equilaterally pentagonal, the commissural surface with two vittae, the dorsal surface with a vitta between each of the primary ribs; oily endosperm large, enclosing a small embryo; odor and taste agreeably aromatic. Under the microscope, transverse sections of Caraway show an epidermal layer of slightly tangentially elongated cells with thick outer walls; a layer of several rows of tangentially elongated parenchyma cells, frequently more or less collapsed; a single, large, elliptical, brown vitta or oil-tube between each of the ribs and surrounded by small epithelial or secretion cells; in each of the ribs a single fibro-vascular bundle surrounded by a layer of thick-walled sclerenchymatous fibers; inner epidermis of broadly elongated cells with very thin side walls, being very frequently broken and closely coherent with the more or less brownish collapsed cells of the seed-coat; commissural surface with 2 large vittae and at the middle portion 2 large transverse hollow spaces formed by the separation of the tissues of the seed-coat on one side and the pericarp on the other, otherwise, the cells resemble those on the dorsal surface; endosperm large, cells polygonal with thick walls and containing a fixed oil and aleurone grains, the latter not infrequently containing a small rosette aggregate or prism of calcium oxalate. The powder is yellowish-brown, mostly of irregular, angular fragments; cells of endosperm, with aleurone grains each usually containing a rosette aggregate of calcium oxalate about 0.001 mm. in diameter; fragments with light-yellow vittae, together with nearly iso-diametric or polygonal, yellowish-brown, inner epidermal cells of pericarp; fragments with trachea and sclerenchymatous fibers, the latter 0.01 mm. in width, slightly lignified and with numerous oblique
pores. Caraway yields not more than 8 per cent. of ash." U. S.

"Mericarps usually separate; each from about four to six millimetres long and about one millimetre broad; brown with paler primary ridges; slightly curved, tapering towards each end, and glabrous. In transverse section, six vittse in each mericarp. Odor and taste aromatic. Ash not more than 9 per cent." Br.

They have an agreeable aromatic odor, and a sweetish, warm, spicy taste. These properties depend on an essential oil, which they afford largely by distillation. (See Oleum Cari.) The residue is insipid. They yield their virtues readily to alcohol and more slowly to water.

"Drawn caraway seeds," a term applied to such as have been recovered from the still residue after obtaining the volatile oil, are used to adulterate caraway; the exhausted "seeds" are much darker in color than are the genuine and are less odorous. (P. J., 1896,150.) While this is the principal form of adulteration, they may contain large amounts of stems, gravel, sand, dust, weed seeds and other impurities.

**Uses.**—Caraway is a pleasant stomachic and carminative, occasionally used in flatulent colic, and as an adjuvant or corrective of other medicines. The dose in substance is from fifteen to thirty grains (1-2 Gm.). An infusion may be prepared by adding two drachms of the seeds to a pint of boiling water. The volatile oil, however, is most employed. (See Oleum Cari.) Three and a half ounces of the oil of caraway caused violent vomiting and abdominal pain, with loss of consciousness, ending, however, in recovery. The urine contained both acetone and albumin. (Cb. I. M., xxii, 1902.) In culinary operations the seeds are added to cakes, to which they communicate an agreeable flavor, while they stimulate the digestive organs.

Dose, fifteen to thirty grains (1-2 Gm.).

**Carya.** Hicoria. Hickory.—Several species of the genus Carya Nuttall (Hicoria, Eaf.) grow in the United States of which Carya illinoensis (Wang.) K. Koch bears the pecan nut, and grows in the Middle and Southwestern States; C. ovata (Mill.) K. Koch, a large and handsome tree known as shell-bark or shag-bark hickory, is the chief source
of the hickory nuts of the market. There are six other common species of carya which are indigenous to the United States and Canada, and all yield edible fruits. The leaves of most if not all of these trees are somewhat aromatic and astringent, and the bark astringent and bitter. In the bark of H. alba F. R. Smith found a crystalline principle, carryin, which he believed to be quercetrin.

**CARYOPHYLLUS. U. S. (Br.)**

**CLOVE Caryoph. [Cloves]**

"The dried flower-buds of Eugenia aromaticā. (Linne) O. Kuntze, Jambosa Caryophyllus (Sprengel) Niedenzu (Fam. Myrtaceae), without the presence or admixture of more than 5 per cent. of the peduncles, stems or other foreign matter." U. S. "Clovess are the dried flower-buds of Eugenia caryophyllata, Thunb." Br.

Eugenia aromaticā (L.), O. Kuntze, is a small tree inhabiting the Molucca Islands and Southern Philippines. It has a pyramidal form, is always green, and is adorned throughout the year with a succession of beautiful rosy flowers. The stem is of hard wood, and covered with a smooth, grayish bark. The leaves are opposite, petiolate, about four inches in length by two in breadth, obovate-oblong, acuminate at both ends, entire, sinuated, with many parallel veins on each side of the midrib. They have a firm consistence and a shining green color, and when bruised are highly fragrant. The flowers are disposed in terminal corymbose panicles, and exhale a strong, penetrating, and grateful odor.

The natural geographical range of the clove is extremely limited, being confined to the Molucca or, as they were one time called, Clove Islands. According to Fluckiger, cloves were known in Western Europe as early as the sixth century, long before the discovery of the Moluccas by the Portuguese. After the conquest of the Molucca Islands by the Dutch, the monopolizing policy of that commercial people led them to extirpate the trees in nearly all the islands except Ambon Yana and Temate, which were under their immediate inspection. Notwithstanding their jealous vigilance, a French governor of the Islands of France and Bourbon, named Poivre, succeeded, in the year 1770, in obtaining plants from the...
Moluccas and introducing them into the colonies under his control. Five years afterwards the clove-tree was introduced into Cayenne and the West Indies, in 1803 into Sumatra, and in 1818 into Zanzibar. At present the spice is cultivated both in the West and East Indies, in tropical Africa, and in Brazil. Approximately seven-eighths of the world's clove supply is grown in Zanzibar, the deliveries in 1911 totaled over 20,000,000 pounds. The amount imported in the United States is approximately 3,500,000 pounds annually.

The unexpanded flower buds are the part of the plant employed under the ordinary name of cloves. They are first gathered when the tree is about six years old. The fruit has similar aromatic properties, but much weaker. The buds are at first white, then become green, and then bright red, when they must be at once collected, which is done by hand picking, or by beating the trees with bamboos and catching the falling buds. In the Moluccas they are said to be sometimes immersed in boiling water and afterwards exposed to smoke and artificial heat before being spread out in the sun. In Zanzibar, Cayenne, and the West Indies they are dried simply by solar heat. The stems of the flowers also enter commerce. They possess the odor and taste of the cloves, but they are worth only about one-fifth the price of the cloves, as they are deficient in volatile oil. They are largely used as an adulterant in ground cloves, and are used in the manufacture of oil of cloves. In France they are generally known by the name of griffes de girofle.

Although it is stated that as early as 266 B.C., during the reign of the Han dynasty, the Chinese court officers were accustomed to hold cloves in their mouths before addressing the sovereign, that their breath might have an agreeable odor, the spice seems to have been first introduced into Europe in the fourth century, and became a great source of wealth to the enterprising merchants of mediaeval Venice, who obtained it from the Arabians. After the discovery of the southern passage to India, the trade in this spice passed into the hands of the Portuguese, but was subsequently wrested from them by the Dutch, by whom it was long monopolized. The United States derive much of their supply from the West Indies and Guiana;

but the great sources of cloves have been recently the islands of Zanzibar and Pemba, on the east coast of Africa. In 1872 the clove orchards in Zanzibar were nearly destroyed by a hurricane, but they have been replanted. (For detailed information as to method of growth,
In commerce the varieties of cloves are known by the names of the localities of their growth, and so closely resemble one another as to be distinguished only by experts. The Penang cloves have been especially esteemed. The Bencoolen cloves from Sumatra are by many druggists deemed equal to them. The Amboyna and Molucca cloves are stated to be thicker, darker, heavier, more oily, and more highly aromatic than those cultivated elsewhere. Formerly cloves were frequently adulterated, but the comparatively low price of later times has discouraged this fraud. (See Kraemer, Proc. A. Ph. A., 1894, 159.)

**Properties.**—Cloves resemble in shape a nail with a round head with four spreading points beneath it.

"From 10 to 17.5 mm. in length, of a dark brown or brownish-black color, consisting of a stem-like, solid, inferior ovary, obscurely four-angled or somewhat compressed, terminated by four calyx teeth, and surmounted by a nearly globular head, consisting of four petals, which enclose numerous curved stamens and one style; odor strongly aromatic; taste pungent and aromatic, followed by slight numbness. When Clove is pressed strongly between the thumbnail and finger the volatile oil becomes visible. Stems either separate or attached to the flower-buds; sub-cylindrical or four-angled, attaining a length of 25 mm. and a diameter of 4 mm., either simple, branching or distinctly jointed, and less aromatic than the flower-buds. The powder varies from dark brown to reddish-brown and consists chiefly of cellular fragments showing the large oil reservoirs, spiral tracheae and a few somewhat thick-walled, slightly-lignified, spindle-shaped bast-fibers; calcium oxalate in rosette aggregates, from 0.01 to 0.015 mm. in diameter; pollen grains numerous, tetrahedral, somewhat ellipsoidal, from 0.015 to 0.02 nun. in diameter. The presence of stems in the powder is shown by stone cells of irregular, polygonal shape, 0.07 mm. in diameter, with thick porous walls and large lumina, the latter frequently filled with a yellowish-brown amorphous substance. Clove yields not less than 10 per cent. of volatile extractive soluble in ether.Clove' yields not more than 8 per cent. of ash. The amount of ash, insoluble in hydrochloric acid, does not exceed 0.5 per cent. of the weight of clove taken." U. S.

"About fifteen millimetres long, each consisting of a dark-brown, wrinkled, subcylindrical, somewhat angular calyx tube which tapers below and is surmounted by four thick, rigid, patent teeth, between which are four paler, imbricated petals enclosing numerous stamens
and a single style. Odor strong, fragrant and spicy; taste very pungent and aromatic. Cloves emit oil when indented with the finger-nail. Ash not more than 7 per cent."

Their color is externally deep brown, internally reddish; their odor strong and fragrant; their taste hot, pungent, aromatic, and very permanent. The best cloves exude a small quantity of oil on being pressed or scraped with the nail. When light, soft, wrinkled, pale, and of feeble taste and odor, they are inferior. Those from which the essential oil has been distilled are sometimes fraudulently mixed with the genuine. For monograph on the microscopical structure of cloves, clove stems and clove fruit see Winton and Moeller, "The Microscopy of Vegetable Foods." Powdered cloves sometime contain an excess of clove stems, and may be adulterated with allspice, wheat middlings and powdered peas or beans. Occasionally clove stems alone are ground and sold as cloves. It is claimed that an enormous quantity of exhausted cloves are dishonestly marketed. The amount of volatile ether extract is the best criterion of the value of cloves.

Trommsdorf obtained from 1000 parts of cloves 180 of volatile oil, 170 of a peculiar tannin, 130 of gum, 60 of resin, 280 of vegetable fiber, and 180 of water. Win. L. Peabody (1895) found the percentage of tannin in cloves to range from 10 to 13 per cent., and that it has the same chemical composition as gallo-tannic acid. Lodibert afterwards discovered a fixed oil, aromatic and of a green color, and a white resinous substance which crystallizes in fasciculi composed of very fine diverging silky needles, without taste or odor, soluble in ether and boiling alcohol, and exhibiting neither alkaline nor acid reaction. This substance, called by Bonastre caryophyllin, was found in the cloves of the Moluccas, of Bourbon, and of Barbados, but not in those of Cayenne, from which, however, it has since been procured. To obtain it, the ethereal extract of cloves is treated with water, and the white substance thrown down is separated by filtration, and treated repeatedly with ammonia to deprive it of impurities. The most recent determination of its formula by Mylius (Ber. d Chem. Ges., 1873, p. 1053) makes it $C_{20}H_{32}O_2$. Theod. Martins obtains it cheaply by exposing cloves, previously deprived as far as possible of oil by distillation with water, to distillation at a higher temperature, redistilling the brown liquid obtained until the distillate nearly ceases to have the taste or odor of cloves, and then purifying the residue by washing with water, and treating it with boiling alcohol and animal charcoal repeatedly until the
caryophyllin, which is deposited by the alcohol on cooling, is perfectly white. (See A. J. P., xxxii, 65.) Dumas has discovered another crystalline principle, which forms in the water distilled from cloves, and is gradually deposited. Like caryophyllin, it is soluble in alcohol and ether, but differs from that substance in becoming red when touched with nitric acid. Bonastre proposed for it the name of eugenin. (J. P. C., xx, 565.) It has the formula $C_{10}H_{32}O_6$, and is isomeric with eugenol or eugenic acid, a constituent of oil of cloves. Water extracts the odor of cloves with comparatively little of their taste. All their sensible properties are imparted to alcohol; and the tincture when evaporated leaves an excessively fiery extract, which becomes insipid if deprived of the oil by distillation with water, while the oil which comes over is mild. Hence it has been inferred that the pungency of this aromatic depends on a union of the essential oil with the resin. Caryophyllic acid, $C_{20}H_{32}O_6$, is obtained by gradually adding caryophyllin to fuming nitric acid, kept cool by immersing the vessel in water until crystals begin to separate; these are purified by dissolving them in ammonia, precipitating with hydrochloric acid, and redissolving in alcohol and crystallizing. For an account of the oil, see Oleum Caryophylli. The infusion and oil of cloves are reddened by nitric acid, and rendered blue by tincture of ferric chloride, facts of some interest, as morphine gives the same reactions.

Uses.—Cloves are among the most stimulant of the aromatics, but, like others of this class, act less upon the system at large than on the part to which they 'are immediately applied. They are sometimes administered in substance or infusion to relieve nausea and vomiting, correct flatulence, and excite languid digestion; but their chief use is to assist or modify the action of other medicines. They enter into several official preparations.

The French Codex directs a tincture of cloves to be prepared by digesting for ten days, and afterwards filtering, a mixture of three ounces of powdered cloves and sixteen of 80 per cent. alcohol.

Dose, in substance, from five to ten grains (0.32 to 0.65 Gm.).

**Cascara Amarga.** Honduras Bark.—The bark of Picramnia antidesma Siv. (Fam. Simarubaceae), a shrub growing in Jamaica, Mexico, Panama, and Columbia. It is a bitter tonic credited with specific alterative properties. For an elaborate discussion of the microscopic and chemical characters of the bark and its alkaloid picramnine, by Thompson, see A. J. P., June, 1884.

"The dried bark of the trunk and branches of Rhamnus Purshiana De Candolle (Fam. Rhamnaceae)." U. S. "Cascara Sagrada is the dried bark of Rhamnus Purshianus, DC., collected at least one year before being used." Br.

Rhamni Purshiani Cortex, Fr. Cod.; Sacred Bark; Chittem Wood Bark, Dogwood bark, Coffee-berry bark, Pigeon-berry bark, Bear-berry bark. Bitter bark and Yellow bark; Cascara Sagrada, Sp.

A number of species of Rhamnus have been described as growing in California, but according to the best authority there are only four species,—R. alnifolia, L’Her., R. crocea, Nutt, R. Purshiana, DC., and R. californica, Esch. Of these species, R. alnifolia is too rare in the Cascara district to be important; while the spinescent twigs, the very thick oval or roundish leaves, and the small roundish red fruit of R. crocea make it so distinct that it cannot be confounded with the Cascara, whose bark, moreover, it does not resemble. On the other hand, R. californica appears to be very commonly confounded with the official species by collectors, and to have yielded some of the cascara sagrada bark of commerce. R. californica is rare in Northern California, but abundant in the countries lying south and southeasterly, while R. Purshiana is abundant in Northern California, but scarce in the south, so that any bark collected in Northern California is probably genuine. R. californica is chiefly distinguished from the official species by its leaves being thin, and, when not smooth, having a short close pubescence, and the primary veins of the under surface not nearly so numerous, straight, or fine as those of R. Purshiana. Rusby thinks that its leaves are especially distinguished by the channel of the midrib of R. californica being
altogether absent, or shallow, or inconspicuous. Nevertheless the species so run into one another that competent botanists believe them identical.

The Rhamnus Purshiana is a small tree, attaining a height of twenty feet. Its leaves are rather thin, elliptic, for the most part briefly acutely pointed, finely serrated, at the base obtuse, somewhat pubescent beneath, from two to seven inches long and from one to three wide. The rather large flowers are in somewhat umbellate cymes; the sepals five; the minute cucullate petals bifid at the apex. The fruit is black, broadly obovoid, four lines long, three-lobed, and three-seeded. The seeds are convex on the back, with a lateral raphe. It is found in California, extending northward to the British territories. For details of manner of collecting the bark see an elaborate and illustrated article by Johnson and Hindman, A. J. P.. 1914, p. 387. The amount of Cascara that is collected annually varies between 3,000,000 and 4,000,000 pounds. Because of the rapid destruction of natural sources of the bark in the Western United States, experiments have been conducted by the Bureau of Plant Industry, U. S. Department of Agriculture, Washington, D. C., to cultivate it.

The Rhamnus californica, or Californian buckthorn or California coffee-tree, yields a bark which is of a dark brown color externally and bright yellow internally, having an intensely bitter taste, with a persistent nauseous aftertaste, and very little odor. It is said to be much more distinctly purgative than that of R. crocea.

It does not seem possible to distinguish with certainty between the barks of the two species by their macroscopic appearance. The bark of R. Purshiana is usually more red than is that of R. californica, but it may be of a distinctly gray color. The microscopic structure of the two barks is, however, different. The medullary rays in R. Purshiana are numerous, thin, for a long distance nearly parallel and straight (according to L. E. Sayre, they converge at their outer ends), run nearly three-quarters of the distance through the bark, and are commonly composed of two rows of cells. In R. californica the medullary rays are much broader, much shorter, and are composed usually of three or more rows of cells; further, they are crooked and not parallel throughout their course. Again, the zone of resin spaces is much broader in R. californica, and the spaces themselves much larger and more numerous than in the official species. For further details and elaborations, see papers by H. H. Rusby, Proc. A. Ph. A., 1890, and by Gathercoal, J. A. Ph. A., 1915, p.
15. According to L. E. Sayre (A. J. P., March, 1897), the powder of the barks can be distinguished by paying attention to the fact that *R. Frangula* contains no stone cells, while in *R. californica* and *R. Purshiana* such cells are abundant, occurring in large, irregular groups below the cork and usually outside the region of the bast: *R. Purshiana* may also be distinguished from *R. californica* by color tests. After several days maceration in dilute alcohol the powder of *R. Purshiana* appears of an orange-yellow color, *R. californica* of a purplish color; or if 0.2 Gm. of the powdered bark be placed in a small test tube, and there be added 2 mils of potassium hydroxide test solution, *R. californica* will give a blood-red and *R. Purshiana* an orange-red color.

The bark of the *Rhamnus crocea*, the so-called California mountain holly, occurs in slightly curved pieces, externally of a dark brown color, internally of a characteristic red delicately streaked with numerous white veins. The odor is somewhat aromatic, the taste warming and not unpleasantly bitter. It is affirmed to be a tonic and mild laxative.

**Properties**.—Cascara sagrada occurs in commerce in the form of small broken pieces, often more or less flattened out into a somewhat compressed mass, and also as separated quills of varying length and size. The bark is " Usually in flattened or transversely curved pieces, occasionally in quills; bark from 1 to 5 mm. in thickness; outer surface dark brown or brownish-red, longitudinally ridged, often nearly covered with grayish or whitish lichens, bearing small blackish apothecia, sometimes with numerous lenticels, and occasionally with mosses; inner surface light yellow, light brown, or reddish-brown, longitudinally striate, turning red when moistened with solutions of the alkalies; fracture short, with projections of bast-fibers in the inner bark; in cross section inner bark shows diagonal or curved medullary rays, forming converging groups, the outer bark showing yellowish groups of stone cells which are especially apparent on moistening the freshly cut surface with phloroglucinol T.S. and hydrochloric acid; odor distinct; taste disagreeable, bitter, and slightly acid. Under the microscope, a transverse section of Cascara Sagrada shows an outer yellowish-brown or reddish-brown corky layer consisting of 10 to 15 or more rows of cells; stone cells in outer bark in tangentially elongated groups of 20 to 50 cells, the walls being very thick and finely lamellated; medullary rays 1 to 4 cells wide, 15 to 25 cells deep, the contents being colored red upon the addition of solutions of the alkalies to the sections; bast-fibers in tangentially elongated groups in the inner bark, the walls being thick.
and strongly lignified; crystal fibers around the bast-fibers with individual crystals from 0.008 to 0.015 mm. in length; parenchyma with spheroidal starch grains about 0.003 to 0.008 mm. in diameter, or with calcium oxalate either in rosette aggregates or prisms from 0.01 to 0.02 mm. in diameter. Add 0.1 Gm. of powdered Cascara Sagrada to 10 mils of hot water, shake the mixture occasionally until cold, filter it and add sufficient water to make 10 mils; on the addition of 10 mils of ammonia water to this liquid, it is colored an orange-yellow. Macerate 0.1 Gm. of powdered Cascara Sagrada with 10 drops of alcohol, boil the mixture with 10 mils of water, when cold filter it and shake the filtrate with 10 mils of ether; a yellow ethereal solution separates. Shake 3 mils of this ethereal solution with 3 mils of ammonia water; the separated ammoniacal solution still possesses, on diluting with 20 mils of water, a distinct, yellowish-red color. The powder is light brown to olive brown, showing characteristic elongated groups of bast-fibers associated with crystal fibers, the crystals in the latter being in the form of monoclinic prisms from 0.008 to 0.015 mm. in length; stone cells in large groups, the cells having thick and finely porous walls; fragments of parenchyma and medullary ray cells colored red upon the addition of solutions of the alkalies; starch grains either free or in parenchyma cells, the individual grains being somewhat spheroidal, from 0.003 to 0.008 mm. in diameter; calcium oxalate in monoclinic prisms or rosette aggregates from 0.01 to 0.02 mm. in diameter; occasional fragments of reddish-brown cork."

"In quilled, channelled, or nearly flat pieces from one to two millimetres thick, but varying in length and width. Cork nearly smooth, dark purplish-brown, marked with transversely elongated lenticels, but usually more or less covered with patches of silvery-grey lichen. Inner surface reddish-brown, with faint transverse corrugations and longitudinal striations. Fracture short, but near the inner surface somewhat fibrous. In transverse section, scattered groups of sclerenchymatous cells in both cortex and bast; the parenchymatous cells contain a yellow substance which is colored violet by solution of sodium hydroxide. Odor characteristic but not powerful; taste nauseous, bitter and persistent." Br.

For articles illustrating the pharmacognosy of Cascara bark see Kraemer, A. J. P., 1912, p. 385; Miller, J. A. Ph. A., 1912, p. 1207; and Farwell, J. A. Ph. A., 1914, p. 649. According to the analysis of A. B. Prescott (N. P., Feb., 1879), it contains a very bitter brown resin (which is colored a vivid purple-red by potassium hydroxide); a red resin; a
light yellow resin; tannic, malic, and oxalic acids; a neutral crystallizable substance; and a volatile oil. H. F. Meier and J. Le Roy Webber have pointed out in addition the presence of a ferment, glucose, and ammonia. According to these investigators, to the action of the ferment are attributed the unpleasant results attending the administration of "fresh bark"; "seasoned bark"—i.e., such as has been kept a year or two—owes its valuable properties as a laxative, free from griping, to the fact that the ferment has exhausted itself; the laxative properties, they state, reside in the resins, and the tonic effects are due to the crystalline principle. (A. J. P., 1888, 91). Schwabe (A. Pharm., ccxxvi, 569) found emodin, or trioxymethylanthraquinone, which he believes is the active principle. Dohme and Engelhardt (Proc. A. Ph. A., 1897, 193) have shown the analogy of cascara sagrada with Rhamnus Frangula by obtaining a glucoside to which they give the name of purshianin. This decomposes, yielding emodin, and a dextrorotatory non-fermentable sugar, while the frangulin of buckthorn yields emodin and rhamnose as the sugar. Purshianin forms brown-red needles, melting at 237° C. (458.6° F.). Dohme and Engelhardt failed to obtain in a pure form (Proc. A. Ph. A., 1898, 340) the bitter principle of cascara sagrada. Le Prince (C. R. A. S., 1892, 286) claimed to have obtained the active principle of cascara bark in a crystalline form, which he named cascarine; his results are doubted by Jowett who believes that cascarine and purshianin are impure forms of emodin. Jowett (Proc. A. Ph. A., 1904, 288) in an exhaustive paper concludes that the active principle of cascara is contained in that portion of an alcoholic extract which is soluble in water and precipitable by lead subacetate and in that portion of the regenerated lead subacetate precipitate which is soluble in ethyl acetate. Pietsch states that a glucoside from the bark of cascara sagrada which has been named peristaltin has the composition C_{14}H_{18}O_{8}. (Th. M., 1910, No. 1, p. 35.)

**Uses.**—Cascara sagrada belongs to the group of vegetable cathartics whose activity depends upon the presence of one or more oxides of methylanthraquinone. This group includes aloes, cascara, rhubarb, and senna. In cascara the active principle appears to be emodin, which is trioxymethylanthraquinone, and which appears also to be the purgative principle of aloes. The action of this principle is chiefly to excite peristalsis in the colon, although after large doses there is probably also some effect upon the upper bowel. As the action is chiefly upon the lower intestine it is not to be recommended as a laxative where it is desired to clean out the bowel, but in the treatment of chronic
constipation it acts very favorably. It often appears to restore tone to the relaxed bowel and in this way produce a permanent beneficial effect. The bark itself is rarely used, either the extract or fluidextract being eligible preparations.

The addition of belladonna to overcome any tendency to griping is an advantage. Ordinarily a single dose is given at bedtime but in some cases better results are obtained by exhibiting smaller doses after meals.

Dose, ten to thirty grains (0.6-2.0 Gm.).

**CASCARILLA. Br.**

**CASCARILLA**

"Cascarilla is the dried bark of Croton Eluteria, J. J. Benn." Br. "The dried bark of Croton Eluteria (Linne) Bennett (Fam. Euphorbiaceae), without the presence of more than 5 per cent. of adhering wood." N. F.

Cascarillae Cortex, Br. (1885), Cascarilla Bark, Sweet Bark, Sweetwood Bark; Cascarille officinale, Fr. Cod.; Cortex Eluteriae, Cortex Thuris; Chacarile, Ecorce eleutherienne Cascarille, Fr.; Cortex Cascarillae, P. G.; Cascarillrinde; Cascarilla, Kaskarinlrrinde, G.; Cascarilla, Cascariglia, It., Chacarilla, Quina aromatica, Sp.

Croton Eluteria is a shrub or a small tree with a stem from four to eight inches in diameter. The stem is straight, and marked at intervals with white or grayish stains. The leaves are petiolate, often somewhat cordate at the base, obtusely acuminate, pale or grayish-green above, and densely covered beneath with shining silvery scales, appearing white at a distance. They are smaller and narrower in the plants of
arborescent growth. The flowers, which have a delicious odor, are monoecious, small, white, petiolate, and closely set in simple terminal or axillary spikes. The shrub is a native of the Bahamas, scarce at present in the island of New Providence, but still abundant in Andros, Long, and Eleuthera islands, from the latter of which is derived its botanical title. Daniell calls the plant sweetwood. The name of sea-side balsam belongs to another species, C. balsamiferum of Linnaeus, which grows in the Bahamas and other West India islands, and owes its name to the exudation of a balsamic juice from its young branches when wounded.

Under the name of "cascarilla," also "Quina morada," the bark of the Pogonopus febrifugus is said to be used in the Argentine Republic as a substitute for cinchona bark. There has been separated from it a blue fluorescent substance, moradm, and an alkaloid, moradeine. (P. J., xx, 854.)

Copalchi bark has been mistaken not only for cascarilla, but also for a variety of cinchona. Portions of it, having been taken to Europe, attracted the attention both of pharmacologists and physicians. Two kinds were noticed: one, in small slender quills, of an ash color, bearing some resemblance to a variety of pale cinchona, but having the flavor of cascarilla, and burning with a similar odor; the other in larger quills, with a thick cork-like epidermis, very bitter, and yielding an aromatic odor when burnt. The former is the product of Croton Pseudochina, Schlechtendal (C. niveus Jacquin); the latter is of unknown origin, but conjecturally referred to C. suberosus. J. E. Howard states that the quilled copalchi bark contains a bitter alkaloid, soluble in ether, and precipitable as a white hydroxide from its acid solution. (P. J., xiv, 319.) Copalchi bark is an aromatic tonic, employed in Mexico in intermittents, and capable of useful application in all cases requiring a mild aromatic bitter. Stark has employed it advantageously in feeble states of digestion with irritable bowels, and found it in one or two cases, to exhibit antiperiodic properties. It may be given in infusion, made with half an ounce of the bark to a pint of water, in the dose of one or two fluidounces three times a day. (Ed. Med. and Surg. Journ., April, 1849, p. 410; see also P. J., 1886, p. 917.)

Croton Cascarilla Bennett, known in the West Indies as wild rosemary, was at one time said to furnish the cascarilla of commerce. The bark is also substituted by the barks of Croton gla-belliis L. and C. lucidus L. of the Bahamas and which were formerly designated as the "mother
plants " of Cascarilla. They are not aromatic but astringent and slightly bitter. They are also distinguished by the presence of stone cells which are wanting in true Cascarilla. (See U. S. D., 19th ed.)

Cascarilla is brought to this market from the West Indies, and chiefly, we have been informed, from the Bahamas. It comes in bags or casks. We have observed it in commerce in two forms, so distinct as to merit the titles of varieties. In one, the bark is in rolled pieces of every size, from three or four inches in length and half an inch in diameter to the smallest fragments, covered externally with a dull whitish or grayish-white epidermis, which in many portions is partially, sometimes wholly removed, leaving a dark brown surface, while the inner surface has a chocolate color, and the fracture is a reddish-brown. The small pieces are sometimes curled, but have a distinct abrupt edge as if broken from the branches. The second variety consists entirely of very small pieces, not more than an inch or two in length, very thin, without the white cork, not regularly quilled, but curved more or less in the direction of their length, often having a small portion of woody fiber attached to their inner surface, and appearing precisely as if shaved by a knife from the stem or branches. Whether these two varieties are derived from distinct species, or differ only because of the mode of collection, it is difficult to determine. A. W. Southall describes a bark (believed to belong to the genus Croton, and obtained from Colombia) in P. J., 1894, 574.

"In quills usually from three to ten centimetres in length and from four to twelve millimetres in diameter, or in small curved pieces, Cork greyish-white, easily detached, and often more or less completely removed disclosing a dull brown cortex. Both cork and cortex frequently marked with numerous longitudinal and transverse cracks. Fracture short, the fractured surface exhibiting under a lens a dark reddish-brown bast traversed by numerous, thin, whitish medullary rays. In transverse section cork cells with strongly thickened outer walls, but thin inner walls, in which minute crystals of calcium oxalate are embedded; both cortex and bast free from sclerenchymatous cells. Aromatic odor, especially when burned; taste aromatic and bitter. Ash not more than 11 per cent." Br.

The National Formulary describes it as " in quills or curved pieces from 0.5 to 2.5 mm. in thickness, externally gray, somewhat fissured; the corky layer easily detached, more or less coated with a white lichen; the uncoated surface dull-brown, inner surface smooth; fracture short, the
fractured surface having a resinous and radially striate appearance. Odor characteristic, strong and musk-like when the bark is burned; taste warm, aromatic and very bitter. The powdered drug is pale-brown and has an odor resembling that of clove. When examined under the microscope, it exhibits simple starch grains up to 0.013 mm. in diameter and occasionally two- to three-compound; calcium oxalate in monoclinic crystals or rosette aggregates up to 0.025 mm. in diameter; fragments of parenchyma tissue, some of the cells containing starch, calcium oxalate or tannin; cells filled with reddish-brown resin or yellow oil; somewhat lignified cork cells, polygonal in outline with evenly thickened, lamellated walls and irregular lumina; non-porous bast fibers, some with lignified walls, up to 0.016 mm. in diameter; tracheas with bordered pores very few or absent. Cascarilla yields not more than 10 per cent of ash." N. F.

Cascarilla should yield not more than 10 per cent. of ash.

Properties.—Cascarilla has an aromatic odor, rendered much more distinct by friction, and a warm, spicy, bitter taste. It is brittle, breaking with a short fracture. When burned it emits a pleasant odor, closely resembling that of musk, but weaker and more agreeable. This property serves to distinguish it from other barks. It was analyzed by Trommsdorff, and more recently by Duval of Lisieux, in France. The constituents found by the latter were albumen, a peculiar kind of tannin, a bitter crystallizable principle called cascarillin, a red coloring-matter, fatty matter of a nauseous odor, wax, gum, volatile oil, resin, starch, pectic acid, potassium chloride, a salt of calcium, and lignin. The oil, according to Trommsdorff, constitutes 1.6 per cent., is of a greenish-yellow color, has a penetrating odor analogous to that of the bark, and is of the sp. gr. 0.938. G. Feudler (A. Pharm., 1900, p. 671) finds the oil to contain about 2 per cent. of free acid, which consists of a liquid acid, $C_{11}H_{20}O_2$, to which the name of cascarillic acid was given, and a solid portion made up of a mixture of palmitic and stearic acids. The oil contains 0.3 per cent. of eugenol, a terpene differing from pinene, cymene, possibly some l-limonene, two sesquiterpenes and an alcohol, $C_{15}H_{23}OH$. To obtain cascarillin, Duval treated the powdered bark with water, added lead acetate to the solution, separated the lead by hydrogen sulphide, filtered, evaporated -with the addition of animal charcoal, filtered again, evaporated at a low temperature to a syrupy consistence, and having allowed the semi-liquid substance thus obtained to harden by cooling, purified it by twice successively treating...
it, first with a little cool alcohol, to separate the coloring and fatty
matters, and afterwards with boiling alcohol and animal charcoal. The
last alcoholic solution was allowed to evaporate spontaneously. Thus
obtained, cascarillin is white, crystalline, inodorous, bitter, very slightly
soluble in water, soluble in alcohol and ether. (J. P. C., 3e ser., vii, 96.) It
melts at 205° C. (401° F.), is not volatile nor a glucoside. Its composition
answers to the formula C_{12}H_{18}O_{4}. P. E. Alessandri regards cascarilline
as an alkaloid, and obtains it economically by mixing powdered
cascarilla with sufficient 3 per cent. aqueous solution of oxalic acid to
cover it, shaking the mixture, and heating it to 60° C. (140° F.), then
allowing it to cool, expressing the mixture and saturating the filtered
liquor with ammonia, then evaporating at a low temperature to two-
thirds of its bulk, allowing it to cool, and separating any deposit. The
clear liquid is then shaken with ether; this takes up the cascarilline,
which may be obtained through evaporation of the ethereal liquid.
(L'Orosi, v, 1; P. J., 1882, 993.) R. A. Cripps was unable to obtain the
alkaloid by Alessandri's method, and suggests that the bitterness of the
so-called cascarilline might be due to adherent resin. (P. J., 1886, 1103.)
Either alcohol or water will partially extract the active matters of
cascarilla; but diluted alcohol is the proper menstruum. Naylor and
Littlefield have reviewed the processes of Duval and Alessandri for
preparing cascarilline, and find that Duval's method gives the purer
product. They find its melting point to be 203.5° C. (398.3° F.), and give
it the formula C_{16}B_{24}O_{5}. (Y. B. P., 1896, 301.) W. A. H. Naylor
subsequently found betaine in cascarilla, (P. J., 1898, 279.)

Uses.—This bark is aromatic and tonic. It was known in Germany as
early as the year 1690, and was much used as a substitute for Peruvian
bark by those who were prejudiced against that febrifuge in the
Treatment of remittent and intermittent fevers. It has, however, lost its
reputation, and is now employed only where a pleasant and gently
stimulant (tonic is desirable, as in atonic dyspepsia, and other cases of
debility of the stomach or bowels, especially in combination with the
more powerful bitters. It may be given in powder or "in infusion. In
consequence of its pleasant odor when burned, some smokers mix it in a
small quantity with their tobacco; but it is said to occasion vertigo and
intoxication.

Dose, twenty to thirty grains (1.3-2.0 Gffl.).

Off. Prep.—Infusum Cascarillae, Br.; Tinctura Cascarillae, Br.
**Casearia.** Casearia esculenta Roxb.—This Indian plant (fam. Samydaceae) is said to be a valuable remedy in hepatic torpor, and to contain an organic acid allied to cathartic acid. (P. J., xx.)

**Casimiroa.** Casimiroa edulis La. Llav. Zapote blanco. Cochilsapote White Sapota.—This is a large tree belonging to the Rutaceae, a native of Mexico, the leaves are employed in diarrhea and as an anthelmintic. The seeds are said to be narcotic. In them dose Sanchez (Breve estudio Zabote blanco, Thesis, Mexico, 1893) has found a resin and a crystalline alkaloidal body. The glucoside casimirose, found in this plant by Alta-mirano, as well as the alkaloidal glucoside casimirin, isolated by Bikorn (A. Pharm., ccxii, p. 186), have been found by Esch and Kochmann (A. I. P. T., 1911, xxi, p. 353) to be inert. The extracts of the crude drug, however, have pronounced narcotic properties. They conclude that this drug has the extraordinary property of abolishing the sensation of pain without affecting consciousness or motility. Somewhat in contradiction to this conclusion, however, are the results of Robin and Cojon (Press. Med., 1909, p. 454) who find that the fluidextract of casimiroa in doses of one to two teaspoonfuls has hypnotic properties.

**Cassia.** Cassia marilandica L. Wild Senna. American Senna,. Sene American, Fr. Amerikanische Senna, G. (Fam. Leguminosae)—This is an indigenous perennial plant of vigorous growth, sending up annually numerous round, erect, nearly smooth stems, which are usually simple, and rise from three to six feet in height. The leaves are alternate, and composed of from eight to ten pairs of oblong-lanceolate, smooth, mucronate leaflets, green on their upper surface, pale beneath, and connected by short petioles with the common footstalk, which is compressed, channelled above, and furnished near its base with an ovate, stipitate gland. The American senna is common from New England to North Carolina. The leaves, which should be collected in August or the beginning of September, are sometimes brought into the market, compressed into oblong cakes, like those prepared by the Shakers from most herbaceous medicinal plants. The leaflets are from an inch and a half to two inches long, from one-fourth to half an inch in breadth, thin, pliable, and of a pale green color. They have a feeble odor, and a nauseous taste, somewhat analogous to that of senna. Water and alcohol extract their virtues. Hermann J. M. Schroeter (A. J. P., 1888, 231) found in them chrysophanic acid; also an active principle corresponding in all respects with cathartic acid. For earlier analysis by Martin, see A. J. P., i, 22. American senna is an efficient and safe cathartic, acting like senna but more feebly.

Cassia nictitans L., or Wild Sensitive Plant, was investigated by Gallaher (A. J. P., 1888, 280), who failed to find any glucoside or alkaloid. The amount of volatile oil found was very small, and cathartic acid could not be prepared from it, although the powder produced griping. The leaves of Cassia alta L. are recommended by Conille-bault in ringworm; they are moistened and the parts affected rubbed with them. (A. J. P., 1887, 266.)

Under the names of Cheshmat, Chashmizok, Schischen, the seeds of C. Absus L. are said to be used in India and Africa in the treatment of inflammations of the eye, either
in the form of a fine powder or an infusion made from the coarsely ground seeds to which several medicinal substances are added.

The root of the Cassia bearensis Miq. is said to be very useful in the so-called black-water fever of Africa. (See P. J., vols. xlvii, xlviii.)

**CASSIA FRUCTUS. Br.**

**CASSIA PODS [Purging Cassia]**

"Cassia Pods are the ripe fruits of Cassia Fistula, Linn." Br. "The dried fruit of Cathartocarpus Fistula (Linne) Persoon (Fam. Leguminosae)." N. F.

**Cassia Fistula.** N.F.IV, Purging Cassia, Pudding-stick (or pipe); Fructus Cassiae Fistulae; Casse Officinale, Fr. Cod.; Casse en batons, Pulpe de Casse, Casse Mondee, Casse, Fr.; Rohrenkassie, Purgircassie, Fistelkassie, G.; Cassia, It.; Cana fistula, Sp.

Cassia Fistula L. (Cathartocarpus Fistula Persoon). This is a large tree, with a trunk of hard, heavy wood, dividing towards the top into numerous spreading branches, and covered with a smooth ash-colored bark. The leaves are 'commonly composed of five or six pairs of opposite leaflets, which are petiolate ovate, pointed, undulated, smooth and of a pale green color. The flowers are large, of a golden yellow color, and arranged in long, pendent, axillary racemes. The fruit consists of long, cylindrical, woody, dark-brown, pendulous pods, which when agitated by the wind strike against each other and produce a sound that may be heard at a distance. This species of Cassia is a native of Upper Egypt and India, whence it is generally supposed to have been transplanted to other parts of the world. It is at present very extensively diffused through the tropical regions of the old and new continents, being found in Insular and Continental India, Cochin China, Egypt, Nubia, the West Indies, and the warmer parts of the continent of America. Under the name of Golden Shower it is known as an ornamental shade tree in all tropical countries. The fruit is the official part of the plant. It is imported from the East and West Indies, chiefly the latter, and from South America. Under the name of Cassia Fistula they were for a long time official.

**Properties.**—Cassia pods are a foot or more in length, straight, or but slightly curved, cylindrical, less than an inch in diameter, with a woody shell, externally of a dark-brown color, and marked with three
longitudinal shining bands, extending from one end to the other, two of which are in close proximity, appearing to constitute a single band, and the third is on the opposite side of the pod. These bands mark the place of junction of the valves of the legume, and are represented as sometimes excavated in the form of furrows. There are also circular depressions at unequal distances. It is described as follows: "Long, narrow, cylindrical, shortly stalked fruits about thirty-five to fifty centimetres in length, and fifteen to twenty-five millimetres in diameter. Pericarp nearly smooth, dark chocolate-brown or nearly black, thin and hard. Internally divided by thin transverse dissepiments into numerous compartments, each of which contains a smooth, oval, reddish-brown seed surrounded by a nearly black, sweet pulp." Br.

The N. F. describes it as in "cylindrical, from 25 to 50 cm. in length, about 20 mm. in diameter, chestnut-brown in color, on one side a longitudinal groove and on the other a smooth line or slight ridge, indicating the sutures; in-dehiscent, the cavity divided transversely into numerous compartments, each containing a reddish-brown, glossy, flattish-ovoid seed embedded in a blackish-brown sweet pulp. Odor resembling that of prunes." N. F.

The pods brought from the East Indies are smaller, smoother, have a blacker pulp, and are more esteemed than those from the West Indies. We have seen pods in the American market sold as cassia pods, which were an inch and a half in diameter, flattened on the sides, exceedingly rough on the outer surface, and marked by three longitudinal very elevated ridges, corresponding to the bands or furrows of the common cassia. The pulp was rather nauseous, but in other respects seemed to have the properties of the official purging cassia. They corresponded exactly with a specimen of the fruit of Cassia brasiliana, Lam., brought from the West Indies, and were probably derived from that plant.

The heaviest pods, and those which do not make a rattling noise when shaken, are to be preferred, as they contain a larger portion of the pulp, which is the part employed. This should be black and shining and have a sweet taste. It is apt to become sour if long exposed to the air, or mouldy if kept in a damp place. The pulp is extracted from the pods by first bruising them, then boiling them in water, and afterwards evaporating the decoction; or, when the pods are fresh, by opening them at the sutures and removing the pulp with a spatula.
CASSIAE PULPA. Br.
CASSIA PULP
"Exhaust crushed Cassia Pods by percolation with Distilled Water;
strain; evaporate on a water bath to the consistence of a soft extract."
Br.
Cassia pulp has a slight odor, and a sweet mucilaginous taste.
According to Henry it contains sugar, gum, coloring matter, and a
tannin-like substance; while Haensel obtained from it by steam
distillation a dark yellow volatile oil, also butyric acid. (Ph. Cb., 41.)
Uses.—Cassia pulp is laxative, and may be advantageously given in
small doses in cases of habitual costiveness. In quantities sufficient to
purge, it occasions nausea, flatulence, and griping. In this country it is
rarely prescribed, except as an ingredient in the confection of senna,
which is a pleasant and useful laxative preparation.
Dose, of the pulp as a laxative, one or two drachms (3.9 or 7.7 Gm.), as a
purge one or two ounces (31-62 Gm.).
Off. Prep.—Confectio Sennse, Br.
Castanea. N. F. IV. Chestnut Leaves.—"The dried leaves of Castanea dentata
(Marshall) Borkhausen (Fam. Fagaceae), collected in September or October while still
green, and without the presence of more than 5. per cent. of twigs or other foreign
matter." N. F. It was official in the U. S. P., 1890. Of the few species included in the
genus Castanea, two are natives of North America. Of these C. dentata has been
considered by many botanists as identical with C. sativa Mill. (C. vesca Gaertn.), of
Europe, and was described by Michaux as a variety of that species under the name of
americana. Botanists at present, however, generally consider the two species as
distinct. "Petioles stout, about 12 mm. in length; blades entire or slightly broken and
usually folded or matted together; about 15 to 25 cm. in length and about 5 cm. in
breadth, oblong-lanceolate, apex attenuate, acute at the base, coarsely and sharply
serrate with ascending, attenuate teeth, nearly smooth, coriaceous in texture, the
upper surface dark green, the lower light green; distinctly pin-nately veined, the veins
of the first order diverging at an angle of about 60 degrees, each terminating in one of
the teeth. Odor slight; taste astringent. The powdered drug, when examined under the
microscope, shows a few non-glandular hairs from 0.1 to 0.5 nun. in length, nearly
smooth, thick-walled, distinctly yellow, occasionally in groups of three to eight and
spreading from the base; numerous calcium oxalate crystals in rosette aggregates or
in monoclinic prisms, from 0.01 to 0.04 mm. in diameter; parenchyma cells containing
irregular yellowish-brown tannin masses which are colored blue with ammonio-ferric
UNITED STATES DISPENSATORY - 1918 - Botanicals Only - C - Page 61
The Southwest School of Botanical Medicine http://www.swsbm.com


alum T.S. Castanea yields not more than 5 per cent. of ash." N. F. It is almost impossible to exhaust the leaves by percolation. Their odor is feeble and their taste slightly astringent. They yield their virtues freely to water, and probably less so to alcohol. John B. Turner found in chestnut leaves chlorophyll, tannin, gallic acid, gum, and albumen. (A. J. P., 1879, p. 542.) In addition to these constituents, L. J. Steltzer found potassium, calcium, magnesium, and iron carbonates, chlorides, and phosphates, and a trace of resin and fat. (A. J. P., 1880, p. 294.)

There is a popular superstition that chestnut leaves are of value in whooping cough, but the possession by them of any physiological or medicinal power is extremely doubtful. They may be administered in the form of a fluidextract which is official in the N. F. Dose, one drachm (4 Gm.).

Castanea pumila. (L.) Mill., Chinquapin of the Southern United States, is a bush or small tree usually eight or ten feet in height, but in the Gulf States reaches sometimes thirty feet. The oblong, acute, mucronately serrated leaves are readily distinguished from those of the ordinary chestnut by being whitish and downy underneath. The tree produces a small, edible nut. The bark has been used as an astringent tonic. (For analysis, see A. J. P., 1899.)

Castela. Castela Nicholsoni texana Jorrey and Gray. (Fam. Simarubaceae)—This plant, which is known among the Mexicans as Chaparro amargosa, that is, bitter bush, has been highly recommended by Nixon (J. A. M. A., 1916, Ixvi, p. 946) in the treatment of amebic dysentery. He found that a detannated fluidextract in the proportion of one part in a million was sufficient to cause the Entamoeba histolytica to become immobile and to assume a spherical shape, with sharp differentiations of ectoplasm and endoplasm. In ordinary diarrhea or in helminthiasis he found the drug of no value.

Putegnat (N. R., 1883, xii, p. 102) has separated a bitter principle, amargosin, which, however, is of doubtful importance. Nixon preferred a decoction of the drug, but the fluidextract is upon the market and may be given in doses of one to three fluidrachms (4.0-12.0 mils).

Catalpa. Catalpa bignonioides Walt. Catalpa-tree, or Catawba-tree Indian Bean.—This is a beautiful, indigenous, flowering tree, of the fam. Bignoniaceae, the seeds of which have been employed in asthma. Eugene O. Eau obtained from them tannin and a bitter crystalline principle. (A. J. P., xlii, 204.) F. K. Brown obtained from the seeds resin, fixed oil, tannin, sugar, and two crystalline bodies, their exact nature not being determined. (A. J. P., 1887, 230.) I. Schneck states that large doses cause nausea, vomiting, and slow, weak, intermittent pulse. He gave two fluidrachms (7.5 mils) of the tincture (1 oz. troy to 1 pint) every one to three hours.

CATECHU. Br.

CATECHU [Catechu Paliidum]
"Catechu is an extract of the leaves and young shoots of Uncaria Gambier, Roxb." Br.

Catechu is described in the Br. Pharm., 1914, as follows: "In cubes, sometimes more or less agglutinated, each side measuring about twenty-five millimetres. Dark reddish-brown externally, pale cinnamon-brown internally, porous and friable. When examined under the microscope they are found to consist chiefly of minute acicular crystals. No odor; taste at first bitter and very astringent, but subsequently sweetish. Almost entirely soluble in boiling water. Not less than 80 per cent. is soluble in alcohol (90 per cent.); the alcoholic solution made strongly alkaline with solution of sodium hydroxide and shaken with petroleum spirit imparts to the latter a brilliant green fluorescence (distinction from Black Catechu); the residue insoluble in alcohol (90 per cent.) exhibits no starch grains when examined under the microscope. Ash not more than 5 per cent.; ash of the powder not more than 8 per cent." Br.

(See Gambir.)

**CATECHU NIGRUM. Br.**

**BLACK CATECHU**

"Black Catechu is an extract prepared from the wood of Acacia Catechu, Willd." Br.

Cutch, Cachou, Fr.: Phgu, Katechu, G; Caticu, Catto, It.; Catecu, Sp.; Cutt, Hindostanee.

The U. S. P. (8th Rev.) dismissed catechu and introduced gambir because of the greater uniformity in quality of the latter. See Gambir.

The U. S. P. 1890 defined catechu as "an extract prepared from the wood of Acacia Catechu (Linnae fil.) Willdenow (Fam. Leguminosae)."

Acacia Catechu is a small tree, seldom more than twelve feet in height, with a trunk one foot in diameter, dividing towards the top into many close branches, and covered with a thick, rough, brown bark. This species of Acacia is a native of the East Indies, growing abundantly in various provinces of Hindostan, and in the Burmese Empire. It is also
common in eastern Africa where it is valued for its wood; but no extract appears to be made from it. Pereira says that its is common in Jamaica.

This drug had been long known before its source was discovered. It was at first called Terra japonica, under the erroneous impression that it was an earthy substance derived from Japan. When ascertained by analysis to be of vegetable origin, it was generally considered by writers on the Materia Medica to be an extract of the betel nut. Its true origin was made known by Kerr, assistant surgeon of the civil hospital in Bengal. According to Kerr, the manufacturer, having cut off the exterior white part of the wood, reduces the interior brown or reddish-colored portion into chips, which he then boils in water in unglazed earthen vessels until all the soluble matter is dissolved. The decoction thus obtained is evaporated first by artificial heat, and afterward in the sun, until it has assumed a thick consistence, when it is spread out to dry upon a mat or cloth, being, while yet soft, divided by means of a string into square or quadrangular pieces. The account subsequently given by Royle, of the preparation of the extract in Northern India, is essentially the same. The process, as he observed it, was completed by the pouring of the extract into quadrangular earthen moulds. It is said that the unripe fruit and leaves are also sometimes submitted to decoction. Three colors of catechu are prepared; the light red or red, which is considered best and is especially employed in Burma and India to chew with the betel nut; the dark red and black, which are made especially for European and American markets, and which are apt to suffer adulteration en route in China.

The name catechu in the native language signifies the juice of a tree, and appears to have been applied to astringent extracts obtained from various plants. Commerce is chiefly supplied with catechu from Bahar, Northern India, and Nepaul through Calcutta, from Canara through Bombay, and from the Burmese dominions. It is frequently called cutch by the English traders, a name derived from the Hindostanee word cutt.

It enters commerce in large masses, sometimes of one cwt., consisting of layers of flat cakes, frequently wrapped in the leaves of the Diptero-carpus tuberculatus Roxb. In this form, however, we do not see it in drug stores, but almost always in angular, irregular fragments, in which portions of two layers sometimes cohere with leaves between them, indicating their origin. It is characterized by its compactness, shining fracture, and blackish-brown or dark port-wine color, so that
when finally broken it bears considerable resemblance to kino. This is an excellent variety of catechu.

Catechu is inodorous, with an astringent and bitter taste, followed by a sense of sweetness. It is brittle, and breaks with a fracture which is rough in some specimens, in others uniform, resinous, and shining. That which is preferred in our market is of a dark color, easily broken into small angular fragments, with a smooth, glossy surface, bearing some resemblance to kino. Catechu is often mixed with sand, sticks, and other impurities.

Black catechu is described in the Br. Pharm., 1914, as follows: "In irregular masses of a dark brown color; brittle, having a porous, glossy, somewhat conchoidal fracture. Partially soluble in cold water, almost entirely soluble in boiling water. Not less than 60 per cent. is soluble in alcohol (90 per cent.). No odor; taste sweetish, astringent. Its dilute aqueous solution gives a dark green color with T. Sol. of ferric chloride, changing to purple when made slightly alkaline with solution of sodium hydroxide. Ash not more than 5 per cent.; ash of the powder not more than 8 per cent. In India, in the Eastern, and in the North American Divisions of the Empire, Black Catechu may be employed in making the official preparations for which Catechu is directed to be used." Br.

The proportion of tannic acid, which may be considered the efficient principle, varies from about 45 to 55 per cent. in catechu or cutch, and from 36 to 40 per cent. in gambir. The portion designated by Davy as extractive is said to contain, if it does not chiefly consist, of a principle discovered by Buchner, and now called catechin, catechuin, or catechuic acid, to which Etti gives the formula $C_{18}H_{18}O_{8}$, and catechu red, $C_{36}H_{34}O_{15}$, which is evidently the first anhydride of catechin. The catechu tannic acid is of the variety which precipitates iron of a greenish-black color, and differs from most of the other varieties in not yielding grape sugar when digested with diluted sulphuric acid. It is not, therefore, a glucoside. It precipitates gelatin, but not tartar emetic (Kane), and is not, like the tannic acid exposure of galls, converted into gallic acid by the access of the air. Catechu is almost wholly soluble in a large quantity of water, to which it imparts a brown color. The extractive or catechuic acid is much less soluble than the astringent principle, which may be almost entirely separated from it by the frequent application of small quantities of cold water. Boiling water dissolves it much more readily than cold, and deposits it of a reddish-
brown color upon cooling. Both principles are readily dissolved by alcohol or proof spirit, and also by ether.

De Meyer affirms that the best method of detecting adulteration of catechu is to treat the suspected drug with ether. Catechu of good quality, after repeated treatment with ether, loses 53 per cent. of its weight, and the dried residue weighs only 47 per cent. of the catechu employed. If this be exceeded, the drug must be proportionately impure. (J. P. C., June, 1870, 479.) A. Jossart (J. P. A., 1881, 41) examined a catechu which was adulterated with from 60 to 65 per cent. of ferrous carbonate. For methods of assaying catechu and gambir, see Trimble's The Tannins, 43; also Ph. Rev., 1897, 27. (See also Gambir, p. 507, and U. S. D., 19th ed., p. 1436.)

Catechu is used for the same purposes and in the same proportions as Gaymbir, see page 507.

Dose, five to fifteen grains (0.3-1.0 Gm.).

**Off. Prep.**—Pulvis Catechu Compositus, Br.; Tinctura Catechu, Br.; Trochiscus Catechu, Br.

**Catha.** Catha edulis.—Under various Arabic names, such as Kat, Khat, Chaat, Kuses Salahin, Tchaad, Tschut, Tohat, Tohai, Gat, the leaves of Catha edulis Forsk. (fam. Celastraceae) (Abyssinian or African tea) are very largely used as a stimulant in Northern Africa, the plant being extensively cultivated. According to Collin, from 1400 to 1500 camel loads are yearly sold in Aden. The plant is a shrub, reaching the height of 9 to 12' feet, with thin coriaceous leaves whose margins are bluntly serrate. The rounded grayish-green twigs are, for commercial purposes, dried with the leaves and tied together in bundles containing about forty twigs; the bundles are commonly from twelve to fourteen inches in length and three to four inches in diameter, but sometimes much smaller. The leaves are chewed both in the green and fresh condition, and are in some places made into a tea. The taste is sweetish and astringent, somewhat suggesting licorice. They are asserted to act as stimulants, overcoming the sense of fatigue in the same way as cocaine, or caffeine. Fluckiger and Gerrock found in it an alkaloid, ratine, C_{10}H_{18}ON_{2}, which has been studied by Chevalier (B. G. T., 1911), who finds that it is a stimulant to the central nervous system. Stockman (P. J., Nov. 30, 1912) found three alkaloids, cathine, cathinine, and cathidine, and also a fourth alkaloid in too small quantities for study. He found (J. P. Ex. T., 1913, iv) that these alkaloids were stimulating to both the brain and spinal cord, and in large doses produced paralysis through a direct action upon the muscle.

**Catnep.** N. F. IV. Cataria. Catmint. Catnip. Cataire Fr. Katsenmunze G. Cattara, It. Gatera, Sp.—It is described in the N. F. as "the dried leaves and flowering tops of
Nepeta Cataria Linne (Fam. Labiateae). Tops, when whole, from 10 to 20 cm. in length, much branched, commonly crushed and broken; stems quadrangular, downy; leaves opposite, those of the stem petiolate, from 2 to 7 cm. in length, rounded heart-shaped at the base, oblong, pointed at the apex, pale gray-green, soft-hairy above, downy beneath, margin deeply crenate, floral leaves small, bract-like; flowers small, in dense, interrupted spikes; calyx hairy, tubular, curved obliquely and sub-equally five-toothed; corolla whitish, dotted with purple, throat dilated, limb bilabiate, the upper lip erect, two cleft, lower spreading, three cleft, the middle lobe largest, crenulate; stamens two pairs ascending under the upper lip, lower pair shorter. Odor faintly aromatic and mint-like; taste bitter, pungent and aromatic. Catnip yields not more than 16 per cent. of ash."

N. F. Catnep is a perennial labiate plant which is common near dwellings in the United States, but is supposed to have been introduced from Europe. It is called catnip on account of the fondness which cats show for it either in the fresh or the dried condition. The active constituents are volatile oil, and tannin of the kind which produces a greenish color with the salts of iron. Therapeutically it is very feeble. Dose, one drachm (4 Gm.).

Caulophyllum, N. F. IV. Pappoose Root. Squaw Root. Blue Cohosh.—"The dried rhizome and roots of Caulophyllum thalictroides (Linne) Michaux (Fam. Berberidaceae)." N. F. This is an indigenous, perennial, herbaceous plant, with matted, knotty rhizomes, from which rises a single smooth stem, about two feet high. "Rhizome of horizontal growth, from 7 to 25 cm. in length, and from 5 to 15 mm. in thickness, much branched, slightly compressed from above, bearing large, cup-shaped stem scars on the upper surface, underneath a tangled or matted mass of long, curved, thin, tough roots which frequently conceal the rhizome; both rhizome and roots of a grayish or yellowish-gray color; fracture tough and woody. Odorless but sternutatory; taste bitter-sweet and acrid. The powdered drug is light brown and, when examined under the microscope, it exhibits numerous starch grains, spherical in outline, mostly simple, up to 0.016 mm. in diameter; fragments of cork with cells about 0.05 mm. in diameter and having yellowish-brown walls; tracheae with bordered pores, the cells being up to 0.05 mm. in width; wood fibers with heavily lignified walls; fragments of parenchyma tissue with many of the cells containing starch grains. Caulophyllum yields not more than 6 per cent. of ash." N. F.

Mayer found caulophyllum to contain a saponin and a colorless alkaloid. (A. J. P., 1863, 99.) The caulophyllin of the eclectics is made by pouring a concentrated alcoholic tincture into water and collecting the precipitate, washing with ether, and drying. For an analysis of this substance by J. F. H. Gilbard, see P. J., 1911, 101. J. U. Lloyd purified the substance which Ebert described as analogous to saponin, and for distinction terms it leontin. (See Drugs and Medicines of North America, vol. ii, 152.) He also obtained caulophylline, the alkaloid first announced by Mayer in 1863. Lloyd describes it as colorless, odorless, possessed of little taste, and dissolving freely in water, alcohol, ether, and chloroform. It crystallizes with difficulty. The hydrochloride has been obtained, however, in crystals. It has not been tested physiologically. The fruit has been analyzed by Edith Stockton and C. G. Eldridge. (See Chem. News, 1908, 190.)
Caulophyllum has been used by eclectic and homoeopathic practitioners. It is said to be sedative, antispasmodic, and oxytocic, and to have the power when uterine inertia occurs during labor to cause the contractions to become very severe, without altering their general character as does ergot. It is also alleged to be capable of arresting threatened abortion, to be very efficacious in hysteria, amenorrhea, dysmenorrhea, menorrhagia, uterine subinvolution, etc.; also to be capable of originating uterine contractions and of producing abortion. For a detailed description of the various contradictory powers ascribed to it, the reader is referred to Lloyd's Drugs and Medicines of North America, vol. ii, p. 155. It is given in decoction, infusion, or tincture, the first two being made in the proportion of an ounce to a pint of water, the last of four ounces to a pint of spirit. Dose, of decoction or infusion, one or two fluid-ounces (30 or 60 mils); of the fluidextract five to ten minims (0.3-0.6 mil). Leontin has been used in doses of six-tenths of a grain (0.04 Gm.) in a one per cent. solution.

**Cayaponia.** Cayaponia globosa. Silva Manso.—This is a cucurbitaceous plant of Brazil, from which Gubler has extracted the alkaloid cayaponine, said to purge without griping. Dose, one grain (0.065 Gm.). (Rep. de Pharm., 1879, 193.)

**Ceanothus.** Ceanothus americanus L. New Jersey Tea. Red-root. Ceanothe, Fr. Seckel-blumen-wurzel, G.—A small indigenous shrub, of the fam. Rhamnaceae, growing from western Ontario and Maine southward. The root is astringent, and imparts a red color to water. H. K. Bowman found in it 9.21 per cent. of tannin. (A. J. P., 1869, 195.) F. C. Gerlach has again examined the root. (A. J. P., 1891, 332.) He finds 6.48 per cent. of tannin and 0.52 per cent. of an alkaloid to which he gives the name ceanothine. J. H. M. Clinch has found in the leaves a resin and a volatile oil. (A. J. P., xi, 1884.) J. A. Buckner (A. J. P., 1891, 428) found 9.45 per cent. of tannin in the leaves. Ceanothus is said to be useful in syphilis. Schoepf states that it is purgative. The leaves were used during the Revolutionary War as a substitute for tea. The Mexican C. cceruleus Lagasca (G. azureus Desf.) is used as a febrifuge.

**Cecropia Obtusa** Tree. (Fam. Urticaceae)—An extract of these leaves is used as a diuretic, having an action similar to that of digitalis though less toxic than it. Dose of the liquid extract, thirty minims (1.8 mils).

**Cedron.**—The seeds of the Simaba Cedron Planch., a tree growing in Colombia and Central America, belonging to the Simarubaceae. The fruit is a large solitary drupe, containing a single seed. Cedron seed is from 3 to 4.5 cm. long, and 1.5 to 2.5 cm. broad, elongated ovate, convex on one side, flat or slightly concave on the other, and presenting an oval scar near one extremity of the flat surface. It is often yellowish, hard and compact, but readily cut with a knife; is inodorous, but of a pure and intensely bitter taste, not unlike that of quassia. It yields its virtues to water and alcohol. Lowry (J. P. C., xix, p. 365) separated from what he believed to be the seeds of Simaba Cedron, a crystalline substance which he named cedrin. Tanret, however, in attempting to confirm his work, was unable to obtain a crystalline substance from this plant, but he did from one closely allied to it, namely, the S. waldivia, and believed that Lowry was mistaken in the identity of his crude material. (See P. J. , 1908, lxxi,
Cedrin is now an article of commerce in the colorless crystals. It is bitter, slowly soluble in water, more readily so in alcohol or ether.

Cedron has been used in Central America as a remedy for snake bite and Purple has recommended it as an antiperiodic. The dose of the crude drug is from five to fifteen grains (0.3-0.9 Gm.). The bitter principle cedrin has been given hypodermically in doses of one-fifteenth of a grain (0.004 Gm.).

Celastrus.—Various species of the Celastraceae have medicinal properties. In the East Indies the oil obtained from the seeds of Celastrus paniculatus Willd. is used as a powerful stimulant and diaphoretic in rheumatism, gout, and various fevers. The oil is said to be deep reddish-yellow, and to become thick and honey-like on keeping. It is sometimes known as oleum nigrum. In Abyssinia, according to Dragendorff, the leaves of C. serratus Hochst. (C. obscurus A. Rich.) are used as an antiperiodic under the name of Add-add. Dragendorff found in them tannic acid, a volatile oil, and a bitter principle, celastrine. (A. J. P., xxvi.) In North America the bark of Celastrus scandens L. (climbing staff tree, false bittersweet, fever twig) has been used in chronic affections of the liver and in secondary syphilis, and is said to be emetic, diaphoretic, and alterative. C. H. Bernhard found in the bark acid and neutral resin, starch, glucose, gum, a caoutchouc-like body, coloring matter, and volatile oil. (A. J. P., 1882, 1.) Wayne stated that he had isolated from C. scandens white minute crystals, to which he gave the name of celastrine. According to Ugolino Mosso (Rivista Clinica, 1891), celastrine arrests the frog's heart in systole; does not affect markedly the blood pressure in mammals, and influences the respiration only through its action on the vagus. The stimulant action is especially manifest on the brain and is not followed by a secondary depression. There is marked, persistent elevation of the temperature.

Celery Fruit. Apii Fructus. N. F. IV. Celery Seed. March, Celeri, Fr. Sellerie, Eppich, G.— "The ripe fruit of Apium graveolens Linne (Fam. Umbelliferae), without the presence of more than 10 per cent. of foreign fruit or other foreign matter." N. F. The ordinary celery of our gardens is too well known to need description. The N. F. recognizes the fruits and describes them as follows: " The fruits consist of two mericarps which may be united or separate. Mericarps ovoid, slightly curved, from 1 to 2 mm. in length, rather more than half as broad and about half as thick, of a rather deep brown color; the inner surface flat, the outer convex, smooth except for five very Blender light-colored ribs, two of which are marginal. Oil-tubes in the pericarp from 6 to 15. Odor characteristic, agreeable; taste aromatic, warm and somewhat pungent. Transverse sections, when examined under the microscope, exhibit nearly equilateral pentagonal mericarps, with somewhat convex surfaces; the carpophore consisting of two groups of strongly lignified sclerenchyma cells; each mericarp has from six to fifteen vitae in the pericarp, the latter closely surrounding a somewhat pentagonal seed; the pericarp has an epidermal layer of cells elongated tangentially and with a thick cuticle; a few of the cells are developed into abort, smooth, papillae; a fibrovascular bundle in each of the prominent ribs, composed of a few tracheae and strongly lignified sclerenchyma fibers; the inner tissue of the pericarp consists of largely tangentially elongated parenchyma with brownish walls; the seed consists chiefly of endosperm; the seed coat is composed of several layers of yellowish more or
less collapsed cells, the endosperm of thick-walled polygonal cells containing fixed oil and aleurone grains, the latter each containing a small rosette aggregate of calcium oxalate. The powdered drug is oily and has a brown color and, when examined under the microscope, exhibits fragments of the pericarp showing yellowish vittae, brown secretion cells and few of the epidermal papillae; tracheae and sclerenchyma fibers; cells of the endosperm with aleurone grains containing rosette aggregates of calcium oxalate from 0.002 to 0.006 mm. in diameter. Celery Fruit yields not more than 8 per cent. of ash."

Oil of Celery Seed was investigated by Swenholt, who found that it consisted of two oils, one heavy, sp. gr. 0.877, at 20° C. (68° F.), the other light, sp. gr. 0.84. Celery seed contains apiol but in less quantity than parsley (see Petroselinum). Celery has by some been believed to act as a nerve sedative and is used in hysteroidal statea, but with doubtful advantage. The dose is twenty to sixty grains (1.2-3.9 Gm.).

Apium nodiflorum (L.) B. et H.-I. (Sium nodiflorum L.) Water parsnip. —This is a perennial, umbelliferous, aquatic, European plant, growing also in the southern section of the United States. It is commonly considered poisonous; but the fresh juice has been used by Withering and others, in the dose of three to four ounces every morning, for scrofulous lymphadenitis and obstinate skin diseases.

**Centaurea.** Cnicusbenedictus L. (Centauriabenedicta L.) Blessed Thistle. Chardon benit, Fr. Herba Cardui Benedicti, P. G. Benedicten Distel, G.—This is an annual herbaceous composite common in Europe and occasionally seen on roadsides and waste places in the United States. The leaves were formerly official. They should be gathered when the plant is in flower, quickly dried, and kept in a dry place. The herb has a feeble, unpleasant odor and an intensely bitter taste, more disagreeable in the fresh than in the dried plant.

Water and alcohol extract its virtues. The infusion with cold water is a grateful bitter; the decoction is nauseous, and offensive to the stomach. The active constituents are volatile oil and cnicin. This is crystallizable, inodorous, very bitter, neutral, scarcely soluble in cold water, more soluble in boiling water, and soluble in all proportions in alcohol. Its formula is $C_{42}H_{56}O_{15}$, and it is analogous to salicin in composition. It has been used as a bitter tonic, and is, in larger quantities, emetic. Tonic dose from half a drachm to one drachm (2.0-3.9 Gm.) preferably given as an infusion.

Silybum Marianum Gaertn. (Mariana Mariana, (L.) Hill, Carduus Marianus L.) was of old used for the same purpose as C.benedictus. Rademacher attributed great value to the seeds in hemorrhages, particularly when connected with diseased liver or spleen. Lobach found the decoction (two ounces to the pint of water), in doses of four fluidrachms (15 mils) every hour, useful in amenorrhea and menorrhagia. (Am. J. M. S., April, 1859.)

The Southwest School of Botanical Medicine http://www.swsbm.com
Gentianaceae) —This is a small, annual herbaceous plant which grows wild in most parts of Europe. The dried flowering plant is found in commerce. It is described in the N. F. as "the dried flowering plant of Erythraea Centaurium (Linne) Persoon (Fam. Gentianaceae). Glabrous, from 1.5 to 5 dm. in height, much branched from the base, but little branched, if at all, from above; stems slender, sharply angled or narrowly winged, sparsely leafy; leaves opposite, entire, mostly three-nerved, sessile, those at the base obovate and obtuse, from 2 to 5 cm. in length, their base narrowed and petiole-like, those of above gradually changing to oval, then ovate or even lance-linear, acute; flowers in a terminal and at length compound cyme, rose-colored; calyx from 5 to 7 mm. in length, deeply five-parted, the tube short, sharply angled, lobes linear-attenuate with a sharp midrib; corolla tube nearly twice the length of the calyx, slender, the limb from 10 to 15 mm. in breadth, its lobes broadly oblong or oval; stamens five, exserted, bright-yellow, their anthers twisted when old; pistil two carpelled. Odor faint but characteristic; taste persistently bitter. Centaury yields not more than 5 per cent. of ash."

The fresh, bitter, odorless herb yields an odorous, pungent distillate in which Mehu (J. P. C., 1862, xliii, 38) has found valeric acid, also a peculiar, colorless, crystalline, non-nitrogenous substance, erythrocentaurin, $C_{27}H_{24}O_8$. Erythrocentaurin occurs in needle-shaped crystals, fusing at 136° G. (276.8° F.), and crystallizing easily on cooling again. They are strongly reddened by exposure to solar light, and reacquire their colorless character upon being again dissolved and crystallized, or by mere heating to 130° C. (266° P.). They are almost insoluble in cold water, more readily soluble in boiling water, alcohol, ether, and chloroform. Carbon disulphide, benzene, volatile and fatty oils dissolve them easily. J. F. Huneker believes that erythrocentaurin exists also in American centaury. (See Sabatia.) Leuderich assigns to erythrocentaurin the formula $C_9H_{14}O_5$ and states that in its decomposition a dextrorotatory carbohydrate is produced, while R. Reis states that the formula of the crystals is $C_{10}H_{10}O_3$. (Ap. Ztg., 1911, 148.) Herissey and Bourdier isolated a glucoside from centaury, erytaurin (J. P. C., 1908, No. 6), but later R. Reis could not detect a glucoside in it. (Ap. Ztg., 1911, 148.) The common centaury of Europe has tonic properties very closely resembling those of gentian. The dose of centaury is from twenty to forty grains (1.2-2.3 Gm.).

A species of Erythraeae, E. chilensis Pers., is employed to a considerable extent in Chili as a mild tonic. (For details, see J. P. C., 3e ser., xxv, 434.) E. acaulis, which grows in great abundance in the territory of French Algiers bordering on the Sahara, yields a root which, under the name of rejagnou, is much employed by the natives for dyeing yellow. (J. P. C., 1867, v, 87.)

Cephalanthus. Cephalanthus occidentalis L. Button Bush. Button Wood. Crane Willow. Swamp Dogwood. (Fam. Rubiaceae)—A common indigenous shrub which grows in moist places, as along streams or on the borders of swamps. Its bark is bitter, is said to be laxative as well as tonic, and has been given in periodical fevers, in decoction or infusion. (See M. R., 1911, 216.) E. M. Hattan found in it a crystallizable fluorescent acid, a bitter uncrystallizable principle, a principle resembling saponin, tannin, two resins, fatty matter, gum, glucose, and starch. (A. J. P., xlii, 314.) According to Claassen (Ph. Rund., Bd. vii, 1889), the fluorescent acid of Hattan is composed of two substances, cephalin and cephaladin. Carl Mohrberg has separated
from the bark a substance which he knows as cephalanthin, and also a toxic saponin-like principle which, like its allied poisons, has the power of dissolving the blood corpuscles. Cephalanthin he finds to be a distinct poison to both cold and warm blooded animals, causing destruction of blood corpuscles with conversion of oxyhemoglobin into methemoglobin, violent vomiting, convulsions, and paralysis. (See Robert's Arbeiten, viii, 1892.)

Ceratopetalum.—The New South Wales species of this genus, viz., C. gummiferum Sm. and C. apetalum Don., of the Saxifragaceae yields considerable quantities of a kino-like gum. The barks contain coumarin. (See P. J., xxi, 742.)

Cercis. Cercis canadensis L. Judas Tree. Redbud.—The bark of this beautiful leguminous tree, indigenous and well-known throughout the Eastern and Central United States on account of its brilliant red-purple flowers, which appear before the leaves, has been highly recommended by Wm. R. Smith as a mild but very active astringent in the treatment of chronic diarrhea and dysentery. Dose, of the fluidextract, from half to one flui-drachm (1.8-3.75 mils).

Cetraria. U. S. 1890. Iceland Moss. Iceland Lichen.—Under this name the U. S. P. formerly recognized the dried plant of Cetraria islandica Acharius, Liche, islandicus L. This plant, although known as a moss, is not a moss, but a lichen which grows in most northern latitudes and on elevated mountains further south, including the Northern United States.

The dried plant is of diversified color, grayish-white, brown, and red, in different parts, with less of the green tint than in the recent state. It was officially characterized as follows: "From 5 to 10 Cm. long, foliaceous, irregularly branched into fringed and channelled lobes, brownish above, whitish beneath, and marked with small, depressed spots; brittle and inodorous; when softened in water, cartilaginous, and having a slight odor; its taste is mucilaginous and bitter." U. S., 1890. Macerated in water, it absorbs rather more than its own weight of the fluid, and, if the water be warm, renders it bitter. Boiling water extracts all its soluble principles. The decoction thickens upon cooling, and acquires a gelatinous consistence without viscosity. After some time the dissolved matter separates, and when dried forms semi-transparent masses, insoluble in cold water, alcohol, or ether, but soluble in boiling water, and in solution forming a blue compound with iodine. Lichenin, or lichen starch, C$_{12}$H$_{20}$O$_{10}$, resembles starch in its general characters, but differs from it in some respects. Lichenin has been found to consist of two distinct proximate principles, for one of which the name lichenin may be retained, while for the other no particular designation has been chosen, but which we may call lichenoid. According to Th. Berg (These de Dorpat, 1872), cetraria yields 35.15 per cent. of the mixed principles, of which 20 per cent. is of lichenin, and 15.15 of the so-called lichenoid. To separate them, a decoction of the moss, concentrated to a small bulk, and still hot, is treated by alcohol. The lichenoid is deposited in flocculi, which gradually unite in a viscid mass. This, being washed by alcohol until it ceases to be bitter, and then dried, yields a light friable matter partly soluble in cold water, with which it forms a yellow, limpid solution. To deprive it of mineral and coloring substances, it is dissolved in a little water, and precipitated.
afresh by alcohol. Lichenin is insoluble in cold water, but swells up and easily dissolves in hot water. It is insoluble in alcohol and in ether. It is only tinged by iodine. Lichenoid is, on the contrary, colored blue by that reagent. It is, in part, dissolved in cold water, and the undissolved part is equally colored blue by iodine. It is, like lichenin, insoluble in alcohol and ether. Both substances have strong analogies with starch, yet are distinct. For a further account, see J. P. C., 1873.

The name cetrarin has been conferred on the bitter principle. Herberger’s process for extracting it may be found in the 18th ed., U. S. D. By it one pound of moss yielded to Herberger 133 grains of cetrarin, Schnedermann and Knop have ascertained that cetrarin consists of three distinct substances: (1) cetraric acid, C₁₈H₁₆O₈, which is the true bitter principle, crystallizable, and intensely bitter; (2) a substance resembling the fatty acids, called lichen-stearic acid, C₁₄H₃₄O₃, the crystals of which melt at 120° C. (248° F.); and, (3) a green coloring substance, which they name thallochlor. These principles are obtained perfectly pure with great difficulty. (Ann. Ch. Ph., Iv, 144.) Hilger and Buchner (Ber. d. Chem. Ges., 1890, p. 461) give to lichen-stearic acid the formula C₄₃H₇₆O₁₃, and to cetraric acid the composition C₃₀H₃₀O₁₂, and both are shown to be dibasic acids.

The gum and starch contained in the moss render it sufficiently nutritive to serve as a food for the Lapps and Icelanders, who employ it powdered and made into bread, or boiled with milk, after having partially freed it from the bitter principle by repeated maceration in water. As suggested by Berzelius, the bitterness may be entirely extracted by macerating the powdered moss, for twenty-four hours, in twenty-four times its weight of a solution formed with 1 part of an alkaline carbonate and 375 parts of water, then decanting the liquid, and repeating the process with an equal quantity of the solution. The powder, being now dried, is perfectly sweet, and has been used to some extent in pharmacy as a substitute for acacia, although lacking in adhesiveness. (See also Gelatina Lichenis Islandici Saccharata Sicca (Germ. Unoff. Formulary), Proc. A. Ph. A., 1892, 455.) This plan which has been proposed of first extracting the bitterness by maceration in water or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, has been criticised, as the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. A pint (473 mils) of the decoction may be taken during the day.

Iceland Moss has been much used in chronic catarrhs, especially of the pulmonary mucous membrane and even in phthisis. It acts chiefly as a mucilaginous drink, but as Kobert has found that cetrarin, is a stimulant to the gastro-intestinal mucous membrane and to peristalsis, cetraria probably is feebly tonic. A 20 per cent. tincture has been recommended in doses of twenty to thirty minims (1.2-2 mils) by Deymg and Brice-Moret as an anti-emetic (P. J., Oct. 30, 1897), which is confirmed by Gigon. (R. T., 1905, p. 610.)

Cetrarin, or Cetraric acid, C₃₀H₃₀O₁₂; a white, crystalline, bitter principle, soluble in solutions of alkalies and their carbonates, in hot water and slowly in cold water. It is administered in the treatment of anemia,, chlorosis and digestive disturbances. Dose, one and a half to three grains (0.096-0.2 Gm.).

"Cetraria, fifty grammes [or 1 ounce av., 334 grains]; Water, a sufficient quantity, to make one thousand cubic centimeters [or 33 fluidounces, 61/3 fluidrachms]. Cover the Cetraria, in a suitable vessel, with four hundred cubic centimeters [or 13 fluidounces, 252 minims] of cold Water, express after half an hour, and throw the liquid away. Then boil the Cetraria with one thousand cubic centimeters [or 33 fluidounces, 6 1/2 fluidrachms] of Water for half an hour, strain, and add enough cold Water, through the strainer, to make the product, when cold, measure onethousand cubic centimeters [or 33 fluidounces, 6 1/2 fluidrachms]." U. S., 1890.

Saccharum Cetrariae.—Cetraria 1, sugar 1, water 100. Wash the cetraria with water to remove bitterness, then boil with 100 mils of water, strain and express lightly, and in the strained liquid dissolve the sugar and evaporate upon a water bath. When sufficiently firm remove from the bath and dry in an oven to a scale or a powder.

The Cetraria juniperina (probably Cetraria vulpina) of Europe is said to be sometimes used as a poison for wolves and foxes, while the wolfs moss (Ulfmossa) of the north of Europe contains vulpinic acid, C_{19}H_{15}O_{5}, which has been found by Kober to be an active protoplastic poison, in frogs it produces tetanus, convulsions, and paralysis of central origin; in mammals it causes dyspnea, vomiting, trembling, and a slowing of the pulse, with rise of the blood pressure due to stimulation of the respective nerve centers. After death the blood is not coagulable, and the secreting kidney cells are found covered with a crystalline or amorphous mass of a vulpinate. The acid is found also in species of Calycium, Culveraria, Parmelia, and Cyphelium. (Schmidt, Ph. Chemie, St. 1319.) No difference of action exists between vulpinic acid derived from wolfs moss and that synthetically produced. From Cetraria pinastrin Zopf has separated pinastrinic acid, which seems to be very closely allied to vulpinic acid. (Sitzungsb. der Dorpat. Naturforsch.-Gesellschaft, 1892.)

Chamaelirium. Chamaelirium luteum (L.) A. Gray. (C. carolinianum Willd.) Starwort. False Unicorn Root. Devil's Bit. Blazing Star.—This plant is indigenous to the United States. The rhizome is the part employed in medicine. It is commonly known by the erroneous name Helonias, under which title it is recognized by the N. F. (for description, see Helonias). F. V. Greene obtained from it in 1878 a bitter principle, chamaelirin. He states that it is a cardiac poison. Helonin is a term used by the eclectics to define the alcoholic extract found in commerce. Cham-aelirium is said to be diuretic, tonic, and anthelmintic. It is usually given in aqueous infusion, one in sixteen, in the dose of a wineglassful.

Champaca.—This is the Michelia Champaca L. (fam. Magnoliaceae), a Javan tree which is famous for the sweet odor of its blossoms. From it Merck has obtained a camphor (C_{17}H_{30}O) to which the name champacol has been applied. For a study of the volatile oil of champaca flowers, see Schim. Rep., Oct., 1907, p. 32.
Cheiranthus. Cheiranthus Cheiri L. Wall flower.—The flowers yield an oil which when highly diluted has the natural pleasant odor, but when concentrated the odor is disagreeable. (Schim. Rep: 1911, 95; also A. Pharm., 1912, 211.) From the leaves of this cruciferous European plant Moritz Reeb (A. E. P. P., 1899, vol. xliii) has obtained a glucoside, belonging to the digitalis group, of such power that 0.0005 Gm. will produce systolic cardiac arrest in the frog; also a crystalline alkaloid, cheirinine, $C_{18}H_{35}O_{17}N_{3}$, which acts upon nerve centers and also upon muscles.

A perennial herbaceous plant growing wild in both Europe and America, recognized readily by its pinnate leaves, small peduncled yellow flowers and yellow opaque juice. The plant was formerly official and was described as follows: "Root several-headed, branching, reddish-brown; stem. about 50 Cm. long, light green, hairy; leaves about 15 Cm. long, thin, petiolate, the upper ones smaller and sessile, light green, on the lower side glaucous, lyrate-pinnatifid, the pinnae ovate-oblong, obtuse, coarsely crenate or incised and the terminal one often three-lobed; flowers in small, long-peduncled umbels with two sepals and four yellow petals; capsule linear, two-valved and many-seeded. The fresh plant contains a saffron-colored milk-juice, and has an unpleasant odor and acrid taste." U. S., 1890.

Probst, of Heidelberg, found in it a peculiar acid denominated chelidonic acid; two alkaline principles, one of which forms neutral salts with the acids, and is called chelerythrine (see Sanguinaria), in consequence of the intense redness of its salts; the other unites with, but does not neutralize the acids, and is named chelidonine, $C_{20}H_{19}C_{5}N$; and lastly a neutral crystallizable, bitter principle, which from its yellow color he calls chelidoxanthin. Orlow believes, however, that the latter is an alkaloid, and gives a process for its preparation in Ph. Z. R., 1893, No. 21. Chelerythrine appears to be an acid narcotic poison. (Ann. Ch. Ph., xxix, 113.) For an elaborate investigation of chelidone, see a paper by Schlotterbeck and Knapp in Proc. A. Ph. A; 1905, 217. For color tests for chelidone, see Proc. A. Ph. A., 1895, 922. Chelidoninephosphate, chelidoninesulphate, chelidoninetannate, and chelidoninemuriate have been used medicinally. (See Proc. A. Ph. A., 1897, 721.)

Although both Peronin and Meyer (A. E. P. P., 1892, xxix, p. 397) asserted that chelidone has distinct narcotic properties, the experiments of Hanzlik (J. P. Ex. T., 1915, vii, p. 99) throw grave doubt on their conclusions. The latter investigator found that its only physiological action was a paralyzing effect on the unstriped muscle and suggested its use in asthma, and spasmodic colic. Ribbing and Rumpf have used chelidonin clinically in gastralgias in doses of one and one-half to three grains (0.1-0.2 Gm.), but Peronin used from one-twentieth to one-third of a grain (0.003-0.02 Gm.). In 1902 J. O. Schlotterbeck showed that the chelidoaxanthine of Probst is really berberine. Schlotterbeck has also established the identity of the most abundant of the alkaloids of sanguinaria with chelerythrine.

Celandine is an irritant purgative to which toxic properties have been ascribed with
doubtful correctness; in the fatal case of poisoning reported in the Zeitschr. f. Medizinallieamte, 1898, it was not the cause of death. The irritant juice has long been used locally upon corns, warts, eczema, and other diseases of the skin, and even in cancer. The dose of the dried root or herb is from thirty grains to a drachm (2.0-3.9 Gm.), that of the fresh root one or two drachms (3.9-7.7 Gm.), and the same quantity may be given in infusion. The dose of the aqueous extract is from five to ten grains (0.32-0.65 Gm.), of the expressed juice from ten to twenty minims (0.6-1.3 mils), to be gradually increased.

**Chelone.** Chelone glabra L. Snake-head. Turtle-head. Balmony. Shelfower. Chelone, Fr., G.—The leaves of this very common indigenous, perennial, herbaceous plant, of the fam. Scrophulariaceae, have a bitter taste, and are said to be tonic and aperient, with a supposed peculiar action on the liver. The decoction (two ounces of the fresh herb to the pint) may be given in the dose of one or two fluidounces (30-60 mils). Chelonin, an eclectic medicine prepared from chelone, is a brown, bitter powder administered as a tonic laxative in one and two grain doses (0.06-0.12 Gm.).

**Chenopodium.** Chenopodium. American Wormseed.—The fruit of C. Ambrosioides var. anthelminticum (L.) Gray (Fam. Chenopodiaceae). This species of Chenopodium, known commonly by the names of wormseed and Mexican Tea, grows in almost all parts of the Eastern United States. The whole herb has a strong, peculiar, offensive, yet somewhat aromatic odor, which it retains when dry. All parts of the plant are occasionally employed, but the fruit alone was official in the U. S. P., 1890. This should be collected in October.

Wormseed, as found in commerce, is a small fruit, about 2 mm. in diameter, having a membranaceous pericarp, irregularly spherical, very light, of a dull greenish-yellow or brownish color, a bitterish, somewhat aromatic, pungent taste, and possessed in a high degree of the peculiar odor of the plant. These fruits, when deprived, by rubbing them in the hand, of the membranaceous covering which invests the proper seed, exhibit the shining, blackish surface of the obtusely-edged seed. They abound in a volatile oil, upon which their sensible properties and medicinal virtues depend and which is obtained by distillation. (See Oleum Chenopodii) The same oil impregnates to a greater or less extent the whole plant.

Of the activity of the wormseed as an anthel-mintic there can be no question, but it has been entirely displaced by the official oil. The dose of the crude drug is from twenty to forty grains (1.3-2.6 Gm.).

**Chimaphila.** N. F. IV (U. S. P. VIII). Pipsissewa. Prince's Pine. Wintergreen. Bitter Wintergreen. King's Cure. Ground Holly. Love-in-winter. Rheumatism Weed. Herbe de Pyrole ombellee, Fr. Doldenbluthiges Harnkraut. Wintergrun, G.—There are two American species, the official variety being described by the N. F. as " the dried leaves of Chimaphila umbellata (Linne) Barton (Fam. Ericaceae), without the presence of more than 5 per cent. of stems or other foreign matter." N. F. It is a small evergreen plant, with a perennial, creeping, yellowish rhizome, which gives rise to several simple, erect or semiprocumbent stems, from four to eight inches in height,
and ligneous at their base. The leaves are "oblanceolate, from 2.5 to 7 cm. in length and from 8 to 20 mm. in breadth, the upper portion coarsely and sharply serrate, acute or somewhat obtuse, the lower wedge-shaped and nearly entire; coriaceous, smooth and uniformly dark green on the upper surface, paler beneath, the veins prominent. Odor slight; taste astringent and bitter. The powdered drug is brownish-green and, when examined under the microscope, exhibits characteristic epidermal tissue composed of cells with unevenly thickened, porous, and wavy vertical walls; the fragments from the lower epidermis show numerous broadly elliptical stomata up to 0.04 mm. in length, the epidermal tissue in transverse view shows outer walls from 0.008 to 0.015 mm. in thickness; fragments of palisade and mesophyll tissue containing chloroplastids; tracheae with spiral or annular markings; a few characteristic, elongated trachea-like cells, about 0.014 mm. in width, thick-walled, slightly lignified and with minute, double-spiral bands or delicate reticulations; fragments of the epidermis from the stems and root-stocks, the cells containing a purplish coloring substance which is intensified when the powder is mounted in hydrated chloral T.S.; parenchyma cells containing a reddish-brown amorphous substance; calcium oxalate in rosette aggregates mostly about 0.035 mm. in diameter, occasionally up to 0.065 mm. in diameter; starch grains few, rounded, simple, up to 0.016 mm. in diameter and sometimes with a central deit or fissure, or two- to four-compound; trichomes absent. Chimaphila yields not more than 7 per cent. of ash." N. F.

The leaves are short petiolate, occurring in irregular whorls, of which there are usually two on the same stem. The flowers are disposed in a small terminal corymb, and stand upon nodding peduncles. It is found in the Northern latitudes of Europe and Asia, also in dry woods from Nova Scotia to Georgia and westward to the Pacific. The flowers appear in June and July.

C. maculata, (L.) Pursh., or spotted wintergreen, though not official, probably possesses similar virtues. The character of the leaves of the two plants will serve to distinguish them. Those of C. maculata, are lanceolate, rounded at the base, where they are broader than near the summit, and of a deep olive green, veined with greenish-white; the leaves of C. umbellata are broadest near the summit, gradually narrowing to the base, and of a uniform shining green color.

Pipsissewa, when fresh and bruised, exhales a peculiar odor. Boiling water extracts the active properties of the plant, which are also imparted to alcohol. Fairbank found in the leaves a peculiar substance which he calls chimaphilin.

Chimaphilin was obtained by extracting the tincture with chloroform, or by distilling the sterna with water. It occurs in golden-yellow auricular crystals, odorless and tasteless, practically insoluble in water, but dissolving in alcohol, ether, chloroform, and the fixed oils. It is possessed of neither acid nor alkaline properties. Peacock (A. J. P., 1892, p. 295) found that chimaphilin has the chemical composition $C_{24}H_{21}O_4$.

Ridenour (A. J. P., 1895, '236) confirms the formula, $C_{24}H_{21}O_4$, given by Peacock. He finds the melting point of the purified chimaphilin to be 114° C. (237.2° F.). He also
prepared another crystalline principle melting above 250° C. (482° F.), to which he
gives the formula $C_{10}H_{19}O$, which agrees with Beshore's product. Arbutin, $C_{12}H_{16}O_7$,
is also found in chimaphila.

This plant is stated to have been used internally by the North American Indians in
scrofula and rheumatism, and was a popular remedy among the settlers of this
country. It has no medicinal properties, however, beyond a feeble diuretic action and
perhaps some antiseptic influence on the urine. It is occasionally prescribed for
cystitis. The best preparation is the fluidextract, which may readily be made into a
syrup. Dose thirty to ninety grains (2-6 Gm.).

**ChinaMorada.**—Under this name there appear to be used in Bolivia several barks.
One of these has been ascertained by Arati and Canzoneri (L'Orosi, Feb., 1889) to be
the product of a rubiaceous tree, Pogonopustubulosus (Rich.) K. Sch., and to contain
an alkaloid, moradéine, besides a fluorescent substance, moradin, allied to scolopetin.
(See P. J., xix.)

**Chionanthus.** N. F. IV. *Chionanthus virginica* L. FringeTreeBark. Old Man's Beard.
It is described in the N. F. as "the dried bark of the root of *Chionanthus virginica*
Linne (Fam. Oleaceae), without the presence of more than 8 per cent. of other parts of
the plant or other foreign matter. Usually in transversely curved pieces, occasionally
in single quills from 1 to 10 cm. in length; bark from 2 to 10 mm. in thickness; heavy,
some pieces of the whole drug sinking when thrown into water; outer surface usually
reddish-brown, occasionally grayish-brown, with few transverse wrinkles, whitish
cork patches and root-scars; inner surface yellowish-brown, more or less striate and
undulate; fracture short, hard, and coarsely granular, due to projecting groups of
stone cells; the broken surface of a light yellowish-white color. Odor characteristic;
taste bitter. The powdered drug is light brown and, when examined under the
microscope, exhibits somewhat rounded, simple or two- to four-compound starch
grains, the individual grains mostly 0.003 to 0.025 mm. in diameter; numerous stones
cells, in groups and isolated, the walls thick, strongly lignified and with simple and
branching pores; brown resin masses; fragments consisting of light brown, thin-walled
cork cells; parenchyma tissue with many of the cells filled with starch grains.
Chionanthus yields not more than 5 per cent. of ash." N. F.

In the bark of this indigenous plant saponin was found by E., S. J ustice (A. J. P., xlvii,
195), but not by W. von Schuiz, who, however (Ph Z. R., 1893, 579), detected a
glucoside. The fluid-extract has been recommended in doses of from one-half to one
fluidrachm (1.8-3.75 mils) two or three times a day, as an aperient and a diuretic.

**Chione.** Chione glabra DO. Palo Blanco.—The bark of this West Indian rubiaceous
plant is said to be largely used as an aphrodisiac and tonic. According to B. H. Paul
and A. J. Cowley, it yields 1.5 per cent. of a pale yellow volatile oil composed largely
of phenols. (P. J., vol. lx.)
CHIRATA. Br.

CHIRETTA

"Chiretta is the plant, Swertia Chirata, Buch.-Ham., collected when in flower, and dried." Br. "The dried plant of Swertia Chirayita (Roxburgh) Hamilton (Fam. Gentianaceae)." N. F.

East Indian Balmony; Chiretta; Churette, Fr.; Chiretta. Ostindischer Enzian, G.

Chirata was for many years official in the IT. S. Pharmacopoeia and is still retained by the British authority and in the N. F. According to Lloyd, this drug has long been held in esteem by the Hindoos. It first attracted attention in England in 1829 and was introduced into the Edinburgh Pharmacopoeia in 1839.

Swertia Chirayita (Roxb.), Hamilton (Ophelia Chirata, Griesbach).—The chirayta, or chirata, is an annual plant, about three feet high, with a branching oblique root, and an erect, smooth, slightly winged branching stem, and furnished with opposite, lanceolate, very acute, entire, smooth, three or five-nerved leaves. The flowers are numerous, peduncled, yellow, with a four-cleft calyx having linear acute divisions, the limb of the corolla spreading and four-parted, four stamens, a single style, and a two-lobed stigma. The capsules are unilocular. The plant is a native of Nepaul and other parts of Northern India. The whole of it is gathered when the flowers are well advanced. In the Indian bazaars the name chirata is applied to various dried gentianaceous plants; the most important of these is the Ophelia angustifolia (Buch.-Ham.). It yields the Paharee or Hill chirata, which is distinguished by its inferior bitterness, and its rectangular, winged stems, whose section presents a thick woody ring and a centre nearly or entirely hollow, with only traces of pith. A false chirata, which also found its way into the London markets, and resembles the official variety in having a well developed pith, but which is completely lacking in bitterness, is affirmed to be the product of Ophelia alata. (P. J., xvii, 903.) Under the name of Indian chirata, the dried plant of the Andrographis paniculata Nees has appeared in the London market. It resembles much more closely recently dried broom tops than the true chirata. It is a little more than two feet long. The branching stems are from $\frac{1}{8}$ to $\frac{1}{4}$ inch in thickness near the base, woody, quadrangular, furrowed, smooth, slightly knotted at the point from which the branches spring, the longitudinal furrows are
continued through the roots, which have numerous fine radicles, the leaves are opposite decussate, branches erect or forming an acute angle with the stem, terminal shoots extremely slender.

The dried plant is imported into Europe in bundles, consisting mainly of the stems, with portions of the root attached. The stems contain a yellowish pith. The drug is officially described as "Stem about one metre long, smooth, brown, or purplish-brown, slightly winged and much branched above, rounded below and containing a large, continuous, easily separable pith. Root oblique. Branches slender, elongated, decussate. Leaves opposite, ovate, glabrous, entire, usually with three to seven lateral veins. Flowers small, numerous, panicled. Fruits superior, bicarpellary, unilocular. No odor; taste extremely bitter." Br.

It is described in the N. F. as "smooth, root simple, about 7 mm. in thickness near the crown, stem about 1 M. in length, externally yellowish-or purplish-brown; cylindrical near the base, quadrangular and slightly winged above, with numerous opposite, ascending branches; wood yellowish, thin, enclosing usually a large yellowish easily separable pith; leaves opposite, sessile, ovate-lanceolate, entire, five nerved, about 6 cm. in length; flowers numerous, panicled, small, with a four-lobed calyx and corolla, capsule ovoid^ acute, one-celled, many-seeded. Odor slight; taste intensely bitter. Chirata yields not more than 6 per cent. of ash." N. F.

The virtues of chirata are imparted to water and alcohol, and are retained in the extract. According to Lassaigne and Boissel, the stems contain resin, a yellow bitter substance, brown coloring matter, gum, and various salts. Fliickiger and Hohn, who subsequently examined the stems and roots of chirata, extracted from them sugar, wax, chlorophyll, soft resin, tannin, an acid which they name ophelic, possessing the formula C_{13}H_{20}O_{10}, and a peculiar bitter substance, denominated chiratin, C_{26}H_{48}O_{15}. The acid is syrupy, deliquescent, yellowish-brown, at first slightly sour, afterwards intensely bitter. It is soluble in water, with some turbidness, probably owing to resin mixed with it, and completely soluble in alcohol, or a mixture of this with ether. It decomposes certain salts, and forms amorphous compounds with acids. Chira-fcin is a yellow, hygroscopic powder, but feebly crystallizable, very bitter, sparingly soluble in cold water, more so in hot water, and readily dissolved by alcohol and ether. It is neutral to test paper, and yields a copious precipitate with tannic acid. By the action of acids,
chira-tin is separated into ophelie acid, and a yellowish-brown, amorphous substance, bitter, scarcely soluble in water, readily soluble in alcohol, and not reducing copper solutions, as the ophelic acid does. Hohn gives it the formula $\text{C}_{13}\text{H}_{24}\text{O}_3$, and names it chiratogenin.

**Uses.**—Chirata has long been used in India. It has been introduced into Europe, and appears to be highly esteemed, but has not been employed to any considerable extent in this country. Its properties are those of the pure bitters, and probably do not differ from those of the other members of the family of Gentianaceae. (See Gentiana.) Like these, in overdoses it nauseates and oppresses the stomach. Some have supposed that, in addition to its tonic properties, it exerts a peculiar influence over the liver, promoting the secretion of bile and correcting it when deranged, and restoring healthy evacuations in cases of habitual costiveness. It has been used in dyspepsia, and in the debility of convalescence, and generally in cases in which corroborant measures are indicated. In India it has been employed in intermittents and remittents, combined with the seeds of Guilandina Bonducella L. It may be given in powder, infusion, tincture, or fluid-extract.

Dose, ten to twenty grains (0.65-1.3 Grin.).

**Off. Prep.**—Infusum Chiratae, Br.; Tinctura Chiratas, Br.; Fluidextractum Chiratae, N. F.

**CHONDRUS. U. S.**

**CHONDRUS [Irish Moss]**

"The dried plant of Chondrus crispus (Linne) Stackhouse or of Gigartina mamillosa (Goodenough et Wood-ward) J. Agardh (Fam. Gigartinaceae) " U. S.

Carrageen, Caragahen, Fucus Crispua, Pigwiaids.; Killeen, Pearl Moss; Carragheen; Carragaheen; Carrageen ou Mousse perlee, Fr. Cod.; Mousse Marine perlee, Fr.; Carrageen, P. G.; Irlandisches Moos, Perimoos, Knorptang, G; Fuco carageo, Musco d'Irlanda, Fuco criso. It.; Caragaen, Musgo marino perlado, Sp.

Chondrus crispus grows upon rocks and stones on the coast of Europe, and is especially abundant on the southern and western coasts of Ireland, where it is collected. It is also a native of the United States, and
is gathered largely on the coast of Massachusetts, below Boston, where it is partly torn from the rocks and partly collected upon the beach, on which it is thrown up during storms. It is prepared for market by spreading it out high on the beach, to dry and bleach in the sun. (Aug. P. Melzar, Proc. A. Ph. A., 1860.) For elaborate accounts of the plant, of its distribution on the sea coast of Massachusetts, and of the mode of gathering and curing, see U. S. Agricultural Report, 1866; also A. J. P., 1868, 417; 1895, 596; 1899, 483. Henry Kraemer witnessed the methods pursued on the Massachusetts coast in the collection of Irish moss at Scituate, which appears to be a particularly favorable situation. The season for collection begins late in May and continues to September, June and July being the best months. The moss at present is only found on rocks that are from 15 to 20 feet below the tide, hence women no longer engage in its collection. The men go out in their sail boats or dories at half tide, and come in at half flood. With their long rakes they scrape the moss off the rocks, collecting thus about 50 pounds to the boat, the total for the season at Scituate being about 10,000 pounds. The moss is spread out on the high beach for a week or so, the action of the sun and dew bleaching it. It is then enclosed in hogsheads, in which it is again saturated with sea water by rolling them in the marshes; after which it is again spread out and subjected to the bleaching process, this alternate treatment being repeated four or five times, until the product is of a yellowish or white color. The final drying is done in barns, where the moss is stored until it is packed in 100 lb. barrels at the end of the season. In the course of his journey he had opportunity to observe the Chondrus growing and gathered in different localities along the coast, and found it to consist chiefly, if not entirely, of Chondrus crispus. While it is stated in Dr. Farlow's "The Marine Algae of New England" that the closely resembling Gigartina mamillosa is common from Boston northward, Kraemer is inclined to believe that Chondrus crispus (L.), Lyngbye, is practically the only source of the American drug. (See Proc. Penn. Pharm. Assoc., 1899, 113-116.) Tunmann (Apoth. Zeit., 1909, pp. 91 and 151) has given an elaborate account of the morphology and composition of Chondrus.

Gigartina mamillosa Ag. resembles the true Irish moss, and, growing with it upon the rocks, is often gathered with it. It can, however, be at once distinguished by the numerous papillae which cover the surface and margins of the fronds and bear the fruit (cystocarps). In chemical and medicinal properties it is probably identical with C. crispus.
Irish moss when collected is washed and dried. It is probably sometimes bleached by the use of potassium permanganate and sodium thiosulphate by the same process as that used for bleaching sponge. Herr Schack was led to suspect this, through discovering the presence of sulphurous acid in a German specimen. (Ph. Ztg., 1886, p. 87.) The presence of arsenic has been determined in some commercial lots, being caused, no doubt, by the impurities in the sulphur used for bleaching Chondrus. Some "faked" samples have yielded as much as 35 per cent. of ash which contained a large quantity of calcium sulphate. The gelatinizing value of specimens of this kind is about 60 per cent. below normal. In the fresh state it is of a purplish color, but, as found in the shops, is yellowish or yellowish-white, with occasionally purplish portions. It is officially described as:

"Entire plants more or less matted together, consisting of a slender stalk from which arises a series of dichotomously branching, more or less flattened segments, emarginate or deeply cleft at the tips; from 5 to 15 cm. in length, and 1 to 10 mm. in width; yellowish-white, translucent, frequently coated with a calcareous deposit which effervesces with hydrochloric acid; sometimes with fruit bodies or sporangia embedded near the apex of the segments (in C. crispus) or with sporangia borne on short tuberculated projections or stalks, more or less scattered over the upper portion of the segments (in G. mamillosa); somewhat cartilaginous; odor slight, seaweed like; taste mucilaginous, saline. Boil one part of Chondrus for about ten minutes with 30 parts of water, replacing the water lost by evaporation; the strained liquid forms a thick jelly upon cooling. When softened in cold water Chondrus becomes gelatinous and transparent, the thallus remaining nearly smooth and uniform and not swollen except slightly at the tips; a solution made by boiling 0.3 Gm. of the drug in 100 mils of water and filtering gives no precipitate on the addition of tannic acid T.S. (gelatin), and when cold does not give a blue color on the addition of iodine T.S. (starch)." U. S.

It swells in cold water, but does not dissolve. Boiling water dissolves a large proportion of it, and the solution, if sufficiently concentrated, gelatinizes on cooling. Herberger found 79.1 per cent. of a so-called pectin (mucilage), and 9.5 of mucus, with fatty matter, free acids, chlorides, etc., but neither iodine nor bromine. Dupasquier discovered in it both of these elements, which had generally escaped attention in consequence of their reaction, as soon as liberated, upon the sodium sulphide resulting from the decomposition of the sodium sulphate of the
moss when charred. (J. P. C., 3e ser., iii, 113.) The analysis made by Church in 1877 gave: mucilage, 55.4; water, 18.8; mineral matter, 14.2; albuminoids, 9.4; and cellulose, 2.2 per cent. The pectin Pereira thought peculiar, and proposed to call it carrageenin.

It is distinguished from gum by affording, when dissolved in water, no precipitate with alcohol; from starch, by not becoming blue with tincture of iodine; from pectin, by yielding no precipitate with lead acetate and from mucic acid by the action of nitric acid. Ch. Blondeau gives the name of goëmine to a substance obtained by boiling carrageen (goémon, Fr.) for several hours in distilled water, and precipitating the mucilaginous liquid by alcohol. Fluckiger, who analyzed this mucilage with care, found in it no sulphur, and only 0.88 per cent. of nitrogen. The drug itself yielded not more than 1.012 per cent. of nitrogen. (Pharmacographia, 2d ed., 748.) Haedicke, Bauer, and Tollens obtained, on extraction with water containing 0.6 per cent. of sulphuric acid, and further purification by alcohol, a small quantity of a crystalline compound which resembles galactose in its composition, in its action on polarized light, and in its behavior with nitric acid. On oxidation with nitric acid, the dry moss yields from 21.6 to 22.2 per cent. of mucic acid. Carrageenin is said to have been used as a substitute for acacia, under the name of imitation gum arabic; the latter occurs in three forms, white, light yellow, and yellow. They all have similar properties, swelling up like tragacanth when mixed with cold water, but not forming a clear solution unless the mixture be boiled, in this latter respect differing from tragacanth or albumen; iodine does not give a blue color, and alcohol does not precipitate the solution, even when 50 per cent. of it is added. It has mild adhesive properties. (E. C. Federer, Ph. Era, 1887, 146.) The mucilage of Irish moss has come into considerable use as an emulsifying agent. (Proc. A. Ph. A., 1887; A. J. P., 1888, 170.)

**Uses.**—Chondrus is nutritive and demulcent, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, barley, etc., are usually employed. It has been particularly recommended in chronic pectoral affections, scrofulous complaints, dysentery, diarrhea, and disorders of the kidneys and bladder. It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon juice may usually be added to improve the flavor. Milk may be
substituted for water when a more nutritious preparation is required. It is recommended to macerate the moss for about ten minutes in cold water before submitting it to decoction. Any unpleasant flavor that it may have acquired from the contact with foreign substances is thus removed.

Dose, four drachms (15.5 Gm.).

**Off. Prep.**—Gelatinum Chondri, N. F.; Mucilago Chondri, N. F.

**Cichorium.** Cichorium Intybus L. Chicory. Succory. Blue Sailors.—A perennial herbaceous composite plant, indigenous in Europe, but naturalized in the Northern United States and Canada, where it grows in fields, and in roads along the fences. The whole plant has a bitter taste, without acrimony or any very peculiar flavor. The taste is strongest in the root and weakest in the flowers. The leaves, when young and tender, are eaten as salad. Chicory is a feeble, non-irritating tonic.

The root is much used as a substitute for or adulterant of coffee. In preparing it, Dausse recommends that the dried root should be cut into rather large and equal pieces, which are to be roasted until they lose 140 out of 500 parts. The pieces are then easily ground in a mill, and afford a yellowish-brown powder. (Ph. Cb., 1850, 688.) For methods of detection in ground coffee, see P. J., 1867, 141; also Alien (Corn. Org. Anal., 2'd ed., vol. iii, part 2, 540), and J. R. Leebody (Chem. News, 1874, 243) ; see also paper by LaWall and Forman (A. J. P., 1913, 535). A glucoside has been obtained from the blossoms of Cichorium Intybus by Nietzki (A. Pharm., (3) 8, 327), to which the formula \( C_{34}H_{34}O_{19} \) is assigned. On boiling with dilute acids it yields glucose and a compound, \( C_{20}H_{14}O_{9} \). This decomposition product seems to exist in the blossoms ready formed along with the glucoside. The garden endive is also a species of cichorium, C. Endivia L.

**Cicuta.** Cicuta virosa L. Water Hemlock. Cowbane. Cigue vireuse, Fr. Wasserschierling, G.—A perennial, umbelliferous European plant, growing on the borders of pools and streams. It is very poisonous to most animals, though said to be eaten with impunity by goats and sheep. A number of the species of cicuta are intensely poisonous; indeed, the statement is made that C. maculata L. is the most poisonous plant native in the United States. The C. vagans (Oregon water hemlock), C. occidentalis Doug. and C. bulbifera L., all of which are found in various parts of North America, are actively poisonous, as is also the European species C. virosa. From the last named. Van Ankum (J. P. C., 1868) obtained a resinous body which was intensely poisonous, resembling picrotoxin in its physiological action, and to which he gave the name of cicutoxin. Bohm (A. E. P. P., v, 281) has since obtained this principle pure, as a thick, tenacious, amorphous substance, of acid reaction, of slight odor but disagreeable taste. The dry root yielded about 3.5 per cent., the fresh 0.2 per cent. of cicutoxin. The presence of a volatile alkaloid resembling coniine, and termed cicunte, has been observed by Wittstein and Buignet. According to Jacobson.
Cicuta maculata L., American water hemlock, Musquash root, Beaver poison, Spotted cowbane. This grows in meadows and on the borders of streams throughout the United States, and is closely analogous, in botanical character and in effects, to the European species. In several instances children have been fatally poisoned by eating its root. This consists of several oblong, fleshy tubers, sometimes as long as the finger, spreading out from the base of the stem, and having an odor and taste not unlike those of parsnip. For microscopic examination of plant, see A. J. P., July, 1891, and Merck's Report, 1909, p. 35. Cicuta has been highly lauded as a specific in nervous and sick headache (Proc. A. Ph. A., 1858, 253), but is rarely if ever used. J. E. Young found in the seeds an alkaloid supposed to be identical with coniine. (A. J. P., xxvii, 294, confirmed by E. Glenk, A. J. P., 1891, 328.)

Egdhal (A. I. M., 1911, viii, p. 348) has collected the history of 46 cases of poisoning by cicuta, of which twenty-one were fatal. Nausea, vomiting, and convulsions occurred in practically all the cases. In most of them there was also bloody froth at the mouth and in many dilated pupils and unconsciousness. In his own case there was cyanosis apparently from interference with the respiration by the convulsions.

In cicuta poisoning there is generally violent vomiting, followed by vertigo, cold, clammy skin, slow, feeble pulse, general convulsions and later paralysis, unconsciousness and dilated pupils. Tannic acid has been suggested as an antidote, but its efficiency has not been proved. The treatment should be evacuation of the stomach, stimulants to combat the collapse, and the cautious use of morphine to control the vomiting and convulsions.

**CIMICIFUGA. U. S.**

**CIMICIFUGA Cimicif. [Black Cohosh, Black Snakeroor, Macrotys]**

"The dried rhizome and roots of Cimicifuga racemosa (Linne) Nuttall (Fam. Ranunculaceae), without the presence or admixture of more than 2 per cent. of stems or foreign matter." U. S.

Cimicifugae Rhizoma, Br., 1898, Acetaae Racemosae Radix; Cohosh; Macrotys; Rattleroot; Squaw Root; Rattle Snake Root; Bugbane; Rattle Weed; Richweed; Bugwort, Rattletop; Racine d'Actee a Grappes, Fr.; Schwarae Schlangenwurzel, G.

Cimicifuga was dismissed from the Br. Pharm., 1914.

Cimicifuga racemosa is a tall stately plant, having a perennial root, and
a simple herbaceous stem, which rises from four to eight feet in height. The leaves are large, and ternately decompound, having oblong-ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, wand-like raceme, with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval ovary and sessile stigma. The fruit is an ovoid capsule containing numerous flat seeds. The plant grows in shady or rocky woods from Southern New England to Wisconsin and southward, flowering in June and July. The name Cimicifuga is derived from the Latin Cimex, bug; and fugare, to drive away.

Properties.—It is officially described as follows: “Rhizome horizontal, more or less branching, from 2 to 12 cm. in length, and from 1 to 2.5 cm. in thickness; externally dark brown, slightly annulate from circular scars of bud scale-leaves, the upper surface with numerous stout, erect or somewhat curved branches terminated by deep, cup-shaped sears, each of which usually shows a distinct radiate structure; inferior and lateral portions with numerous root-scars and a few short roots; fracture horny; internally whitish and mealy or dark brown and waxy, bark thin, wood distinctly radiate and of about the same thickness as the pith; odor slight; taste bitter and acrid. Roots somewhat cylindrical or obtusely quadrangular, from 1 to 3 mm. in thickness, externally dark brown, longitudinally wrinkled; fracture short; internally bark dark brown, wood yellowish, 4 to 6-rayed. Under the microscope, sections of the rhizome of Cimicifuga show a yellowish-brown suberized epidermis, a cortex made up of about 30 layers of starch-bearing parenchyma cells; the fibro-vascular bundles collateral, the xylem consisting of tracheae with bordered pores, and resembling tracheids in that the ends are rather acute; wood-fibers numerous, thin-walled, strongly lignified and with simple, oblique pores, the bundles separated by starch-bearing parenchyma strands from 5 to 30 cells wide; pith cells numerous, resembling those of the cortex. Under the microscope, sections of the root of Cimicifuga show a hairy epidermis, which becomes suberized in older roots; the cortex shows about 12 rows of starch-bearing parenchyma cells; endodermis distinct; fibro-vascular bundles 4 to 6, showing in older roots as separate collateral bundles. The powder is light to dark brown; starch grains numerous, single or compound, the individual grains spherical or more or less polygonal, each with a somewhat central cleft, from 0.003 to 0.015 mm. in diameter; fragments showing trachea with bordered pores and lignified wood-fibers; irregular, yellowish-brown
fragments of suberized epidermis made up of more or less tabular cells, sometimes elongated and considerably thickened. Cimicifuga yields not more than 10 per cent. of ash." U. S.

For a detailed description of the microscopic character of the root, see A. J. P., 1884, 460; also 1895, 121; Holm., M. K., 1911, p. 6.

The roots "exhibit in transverse section from three to five wedge-shaped wood-bundles, separated by as many broad medullary rays. Both rhizome and roots are blackened by test-solution of ferric chloride (presence of tannic acid)." Br., 1898.

The odor, though not strong, is peculiar and rather disagreeable, and is gradually lost with age. The drug of commerce is likely to be unintentionally admixed with other species of Cimicifuga and Actaea. Cimicifuga yields its virtues to boiling water.

Tilghman found gum, starch, sugar, resin, wax, fatty matter, taunic and gallic acids, a black coloring matter, a green coloring matter, lignin, and salts of potassium, calcium, magnesium, and iron. (A. J. P., vi.) It no doubt also contains, when fresh, a volatile principle, with which its virtues may be in some degree associated. Davis separated by distillation a small proportion of volatile oil having decidedly the peculiar odor of the root. He also found albumen, extractive, and silica. The sugar noticed by him was of the uncrystallizable variety, and the resin of two kinds, one soluble in alcohol but not in ether, the other soluble in both these menstrua. (A. J. P., xxxiii.) A crystallizable principle has been obtained by T. Elwood Conard from a strong tincture of the root by treating with solution of lead sub-acetate to precipitate resin, tannin, and coloring matters, then filtering, and precipitating the lead by hydrogen sulphide in excess, and allowing the tincture to evaporate spontaneously; and, finally, having treated the residuary powder with petroleum benzin, afterwards washing it with water, dissolving it to saturation in strong alcohol, and treating the solution with alumina. The mixture was allowed to evaporate to a dry mass, which was nearly exhausted with alcohol. The solution, being allowed to evaporate, left behind a crystalline mass, somewhat resembling alum. This substance has little taste, on account of its extreme insolubility in the saliva, but in alcoholic solutions has very strongly the acrid taste characteristic of the fresh root. The crystals are very soluble in cold, and more so in hot alcohol, soluble also in chloroform, and slightly so in ether. They are
fusible and inflammable. They are neutral, possessing neither acid nor alkaline properties. Their effects on the system were not determined. (A. J. P., 1871.) L. F. Beach (A. J. P., 1876) obtained from commercial resin of cimicifuga (the so-called cimicifugin or macrotin) a crystalline principle by Conard's process. M. S. Faick (A. J. P., 1884) found in the juice of the fresh plant a crystalline principle resembling the principle announced by Conard. On the other hand, neither F. H. Trimble (A. J. P., 1878) nor Warder and Coblentz were able to obtain a crystalline principle, while C. S. Gal-lagher obtained crystals of cane sugar from the fluidextract. (A. J. P., 1887.) In view of these facts, it would appear that the active principle is a resinous amorphous body. (See Drugs and Medicines of North America, vol. i.) Pinnemore reports on the chemical examination of the rhizome of cimicifuga. A systematic examination has resulted in the isolation and identification of isoferulic acid, also a minute quantity of an acid whose melting point was unaffected by admixture with salicylic acid. Palmitic, oleic, and other unsaturated acids, and phytosterol, are also present, and distinct reactions for alkaloids have been found, but the amount present is very small. (P. J., 1910, 31 (85), pp. 142-144,178.)

Uses.—In 1831 cimicifuga was introduced to the notice of the profession by Young. In overdoses it is said to cause general relaxation, vertigo, tremors, decided reduction of the pulse; occasionally it causes vomiting, but its emetic action is never violent, and is probably simply the result of a mild gastric irritation. It certainly, in large doses, produces giddiness, with intense headache and prostration. It has been found by R. Hutchinson to cause in frogs complete anesthesia by a direct action upon the sensory side of the spinal cord. The same observer noted that toxic doses produce in mammals slowing of the pulse and fall of the arterial pressure, results which appear to be due in part to a direct depressant action upon the heart muscle or its ganglia, in part to a paralysis of the vasomotor center. Clinical experience has shown this drug to be a useful remedy in the treatment of chorea. It has also been employed, though with less certainty of benefit, in chronic rheumatism, urticaria, neuralgia, and dysmenorrhea. It is also asserted to act as a specific in tinnitus aurium.

In chorea it is necessary to give large doses. The proper method of administration is to start with about fifteen minims of the fluidextract three times a day, increasing one minim daily until the occurrence of frontal headache or improvement in the condition. The practitioners
calling themselves eclectics use, under the name of cimicifugin, or macrotin, an impure resin obtained by precipitating a saturated tincture of the root with water; dose, a grain or two (0.065-0.13 Gm.). (See N. J. Med. Rep., viii, 247.)

Dose, of powdered cimicifuga, five to thirty grains (0.3-2.0 Gm.).

CINCHONA. U. S.

CINCHONA Cinch. [Peruvian Bark, Yellow Peruvian Bark]

"The dried bark of Cinchona Ledgeriana Moens, Cinchona Calisaya Weddell, and of hybrids of these with other species of Cinchona (Fam. Rubiaceae), yielding not less than 5 per cent. of the alkaloids of Cinchona." U. S.

Cinchonae Flavae Cortex; Yellow Cinchona Bark, Cinchona Flava, U. S. 1880, Yellow Cinchona, Calisaya Bark; Cortex Chinea Calisayae, Cortex Chinea Regiae; China Regia; Konigschina, Calisayarinde, G.; Quinquina jauneroyal, Quinquina Calisaya, Fr. Cod.; China gialla. It.; Quina calisaya, Quina amarilla, Sp.

CINCHONA RUBRA. U. S. (Br.)

RED CINCHONA Cinch. Rub.

"The dried bark of Cinchona succirubra Pavon (Fam. Rubiaceae), or of its hybrids, yielding not less than 5 per cent. of the alkaloids of Red Cinchona." U. S. "Red Cinchona Bark is the dried bark of the stem and branches of cultivated plants of Cinchona succirubra, Pav." Br.

Cinchonae Rubrae Cortex, Br.; Red Cinchona Bark; Cortex Chinea Ruber, China Rubra; Red Peruvian Bark; Bed Bark; Quinquina rouge, Fr.; Cortex Chinee, P. G; Chinarinde, Rothe Chinarinde, G.; China rossa, It.; Quina roja, Sp.
Botanical History.

"Though the Peruvian bark was introduced into Europe so early as 1640, it was not until the year 1737 that the plant producing it was known to naturalists. In that year La Con-damine, on a journey from Quito to Lima, through the province of Loxa, had an opportunity of examining the tree, of which, upon his return, he published a very complete description, with plate, under the name Quinquina, stating that three species were recognized. (Mem. Ac., Paris, 1738, p. 226.) Four years later, Linne proposed a new name, Cinchona, in honor of the Countess of Chinchon, who first made the bark known in Europe. Linne recognized but one species, which he called C. officinalis, and this continued for a long time to be recognized by the Pharmacopoeias as the only source of the Peruvian bark of commerce. But a vast number of plants belonging to the Linnaean genus Cinchona were in the course of time discovered; and the list became at length so unwieldy and heterogeneous that botanists were compelled to distribute the species into several groups, each constituting a distinct genus, and all associated in the natural family of Rubiaceae.

For our knowledge of these plants as they existed naturally, we are chiefly indebted, to the following botanists, besides La Condamine, of whom we have before spoken: Joseph de Jussieu, who, in the year 1739, explored the country about Loxa, and gathered specimens which still exist in the cabinets of Europe; Mutis, who in 1772 discovered Cinchona trees in Colombia, and afterwards, aided by his pupil, Zea, made further investigations and discoveries in the same region; Ruiz and Pavon, who in 1777 began a course of botanical inquiries in the central portions of Lower Peru, and discovered several new species; Humboldt and Bonpland, who visited several of the Peruvian bark districts, and published the results of their observations after 1792; Poppig, who travelled in Peru so late as 1832, and published an account of his journey about the year 1835; Wed-dell, whose researches in Bolivia are so well known and have been productive of valuable information in relation to the Calisaya bark and allied species; while Karsten, Caldas, Martius, Ledger, Markham, and other intrepid explorers have in later times largely added to our information. At the present time (1917) thirty or forty more or less clearly defined species of Cinchona are recognized. Of all of these probably but four with their cultivated hybrids yield the Cinchona Bark of commerce. The principal sources of information bearing on this phase of the subject are the
several reports of the plantations in Java, India, and Jamaica. Howard's Quinology of the East Indian Plantations, Markhanrs Peruvian Bark, Kuntze's Arten, Hybriden und Cultur der Chininbaume, Hooper in the Pharmacographia Indica, several contributions by Trimen to the Tropical Agriculturist, and Rusby in the Pharmaceutical Record, October, 1887. The literature of the cinchona hybrids is hopelessly confused by the same name being frequently used by different authorities for the different hybrids and the one hybrid having various names. Thus, C. robusta of Trimen is known in Ceylon as C. lanosa, and in the Neilgherry Hills as C. magnifolia, also as C. pubescens.

C. Calisaya Weddell, is tall, usually surpassing those about it, the trunk often more than two feet in diameter. Leaves petiolate, the blade ovate-oblong to slightly obovate, 7 to 17.5 cm. long by 2.5 to 7 cm. broad, obtuse, the base acute or slightly attenuated, very thin, smooth, and, especially below, with a satiny luster, above dark green, below emerald-green or deep purple-green, scrobiculate, the glands scarcely visible above. Stipules oblong, about equalling the petioles, very smooth, very obtuse. Panicles ovate to subcorymbose. Calyx pubescent, with a cup-shaped limb and short triangular teeth. Corolla rose-colored (in cultivation often white or nearly so), the tube cylindrical and about 8 mm. long, the laciniae more deeply colored, the edges white-hairy. Stamens included. Capsule ovate, scarcely as long as the flowers. Seeds elliptical lanceolate, the margin irregularly fimbriate-toothed. Bolivia and Southern Peru, 4000 to 6000 feet. Source of the Calisaya or Yellow Bark. The species presents many forms, and two varieties are recognized.

C. Ledgeriana Moens., formerly recognized as a variety of C. Calisaya, differs from the type chiefly in its thicker, narrower, oblong leaves, with attenuate base, often bluish-green below. It yields a thick and remarkably rich bark, and is probably the most valued of all the cinchonas. This species was named in honor of Ledger, who first brought seed of this species from Bolivia.

C. succirubra Pavon, Mas. (Howard in P. J., Oct., 1856, p. 209, with a figure). Extreme size even greater than that of the last. Branches silvery. Petiole pubescent, leaf ovate to oval, acute with a very short point, the base more or less narrowing, often 6 by 9 inches, dark green and smooth above, below paler and pubescent to a variable degree, especially on the veins, not scrobiculate, the margin slightly revolute.
Stipules entire, oblong, obtuse, sub-amplexicaul. Flowers much as in the last, but rather smaller. Fruit lanceolate. Western slopes of Mt. Chimborazo. The source of the Red Bark.

*C. officinalis* Hooken fil.—Petioles smooth, cylindrical, and, like the veins, reddish; blade 10 to 12.5 cm. long, varying from broadly oval to lanceolate, acute at both ends, the margins usually recurved, smooth and deep green above, paler, but bright green below, scrobiculate, the principal veins pubescent. Stipules equalling the petioles, ovate, acute, entire, pubescent. Flowers and fruit much as in *C. Calisaya*. Widely distributed in the equatorial Andes, at an elevation of from 5000 to 7500 feet. The source of the barks known as Pale, Crown, Loxa, Cuenca, and Huanuco. This is the original species, upon which the genus *Quinquina* or *Cinchona* was founded. All things considered, it is, perhaps, to be regarded as the principal species of the genus and its variability is extreme.

The specific variations produced by hybridization in the above characters may not be here considered, though it may be stated that they are entirely characteristic. The parentage of a hybrid is ordinarily fully and strongly indicated in its appearance. As a rule, also, the alkaloidal yield takes a mean between that of the parents, but sometimes this is conspicuously not the case. Goris and Reimers (Trav. Lab. Nat. med. Ecol. supe. Pharm., in Bot. Centdlbl., 1906, p. 462) pointed out the use of *Cinchona robusta* Trimen as a collective name for all hybrids of *C. succirubra* and *C. officinalis*. Rosenthaler gives an account of the structural characteristics and alkaloidal content of *C. robusta* and other cinchona hybrids produced by grafting. (B. P. G., 1908, p. 126.)

Geographical Distribution.

The genuine Cinchona trees are natives exclusively of South America. In that continent, however, they are widely diffused, extending from the 19th degree of south latitude, considerably south of La Paz, in Bolivia, to the mountains of Santa Marta, or, according to Weddell, to the vicinity of Caracas, on the northern coast, in about the 10th degree of north latitude. They follow, in this distance, the circuitous course of the great mountain ranges, and for the most part occupy the eastern slope of the second range of the Cordilleras. Except northward from Guayaquil, both the western slope and the plateau are entirely too dry.
or too cold for these plants, which require a moderate and equable temperature and an abundant and fairly constant supply of water. Irrigation cannot supply the place of a humid climate, for the atmosphere as well as the soil must be well charged with moisture. A certain amount of dry weather is, however, required for the ripening of the capsules. Free drainage is an important condition. Cross and others, who have personally inspected the region in the Andes where the best barks are obtained, have found the Cinchona trees only on the well drained slopes, and never on wet ground. With regard to temperature, Cross found that in the region of the C. officinalis the variation was from 1.1° to 21.1° C. (34°-70° F.), a fall below 40° or a rise above 65° being rare, and the mean range being from 45° to 60°.

The limits of altitude and climatic conditions are closely drawn. In the most southern districts, the trees descend to about 2500 feet, "while in the warmest regions they scarcely ascend to the 10,000-foot level. The individual species are for the most part rigidly restricted as to altitude and latitude, and, indeed, it has not always been found easy to detect the climatic conditions which would cause one species or variety to thrive while another very near it would languish. This is especially true of the more valuable forms.

It is to be noted that at present the stocks of wild barks have been enormously reduced, as detailed under Commercial History. Indeed, in certain sections, as the Calisaya district, the tree was practically exterminated in the wild state, so far as relates to a bark supply. From the far interior, however, occasional bales of wild Calisaya have been received. The low price of cultivated bark since 1885 has resulted in checking the destruction of the wild trees, which have begun again to multiply, so that they may possibly become once more common or even abundant. The Crown Bark region of Ecuador is still fairly productive, and in Colombia and Venezuela there are vast supplies of more or less inferior barks which await some favorable change in the market—never very likely to take place—that will render their collection profitable. Even at present a limited and irregular supply of one of these barks is furnished. With the exceptions here noticed, our present supplies of bark are entirely the product of cultivation, to which, therefore, we must give our chief attention.
Cultivation and Production.

The alarming prospect of the failure of the supply of Cinchona bark (see Commercial History) induced Europeans, about the middle of the nineteenth century, to turn their attention to the possibility of introducing the trees to cultivation. So early as 1737, La Condamine had collected a large number of young plants, with a view of conveying them to Europe; but, after having descended the Amazon in safety for more than a thousand leagues, they were washed overboard, near the mouth of that river, from the boat containing them, and were all lost. After this failure, though the idea of transplanting the Cinchonas was occasionally suggested, nothing was done until 1846, when Weddell, now celebrated for his successful exploration of the region of the Calisaya bark, sent some seeds to France, which were planted with success in the Jardin des Plantes, and thus supplied some of the conservatories of Europe with specimens of the plant. But the first successful effort with a view to great practical results was made in 1853 by the Dutch government, by which Hasskarl, formerly superintendent of the Botanical Garden in Java, was sent to South America on this important mission. Five hundred Calisaya seedlings were forwarded by him directly across the Pacific to Batavia, which they reached before the close of 1854. From these, and from seeds obtained from other sources, which were planted in the mountains of Java, in sites selected for their supposed conformity in climate with the native locality of the Cinchona, have sprung the most important plantations now in existence.

Stimulated by the suggestions of Royle, and by the partial success of the Dutch, the English government engaged, in 1859, the services of Clements R. Markham, who proceeded to Bolivia, in South America, and, after almost incredible hardships, arising partly from the nature of the country and partly from the jealousy of the native authorities, succeeded in collecting and transmitting to England upwards of 400 Calisaya plants. Most of these, however, were so much injured on their way from England to India, by the excessive heat of the Red Sea, that very few, on their arrival in Hindostan, had sufficient life remaining to grow when planted. Happily, the deficiency was supplied by seeds of C. Calisaya sent from Java, to Calcutta, at the request of the English Governor-General. While Markham was in Bolivia, other agents were collecting other species in Peru and Ecuador, whence seeds of the pale and red bark Cinchonas reached India, and, being planted in the selected sites, proved to be very productive.
Careful attention to the conditions of growth enumerated under Geographical Distribution was found essential in the selection of sites for the plantations. Those selected were near the Sanitary Station of Ootacamund in the Nilgerry Hills of Southern India, at heights varying from 5000 to 7450 feet. These positions unite the peculiar characters of the native regions of the Cinchonas in the Andes, not only as regards elevation and latitude, but also as to atmospheric moisture. Other sites were selected for experimental plantations, and since the first introduction of the Cinchona trees, their culture has been extended to various points from Hakgalla, in the island of Ceylon, to the Himalaya Mountains,—as in the Wynaad, the Coorg, the hills of Travancore, and especially at Peermede in the Presidency of Madras; in Sikkim and Darjeeling in the Presidency of Bengal; at Lingmulla in the Presidency of Bombay; and in the valley of Kangra in the Punjab,—from the southern to the northern extremity of British India. Outside of India and Ceylon, culture by the British has been undertaken in the West Indies, particularly Jamaica, in Guiana, and in the Fiji Islands. The first plants taken by Weddell from Peru to Paris all perished, but the French afterward established plantations in the Isle of Bourbon, at Guadeloupe, and in Algiers, none of which are known now to exist. The Portuguese have established plantations upon the west coast of Africa, and these now yield considerable quantities of bark. Very extensive plantations have been formed, chiefly by the Germans, in Bolivia, A rather large plantation in Colombia is now old enough to be productive. In Mexico and Central America various attempts to introduce the industry have been made. The question of introducing it into the United States has frequently been raised, but it may be stated that there is no spot in North America where the conditions warrant the slightest hope of success in this direction.

The history of Cinchona cultivation affords a striking illustration of the importance of government aid in the establishment of a new industry of this kind. The early and repeated disappointments and failures, owing to the natural obstacles in the way of securing stocks, and to an almost total ignorance of the conditions determining the successful propagation and growth of the plant, and the composition of its bark, were such as to have discouraged the most hopeful of private enterprises. Repeated and expensive expeditions were necessary before the first transplantings were accomplished, and these stocks were preserved and propagated only through the instrumentality of well appointed public gardens and
plantations. In Java, after these early difficulties had been surmounted and success apparently attained, it was found that owing to cross fertilization much of the progeny was entirely worthless, and the work of propagation had to be begun anew. The same difficulty was encountered elsewhere, and the slow and expensive method of propagation by cuttings was largely resorted to. In Ceylon the public were slow to become interested, and the officials were obliged not only to give away the young plants, but to solicit experiments with them as a personal favor. In Jamaica a hurricane visited the young and flourishing plantations and almost completely destroyed them. But at length, in spite of all, not only were thriving and permanent government plantations established, but private capital and enterprise upon a vast scale were enlisted. The question of commercial success is dominated not simply by climatological surroundings, but also by the price of labor. It is stated that both in India and Java the natives who work in the cinchona forests are paid from one dollar to one dollar and seventy cents per month, without food, according to the age and sex. The ability to extract the bark upon the spot is capable of largely counterbalancing a lack of market facilities; but it so happens that this advantage also inures to the benefit of the Eastern countries. Originally undertaken in India for the purpose of affording a cheap antiperiodic (the crude alkaloids known as "febrifuge" or "quinetum") home extraction has become a most important industry, and has assumed various forms. In Java the powdered bark is thrown into a 5 per cent. solution of caustic soda at 50° C. (122° F.) treating this with Java petroleum, separating, treating the petrolic solution with water acidulated with sulphuric acid and evaporating; the result is said to be a quinine containing less than 1 per cent. of cinchonine. (J. P. C; 1901.) It is imported largely into the United States—50,000 kilogrammes a year—but on account of its yellow color is chiefly employed in the making of proprietary medicines rather than tablets. Through the influence of the above conditions the locations of the important industry of Cinchona cultivation have been gradually wrought out, and at present about four-fifths of the cinchona barks of the world, outside of India, are furnished by Java. The first shipment from Java was of 900 pounds, in 1869. In 1902 it was 14,700,000 pounds and in 1911 over 20,000,000 pounds. India produces annually over 2,000,000 pounds; Ceylon about 400,000 pounds; Portuguese West Africa about 180,000 pounds, and South America 775,000 pounds. Tunmann estimates that the yearly output of cinchona bark is about 10,000,000 kilogrammes, and the production of quinine as about 500,000 kilogrammes. (Apoth.}
It is to be remembered that a great part of the Indian product is not exported.

Methods of Cultivation.

The history of Cinchona cultivation teems with evidence as to the difficulty of obtaining pure seeds, owing to the tendency of the plants towards cross-pollination. In every locality where the industry has been established has the disgust of the gardener been excited by the discovery that the plants which he had reared, with great care, and upon which he had based great expectations, were contaminated by the admixture of foreign pollen. This was especially true in case of the earlier attempts, before this tendency had become known. Experience at length established the fact that absolute isolation of the seed-trees was essential. One of the curious developments of these experiments was the fact, already referred to, that the value of the progeny was not always assured by the value of its parentage. Some of the hybrids, even when least expected, would develop a surprisingly rich yield; and this tendency has been utilized to develop the most valuable stocks in existence. So certain is it that some of the plants from the best seed will prove worthless, that the careful selection of the seedlings while young is deemed necessary, and in South America, at least, all planting contracts are based upon this expectation, the contractor not being paid for his work until the plants have become old enough to show with certainty the proportion of good plants contained. Both in the selection of the young seedlings and the acceptance of the plantation, the test of identity is found in the leaf. Propagation by cuttings, extensively practised in some localities, has been found too slow and expensive to become general. A thorough preparation of the soil is as beneficial in the case of Cinchona as in that of other crops. Thorough tillage after transplantation is also essential, a free growth of weeds meaning destruction to a large number of the young trees. The cultivation of a secondary crop between the rows of trees is, however, practicable. A large percentage of profit depends upon the selection of a suitable age for collecting the bark. There comes a time when the use of the ground for starting a new crop is more valuable than the gain by permitting the present crop to remain, and after some years an actual deterioration of the bark sets in. This age is not the same for all the trees in the plantation. Several years' difference may occur in the maturing of trees.
germinated at the same time. In the case of Calisaya it occurs at from six to nine years from seed, and its indication is the "it chicken-leg" scaliness of the bark, as described under Classification. The "officinalis" matures somewhat less early. In the Bolivian plantations the most experienced hand is selected as the marker, and the cutters follow him peeling the trees which he has indicated. How far these careful methods of selection are followed elsewhere, the writer is not informed.

Collection of Bark.

Four principal methods of collecting the bark are in vogue, these being variously modified in different sections. The first is uprooting, the most primitive, by which the trees are simply uprooted at the proper age, and the ground replanted. The barks of root, stem, and branches are preserved and marketed separately. The second method is coppicing, by which, after peeling a quill from the lower portion of the trunk, the latter is cut a few inches from the ground and the remainder of the stem bark and the branch bark are removed. The "coppice" is formed by a second growth of two shoots from each of the stumps. A second coppice is commonly grown, and this is harvested by uprooting. By the third method, scraping, the outer bark is scraped off, leaving the liber untouched. This has been found especially applicable to young trees, in which the second growth of bark is rapidly formed and contains 20 to 30 per cent. more alkaloid than that which has been taken off. It seems to be a general opinion among the planters that scraping checks the growth of the tree after it is five years old, so that from three to five years is the age at which it is best practised. The fourth method is known as mossing. It having been noticed that the Cinchona alkaloids, especially in any other form than that of sulphate, were apt, on exposure to the direct light of the sun, to become reddened by the generation of coloring matter, at the expense of the alkaloid, it was a very natural inference that a similar change might take place in the living plant, as a consequence of which the proportion of alkaloids they were capable of producing might be greatly diminished. It was also observed that the bark upon that side of the tree where the sun struck it was less rich than that upon the shady side. To obviate this presumed effect, Maelvor was induced to make the experiment of covering the stems of the growing trees with a layer of moss, so as to completely protect the bark against the influence of sunlight. The result was favorable beyond all expectation, and the yield of alkaloids in the bark thus protected is said to be doubled, tripled, or increased even in larger
proportion. A tree can thus be made continuously productive; for if a slip is removed longitudinally from the trunk, from top to bottom, by covering the decorticated portion with moss, the bark is renewed at least as rich as previously in the alkaloids, while from time to time other strips may be taken, until the whole of the old bark is removed, and the new ready for removal by a repetition of the same process; and the tree is thus preserved indefinitely, probably for the whole normal length of its life. Hooper says that renewed bark is always of greater value than the mossed, and mossed than the natural, so long as the trees are under twenty years old, for it has been found that after that time the bark ceases to thicken, and the alkaloids remain stationary or even decrease. Perhaps twenty years is even too old. The practical difficulty with the process is that it requires skilled workmen, not always attainable, and hence the "coppicing system" still largely prevails in India.

The methods of packing the bark have also undergone important modifications since the early days of cultivation. The extensive adulteration practised when the wild bark brought very high prices led to a demand for it in large pieces which could be readily and quickly examined; hence the appearance of the large tabla and quill forms, the latter afterwards becoming the standard for the cultivated bark. The bark of the trunk, and sometimes of the branches when very large, is cut into two-foot lengths, and each length removed in a single piece, which in drying rolls up to form a quill. Such peeling can of course be successfully practised only at the appropriate season of the year. The bark or the roots, branches, and dead or dry trunks must be removed by chipping, scraping, or shaving, commonly the latter. The quills, after thoroughly drying, are carefully packed in bales, or preferably in boxes, to avoid breakage, and are marketed in packages of from 100 to 250 pounds. Large quantities of cultivated bark are still marketed in this way, but, increasing competition having lowered prices so that economy in freight has become a very important item, most of the bark is now broken up, and its bulk even reduced by high pressure, and in fact only a trifling amount of wild South American bark comes into commerce. Cultivation has very greatly increased, not only the quantity, but also the quality of bark. For some years, in India the attempt was made largely to increase the general average in total alkaloids rather than in quinine, so as to increase the production of the impure alkaloids which are so largely used as febrifuges in the British East Indies. Of recent years, however, even in India, efforts have been directed to the obtaining of quinine rather than of inferior alkaloids. The barks of
Ceylon have always been of poor quality, while those of Java to-day are probably the best that have ever been put upon the market. The effect of the efforts of arboriculturists is well shown by the facts that in 1889 the average percentage of quinine in Java bark was 4; in 1893 it had risen to 4.6; while in the five years, from 1900 to 1904 inclusive, the average quinine percentage of all the Java barks sold in the Amsterdam market was 5.37. The result does great credit to Java, for during the early history of her bark enterprise her plantations were stocked with discouraging quantities of poor or even worthless barks, which have been eliminated by the most steady enterprise and patient industry. David Howard presented a comprehensive survey of cinchona barks and their cultivation. (J. Soc. Ch. Indus; 1906, p. 97.) Winkler describes the methods employed in the cultivation of Cinchona in Java, also the manner of collecting the bark and preparing it for market. (Der Tropenpflanzer, 1906, p. 222.) Bohringer gives a review of the progress in the cultivation of Cinchona in Ceylon. (Tropenpflanzer, 1909, p. 269.) Sehneider discusses the possibility of cultivating Cinchona in California. (W. D., 1906, p. 136.)

Commercial History.

The above general history of Cinchona leaves little necessary to be said of its commercial history, except to deduce from the facts already presented certain practical conclusions showing the present conditions of supply and demand, these bearing especially upon our concluding remarks concerning pharmacognosy and classification.

For more than a century after Peruvian bark came into use, it was procured almost exclusively from the neighborhood of Loxa. In a memoir published in 1738, La Condamine speaks of the bark of Riobamba, Cuenca, Ayavaca, and Jaen de Braecomoros. Of these places, the first two, together with Loxa, lie within the ancient kingdom of Quito, at the southern extremity; the others are in the same vicinity, within the borders of Peru.

Towards the end of the eighteenth century, however, the trees were discovered to exist in Colombia, in central Peru, near Lima (whence the name Lima bark, at one time applied to the drug) and in Bolivia.

The consequence of these discoveries was a vast increase in the supply of bark, which was now shipped from the ports of Guayaquil, Payta,
Luna, Africa, Buenos Ayres, Cartagena, and Santa Marta. At the same time the average quality was probably deteriorated; for, though many of the new varieties were possessed of excellent properties, yet equal care in superintending the collection and assorting of the bark could scarcely be exercised in a field so much more extended. The varieties poured into the market soon became so numerous as to burden the memory if not to defy the discrimination of the druggist, and the best pharmacologists found themselves at a loss to discover any permanent peculiarities which might serve as the basis of a proper and useful classification. More or less perplexity attending the recognition of the barks continued until after the firm establishment of the bark culture and the cheapening of the price, to the exclusion of the worthless varieties, as already described.

One of the most important developments of the modern bark trade is the fixing of the price in accordance with the quality as determined by assay. The most accurate method of selecting a characteristic sample for assay is a subject which has received much study, without the discovery of any method which does not depend for its value upon the discrimination and care exercised in its employment. The plan which is regarded as the safest, is to take a given weight, say eight ounces, from the inner portion of each package constituting the lot, mix and powder the whole of it, and furnish to applicants the required amount of the resulting powder. If any portion of any bale or bales is damaged, care is taken to add a proportionately large fragment of such portion. The bark is then recorded as containing so many units, a "unit" being each per cent. of quinine contained in a pound of bark. In rich bark the units are of course worth more than in poor, owing to the increased yield of alkaloid for the same cost of manufacture.

In the United States, at least, some difficulty has been experienced by druggists in securing the better grades of bark at regular rates, owing to the activity of the manufacturers in draining the market of the most desirable stock. The finer appearing packages of unbroken bark, having been marketed at greater cost, are necessarily held at higher prices. Possessing no special value for manufacturing purposes, these fall to the share of the druggist, but at higher prices than broken bark of the same richness. This fact has led to the recognition of two distinct classes, known as manufacturers' bark and druggists' bark. Druggists' bark, though in quills or unbroken pieces, and of a much finer appearance than manufacturers' bark, is on the average, inferior in quinine
percentage. The druggists' bark finds its entrance into commerce through various channels but the bulk of the cinchona trade, including practically all that is known as manufacturers' bark, centres in Amsterdam and London; of these marts that at Amsterdam is much the more important. In 1916 there were imported into the United States 3,947,320 pounds of cinchona barks, and 1,791,738 pounds of quinine sulphate and other salts of the cinchona alkaloids. The bark which is sold in Amsterdam comes almost exclusively from Java; that in London from India, Ceylon, and South America. Manufacturers' bark is sold, without respect to its physical characters or place of origin, entirely by its chemical analysis, the buyer in London being furnished with samples of the different lots of the bark sufficient time before the sale to enable him to make his own analysis, while in Amsterdam the percentage of quinine sulphate in any lot is given in the catalogue and often tagged upon the bale.

Formation of the Alkaloids.—In a very careful series of experiments made at the Java governmental cinchona plantations, Lotsy (Bull. Inst. Botanique Buitenzorg, 3, 1900) found that the seeds of C. succirubra and C. Ledgeriana contain no alkaloids, but that these alkaloids appear in the cotyledons shortly after they become green. They exist chiefly in the bark in combination with a tannic acid. Lotsy found that the percentage of alkaloids is ten times greater in young than in old leaves; also that the petioles are richer in alkaloids than is the blade, and that the branch bark contains more than the trunk bark, and that the root bark is practically free from alkaloids. During the active life of the parenchymatous cells of the leaves, wood, and cortex, the alkaloids can always be found in the active protoplastic contents, but when these cells pass into the inactive condition, are deposited in the cell-walls. The alkaloids found in the leaves are, however, never crystalline, hence it would appear that these organs produce by direct synthesis, probably as the result of the action of cinchonic acid with ammonia, a fundamental alkaloidal base, which probably in the cambium layer of the tree, and during its deposition in the growing bark, is elaborated into the true cinchona alkaloids.

Classification.

Extreme difficulty attended the earlier attempts to classify the Cinchona barks of commerce,—difficulties not probably encountered elsewhere in the Materia Medica. The varieties have, however, been reduced to a
very few, and the whole subject decreased greatly in importance by the chemical method of the sale now in vogue. Most of the discarded barks will be found described in previous editions of this work. We find it necessary to enumerate and describe here only the Pale bark, from *C. officinalis*, the Red bark, from *C. succirubra*, the Yellow bark, from *C. Calisaya* and its var. *Ledgeriana*, and the Hard Yellow or Maracaibo bark, and to refer briefly to the hybrid forms. First, a few words concerning the forms in which Cinchona bark occurs. We have (1) the large flat pieces or chips of irregular shape and size,—this referring at present almost wholly to the Maracaibo variety; (2) the small chips or broken bark, referring in large part to the root bark, and to other bark broken for close packing; (3) the shaved bark, referring to some root bark and to stem bark taken from dry stems, but chiefly to branch bark; (4) the quill bark, referring to natural bark taken from the stem and root in quill form, this including the uncultivated pale bark and all the varieties of cultivated bark; and (5) the renewed and mossed bark, which may be of any cultivated variety. The classification of all varieties and forms into druggists' and manufacturers' barks enables us to dispense in great part with a description of some of these forms. The manufacturer cares nothing for form, appearance, or structure, and but little for the variety of his supplies. He is interested wholly in its composition, and this he determines by assay. For this reason most of the broken bark goes to him. The druggist requires the quill or large chip bark; so that the great bulk of the branch bark is also thrown, at low prices, upon the hands of the manufacturer.

As regards the root barks, no classified description is available. In their structure they correspond very closely to the stem barks of the same variety. They can be readily distinguished from the latter by being thinner, having lighter external and darker inner color, greater softness, and twisted or contorted structure. They occur in short, irregular quills or chips, or sometimes as shavings, and contain very much more dust than any other form. Except partly as regards structure, the description of stem barks will not apply to branch barks of the same variety, for the characteristic markings do not appear in the young condition. The branch bark appears in shavings, to the inner surfaces of many of which more or less wood adheres. If the branches were shaved while yet fresh, these shavings will be more or less rolled up and curled; but if dry before being removed, this rolling and curling will not occur. Shaved bark taken from living trees is thin, soft, and brittle, consisting of the outer bark only. The large quills are of uniform
length from the same plantation, but not necessarily so from different plantations or different sections. They are commonly from two to three feet in length, but some have been marketed having a length of five feet. Usually they represent the entire circumference of the stem, but occasionally only half of it. In drying they roll up very tightly from one or both edges, and rarely one will be wholly or partly involved in another. The periderm, with all its markings, remains intact, and no other form so well displays the natural appearance as this. Mossed bark differs from natural stem bark in its great thickness and weight, less breadth of the quills, freedom from lichens, very dark color, and rough, corrugated or warty surface. The outer bark or cellular portion bears a greater ratio to the inner or fibrous portion than in natural bark. Renewed bark is lighter, both in color and weight, thinner, soft and brittle, and marked by a very peculiar external smoothness, sometimes very marked indeed. In its general appearance it is strikingly like a root bark, except for the relative straightness of its fibres. Like the mossed bark, it is in narrow, only partly rolled quills or bands, and is entirely free from lichens.

As they differ so greatly among themselves in coloration, lichen-growth, degree and form of exfoliation, structure and consequent fracture, there are but few characters which can be combined in a general description of the Cinchona barks which we consider. The external color varies from light ashy gray to nearly black, the inner varies less in its shades of yellow-brown and red-brown. All are more or less bitter, and most are astringent, but only Loxa bark has a distinctive odor. The fracture is never very long-splintery and never tough. As to structure, the bast fibers are loosely arranged, the radial rows being neither continuous nor very long. The fibers themselves are always unbranched, which distinguishes the true from the false barks, are rather short and obtuse, brittle, and usually easily detached from the bark. Laticiferous ducts and stone-cells may or may not be present. The former become less conspicuous as the bark grows older, so that their relative absence becomes indicative of a stage in which the due proportion of alkaloid should have been acquired.

It may be noted here that by far the greater portion of the alkaloid, particularly quinine, is stored in the outer bark, though that in the inner bark is in a purer state. The latter is not stored in the fibers, but in the cellular tissue between them.
As regards the former classification of barks by color, it referred only in small part to the external color, chiefly to the powder. These colors were never regarded as absolutely characteristic, as the three barks, yellow, red and pale, exhibited gradations by which they mingled at their extremes. Under present conditions, the lines of demarcation have become even more indistinct, and, as a matter of fact, in the market the terms "yellow" and "red" are used with great looseness. It is true that we receive much pure-blooded Yellow Bark, Ledgeriana from the East, and Calisaya both from there and from South America; but it is also undeniable that much of the bark sold under the several names is of mixed hybrid, and the typical characters are often greatly obscured. The presence in our market of these mixed forms has made the terms even less valuable than they once were, and dealers cannot be found to agree as to the character of many samples. Nevertheless, the occurrence of the typical forms, and appearance in a hybrid of the blended characters, render it desirable to preserve this classification, and to group the new forms around the types.

YELLOW OR CALISAYA BARK. CINCHONA FLAVA.

The official description is as follows: "In quills or curved pieces of variable length, bark from 3 to 5 mm. in thickness, or in small broken fragments or in transversely curved pieces from 3 to 7 mm. in thickness, externally gray, rarely brownish-gray, with numerous intersecting-transverse and longitudinal fissures having nearly vertical sides, and usually with patches of foliaceous lichens with their small, brownish-black apothecia; when the outer bark is absent, the color externally is cinnamon-brown; inner surface light cinnamon-brown, finely striate; fracture of the outer bark short and granular, of the inner bark finely splintery; odor faintly aromatic; taste very bitter and somewhat astringent. The powder is reddish-brown; bast-fibers spindle-shaped, yellowish, from 0.3 to 1.35 mm. in length, with thick, strongly lignified, lamellated walls having slit-like, oblique pores; starch grains single or 2- to 5-compound, the individual grains spherical or plano-convex and from 0.003 to 0.015 mm. in diameter; sphenoidal micro-crystals of calcium oxalate numerous. Heat 1 Gm. of powdered Cinchona in a dry test tube; a tarry distillate forms, having a purplish color and a somewhat granular appearance." U. S.

Its lichens are thin and closely adherent, not rendering it shaggy. External markings very characteristic, consisting of a very light
longitudinal ridging or none at all, but of numerous transverse and longitudinal fissures or cracks, the presence and arrangement of which constitute the chief characteristic of Calisaya. Upon the young stems and branches they do not appear. The first to appear are the usually large primary fissures, which encircle the stem at the nodes, or points where pairs of leaves once stood. Subsequently, numerous smaller secondary transverse fissures appear upon the internodes, and these quickly become connected and crossed by longitudinal cracks, thus dividing the periderm up into more or less quadrangular checks, which may remain attached or fall away. This gives to mature Calisaya bark an appearance of scaliness like that upon the tarsus of a fowl, and this is known to the South American collectors by a term which signifies the "chicken-leg appearance." It has also been spoken of as a "carving-like" marking. Like the roughness upon a musk-melon, its great development is regarded as an indication of high quality, and especially is this true of a close proximity of the primary fissures. This roughness is also regarded as a sure indication of maturity. There are excellent distinctions between these and the somewhat similar fissures upon the bark of C. officinalis. In the latter they are coarser and more gaping. Even more important is the absence from Pale Bark of most of the longitudinal cracks, so that it does not become "chicken-legged," or at most only very slightly so. The external color of Yellow Bark is lighter than that of the Pale Bark. Longitudinal ridges are few if any, short, irregular, and inconspicuous. In fine South American bark some very small bright-red spots can be detected upon the periderm. East Indian Calisaya can commonly be recognized by its somewhat dingy or brownish shade of gray, the gray of the South American bark being bright and somewhat bluish-steel-colored.

In structure, the zone of large, rather numerous laticiferous ducts just outside the bast is conspicuous in young, and therefore inferior, samples. The rather small bast fibers are loosely scattered, almost uniformly single or a radial arrangement being apparent. The fracture is rough-splintery, though not coarse. Stone cells few or none. Odorless, more bitter, and less astringent than the Pale Bark. Ledger bark is the same as Calisaya in all its essential characters, but does not reach so great a size. In hybrids of Calisaya with succirubra the characters and quality of the latter appear to predominate.

This bark is scarcely collected in a wild state, but cultivated in all plantations. It is the largest quinine yielder, its amount being 70 to 80
The var. Ledgeriana yields a very valuable hybrid bark with C. succirubra. C. Calisaya also hybridizes with the latter species. Hartwich describes the microscopical characteristics of Cinchona and related barks in S. W. P., 1909, p. 249. Grutterink discusses the micro-chemistry of Cinchona alkaloids, with illustrations in Zeit. anal. Chem., 1912, p. 215. Rosenthaler reviews the pyro-analytical results that have been obtained with Cinchona bark and describes the crystals found in the tar. (B. P. G., 1911, p. 203.)

RED BARK. CINCHONA RUBRA.

This bark is recognised by the U. S. and Br. Pharmacopoeias (for definition, see page 333). It is described in the U. S. P. IX as "in quills or curved pieces of variable length, bark from 2 to 4 mm. in thickness, or in small broken fragments or in transversely curved pieces from 3 to 7 mm. in thickness; externally gray, grayish-brown, or reddish-brown, more or less rough from corky protuberances, occasionally with transverse fissures which are rarely numerous or much intersected, and having their sides sloping, and with occasional patches of foliaceous lichens; inner surface reddish or orange-brown, distinctly striate; fracture short and granular in the outer bark, shortly and rather coarsely splintery in the inner bark; odor slight; taste very bitter and astringent. The powder is light brown; bast-fibers and sphenoidal micro-crystals of calcium oxalate, resembling those in cinchona; starch grains resembling those of cinchona relatively few, from 0.003 to 0.01 mm. in diameter. Heat 1 Gm. of powdered Red Cinchona in a dry test tube; a tarry distillate forms having a bright red color." U. S.

In the British Pharmacopoeia it is described as "In quilled or curved pieces, length varying from 5 to 30 cm. or more; usually from about 2.5 to 6 mm. thick; cork brownish or reddish-brown, with longitudinal ridges which are most apparent in the branch bark, and sometimes with reddish warts; inner surface brick-red or deep reddish-brown, irregularly and coarsely striated; fracture shortly fibrous in the smaller, and finely fibrous in the larger, pieces. In transverse section in the cortex, cells filled with minute crystals of calcium oxalate, and also large secretion tubes; in the bast numerous, large, strongly-thickened fibers usually 0.050 to 0.070 mm. wide and about 1 mm. long, isolated or in small groups. The powdered Bark is brownish or reddish-brown, exhibits abundant parenchymatous tissue with brownish cell-walls, and often
with brownish contents, small starch grains, and large isolated bast fibers about 0.060 mm. in diameter, with distinctly striated walls. No marked odor; taste bitter and somewhat astringent."

The quills are similar to those of Calisaya, though running somewhat broader and thicker. Externally of a dingy brown gray, less lichen-bearing than either of the others. Inner surface of a more reddish cinnamon-brown than in Calisaya. Powder reddish-brown.

The important characteristic of red bark is the prominent longitudinal ridges, many of them short and confluent, with intervening furrows or elongated meshes. The ridges are suberous, bear numerous small warty protuberances, and may be traversed by faint fissures. Transverse fissures may or may not be present in red bark. If so, they are few, short, and irregularly disposed, and not connected by longitudinal cracks to give the checkered appearance of Calisaya. Hybrids with "officinalis" display numerous transverse fissures, and the external color is lighter and more dingy. Fracture short-splintery, not coarse. Odor none. Taste bitter and astringent.

It is scarcely collected in a wild state, but cultivated in all plantations except those of South America. Demand and production rapidly decreasing. A large alkaloid yielder, but of this only about 20 per cent. is quinine. Largely hybridized with C. officinalis. Also hybridized with C. Calisaya and its var. Ledgeriana.

PALE BARK.

Varieties and Synonyms.—Crown Bark, Loxa or Loja Bark, Cuenca Bark, Huanuco Bark. Derived from C. officinalis. Collected in a wild state above Loxa and other parts of Ecuador, and cultivated in all plantations except the South American, especially in India. Demand and production decreasing. Quinine constitutes 60 to 70 per cent. of the total alkaloids. Largely hybridized with C. succirubra.

Description.—Quills single or double, irregularly broken or entire, attaining a length of nearly 2 dm., a width of nearly 2.5 cm., and having a very wide range in thickness, the natural mostly 2 to 4 mm. thick. Shaggy, with more abundant lichens than in any other species, the abundance of these having been considered, not entirely without reason, as an indication of the relative quality. Color of periderm darker
than in the other species, but varying much from a brown gray to nearly black. Inner surface of a paler brown than in the other species, finely striate. Color of powder pale brown. The external markings consist of transverse fissures and longitudinal ridges, some of them wart-bearing. It is only in the thinner samples, in which the warts and fissures scarcely appear, that the ridges are continuous and conspicuous. In the prominence and breadth of its fissures and the inconspicuousness of its ridges, this bark is most distinct from the Red Bark. These characters are yet sufficiently distinct from the somewhat similar ones of Calisaya, as noted in describing that bark.

Fracture short, the inner fibrous zone sharp and narrow. Taste not so bitter as in the others. Odor of the genuine Loxa variety peculiar and characteristic. Its structure shows the rather short and not numerous bast fibers in short interrupted single or double radial rows, and much disposed to occur in bundles of three to six or more. Stone cells rarely seen, and lactiferous ducts conspicuous only when young.

HARD YELLOW, OR MARACAIBO BARK. PUERTO CABELLO BARK.

Derivation not at all certain. Collected only in a wild state in the mountains of Southern Colombia, and yielding almost the whole of the inferior wild bark now collected for market. Importation and sale in the United States quite irregular and unimportant. One of the best of the lower-grade barks, but not to be compared with any of those already described. Said to yield about 2 per cent. of crystallizable sulphates, three-fourths of which is quinine sulphate, but a characteristic specimen assayed for this investigation by Virgil Coblentz yielded 2.65 per cent. of total alkaloids, only a trace of which was quinine. Contains a large amount of resin. The common or commercial names by which have been designated the several barks of the northern countries related to this one are of very irregular application. At the time when the trade in them was large and important, the term "Maracaibo Bark" was; restricted to the less resinous variety, derived from C. cordifolia. It was also formerly sold simply as "Yellow Bark," and it's not impossible that it was sometimes accepted, under this synonym, for Calisaya. The investigations of Morgenthau into the value of certain derivatives of cuprein may give these barks a real value. For a description of Cuprea Bark, see 19th ed., U. S. D., p. 349.

Description.—Rusby described it as occurring in irregular broken pieces,
mostly from 5 to 15 cm. long, 2.5 to 7 cm. broad, and 3 to 10 mm. thick. Formerly it included many much smaller fragments as well as much dust, but these portions are now mostly sifted and winnowed out before marketing. The pieces are more or less flat, the thinner and narrower ones somewhat incurved, the broader and thicker recurved. The bark is compact, heavy, and fibrous. Most of the pieces display upon the outer surface more or less of the periderm, forming silvery-white or yellowish-white patches, very thin and rather soft. Occasionally the periderm is instead dark, hard, very rough, and much fissured. From many pieces the entire periderm is absent, disclosing the outer face of the bast, very similar to the inner face. This is compactly and rather finely fibrous, of a deep yellow, with a slight rust-brown tinge. Throughout, the bast is of this structure and color. Between it and the periderm there may be seen with varying distinctness, in most pieces, a characteristic resinous band of irregular width, dark reddish-brown and waxy-lustrous on the cut surface. The radial rows of bast fibres are irregular. The fracture is long-fibrous. The odor is distinct, and the taste quite bitter.

Chemical History.

I have deleted 14 pages of agonizingly precise discussion of the alkaloids of Cinchona...trust me—you don't need to know...

Uses.—This valuable remedy was unknown to the civilized world until about the middle of the seventeenth century, though the natives of Peru are generally supposed to have been long previously acquainted with its febrifuge powers. Humboldt, however, is of a different opinion. In his memoir on the Cinchona forests, he states that it is unknown as a remedy to the Indians inhabiting the country where it grows, and, as these people adhere pertinaciously to the habits of their ancestors, he concludes that it never was employed by them. They have generally the most violent prejudices against it, considering it poisonous, and in the treatment of fever prefer the milder indigenous remedies. Ruiz and Pavon, however, ascribe the discovery to the Indians; and Tschudi states, in his “Travels in Peru” (Am. cd., ii, 280), that the inhabitants of the Peruvian forests drink an infusion of the green bark as a remedy in intermittent fever. On the other hand, the statements of Humboldt have been confirmed by the travellers Markham and Spence, the former remarking that the native Indian doctors did not use the bark, and the latter that the Cascarilleros of Ecuador believed that their red bark is used solely for dyeing. It is uncertain whether, as Jussieu stated in
1739, the Jesuit fathers received their knowledge from the Indians, or, as Humboldt believes, discovered the virtues of the drug for themselves, having been led to make trial of it by its extreme bitterness. The Countess Chinchon, wife of the Viceroy of Peru, having in her own person experienced the beneficial effects of the bark is said, on her return to Spain in the year 1640, to have first introduced the remedy into Europe. Hence the name of pulvis Comitissae, by which it was first known. After its introduction it was distributed and sold by the Jesuits, who are said to have obtained for it the price of its weight in silver. From this circumstance it was called Jesuits' powder, a title which it long retained. In 1653, Chifflet, physician to the Archduke Leopold, directed the attention of all Europe to the bark by his work entitled Pulvis Febrifugns Orbis Americani. This gave rise to a very active controversy, the high price of the drug aiding very greatly those who opposed its introduction. According to Stunn, twenty doses in 1658 cost sixty florins. It seems first to have been advertised in England for sale in 1658 by James Thomson, and by 1660 it was much employed. It still, however, encountered much prejudice and ignorance, and was not made official in the London Pharmacopoeia until 1677. Sir Robert Talbot (or Talbor) used it as a secret remedy with so much address and success that in 1679 he cured Charles II of a tertian, and subsequently sold his secret to Louis XIV of France, who published it in 1681.

When taken into the stomach, the bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state; and its action is not unfrequently accompanied by purging. If the dose of the cinchona bark has been large enough, the symptoms of cinchonism may result. At one time cinchona bark and its preparations were used as antiperiodics, but at present for such purpose one of its alkaloids is always selected. The best preparation for use as a tonic is the compound tincture.

Dose, ten grains to one drachm (0.65-3.9 Gm.).

**Off. Prep.**—Cinchona.—Fluidextractum Cinchonas, U. S.; Tinctura Cinchonae, U. S.; Extractum Cinchonae, N. F.

Red cinchona.—Extractum Cinchonse Liqui-dum, Br.; Infusum
Cinquonas Acidum, Br.; Tinctura Cinchonae, Br.; Tinctura Cinchonae Composita, U. S. (Br., from Tincture); Fluidextractum Cinchonae Aquosum, N. F.: Gargarisma Guaiaci Compositum (from Compound Tincture of Cinchona), N. F.

Cineraria Maritima L.—This composite plant, known popularly as Dusty Miller, is a native of the West Indies, and has been introduced as a house plant into this country. There is upon the market a proprietary preparation which professes to be the expressed juice of this plant, and is recommended in diseases of the eye, especially as an absorbent of cataracts. We do not know, however, of any sufficient scientific justification for a belief in this improbable property.

CINNAMOMUM SAIGONICUM. U. S.

SAIGON CINNAMON Cinnam. Saigon.

"The dried bark of an undetermined species of Cinnamomum (Fam. Lauraceae)." U. S.

Annam cinnamon, China cinnamon. God's cinnamon; Cannelle de Saigon, Fr.; Saigonzimmt, G.

CINNAMOMUM ZEYLANICUM. U. S. (Br.)

CEYLON CINNAMON Cinnam. Zeylan.

"The dried bark of cultivated trees of Cinnamomum zeylanicum Breyne (Fam. Lauraceae), without the presence or admixture of more than 3 per cent. of the outer bark or other foreign matter." U. S. "Cinnamon Bark is the dried inner bark of shoots from the truncated stocks of Cinnamomum zeylanicum, Breyn. Obtained from cultivated trees. Imported from Ceylon, and distinguished in commerce as Ceylon cinnamon." Br.

Cinnamomi Cortex, Br.; Cinnamonum, U. S. 1880; Cinnamon Bark; Cortex Cinnamomi Zeylanici; Cinnamomum Acutum, s. Verum; Cannelle de Ceylan, Fr. Cod.; Cannelle, Fr.; Brauner Kaneel, Zeylonzimmt, Zimmt, G.; Cannella, It.; Canela, Sp.; Kurundu, Cingalese; Karua puttay, Tamil.

Both cinnamonum and cassia were terms employed by the ancients, but whether exactly as now understood it is impossible to determine. The term cassia, or cassia lignea, has been generally used in modern times to designate the commoner barks of Cinnamomum Cassia (Nees)
Blume. The barks sold as cinnamon and cassia in different parts of the world are derived from various species of Cinnamomum.

Cinnamomum zeylanicum is a tree about 20 or 30 feet high, covered with a thick, scabrous bark. The branches are numerous, strong, horizontal, and declining, and the young shoots are beautifully speckled with dark green and light orange colors. The leaves are petiolate, opposite for the most part, coriaceous, entire, ovate or ovate-oblong, obtusely pointed, and three-nerved, with the lateral nerves vanishing as they approach the point. There are also two less obvious nerves, one on each side arising from the base, proceeding towards the border of the leaf, and then quickly vanishing. In one variety the leaves are very broad and somewhat cordate. When mature, they are of a shining green upon their upper surface, and lighter-colored beneath. The flowers are small, white, and arranged in axillary and terminal panicles. The fruit is an oval berry, which adheres like the acorn to the receptacle, is larger than the black currant, and when ripe has a bluish-brown surface, diversified with numerous white spots. The tree emits no odor perceptible at any distance. The bark of the root has the odor of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odor when rubbed, and a hot taste. A volatile oil has been distilled from them. The petiole has the flavor of cinnamon. It is a singular fact that the odor of the flowers is to most persons disagreeable, being compared by some to the scent exhaled from newly-sawed bones. The fruit has a terebinthinate odor when opened, and a taste in some degree like that of juniper berries. A fatty substance, called cinnamon-suet, is obtained from it when ripe, by bruising it and then boiling it in water, and removing the oleaginous matter which rises to the surface, and concretes upon cooling. It is the prepared bark that constitutes the genuine cinnamon.

This species is a native of Ceylon, where it has long been cultivated. It is said also to be a native of the Malabar Coast, and has at various periods been introduced into Java, the Isle of France, Bourbon, the Cape Verds, Brazil, Cayenne, several of the West India islands, and Egypt, and in some of these places is at this time highly productive, especially in Cayenne, where the plant was flourishing so early as 1755. It is exceedingly influenced, as regards the aromatic character of its bark, by the circumstances of soil, climate, and mode of culture. Thus, we are told by Marshall that in Ceylon, beyond the limits of Negombo and Matura, in the western and southern parts of the island, the bark is never of
good quality, being greatly deficient in the aromatic flavor of the cinnamon, and that even within these limits it is of unequal value, from the various influences of exposure, soil, shade, and other circumstances. Cinnamon closely resembling Ceylon cinnamon is said to have been sent to Europe from Brazil.

Cassia Cinnamon which was formerly official is the product of Cinnamomum Cassia (Nees) Blume, a tree resembling C. Zeylanicum but distinguished by the hairiness of the young twigs, petioles and under surfaces of the leaves. The tree is indigenous to and cultivated in southern China, Annam and Cochin-China. It is also cultivated in Sumatra, Ceylon, Japan, Mexico and South America. The bark is known in commerce as China or Canton Cassia and the commonest or cheapest grade as "Cassia lignea."

Besides the two species above described, others have been thought to contribute to the cinnamon and cassia of commerce. In 1839 (Madras Journ. Lit. and Sci., No. 22), Wight stated that in his belief cinnamon was derived from 12 to 18 specifically distinct trees. C. inners, Reinw., is distinguished from C. zeylanicum by the nervation of its leaves, which are also paler and thinner than those of the official plant, of which, however, it is probably only a variety.

It yields the so-called wild cinnamon of Japan. C. obtusifolium Nees, growing in Ceylon, Java, and on the mainland of India, is said to have been the chief source of the drug known formerly by the name of Folia Malabathri and consisting of the leaves of different species of Cinnamomum mixed together. C. Culilawan Blume of the Moluccas yields the aromatic bark called culilawan, noticed in Part II of this work; and similar barks are obtained from C. Sintoc of Java. Massoy bark, from which an aromatic volatile oil is obtained called oil of massoy, is the product of Sassafras Goesianum Leijom. In the mountains of Eastern Bengal, at a height of 1000 to 4000 feet, flourish C. obtusifolium Nees, C. pauciflorum Nees, and C. Tamala Nees et Ebern, and these, with other unknown species, afford quantities of bark which are shipped from Calcutta, Java, Timor, etc., to Europe under the name of wild cassia. The bark of the C. pedatinervium Meissn, a tree indigenous to Fiji, yields nearly one per cent. of a white aromatic volatile oil, with a pungent spicy taste. For constitution, etc., see Proc. Chem. Soc., xix. These barks are mostly highly aromatic, resembling cinnamon more or less closely in flavor, and are distinguished by yielding to cold
water an abundant mucilage. Holmes described the bark of C. pedativum Meis., and concludes that it might be of value as a source of safrol and linalool in P. J., 1904, p. 892.

Cassia Buds.—This spice consists of the calyx of Cinnamomum Cassia (Nees) Blume, surrounding the young ovary, and, as stated by Martius, on the authority of the elder Nees, about one-quarter of the normal size. It is produced in China; and Reeves states that great quantities of it are brought to Canton from the province which affords cassia. Cassia buds have some resemblance to cloves, and are compared to small nails with round heads. The enclosed ovary is sometimes removed, and they are then cup-shaped at top. They have a brown color, with the flavor of cinnamon, and yield an essential oil upon distillation. They may be used for the same purposes as the bark.

Culture, Collection, Commerce, etc.—In Ceylon, cinnamon bark was originally collected exclusively from the tree in a wild state; but the Dutch introduced the practice of cultivating it, which has been continued since the British came into possession of the island. The principal cinnamon gardens are in the vicinity of Colombo, but the plant is grown from the sea-level up to a considerable elevation, giving the finest product, however, on the sandy soil of the coast line. The seeds are planted in a prepared soil at certain distances, and, as four or five are placed in a spot, the plants usually grow in clusters like the hazel-bush. In favorable situations they attain the height of five or six feet in six or seven years; and a healthy bush will then afford two or three shoots fit for peeling, and every second year afterwards from four to seven shoots in a good soil. The cinnamon harvest commences in May and continues until late in October. The first object is to select shoots proper for decortication, and those are seldom cut which are less than half an inch or more than two or three inches in diameter. Before decortication these shoots are trimmed up, and the small pieces, when dried, constitute cinnamon chips. The bark is divided by longitudinal incisions, of which two are made in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation, which facilitates the separation of the epidermis. This, with the green matter beneath it, is removed by placing the strip of bark upon a convex piece of wood and
scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, and connects them also endwise, thus forming a congeries of quills which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about, thirty pounds and bound together by pieces of split bamboo. The commerce in Ceylon cinnamon was formerly monopolized by the East India Company; but the cultivation is now unrestricted, and the bark may be freely exported upon the payment of a fixed duty. It is assorted in the island into three qualities, distinguished by the designations of first, second, and third. The inferior kinds, which are of insufficient value to pay the duty, are used for preparing oil of cinnamon.

The importations of cassia buds into the United States in 1916 amounted to 197,056 pounds, and of cassia and cassia leaves to 7,487,156 pounds, valued at $493,161. Immense quantities of cinnamon barks are exported from China, the finest of which is little inferior to that of Ceylon, though the mass of it is much coarser. It passes in commerce under the name of cassia, was formerly official, and is said by Reeves to be brought to Canton from the province of Kwangse, where the tree producing it grows very abundantly. It is, indeed, asserted that true cinnamon of very fine grade occurs in China, although it never enters foreign commerce, because of the high price which it commands at home. (P. J., xxi, 1890.) These fine cinnamons are said to be produced in the mountainous district of Annam, or Cochin-China. Cinnamon of good quality is said to be collected in Java, and considerable quantities of inferior quality have been thrown into commerce, as cassia lignea, from the Malabar Coast. Manila and the Isle of France are also mentioned as sources whence this drug is supplied. Little, however, reaches the United States from these places. The island of Martinique, Cayenne, and several of the West India islands yield to commerce considerable quantities of cinnamon of various qualities. That of Cayenne is of two kinds, one of which closely resembles, though it does not quite equal, the aroma of Ceylon, the other resembles the Chinese. The former is supposed to be derived from plants propagated from a Ceylonese stock, the latter from plants which have sprung from a tree introduced from Sumatra. By far the greater proportion of cinnamon brought to this country is imported from China. It is entered as cassia and Saigon cassia at the custom house.

From what source the ancients derived their cinnamon and cassia is not
certainly known. Neither the plants nor their localities, as described by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is probable that the Arabian navigators at a very early period conveyed this spice within the limits of the Phenician and Uredan and subsequently of Roman commerce.

Properties.—Saigon cinnamon takes its name from Saigon, the capital of French Cochin China. It is a thick cassia bark, which has come into European commerce, and was recognized for the first time by the U. S. P., 1890. It is officially described as "in quills attaining a length of 30 cm., and from 3 to 30 mm. in diameter; the bark from 0.5 to 3 mm. in thickness; outer surface light brown to dark purplish-brown with grayish patches of foliaceous lichens and numerous bud-scars; finely wrinkled, especially the bark of younger twig's, otherwise more or less rough from corky patches surrounding the lenticels; inner surface reddish-brown to dark brown, granular, and slightly striate; fracture short; inner bark porous, owing to the presence of large oil cells and mucilage cells, and separated by a continuous layer of stone cells from the outer bark; odor aromatic; taste sweetish, aromatic and pungent. Under the microscope, sections of the older bark of Saigon Cinnamon show a thin layer of more or less lignified cork cells; a narrow layer of starch-bearing parenchyma with scattered stone cells; a nearly continuous zone, several layers wide, of stone cells, among which are small groups of bast-fibers with thickened and slightly lignified walls; a wide inner bark with medullary rays 1 to 3 cells in width, isolated bast-fibers, mucilage cells, oil cells and parenchyma, the cells of the latter either filled with starch grains or containing very small rap hides of calcium oxalate; the lumina of parenchyma cells, stone cells and bast-fibers frequently filled with an amorphous reddish-brown substance, which is for the most part insoluble in the ordinary reagents. In the bark of young twigs there is an epidermal layer with a thick yellowish cuticle, fewer stone cells in the zone associated with bast-fibers, and the inner bark is narrower and with fewer secretion cells than in the older bark. The powder is yellowish- or reddish-brown; starch grains numerous, single or compound, the individual grains being somewhat ellipsoidal or polygonal and from 0.003 to 0.02 mm. in diameter; fragments, with colorless stone cells, rather prominent. the cells being very irregular in shape and the lumina containing either air or a reddish-brown amorphous substance; bast-fibers from 0.3 to 1.5 mm. in
length and usually in groups of from 2 to 20 with very thick and scarcely lignified walls; numerous cellular, reddish-brown fragments in which the oil cells are not readily distinguishable. Saigon Cinnamon yields not less than 2 per cent. of volatile extractive, soluble in ether. Saigon Cinnamon yields not more than 6 per cent. of ash. The amount of ash insoluble in diluted hydrochloric acid does not exceed 2 per cent. of the weight of Saigon Cinnamon taken." U.S.

"In closely rolled quills, each about nine millimetres in diameter, and containing numerous smaller quills or channelled pieces. Dull, pale yellowish-brown, darker on the inner surface; thin, brittle and splintery; entirely free from cork; marked with small scars or holes and with faint, shining, wavy longitudinal lines. The powdered Bark exhibits abundant parenchymatous tissue with brown cell-walls, isolated bast-fibers not more than 30 microns in diameter, small simple or compound starch grains and thick-walled sclerenchymatous cells, but no cork or fragments of wood. Fragrant odor; taste warm, sweet, and aromatic. Ash not more than 5 per cent." Br.

The odor of this cinnamon is fragrant, the taste is highly aromatic, markedly that of cinnamon, and, in the specimens that we have seen, only slightly astringent. It also occurs in commerce much broken, in which state it commands a somewhat smaller price than in quills. The Saigon buds also are brought into the port of New York. The quality of Saigon cassia, as it is commonly termed in trade journals, is distinctly superior to that of other cassias, and the price which it commands much higher. It is obtained from an undetermined species of Cinnamomum but is sometimes ascribed to Cinnamomum Loureirii of Nees, the Laurus Cinnamomum of Loureiro, a tree which grows in Cochin-China and Japan. According to Siebold, the bark of the large branches is of inferior quality and is rejected; that from the smallest branches resembles the Ceylon cinnamon in thickness, but has a very pungent taste and odor, and is little esteemed, while the intermediate branches yield an excellent bark, about 2 mm. in thickness, which is even more highly valued than the cinnamon of Ceylon, and yields a sweeter and less pungent oil. It yields about 2 per cent. of a volatile oil, the oil of Nikkei, having an odor resembling that of cinnamon and consisting of citral, having a specific gravity at 15° C. (59° F.) of 0.9005, and containing about 27 per cent. of aldehyde, chiefly citral.

Ceylon cinnamon occurs "in closely rolled double quills, composed of
from 7 to 12 thin layers of separate pieces of bark, from 30 to 50 cm. in length and from 8 to 13 mm. in diameter; the bark attaining a thickness of 1 mm.; outer surface pale yellowish-brown, smooth, longitudinally striate with narrow yellowish groups of bast-fibers, and showing circular or irregular brownish patches, occasionally with perforations marking the nodes; inner surface light brown, with faint, longitudinal striations; fracture short with projecting bast-fibers; odor agreeably aromatic; taste sweetish and warmly aromatic. Under the microscope, sections of Ceylon Cinnamon usually show no cork but an almost continuous outer layer of stone cells, among which are small groups of bast-fibers resembling those found in Saigon Cinnamon; in the inner bark occur numerous bast-fibers singly or in small groups, medullary rays 1 to 2 cells in width, usually with raphides of calcium oxalate; parenchyma with either reddish-brown contents or more or less filled with starch grains; scattered throughout the parenchyma occur oil secretion cells and mucilage cells. The powder is light brown or yellowish-brown; starch grains numerous, varying from spherical to polygonal, from 0.003 to 0.02 mm. in diameter, frequently in small aggregates; bast-fibers from 0.3 to 0.8 mm. in length, usually single, spindle-shaped, with attenuated ends, the walls being very thick and but slightly lignified; colorless stone cells resembling those of Saigon Cinnamon; numerous cellular fragments with yellowish-brown walls or contents; cork cells few or none; calcium oxalate in raphides, from 0.005 to 0.008 mm. in length. Ceylon Cinnamon yields not less than 0.5 per cent. of volatile extractive, soluble in ether. (See Part III, Test No. 12.) Ceylon Cinnamon yields not more than 6 per cent. of ash. The amount of ash insoluble in diluted hydrochloric acid does not exceed 2 per cent. of the weight of Ceylon Cinnamon taken." U. S.

When distilled Ceylon Cinnamon affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavor. It is brought to this country from England, but it is costly. The inferior sorts are browner, thicker, less splintery, and of a less agreeable flavor, and are little if at all superior to the best Chinese. The finer variety of Cayenne cinnamon approaches in character that a. Love described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young is scarcely distinguishable from the cinnamon of Ceylon.

Chinese cinnamon, or Cassia (Cinnamomum Cassia, Cassia Cinnamon, U. S., 1890), occurs in quills, usually single, sometimes double, very
rarely more than double, from 30 to 60 cm. long, 2 to 5 cm. wide, and 0.2 to 3 man. thick. In some instances the bark is rolled very much upon itself, in others is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker color than the finest Ceylon cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and astringent but less sweet and grateful taste, and though of a similar odor, is less agreeably fragrant. It is the kind almost universally kept in our shops. Of a similar character is the cinnamon imported directly from various parts of the East Indies. But under the name of cassia have also been brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or injured by want of care in keeping, or perhaps derived from inferior species. It is said that cinnamon from which the oil has been distilled is sometimes fraudulently mixed with the genuine. These inferior kinds are detected, independently of their greater thickness and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice. Chinese cinnamon is "in quills of varying length and about 1 mm. or more in thickness; nearly deprived of the corky layer; yellowish-brown; outer surface somewhat rough; fracture nearly smooth; odor fragrant; taste sweet, and warmly aromatic." U. S. 1890. Cassia is no longer official in the U. S. P., it having been dropped at the 8th Revision.

Powdered cinnamon is often grossly adulterated with sugar, ground walnut shells, galanga rhizome and various other substances. Galanga, according to Schmitz-Dumont, may be detected by the presence of small club-shaped, rod-shaped, partly bent, microscopic pieces of resinotannol. (Zeit. oeff. Chew., 1903, No. 2.) Powdered cassia buds are frequently added to the inferior cinnamon powders, but can hardly be looked upon as an adulterant, as they contain a larger proportion of volatile oil than the lower grades of cinnamon.

The Pharmacographia gives the following tests for distinguishing powdered cassia from powdered cinnamon, and for recognizing the inferior varieties of cassia. Make a decoction of powdered cinnamon of known genuineness, and one of similar strength of the suspected powder; when cool and strained, test a fluidounce of each with one or two drops of tincture of iodine. A decoction of cinnamon is but little affected, but in that of cassia a deep blue-black tint is immediately
produced. The cheap kinds of cassia known as cassia vera may be distinguished from the more valuable Chinese cassia as well as from cinnamon by their richness in mucilage; this can be extracted by cold water; it is a thick glairy liquid, giving dense ropy precipitates with corrosive sublimate or neutral lead acetate, but not with alcohol.

**Microscopic Structure.**—Ceylon cinnamon usually consists simply of the inner bark, the outer coatings having been stripped off during its preparation for market. Three layers are distinguishable in the liber. 1. The external surface, which is composed of one to three rows of large thick-walled cells, forming a coherent ring; it is only interrupted by bundles of bast fibres, which are obvious even to the unaided eye. 2. The middle layer is built up of about 10 rows of parenchymatous thin-walled cells, interrupted by much larger cells containing deposits of mucilage, while other cells not larger than those of the parenchyma itself are filled with essential oil. 3. The innermost layer exhibits the same thin-walled but smaller cells, yet intersected by narrow somewhat darker medullary rays, and likewise interrupted by cells containing either mucilage or essential oil, instead of bundles of bast fibres. Fibres mostly isolated are scattered through the two inner layers, the parenchyma of which abounds in small starch granules accompanied by tannic and on a longitudinal section the length of the liber fibres becomes more evident, as well as the oil-cells and mucilage cells. (Pharmacographia.)

The coarser cassia bark, or cassia lignea, usually has some of the external or corky layer adherent to it, and always the parenchymatous mesophleum or middle bark, but the inner bark constitutes the chief mass. Isolated bast fibers and thick-walled stone cells are scattered even through the outer layers of a transverse section. In the middle zone they are numerous, but do not form a coherent sclerenchymatous ring as in Ceylon cinnamon. The innermost part of the bast shares the structural character of cinnamon, with differences due to age, as, for instance, the greater development of the medullary rays. Oil cells and mucilage cells are likewise distributed among the parenchyma of the former. The finest cassia or Chinese cinnamon has the three layers described in Ceylon cinnamon, but is distinguished by the adherent outer parenchymatous and suberous layer. For an excellent description of the microscopical structure of the commercial cinnamon see Win-ton and Moeller, "The Microscopy of Vegetable Foods" Spaeth gives the microscopical characteristics of the several kinds of cinnamon, discusses the

**Chemical Composition.**—According to the analysis of Vauquelin, cinnamon contains a peculiar volatile oil, tannin, mucilage, a coloring matter, an acid, and lignin. The tannin is of the variety which yields a greenish-black precipitate with the salts of iron. Thos. R. Thornton (A. J. P., 1895, 400) has examined the tannin of C. Cassia. He found it to amount to about 3.90 per cent., as an average of three different determinations on different samples. He found it impossible to extract the tannin by any one of several methods tried, and concludes that it either has the phlobophene (anhydride) character as it exists in the drug or acquires such character when brought into contact with water.

Jas. A. Ferguson (1887), in the laboratory of the Philadelphia College of Pharmacy, determined the ash of several samples of Ceylon cinnamon, finding an average of 4 per cent., while in powdered cassia cinnamon he found 2.8 and 2.5 per cent. (A. J. P., 1887, 278, 279.) The oil obtained from the Cayenne cinnamon was found to be more biting than that from the Ceylon. Bucholz found in 100 parts of cassia lignea 0.8 of volatile oil, 4.0 of resin; 14.6 of gummy extractive (probably including tannin), 64.3 of lignin and bassorin, and 16.3 of water, including loss.

This aromatic yields its virtues wholly to alcohol, and less readily to water. At the temperature of boiling alcohol very little of the oil rises, and an extract prepared from the tincture retains, therefore, the aromatic properties. For an account of the volatile oil, see Oleum Cinnamomi.

**Uses.**—Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, distinctly astringent, and, like most other substances of this class, more powerful as a local than as a general stimulant. It is seldom prescribed alone, though, when given in powder or infusion, it will sometimes allay nausea, check vomiting, and relieve flatulence. It is chiefly used as an adjuvant, and enters into a great number of official preparations. It is often employed in diarrhea, in connection with chalk and astringents.

Dose, of powder, ten to twenty grains (0.65 tol. 3Gm.).

Clematis. Clematis recta L. (C. erecta L.) Upright Virgin's Bower. Clematite, Fr. Waldrebe, G.—A perennial European plant. The leaves and flowers have an acrid, burning taste. When bruised in a mortar they irritate the eyes and throat, giving rise to a flow of tears and to coughing, and applied to the skin they produce inflammation and vesication; hence their old name of Flammula Jovis. The acridity is greatly diminished by drying. Storck found this clematis to be diuretic and diaphoretic, in doses of from one to two grains (0.065-0.13 Gm.) of the extract a day, or from thirty to forty grains (2-2.6 Gm.) of the leaves given in infusion three times a day, and to be useful, locally and internally, in syphilitic, cancerous, and other foul ulcers.

Other species of clematis have the same acrid properties; among these C. flammula L., or sweet-scented virgin's bower, which, though a native of Europe, is cultivated in our gardens, C. vitalba L., or traveller's joy, also a native of Europe, and several indigenous species, of which C. virginiana L., or common virgin's bower, C. viorna L., or leather flower, and C. crispa L. have been used as substitutes for C. recta L. All these are climbing plants. Rochebrune (Toxical. Africaine i) affirms that he has found in C. flammula L. an alkaloid, dematine, two milligrammes of which will produce in the guinea-pig copious and frequent urination, general tremors, great disturbance of respiration, feeble-ness and intermittency of the heart beat, followed in seven minutes by convulsions ending in coma and death.

From the bruised roots and stems of C. vitalba L., boiled for a few moments in water to diminish their acridity, and then digested in sweet oil for a little while, is made a preparation used locally in Europe for the itch. Twelve or fifteen applications are said to be usually sufficient. Gaube has found in this species an alkaloid, also named dematine, which forms with sulphuric acid a salt crystallizable in six-sided needles; also an acrid volatile oil analogous to mezereon in its properties, tannic acid, mucilage, and earthy salts. (J. P. C., Aout, 1869.)

CloveBark. Cortex Caryophyllatus. Cassia Caryophyllata.—Under these names two barks occur in the market. Of these the most abundant comes from the West Indies,
and is derived from a tree, Dicypellium caryophyllatum Nees. (Fam. Lauraceae.) It is usually in large compound quills, 1 to 2 mm. thick, composed of numerous separate pieces rolled around one another and having a dark brown color, being more or less flaky on the outer surface and finely striate on the inner surface, a pungent taste, and an odor similar to that of cloves. The second variety of clove bark occurs in fragments, resembling the other form in odor and color but softer and lighter, and supposed to be derived from Eugenia caryophyllaæ, Wight (Fam. Myrtaææ) which grows in Ceylon. This clove bark has aromatic properties not unlike those of the spice from which it derived its name, but it is much inferior and is not used in this country. Some authors have confounded with it a different bark, produced in the Moluccas and known by the Indian name of culilawan. (See Culilawan.) For description of a false clove bark, see A. J. P., vol. xv.

**Cnicus.** *Cirsium arvense* (L.) Scop. (*Cnicus arvensis*, Hoffm.) Canada Thistle—This European composite plant, to which have been attributed diaphoretic, emetic, and tonic properties, according to Herman J. Pierce (A. J. P., lxviii, 1896), contains a volatile alkaloid, and also Cnicin, *C₄₂H₅₆O₁₅*, which is said to possess emetic and emmenagogue properties.

It is described in the 'N. F. as "the dried fruit of Anamirta Cocculus (Linne) Wight et Arnott (Fam. Menispermacææ).""

This is a climbing shrub, with a. suberose or corky bark, and grows along the Malabar Coast, and in Eastern Insular and Continental India. By Roxburgh it was proved to be one source of Cocculus, which is, however, probably derived also from other plants, notably from the Cocculus Plukentii, DC. (now *Pachygoneovata* Miers.), of Malabar, and *C. laconusus* DC. (now *Anamirta paniculate* Colebr.); of Celebes and the Moluccas. It was known to the Arabian physicians, and was imported into Europe from the Levant, from which circumstance it was called Cocculus levanticus. It is now brought exclusively from the East Indies.

The fruit bears some resemblance to the bay laurel berry, but is not quite so large, and may be distinguished by the fact that in the Cocculus Indicus the kernel never wholly fills the shell. When the fruit is kept long, the shell is sometimes almost empty. The Edinburgh College directed that "the kernels should fill at least two-thirds of the fruit." It is described by the N. F. as "reniform, about 10 mm. in length and 6 mm. in breadth and thickness, blackish-brown, wrinkled; hilum and micropyle close together, separated by a shallow sinus and connected by an obscure ridge running around the convex side. Seed urn-shaped, its longitudinal and transverse sections crescent-shaped. Taste slightly bitter; the 'seed whitish-yellow and intensely bitter. Cocculus Indicus yields not more than 5 per cent. of ash." N. F.

According to Merck its main constituents are menispermine, paramenispermine, picrotoxin, *C₃₀H₃₄O₁₃*, picrotoxic acid and cocculin.
A tincture of Cocculus Indicus is official in the N. F. For Procter's formula for preparing a fluidextract, see U. S. D., 17th ed., or A. J. P., 1863.

Cocculus Indicus is used in India to stupefy fishes. Both its poisonous properties and any therapeutic virtues it may contain depend upon picrotoxin (see p. 1550). It has been used in medicine for the purpose of destroying vermin in the hair, but it is an extremely dangerous drug. For cases of poisoning see Sozinsky (M. News, 1883, xliii p. 485), Swift (N. Y. M. J., 1897, lxvi, p. 664), and Haines (P. M. T., 1884, xiv, p. 748). In spite of its highly toxic properties, Merck's Index, 1907, reports it as having nerve and sedative properties in doses of 1 to 3 grains (0.06-0.2 Gm.) doses of the powdered berries.

**Coca.** Coca Folia. U. S. P. VIII. Br. 1898. Coca Leaves. Cuca: Feuilles de Coca, Fr. Coca blatter, G. Coca del Peru, Ipadu, Sp.—"The dried leaves of Erythroxylon Coca Lamarck (Fam. Erythroxylaceae), known commercially as Huanuco Coca, or of E. Truxillense Rushy, known commercially as Truxillo Coca, yielding when assayed by the process given below, not less than 0.5 per cent. of the ether-soluble alkaloids of Coca," U. S. VIII. "The dried leaves of Erythroxylum Coca, Lam., and its varieties." Br., 1898.

The coca plants are shrubs or small trees, some of the species reaching the height of fifteen or twenty feet. It is conjectured that the original habitat was in the Peruvian mountains, from 7° South to 10° North, but either spontaneously or through cultivation the coca shrubs have spread until they are found in the whole Eastern curve of the Andes, from the Straits of Magellan to the borders of the Caribbean Sea, growing on the moist sides of the mountains at the elevation of 1500 to 6000 feet, the climatic requisites being moisture and equable temperature, with a mean of about 17.7° C. (64° F.) The wild coca shrub commonly reaches the height of 12 feet, and some are 18 feet, but the cultivated coca is usually kept down to about 6 feet. The leaves are gathered three times a year; the first harvest, or preliminary picking, is taken at the time of the trimming of the bushes, from the cut-off twigs. Then about the end of June, a scanty crop is gathered, while the last crop of the season is gathered in October or November. Harvesting must always take place in dry weather, so that the fresh leaves when spread out in layers two or three inches thick on the drying pavement can be collected in six or eight hours.

The coca plant, which is propagated from the seed in nurseries, begins to yield in eighteen months, and continues productive for half a century. The leaves, when mature, are carefully picked by hand so as to avoid breaking them or injuring the young buds, are slowly dried in the sun, and are then packed in bags (cestos) holding from twenty-five to one hundred and fifty pounds each. They were in general use among the natives of Peru at the time of the conquest, and have continued to be much employed to the present time. It is affirmed that nearly ten million dollars' worth, or forty million pounds, are annually produced, some plantations yielding three or four harvests a year. The importations into the United States have averaged for some years past about 1,000,000 pounds. For details as to method of cultivation, etc.,
see T.G., Jan., 1886; also C. D., 1897, 182'. Two varieties of the coca leaf occur in the commerce of the United States, namely, the so-called Huanuco coca, and the Truxillo coca, the Huanuco variety being produced in Bolivia, Huanuco, Brazil, Venezuela and Argentina, while the Truxillo coca is produced chiefly in Northern Peru. The great variation in the leaves and other portions of the coca plant, produced by its long-continued cultivation, has produced much doubt and discussion as to the specificity and characteristics of the plant; H. H. Rushy has made an elaborate study of the subject (D. C., Nov., 1900).

Huanuco coca, has been for a long time believed to be obtained from Erythroxylon Coca; this belief is confirmed by Rusby and has been accepted by the Pharmacopoeial authorities. The plant was first described in 1786, in Lamarck's Dictionary, vol. ii, 393.

Truxillo coca is the product of the E. Coca Spruceanum, of Burck; the name "spruceanum" had, however, been used elsewhere before it was suggested by Burek, and in obedience to the ordinary rules of botanical nomenclature it was changed by Rusby, who regards it as a distinct species, to E. Truxillense.

Coca is cultivated in the British East and West Indies, and in Java, and the product is said to appear, in the London markets, under the names of Truxillo coca and Java coca. This coca is entirely distinct from the Truxillo coca of the American market, and does not reach the United States. The coca shrubs of India and Ceylon are the offspring of plants originally sent out from Kew Gardens, which plants were derived from seeds obtained in Huanuco, and were considered by Morris as representing a variety of E. Coca to which he gave the name of E. Nova-Garantense. According to Rusby, however, this plant is a distinct species, and the same as that previously described by Jacquin, from Colombia, under the name of E. carthagenense (the name E. carthagenense not being, as it is held in the Kew Index, a synonym of E. areolatum).

The leaves of the different varieties of coca do not, on the whole, resemble one another at all closely, but are distinguished from most other leaves by a slightly curved line on each side of the midrib, running from the base to the apex. This line has the appearance of a rib, but is really not of this character, having been produced during development by the peculiar folding of the leaf in the bud. The two commercial varieties were very well described in the U. S. Pharmacopoeia VIII as follows:

"Huanuco Coca.—Greenish-brown to clear brown, smooth and slightly glossy, thickish and slightly coriaceous, stoutly and very shortly pectioled; blade 2.5 to 7.5 Cm. long and nearly elliptical, with a very short and abruptly narrowed basal portion and a short point, the margin entire; midrib marked above by a slight ridge, very prominent underneath, the remaining venation rather obscure, especially above; underneath, a conspicuous line of collenchyma tissue runs longitudinally on either side of the midrib and about one-third of the distance between it and the margin, the enclosed areola being of a slightly different color from the adjacent surface; odor characteristic; taste bitterish, faintly aromatic, followed by a numbness of the tongue, lips, and fauces.

"Truxillo Coca.—Pale green, thin, brittle and usually much broken, smooth, but not
shining, shortly and stoutly petioled; blade 1.6 to 5 Cm. long and one-third to one-half as broad, obovate to oblanceolate, narrowed from near the middle into the petiole, usually with a slight projecting point at the summit, the margin entire; underneath two irregular lines of collenchyma tissue, usually incomplete or obscure, and frequently wanting, run beside the midrib at about one-third the distance from it to the margin; odor more tea-like than that of Huanuco Coca; taste and numbing effect similar." U. S. VIII. " The midrib itself is prolonged into a minute horny apiculus, which, however, is frequently broken off. Most of the epidermal cells of the under surface are seen in transverse section to project in the form of small papillae." Br., 1898.

Chemical Constitution.—In 1853, Wackenroder demonstrated the existence of tannic acid in coca leaves, and in 1859, Stanislaus Martin found in them a peculiar bitter principle, resin, tannin, an aromatic principle, extractive chlorophyll, a substance analogous to theine, and salts of lime. Previous to this (1855) Gardeke had isolated the crystalline alkaloid and given it the name of erythroxyline. Albert Niemann, of Goslar, made the first thorough investigation of the leaves, and gave to the alkaloid the name it now usually bears of cocaine.

Assay. U. S. VIII.—" Coca, in No. 60 powder, ten grammes; chloroform, ether, normal sulphuric acid V.S., ammonia water, distilled water, tenth-normal sulphuric acid V.S., fiftieth-normal potassium hydroxide V.S., cochineal or odeosin T.S., each, a sufficient quantity. Place the Coca in an Erinenmeyer flask, add 50 Cc. of a mixture of chloroform 1 volume and ether 4 volumes and insert the stopper securely. Allow the flask to stand ten minutes, then add 2 Cc. of ammonia water mixed with 3 Cc. of distilled water, and shake the flask well, at frequent intervals, during one hour. Then transfer as much as possible of the contents of the flask to a small percolator which has been provided with a pledge of cotton packed firmly in the neck, and inserted in a separator containing 6 Cc. of normal sulphuric acid V.S., diluted with 20 Cc. of distilled water. When the liquid has passed through the cotton, pack the Coca firmly in the percolator with the aid of a glass rod, and, having rinsed the flask with 10 Cc. of chloroform-ether mixture, transfer the remaining contents of the flask to the percolator by the aid of several small portions (5 Cc.) of a chloroform-ether mixture, using the same proportions as before, and continue the percolation with successive small portions of the same liquid (in all 50 Cc.). Next, shake the separator well for one minute, after securely inserting the stopper, and when the liquids have completely separated, draw off the acid liquor into another separator. Add to the chloroform-ether mixture 10 Cc. of a sulphuric acid mixture, using the same proportions as before, agitate well and again draw off the acid liquid. Repeat this operation once more, drawing off the acid solution as before into the second separator, introduce a small piece of red litmus paper, add ammonia water until the liquid is distinctly alkaline, and shake out with three successive portions of ether (25, 20, and 15 Cc.). Collect the ether-solutions in a beaker, place it on a water-bath filled with warm water, and allow the ether to evaporate entirely. Dissolve the residue in 3 Cc. of ether, and let this also evaporate completely. To the alkaloidal residue add 4 Cc. of tenth-normal sulphuric acid V.S. and 5 drops of cochineal or iodineosin T.S., then titrate the excess of acid with fiftieth-normal potassium hydroxide V.S. Divide the number of cubic centimeters of fiftieth-normal potassium hydroxide V.S. used, by 5, subtract this number from 4 (the 4 Cc.
of tenth-normal sulphuric acid V.S. taken), and multiply the remainder by 0.03 and this product by 10, to obtain the percentage of ether-soluble alkaloids contained in the Coca." U. S. VIII. For methods of assaying coca leaves, see Lyons, Ch. Ph., Sept., 1885; Squibb, Ephem., 1887; Dohme, Proc. A. Ph. A., 1893, 159; Prescott, Organic Analysis; Proc. A. Ph. A., 1895, 268; P. J., 1896, 1901, 222, 254; Ph. Ztg., 1901, 965.

In South America many of the Indians habitually chew the leaf of the coca plant generally mixed with some alkali, as ashes or lime. It is stated on good authority that they will go for days performing hard physical labor without any other food. It is, however, clearly proven that these leaves do not take the place of nutriment, but simply put off the sense of fatigue and hunger. Eventually, however, this habit undermines the health and finally the inveterate excessive coca-chewer can be recognized by his uncertain step, general apathy, sunken eyes surrounded by deep purple aureoles, trembling lips, green and crusted teeth, and excessively fetid breath, with peculiar blackness about the corners of the mouth. An incurable insomnia is apt to be developed, emaciation becomes extreme, dropsy appears, and even death results from a condition of general marasmus. It has been believed that the effects of coca chewing are different from those produced by the alkaloid cocaine and hence it has been by some argued that the coca leaf contains other active principles, but there is no difference between the results of the habit as practised by the South American Indian and the use of the alkaloid by depraved Caucasians, which cannot be readily explained on the ground of difference in the mode of taking the stimulant or racial variation. While there are other active substances present in the coca leaf, it is not manifest that they modify the action of the crude drug materially. For a study of the uses and effects of cocaine, see p. 362, and of tropa-cocaine, see p. 1649.

Coca has a slight bitter tonic effect as well as a stimulant action upon the central nervous system and has been used as a tonic in neurasthenia and other debilitated conditions. The danger of the formation of the habit, however, far outweighs any value the drug may possess, and the use of the crude preparation of coca seems to us hardly justifiable, except under the most extraordinary conditions. The U. S. P., VIII, recognized a fluidextract, the dose of which was from thirty to sixty minims (2-3.9 mils), and a wine the dose of which was two to eight fluidrachms (7.5 to 30 mils).

**Cochlearia.** Cochlearia officinalis L. Common Scurvy-grass, Herbe au Scorbut, Fr. Herba Cochleariae, P. G. Loffelkraut, G. Spoonwort.—This annual or biennial cruciferous plant, is a native of northern and middle Europe and growing in Arctic America generally. The whole herb is active. It has, when fresh, a pungent, unpleasant odor if bruised, and a warm, acrid, bitter taste. These properties are lost by drying. They are imparted to water and alcohol by maceration, are retained by the expressed juice, and probably depend on a peculiar volatile oil, which is separable in very small quantity by distillation with water, and is probably produced by reaction between a fixed principle in the plant and water, under the influence of myrosin acting as a ferment. (Chem. Cb., 1856, 124.) According to Hofmann, the oil is a sulphur-containing oil of the butylic series, having the formula $\text{C}_5\text{H}_9\text{NS}=\text{C}_4\text{H}_9\text{CSN}$

Common scurvy-grass has been much used in scurvy, and even in chronic
rheumatism. The fresh plant may be eaten as a salad, or used in infusion; the expressed juice has also been used.

**Cocillana.** N. F. IV.—It is described in the N. F. as "the dried bark of Guarea Rusbyi (Britton) Rusby (Fam. Meliaceae). In flat or curved pieces of variable size and from 3 to 5 mm. in thickness; outer surface shallowly or deeply fissured, according to age and thickness, gray-brown, often ashy-gray from lichen growths, or of a deeper brown where the cork has been removed; inner surface of medium brown color, strongly and coarsely longitudinally striate, the striae straight or wavy; inner bark usually much thicker than the outer, its fracture coarsely splintery-fibrous. Odor characteristic; taste slightly astringent, peculiar and slightly nauseous. Cocillana yields not more than 10 per cent. of ash." N. F. The bark of this large Bolivian tree, which was discovered by H. Rusby, is believed by him (T. G.) 1888) to contain an alkaloid; but by John W. Eckfeldt (Med. Bull., 1891) its active principle is thought to be a glucoside. In doses of from twenty to fifty grains (1.3-3.2 Gm.) the bark causes vomiting, with prostration and some purging; also, it is said, much sneezing, dull frontal headache, and discharge from the nasal mucous membrane. The therapeutic action of the drug resembles that of ipecac, although as an expectorant it is somewhat more stimulant. (See N. T. M. J., Dec., 1889, and April, 1890). It has been used in various forms of bronchitis with asserted success. Dose, of the drug, fifteen grains.

**Coeloctline.** Xylopia polycarpa, Oliver. (Coelodine polycarpa, D.C.) Berberin Tree. Yellow dye Tree of Soudan.—This small tree, of the Fam. Anonaceae, growing in Soudan, Sierra Leone, and certain parts of Western Africa, was described by William F. Daniell. (P. J., Feb., 1857). When wounded, the tree exudes a juice which produces a yellow stain upon linen that cannot be washed out. The outer surface of the bark is greenish-gray interrupted by occasional blackish patches; the inner layers are of a golden yellow, and very fibrous, so that they can be separated in ribbon-like bands. The bark is moderately but disagreeably bitter, and stains the saliva yellow. Water extracts its color and bitterness. Stenhouse has ascertained that it contains berberine. The bark is much used in Africa for dyeing yellow. In Sierra Leone it is employed topically, in powder or decoction, for obstinate ulcers.

**Coffee.** N. F. IV. Coffea Tosta. Roasted Coffee. Caffen. Semen Caffeae. Cafe, Fr. Caffee, G. Caffe, It. Cafe, Sp. Bun, Ar. Copi Cotta, Cingalese. Kaeva, Malay.—The N. F. describes it as "the dried ripe seeds of Coffea arabica Linne or Coffea liberica Bulliard (Fam. Rubiaceae), roasted until they develop a dark brown color and a characteristic aroma, and yielding not less than 1 per cent. of caffeine." N. F. The C. arabica is a small evergreen tree from fifteen to thirty feet in height; native of Southern Arabia and Abyssinia, but cultivated in many parts of the world. The coffee berry is globular, umbilicate at top, at first green, then red, and ultimately dark purple. It is about as large as a cherry, and contains two seeds surrounded by a paper-like membrane, and enclosed in a yellowish-purple matter. These seeds, divested of their coverings, constitute coffee. The Coffee grains as seen in commerce are oval, having one side strongly convex, the other flat with a longitudinal groove upon the flat side and showing traces of the papery seed coat in the cleft. It has a
characteristic aroma and a pleasantly bitter taste. About the year 1690 it was introduced by the Dutch into Java, and in 1718 into their colony of Surinam. Soon after this latter period the French succeeded in introducing it into their West India Islands, Cayenne, and the Isles of France and Bourbon.

The tree is raised from the seeds, which are sown in a soil properly prepared, and, germinating in less than a month, produce plants which, at the end of the year, are large enough to be transplanted. These are then set out in rows at suitable distances, and in three or four years begin to bear fruit. It is said that they continue productive for from thirty to forty years. Though almost always covered with flowers and fruit, they yield most largely at two seasons, and thus afford two harvests during the year. Various methods are employed for freeing the seeds from their coverings; but that considered the best is, by means of machinery, to remove the fleshy portion of the fruit, leaving the seeds surrounded only by their papyraceous envelope, from which they are separated by peeling and winnowing mills. They appear in commerce as "oval, of variable size, having one side strongly convex, the other flat with a longitudinal groove, and showing traces of the papery seed coat in, the cleft. It has' a characteristic aroma and a pleasantly bitter taste. Percolate 1 Gm. of powdered Coffee with ether until exhausted and evaporate the percolate to dryness; the residue weighs not less than 0.1 Gm. (presence of at least 10 per cent. of fat). Boil 1 Gm. of powdered Coffee with 10 mils of distilled water, filter and acidify the filtrate with one mil of diluted sulphuric acid, and then decolorize it by the cautious addition of potassium permanganate T.S. This decolorized solution shows no blue coloration upon the addition of iodine T.S. (starch). Shake 1 Gm. of Coffee with 20 mils of water; the strained liquid shows no colored or heavy deposit. Shake 1 Gm. of Coffee with 20 mils of alcohol; the strained liquid shows no colored or heavy deposit, nor is any color imparted to the alcohol (artificial colors or facings). Powdered Coffee, when examined under the microscope, exhibits numerous fragments of the seed coat made up of parenchyma and irregular stone cells, the latter from 0.2 to 1 mm. in length and from 0.015 to 0.05 mm. in width with walls having simple pores; numerous brownish endosperm cells having porous walls about 0.01 mm. in thickness and containing oil and aleurone grains; starch grains few or absent. Coffee yields not less than 3 per cent. nor more than 5 per cent. of ash." N. F.

Assay.—"To 6 Gm. of Coffee, in No. 60 powder, contained in a small flask, add 50 mils of purified petroleum benzoin and agitate the mixture occasionally during one hour. Then allow it to settle and decant the benzoin solution. Add 50 mils more of the petroleum benzoin, shake the mixture occasionally during fifteen minutes, then filter off the benzoin and dry the drug. Now transfer the Coffee residue to a bottle having a capacity of about 250 mils and pour upon it 120 mils of chloroform and 6 mils of ammonia water. Stopper the bottle securely and shake it vigorously at intervals during six hours. Then allow it to stand one hour, and filter off 100 mils of the chloroform solution. Transfer this to a beaker and evaporate the chloroform at a gentle heat. Dissolve the alkaloidal residue in 10 mils of a mixture of 1 mil of diluted sulphuric acid and 9 mils of distilled water, by aid of a gentle heat, and filter the solution through a small filter, not exceeding 5 cm. in diameter, into a separator. Wash the beaker and filter with successive small portions of acidulated water, until a few drops of the filtrate give no test for caffeine when tested with iodine T.S. To the
mixed acid washings, add a slight excess of ammonia water, and shake out the caffeine with successive portions of chloroform, collecting the chloroformic solutions in a tared flask or beaker. Evaporate or distil off the chloroform at a temperature not exceeding 75° C. (167° F.) and add to the residue 5. mils of ether. Evaporate off the ether cautiously, then dry the residue to constant weight at a temperature not exceeding 80° C. (176° F.) and add 0.0025 Gm. to the final weight of caffeine to replace that lost in the petroleum benzin washing. The weight represents the amount of caffeine in 5 Gm. of Coffee." N. F.

In recent years, because of the spread of a leaf disease, the cultivation of the more hardy Coffea liberica has been undertaken in the Island of Ceylon. This may be distinguished from the C. arabica by the fact that the corolla is nine-cleft in the Liberian and from four to five-cleft in the Arabian. The seeds of the Liberica plant are much larger than those of the Arabica; are not greenish and have the groove deeply wrinkled along its edges.

The annual production of coffee for the world is about one million tons, of which the American countries produce in the neighborhood of nine-tenths, Brazil giving to commerce three-fourths of the world's supply. After South America, the chief producer of coffee is Java, that island sending into commerce nearly twice as much as the remaining Asiatic countries. The amount of coffee entering commerce from Africa is small. The character of coffee varies greatly, not only with the climate in which it is grown but with the circumstances of its cultivation and the character of the stock which produces it. The most esteemed varieties are those which are known as Mocha, and Java, but probably the bulk of the berry retained as Mocha or Java is of South American origin. Coffee improves by age, losing a portion of its strength and acquiring a more agreeable flavor. It is said to be much better when allowed to ripen perfectly on the tree than as usually collected. The grains should be hard, and should readily sink in water. When soft, light, black or dark colored, or musty, they are inferior.

The composition is very complex. The principal constituents are (1) caffeine (identical with theine), (2) caffetannic acid, (3) fat, (4) carbohydrates, (5) albumenoids, (6) essential oil and aromatic substances. Parry (Food and Drugs, vol. I, 1911, p. 31) gives the following comparative figures for coffee before and after roasting:

<table>

Among the adulterations of roasted coffee are the roasted or ground cereals; these are readily detected microscopically as well as by the positive reaction for starch in the decoction, which has been cautiously decolorized by the addition of potassium permanganate solution followed by diluted sulphuric acid. Coffee naturally contains no starch.
Chicory, dandelion and other similar roots used as adulterants may be detected microscopically, but a chemical method of detection has been proposed by LaWall and Forman (A. J. P., Ixxxv, p. 537 and J. A. Ph. A., iii, p. 1669), which depends upon the determination of the ratio of reducing sugars to extractive matter in the aqueous decoction.

Mussaenda coffee, so called, is not a true coffee; but the seeds of Gaertnera vaginata Lam. (Fam. Loganiaceae). (P. J., Nov., 1889.)

Coffee has a faint peculiar odor and a slightly sweetish, somewhat harsh taste. The sugar which is present is a reducing sugar, probably glucose, and is almost completely caramelized in the roasting process. Caffetannic acid has been ascertained by Hiasiweztz to be a glucoside with the formula $C_{14}H_8O_7$ and resolvable into glucose and a peculiar crystallizable acid, $C_8H_8O_4$, named by him caffeic acid (J. P. C., 1867, 307), and which may be obtained from coffee by boiling a solution of the extract with potassium hydroxide, treating the resulting liquid with sulphuric acid in excess, and extracting the caffeic acid with ether, which yields it somewhat impure by evaporation. (Ibid., January, 1868, 75.) Caffeic acid has the constitution of a dihydroxy-cinnamic acid, and on fusion with potassium hydroxide yields protocatechuic and acetic acids. The coffee fat, which ranges in different varieties from 14 to 21 per cent., is, when purified, white, without odor, of a buttery consistence, melting at 37.5° C. (100° F.), and becomes rancid on exposure. According to Rochleder (Wien. Akad. Ber., xxiv, 40), it contains glycerides of palmitic acid and of an acid of the composition $C_{13}H_{24}O_2$.

The caffeine, according to Payen, is present partly free and partly as a potassium and caffeine chlorogenate, but H. Gorter (Lieb. Annal., ccclix, 217, ccclxii, 237), in investigations made upon Liberian coffee, stated that caffeine does not exist free in coffee, but is all combined. The compound is given the following formula: $C_{32}H_{36}C_{19}K_2(C_8H_{10}O_{12}N_4)_{2}+2H_2O$. It decomposes at 225° C. (437° F.), without melting. The yield is 3.3 per cent. The salt is scarcely decomposed by dry chloroform, but is easily decomposed by the presence of water and then gives up its caffeine. This explains the fact observed by the manufacturers of decaffeinated coffees, that dry coffee yields only a small amount of its caffeine to chloroform, but that the extraction takes place readily and almost completely if the coffee is simultaneously treated with water or steam.

Chlorogenic acid is given the formula, $C_{32}H_{38}O_{19}$, and is a colorless, crystalline compound melting at 206° 0. (402.8° F.), and with a marked laevorotatory power. It is hydrolized by alkalies into caffeic and quinic acids. When strongly heated it emits an odor of roasted coffee and by some is believed to be the principle to which the flavor of the beverage is to be attributed. It is stated that when acted on by sulphuric acid and manganese dioxide it is converted into quinone, being in this respect analogous to quinic acid. Another acid was found which the author named coffalic acid. The coffee also contained citric acid, trigonelline, a pectin and an oxydase.
Julian E. Walter gives the following results of the analyses of several kinds of unroasted coffee: Java, 0.89 per cent. caffeine; Liberian Java, 1.08 per cent. caffeine; Costa Rica, 1.24 per cent. caffeine; Mocha, 0.54 per cent. caffeine; Pea-berry or Fenroll, 0.77 per cent. caffeine; Rio, 1.12 per cent. caffeine. (Ph. Rec., May 5, 1890, 176.) Bertrand (Bull. des Sci. Pharm., iv) gives the following results of studies of the percentage of caffeine in various coffee berries: In Coffea arabica the percentage varied from 0.69 to 1.60. Of species other than the (C. arabica, C. canephora was found to be the richest in alkaloid, the berries yielding 1.97 per cent., while those of the C. humboldtiana, Baill., were remarkable by reason of their containing a bitter principle, cafamarin, but no caffeine at all, the berries of C. mauritiana contained only 0.07 per cent.

During the roasting process coffee swells to almost double its original volume, losing from 10 to 23 per cent. of its weight (Ph. Cb., 1850, 687), and acquires a new, peculiar odor and a bitter taste. An active empyreumatic oil (caffeol, C₈H₁₀O₂) is developed during the process, probably at the expense of a portion of the caffeine. Much of the alkaloid, however, escapes change, and a portion of it is volatilized. The excellence of the flavor of roasted coffee depends much upon the manner in which the process is conducted, and the extent to which it is carried. It should be performed in a covered vessel, over a moderate fire, and the grains should be kept in constant motion. When they have acquired a chestnut-brown color, the process should cease. If too long continued, it renders the coffee bitter and acrid, or, by reducing it to charcoal, deprives it entirely of flavor. During a severe roasting the coffee loses a portion of caffeine, which sublimes, while in a slight roasting it loses none; yet 'ordinary coffee for drinking, prepared by percolation, contains rather more caffeine when prepared from strongly roasted than from slightly roasted coffee, because the caffeine is more easily extracted from the former. (Herman Aubert. See A. J. P., 1873, 121.) Paul and Cownley found in preparing "low and medium roasted" coffee no perceptible loss of alkaloid, while in "over-roasted" coffee the loss amounted to one-third. The average of caffeine in roasted coffee they fix at 1.3 per cent. (P. J., 1887, 822.) Seissir has devised a method for removing the caffeine from coffee. About 5 kilos of unroasted coffee berries are placed in a closed centrifugal drum which is surrounded by a hot-water jacket. After the addition of about 15 kilos of ethyl acetate, the drum is set in motion, so that the solvent and berries are thoroughly mixed, the temperature being maintained at 68° C. (154.4° F.). At the end of three hours the solvent is drawn off, and replaced by a further quantity of about 10 kilos, and the mixing and extraction are continued for a further two hours. The ethyl acetate is then run off, the berries are heated to 100° 0. (212° F.) to remove the last traces of solvent, and finally dried at 40° to 46° C. (104°-114.9° F.), the drum being rotated meanwhile. The ethyl acetate may be recovered by distillation, and the caffeine separated from the residue. The method is the subject of a French patent. (Journ. Soc. Chem. Ind., 1909, 622.)

The leaves of the coffee plant possess properties analogous to those of the fruit, and are extensively used by the Malays. Stenhouse found them to contain caffeine in larger proportion than the coffee bean, and also caffeic acid. The leaves are prepared for use by drying over a clear fire and then powdering by rubbing in the hands. The powder is made into an infusion like common tea. The taste is like that of tea and
coffee combined. (P. J., xii, 443; xiii, 207 and 382, and xvi, 1067.)

The effects of coffee are due chiefly, if not solely, to the caffeine which it contains. Some writers, however, believe that the volatile oil, caffeol (caffeone) possesses stimulating properties. The evidence of this point, however, is so contradictory as to render conclusions impossible. (See Reichert, M. News, 1890, Ivi; Erdmann, A. E. P. P., 1902, xlviii; Geiser, A. E. P. P., liii, p. 112.)

As a medicine coffee has been almost entirely replaced by the alkaloid caffeine. The infusion is, however, sometimes administered by rectal injection in cases of narcotic poisoning. The disturbances of digestion which follow excessive coffee drinking are not considered by J. Burmann to be due to caffeine, but to a volatile toxic substance formed during roasting and only partly volatilized, named cafeotoxin, which can be eliminated by subjecting roasted coffee to successive treatments with steam under pressure of several atmospheres (J. P. C., 1913, 8, 281.)

Syrup of coffee of the N. F. III was prepared by pouring 500 mils [or 16 fluidounces] of boiling water upon 250 Gm. [or 8 oz. troy] of roasted coffee, in moderately coarse powder, covering and boiling for five minutes, then straining and adding water through the strainer to make 500 mils [or 1 pint]. Then 800 Gm. [or 24 oz. troy] of sugar is dissolved in the strained liquid, by agitation without heat, and enough water added to make 1000 mils [or 2 pints]. Two tablespoonfuls of this syrup may be added to a cup of hot water or milk. It is also used with carbonic acid water.

"The dried seeds of Colchicum autumnale Linne (Pam. Liliaceæ), yielding not less than 0.45 per cent. of colchicine." U. S. "Colchicum
Seeds are the dried ripe seeds of Colchicum autumnale, Linn." Br.

Colchicum autumnale, often called meadow saffron, is a perennial bulbous plant, the leaves of which appear in spring, and the flowers in autumn. Its manner of growth is peculiar, and deserves notice as connected in some measure with its medicinal efficacy. In the latter part of summer, a new bulb, or corm, as the part is now called, begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom and embraces it half round. The new plant sends out roots from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a lilac or pale-purple color, emerge from the spathe, unaccompanied by leaves. The corolla consists of a tube from 10 to 12 cm. long, concealed for two-thirds of its length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground until the following spring, when they rise upon a stem above the surface, in the form of a three-lobed three-celled capsule. The leaves of the new plant appear at the same time, so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about 12 cm. long, and 2.5 cm. broad at the base. In the meantime, the new corm has been increasing at the expense of the old one, which, having performed its appointed office, perishes; while the former, after attaining its full growth, sends forth shoots, and in its turn decays. The old corm in its second spring, and a little before it perishes, sometimes puts forth one or more small corms, which are the sources of new plants. The usual method of propagating colchicum is by planting the bulbs about August or September in deep rich soil, about 2 or 3 inches below the surface and about 3 inches apart in the row. (D. C., 1912, p. 134.)

C. autumnale is a native of the temperate parts of Europe and of Northern Africa, growing in moist pastures and meadows. Attempts have been made to introduce its culture into this country, but with no great success, though small quantities of the corm, of apparently good quality, have entered commerce. The flowers possess virtues similar to those of the corm and are recognized by the French Codex.
COLCHICI CORMUS.—The medicinal virtue of the corm depends much
upon the season at which it is collected. Early in the spring it is too
young to have fully developed its peculiar properties, and late in the fall
it has become exhausted by the nourishment afforded to the new plant.
The proper period for its collection is from the early part of June, when
it has usually attained perfection, to the middle of August, when the
offset appears. It may be owing, in part, to this inequality at different
seasons that entirely opposite reports have been given of its powers.
Krapf ate whole corms without inconvenience; Haller found them
totally void of taste and acrimony, and we are told that in Carniola the
peasants use them as food with impunity in the autumn. On the other
hand, there can be no doubt of its highly irritating and poisonous
nature, when fully developed, under ordinary circumstances. Perhaps
soil and climate may have some influence in modifying its character.

Christison found the roots collected in April to be more bitter than those
gathered in July, and conjectures that the (tonunon opinion of their
superior efficacy at the latter season may not be well founded. Sehroff
states, as the result of his observation, that the autumnal root is much
stronger than that dug in the summer. (See A J. P., xxix, 324.)

The corm is often used in the fresh state in the countries where it grows,
as it is apt to be injured in drying, unless the process is carefully
conducted. The usual plan is to cut the corm, as soon as possible after it
has been dug up, into thin transverse slices, which are spread out
separately upon paper or perforated trays and dried with a moderate
heat. The reason for drying it quickly after removal from the ground is
that it otherwise begins to vegetate, and a change in its chemical nature
takes place; and such is its retentiveness of life that, if not cut in slices,
it is liable to undergo a partial vegetation even during the drying
process. Houlton recommends that the corm be stripped of its dry
coating, carefully deprived of the bud or young bulb, and then dried
whole. It is owing to the high vitality of the bud that the corm is so apt
to vegetate. During desiccation there is great loss of weight, 70 per cent.
being the average for a number of years in the laboratory of Alien &
Hanburys, in London.

The recent bulb or corm of C. autumnale resembles that of the tulip in
shape and size, and is covered with a brown membranous coat.
Internally it is solid, white and fleshy, and, when cut transversely,
yields, if mature, an acrid milky juice. There is often a small lateral projection from its base, which is the bud for the development of a new plant; this bud is frequently broken off in drying. When dried, and deprived of its external membranous covering, the corm is of an ash-brown color, convex on one side, and somewhat flattened on the other, where it is marked by a deep groove extending from the base to the summit. As found in commerce, it is always in the dried state, sometimes in segments made by vertical sections of the bulb, but generally in transverse circular slices. The U. S. Pharmacopoeia describes the corm as follows: "Usually in reniform, transverse or in ovate, longitudinal slices; from 2 to 5 mm. in thickness; flat surfaces whitish, slightly roughened, and of a crystalline appearance under a hand lens; epidermis thin, light brown and finely wrinkled; fracture short and mealy, odor slight; taste bitter and somewhat acrid. The powder is light brown or grayish-brown; starch grains numerous, single or 2- to 6-compound, the individual grains varying from spherical or ovoid to polygonal, and marked with a triangular or star-shaped, central cleft, the grains being from 0.003 to 0.03 mm. in diameter; tracheae few and with spiral or scalariform thickenings; occasional fragments of epidermal cells with thin, reddish-brown walls. Colchicum Corm yields not more than 6 per cent. of ash.

"Assay.—Proceed as directed under Colchici Semen, using 15 Gm. of Colchicum Corm." U.S.

"Fresh corm about thirty-five millimetres long and twenty-five millimetres broad, somewhat conical, hollowed on one side where a new corm is in process of development, and rounded on the other; covered with a thin brown membranous outer coat, and an inner reddish-yellow one; internally white and solid, and when cut yielding a whitish, turbid juice of a disagreeable odor and bitter taste. Dried slices two or three millimetres thick, yellowish at their circumference, somewhat reniform in outline; firm, whitish, amylaceous; breaking readily with a short fracture. No odor; taste bitter." Br.

The cut surface is white and of an amylaceous aspect. Examined with the microscope, the corm is seen to be composed of large irregular cells, full of ovoid, angular, sometimes compound, starch grains, and interspersed with spiral vessels in vascular bundles. The odor of the recent corm is said to be hircine. It is diminished, but not lost, by drying. The taste is bitter, hot, and acrid.
Colchicum corm contains the alkaloid colchicine, \( \text{C}_{22}\text{H}_{25}\text{NO}_{6} \), which was made official in the U. S. P.; see Colchicina. Colchicine is the active principle and as much as 0.4 per cent. is found in good specimens of the corm; the official requirement is that not less than 0.35 per cent. shall be present, to be determined by assay. See Assay for Colchicum Seed, p. 371.

A. T. Thompson states that the milky juice of fresh colchicum produces a fine blue color if rubbed with the tincture of guaiac, and that the same effect is obtained from an acetic solution of the dried corm. He considered the appearance of this color, when the slices were rubbed with a little distilled vinegar and tincture of guaiac, a proof that the drug was good and had been well dried. J. M. Maclagan has shown that this change of color is produced with the albumen, which is not affected if previously coagulated; so that the value of the test consists simply in proving that the drying has not been effected at a heat above 82.3° C. (180° F.), or the temperature at which albumen coagulates. It is probable that this color reaction is not due to the albumen itself, but to an oxidizing enzyme or oxydase which would be susceptible to the same decomposing influences as albumen. A very deep or large notch in the circumference of the slices is an unfavorable sign, as it indicates that the bulb has been somewhat exhausted in the nourishment of the offset. The decoction yields a deep blue precipitate with solution of iodine, white precipitates with lead acetate and subacetate, mercurous nitrate, and silver nitrate, and a slight precipitate with tincture of galls. The value of colchicum is best tested by its bitterness. For method of assaying colchicum, by K. Schwickerath, see Ph. Rund., 1893, 282. Important improvements have been made in the assay by Bredemann. (Ap. Ztg., 1903, 18, Nos. 93, 94, 95.)

COLCHICI SEMEN.—The seeds of the meadow-saffron ripen in summer, and should be collected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil or in confined gardens. (Williams.) They are officially described as follows: "Ovoid or irregularly globular, more or less pointed at the hilum; from 2 to 3 mm. in diameter; when fresh, several seeds cohering, externally dark brown, finely pitted; tough and of almost bony hardness; internally whitish or light brown; nearly inodorous; taste bitter and somewhat acrid. Under the microscope, transverse sections of Colchicum seed show a seed-coat of a few more or less collapsed cells.
with thin reddish-brown walls; an endosperm, making up most of the seed, consisting of cells with rather thick, porous walls, the lumina containing oil globules and aleurone grains, the latter being from 0.003 to 0.015 mm. in diameter; a small embryo, the beaked portion, or caruncle, containing numerous, somewhat ovoid, ellipsoidal or polygonal starch grains, from 0.005 to 0.016 mm. in diameter. Colchicum Seed yields not more than 8 per cent. of ash.” U. S.

“About two and a half millimetres in diameter, subglobular, slightly pointed at the hilum, rough and of a dull reddish-brown color, minutely pitted, very hard and tough. Endosperm oily; its cells with thickened walls and large pits. No odor; taste bitter and acrid.” Br.

They are chiefly composed of a gray horny endosperm constituted of very thick-walled cells, and surrounded by a closely adherent testa. The leafless embryo is very small, and is situated close to the surface opposite the strophiole. Williams, of Ipswich, England, first brought them into notice in 1820 as superior to the corm. Schroff, however, has found that their activity is inferior to that of the dried corm dug in autumn. (A. J. P., xxix, 324.) A fluid-extract and tincture of the seeds are directed in the U. S. Pharmacopoeia. Their dose is slightly less than that of the similar preparations made from the corm. The seeds and powder are very seldom adulterated. Judd, however, reports examining a powder which contained fully 50 per cent. of powdered foenugreek seed. (Bull. A. Ph. A., 1909, p. 193.)

The U. S. Pharmacopoeia IX directs that col-chicum seed should contain not less than 0.45 per cent. of colchicine, to be determined by the following process:

**Assay of Colchicum Seed.**—“Introduce 15 Gm. of Colchicum Seed, in No. 60 powder, into a 500 mil flask, and add 10 mils of solution of lead subacetate and 290 mils of distilled water. Weigh the flask and contents, and digest the mixture at from 60° to 70° C. (140°-158° F.) for three hours, with occasional agitation. Cool, add distilled water to restore the original weight and filter off 200 mils. Add 0.75 Gm. of sodium phosphate to the clear filtrate, shake the mixture frequently during half an hour, and filter off 100 mils representing" 5 Gm. of Colchicum Seed. Shake out the alkaloid from the filtrate with chloroform until completely extracted, as shown by testing with iodine T.S. (in place of the usual mercuric potassium iodide T.S.), and evaporate the chloroform solution;
add about 1 mil of alcohol and again evaporate. Repeat this operation once more and dry the residue to constant weight at 100° C. (212° F.). To this weighed residue contained in a flask add 5 mils of tenth-normal sulphuric acid V.S. and 5 mils of distilled water and heat the mixture for ten minutes at 70° C. (158° F.). Now filter the liquid through a pledget of purified cotton, wash the flask and cotton with distilled water, reject the filtrate and washings and remove as much of the water from the cotton as possible. Dissolve any insoluble residue that may remain on the cotton by washing it first with a little alcohol and then with ether; collect the alcohol-ether washings in the flask, evaporate, and dry the residue to constant weight at 100° C. (212° F.). Deduct this weight from the weight of residue previously obtained. The difference will be the weight of colchicine obtained from 5 Gm. of Colchicum Seed (see Proximate Assays, Part III)." U.S.

**Uses.**—The investigations into the physiological action of Colchicum have not as yet yielded a very clear explanation of its therapeutic effects. Dixon and Maiden (J. P., 1908, xxxvii, p. 50) have found that it is an active stimulant to the unstriped muscle, increasing intestinal and uterine contractions and bronchial tonus. After large doses it depresses the vasomotor system, causing a marked fall in the blood pressure. When injected subcutaneously in somewhat smaller doses it produces a transient decrease in the number of leukocytes followed after twenty-four hours by an enormous increase, the alterations being especially notable in the number of polymorphonuclear corpuscles. These effects appear to be the result of an action upon the bone marrow. Jackson and Blackfan (J. A. M. A., 1906, xlvi) find an increased output of uric acid under its influence, but they believe this is due rather to an increased formation than a more active elimination, but Denis (J. P. Ex. T., 1915, vii, 609) was unable to detect any change in the amount of uric acid either in the urine or blood.

The poisonous properties of colchicum were known to the ancients, but, while it is generally supposed that the hermodactyls were derived from some species of the genus, the use of meadow-saffron cannot be certainly traced back further than the sixteenth century. Although it has from time to time been recommended for various complaints, it is used to-day only in the treatment of gout. There is considerable clinical evidence that full doses of colchicum administered during the acute attack of a podagra will often abort it. The treatment, however, is not
without serious danger—and most clinicians urge caution in the use of colchicum during the attack. It appears also to be of service in those more chronic conditions of disturbed metabolism known variously as uric acid diathesis or lithemia.

In preparing colchicum pharmaceutically, if it be desired to retain the colchicine unchanged, both acids and alkalies should be avoided and as far as possible also heat. As pointed out below, under various conditions colchicine may be decomposed into colchicine, colchicinic acid, and various allied products. Whether these derivatives of colchicine possess the therapeutic virtues of the natural alkaloid is uncertain, but Fuehner (A. E. P. P., 1913, lxxii, p. 228) has shown that colchicine is very much less toxic than colchicine.

When taken internally in therapeutic dose, colchicum usually produces no other symptoms than intestinal pains and looseness of the bowels. In some rare cases it is said to give rise to copious diuresis or diaphoresis instead of purging. When larger amounts are exhibited, the purging is more pronounced, and there may be also vomiting. With these 'symptoms there may be some depression, which seems to be due to the gastro-intestinal irritation rather than to the direct action of the poison. In an overdose, it may produce dangerous and even fatal effects. Excessive nausea and vomiting, abdominal pains, purging and tenesmus, great thirst, sinking of the pulse, coldness of the extremities, and general prostration, with occasional symptoms of nervous derangement, such as headache, delirium, and stupor, are among the results of its poisonous action. A peculiarity of its influence is that when its dose is increased beyond a certain point there is not a corresponding increase in the rapidity of the fatal issue. This is probably because it kills not by a direct influence upon the heart or the nervous system, but by causing gastro-enteritis. On post-mortem examination the alimentary mucous membrane is found much inflamed.

Dose, of the dried corm and seed, from two to eight grains (0.13-0.52 Gm.), which may be repeated every four or six hours until its effects are obtained.

**Off. Prep.**—Colchicum seed.—Fluidextractum Colchici Seminis, U. S.; Tinctura Colchici Seminis, U. S. (Br.); Vinum Colchici Seminis (from Fluidextract), N. F.

**Collinsonia.** Collinsonia canadensis L. Horse-weed. Horse-balm. Richweed. Heal-all. Stone-root. Knot-root. Knot-weed. Guerit-tout, Baume de Cheval, Fr. Collinsonie, G.—A labiate plant, which grows in woods from Canada to the Carolinas*. The whole plant has a strong disagreeable odor, and a warm pungent taste. C. N. Lochman (A. J. P., 1885, 228) found in the root a resin, tannin, starch, mucilage, and wax; in the leaves resin, tannin, wax, and volatile oil. The alkaloid discovered by H. J. Lohmann in the root of the Collinsonia canadensis appears to have been a magnesium salt. (See D. C., 1902.) Collinsonia is tonic, astringent, diaphoretic, and diuretic. It is said to be locally irritant. A decoction of the fresh root has been used in catarrh of the bladder, leucorrhea, gravel, and dropsy.

**COLOCYNTHIS. U. S. (Br.)**

**COLOCYNTH Colocyn. [Bitter Apple, Colocynth Apple]**

"The dried pulp of the fruit of Citrullus Colocynthis (Linne) Schrader (Fam. Cucurbitaceae), without the presence or admixture of more than 5 per cent. of seeds or more than 2 per cent. of epicarp." V. S. "Colocynth Pulp is the dried pulp of the fruit of Citrullus Colocynthis, Schr., freed from seeds." Br.

**ColocynthidisPulpa.** Br., Colocynth Pulp, Bitter Gourd, Apple, or Cucumber, Poma Colocynthisa; Coloquinte, Fr. Cod.; Puipé de Coloquinte, Fr.; Fructua Colocynthidis, P. G.; Coloquintenapfel, Koloquintenmark, Koloquinten, G.; Coloquintide, It.: Coloquintida. Sp.

Colocynth is another one of those drugs which has given a great amount of trouble to manufacturers because the definition of the U. S. Pharmacopoeia, in previous revisions, simply stated that it was the "peeled dried fruit." Notwithstanding the fact that at the end of the description there was a statement that "the seeds should be separated and rejected" the powdered drug consisted frequently of the seeds as well as pulp. In order to avoid any misunderstanding the U. S. Pharmacopoeia has followed the British authority and defined Colocynth as the dried pulp. As it is not commercially possible to exclude the seeds entirely, a few being imbedded in the pulp itself, the
Pharmacopoeia wisely allows a minimum of 5 per cent. of seeds. It is estimated that every 100 pounds of colocynth fruit will yield 30 pounds of pulp and about 70 pounds of seeds. Tunmann (Suedd. Apoth. Zeit., 1907, p. 503) states that the seeds do not contain medicinally active constituents. Francis (Proc. A. Ph. A., 1906, p. 336), on the other hand, says that if the seeds are first deprived of their fixed oil with benzin, dried and then extracted with 75 per cent. alcohol, the extract is almost as active as the U. S. P. product.

*Citrullus Colocynthis*, or bitter cucumber, is an annual plant, bearing considerable resemblance to the common watermelon. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighboring bodies, to which they attach themselves by their numerous tendrils. The leaves, which stand alternately on long petioles, are triangular, many-cleft, variously sinuated; obtuse, hairy, of a fine green color on the upper surface, rough and pale on the under. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular pepo, of the size of a small orange, yellow and smooth when ripe, and contains, within a hard, coriaceous rind, a white, spongy pulp, enclosing numerous ovate, compressed, white or brownish seeds.

The plant is a native of Turkey, and abounds in the islands of the Archipelago. It grows also in various parts of Africa and Asia. Burckhardt, in his travels across Nubia, found the country covered with it; Thunberg met with it at the Cape of Good Hope, and Ainslie says that it grows in many parts of Lower India, particularly in sandy places near the sea. It is said to be cultivated in Spain, the island of Cypress, Morocco and in the neighboring countries, and even to have been collected in Japan. Colocynth from the maritime plain between the mountains of Palestine and the Mediterranean is chiefly shipped from Jaffa, and is known as Turkish Colocynth. It is said to be of superior quality. The fruit is gathered in autumn, when it begins to become yellow, and, having been peeled, is dried quickly in a stove or in the sunshine. Thus prepared, it is imported from the Levant. Small quantities are said to be imported into England from Mogador in the form of brown, unpeeled globular gourds. The so-called Persian colocynth of the London markets is very small, and has apparently been compressed in a fresh state, so that the position of the seeds is perceptible through the dry pulp. The microscopic structure and the proportion of the pulp to the seed appear to be the same as in other colycynths. (P. J.) xvi, 107.) Colocynth has been grown in New Mexico,
but, according to Sayre, the American colocynth possesses only about two-thirds the cathartic action of the Trieste variety.

**Properties.**—As found in commerce, colocynth is in whitish, globular berries, from 6 to 7 cm. in diameter, very light and spongy, and abounding in seeds which constitute three-fourths of their weight. The seeds are somewhat ‘bitter, but possess little activity, and, according to Captain Lyon, are even used as food in the north of Africa. Nachtigal confirms this statement of Captain Lyon’s, but with the qualification that, before being eaten, the seeds are deprived of their coating by some mechanical means, and the kernels are heated to the boiling point, then washed with cold water, dried, and powdered. Fluckiger found a bitter principle in the testa, which accounts for its rejection as food, though rendering improper the rejection of the seed in preparing the extract. He found in the kernels about 45 per cent. of fixed oil and 18 per cent. of albumen. (A. J. P., 1872, 538.) They should be separated and rejected, the pulpy matter only being employed. The U. S. Pharmacopoeia thus describes colocynth; "Fruits, before the removal of the seeds, nearly globular, from 4 to 7 cm. in diameter, usually more or less crushed and in broken pieces, with occasional patches of the nearly smooth epicarp; yellowish-white or brownish; light, spongy; separable longitudinally when entire into three carpels, each containing, near the outer surface, the ovoid, compressed, yellowish seeds; odor slight; taste intensely bitter. The powder is yellowish-white or buff, consisting chiefly of fragments of parenchyma cells and an occasional fragment with tracheae; very few lignified tissues of the seed-coat, showing the characteristic stone cells which are nearly isodiametric, irregular, with either straight or undulate walls that are strongly lignified and possess simple pores; globules of fixed oil and aleurone grains very few. Powdered Colocynth must be made from colocynth pulp containing not more than 5 per cent. of seeds and, upon extraction with purified petroleum benzin, yields not more than 2 per cent. of fixed oil. Colocynth yields not more than 15 per cent. of ash." U. S.

"White, spongy, light fragments. The powdered Pulp exhibits abundant debris of large, thin-walled parenchymatous cells but no starch, and not more than an occasional sclerenchymat-ous cell or group of such cells. No odor; taste intensely bitter. Yields not more than 2 per cent. of fixed oil to petroleum spirit. Ash not less than 9 per cent." Br.

Barclay considers the estimation of ash in powdered colocynth useful in
proving its freedom from seeds. The pulp yields from 8.6 to 14 per cent.
of ash, the seeds from 2 to 4 per cent., the whole apple 4.6 per cent.
(Am. Drug., 1896, 152.) Water and alcohol extract the virtues of
colocynth. It is a matter of importance to be able to determine whether
the drug miller who usually powders colocynth is careful to reject the
seeds. If the seeds have been ground with the dried pulp, the microscope
will show the presence of numerous albuminous granules derived from
the cotyledons. (W. T. dark, P. J., vii, 509.) These are best found by
putting a small amount of the powder on the glass slide, adding a drop
of water, and gently rubbing the cover glass over it; fragments of the
double-walled embryo sac show on the outer side elongated, more or less
hexagonal, thin-walled cells, and on the inner side irregular, tabular,
 thick-walled cells. If powdered colocynth contains a large number of
starch granules it has probably been adulterated. Power and Moore (Tr.
Chem. Soc., xcvii, p. 99) have separated from colocynth an alkaloidal
principle which has a violent purgative effect, but this is not the only
active principle of the crude drug, because both ether and chloroform
extracts of the resin, when free from the alkaloidal principle, were still
purgative. They find also alpha-elaterin, but none of the active beta-
elaterin. (See Elatinum.) Vauquelin obtained the bitter principle of
colocynth in a separate state, and called it colocynthin. According to
Meissner, 100 parts of the dry pulp of colocynth contain 14.4 parts of
colocynthin, 10.0 of extractive, 4.2 of fixed oil, 13.2 of a resinous
substance insoluble in ether, 9.5 of gum, 3.0 of pectic acid (pectin), 17.6
of gummy extract derived from the lignin by means of potassium
hydroxide, 2.7 of calcium phosphate, 3.0 of magnesium phosphate, and
19.0 of lignin, besides water. Walz supposed that he had found another
peculiar principle, colocynthitin. It was obtained by treating with ether
the alcoholic extract previously exhausted by water, decolorizing the
ethereal solution with animal charcoal, evaporating to dryness, and
dissolving the residue in anhydrous alcohol, which deposited it in
crystals on spontaneous evaporation. It is white and tasteless, and is
probably a resin. (N. Jahrbuch der Pharm., xvi, 10.) Colocynthin is
obtained by boiling the pulp in water, evaporating the decoction,
treating the extract thus procured with alcohol, evaporating the
alcoholic solution, and submitting the residue, which consists of the
bitter principle and potassium acetate, to the action of a little cold water,
which dissolves the latter and leaves the greater part of the former
untouched. Bastick obtained it by exhausting the pulp with cold water,
heating the solution to ebullition, adding lead subacetate so long as a
precipitate was produced, filtering the liquor when cold, adding diluted
sulphuric acid gradually until it no longer occasioned a precipitate, boiling to expel free acetic acid, filtering to separate lead sulphate, evaporating cautiously nearly to dryness, extracting the colocynthin from the residue by strong alcohol, which left the salts, and finally evaporating the alcoholic solution.

The following process, employed by Walz, yields it in a purer state. Colocynth is exhausted by alcohol of sp. gr. 0.84, the tincture evaporated to dryness, the residue treated with water, and the solution precipitated first with lead acetate and afterwards with lead subacetate. The yellow filtered liquor is then treated with hydrogen sulphide to separate the lead, and, after filtration, with solution of tannic acid, which throws down a compound of tannic acid and colocynthin. This is dissolved in alcohol, the tannin thrown down by lead subacetate, the excess of lead separated, and the liquid digested with animal charcoal, filtered, and evaporated. The residue, washed with anhydrous ether, is pure colocynthin. This is yellowish, somewhat translucent, brittle and friable, fusible by a heat below 100° C. (212° F.), inflammable, more soluble in alcohol than in water, but capable of rendering the latter intensely bitter. Mouchon states that it is insoluble in ether. It is neither acid nor alkaline; but its aqueous solution gives with infusion of galls a copious white precipitate. Ahrends (Neue Arzneimittel, 1909) gives the synonym of this principle as citrullin and gives the formula as C_{56}H_{84}O_{23}. Its formula, according to Walz, is C_{56}H_{42}O_{23}. Upon the same authority it is a glucoside, being resolved by the action of sulphuric acid into sugar and a peculiar resinous substance termed colocynthein, to which he gives the formula C_{44}H_{32}O_{13}. Henke doubts the probability of colocynthin being a glucoside, and states that it is uncrystallizable; he reviews the methods of previous investigators, and obtained by his own process but 0.66 per cent. of colocynthin. (A. Pharm., 1883, p. 200; A. J. P., 1883, p. 301.) According to Johannson, colocynthin, when heated with diluted sulphuric acid, yields colocynthein, elaterin, and bryonin. (A. J. P., 1885, p. 451.) An infusion of colocynth, made with boiling water, gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and then with water, 168 parts of alcoholic and 216 of aqueous extract. (See also paper by George Wagner, Proc. A. Ph. A., 1893, 179.)

**Uses.**—The pulp of coloeynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and
sometimes bloody discharges, with dangerous inflammation of the bowels. Death has resulted from a teaspoonful and a half of the powder. (Christison.) Even in moderate doses it sometimes acts with much harshness, and it is therefore seldom prescribed alone. By some writers it is said to be diuretic. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used in obstinate dropsy, and in various affections depending on disordered action of the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy, and in this form is extensively employed. The compound extract of colocynth is a favorite preparation with many practitioners, and, combined with calomel, extract of jalap, and gamboge, it forms a highly efficient and safe cathartic, especially useful in congestion of the portal circle and torpidity of the liver. (See Pilules Catharticae Composite.) It is best administered in minute division, effected by trituration with gum or farinaceous matter. The active principle has sometimes been employed, and, in the impure state in which it is prepared by the process of Emile Mouchon, may be given in the dose of a grain (0.065 Gm.).

Thunberg states that the fruit of C. Colocynthis, at the Cape of Good Hope, is rendered so mild by being properly pickled that it is eaten both by the natives and by the colonists; but, as it is thus employed before attaining perfect maturity, it is possible that the drastic principle may not have been developed.

Dose, one to five grains (0.065-0.32 Gm.).

**Coltsfoot.** N. F. IV. Farfara. Coltsfoot Leaves. Tussilage, Pas d'ane, Fr. Huflattig, Rosshuf, G. —"The dried leaves of Tussilage Farfara, Linne (Fam. Compositae), without the presence of more than 5 per cent. of other parts of the plant or other foreign matter." N. F. Coltsfoot is a low perennial herb, indigenous to Europe and growing in wet places from Quebec to Pennsylvania.
and westward to Minnesota. It possesses a horizontal rhizome from which, early in
the spring, arise several leafless, erect, simple, unifloral scapes or flower-stems and
bearing appressed scale-like bracts of a brownish-pink color. The flower, which stands
singly at the end of the scape, is large, yellow, compound. The leaves do not make
their appearance until after the flowers. The flowers have an agreeable odor, which
they retain after desiccation. The dried root and leaves are inodorous, but have a
rough, bitterish, mucilaginous taste.

The leaves are described as "petioles long, pubescent; blades very brittle, nearly
orbicular or broadly ovate-reniform, from 8 to 15 cm. in length and nearly as broad,
deeply cordate at the base, angurally lobed and dentate with red-brown teeth,
palmately five- to nine-veined; young leaves white floccose all over, the older leaves
with upper surfaces dark green and nearly smooth, the younger densely white
floccose. Odor indistinct; taste mucilaginous, faintly herbaceous, bitter. The powder,
when examined under the microscope, exhibits numerous multicellular, non-branching
hairs, usually curved and twisted together. We lower cells about 0.035 mm. in width,
the terminal cells much elongated, about 0.012 mm. in width and at times with spiral
bands; broadly elliptical stomata about 0.05 mm. in length and associated with finely
striated epidermal cells, the latter having wavy vertical walls; non-porous
sclerenchymatous fibers few with walls from 0.006 to 0.01 mm. in thickness;
parenchyma cells containing chloroplastids; tracheae few, spiral, annular or with
simple pores. Coltsfoot yields not more than 20 per cent. of ash." N. F. Boiling water
extracts their virtues. C. S. Bondurant (A. J. P., 1887, 340) examined coltsfoot
chemically. He found evidences of a bitter glucoside. Klobb isolated two phytosterols
from coltsfoot flowers. (P. J., 1909, 999.) Coltsfoot exercises little sensible influence
upon the human system. It is, however, demulcent, and is sometimes used in
chronic coughs, consumption and other affections of the lungs. The expectorant properties
which it was formerly thought to possess are not obvious. The leaves were smoked by
the ancients in pulmonary complaints, and in Germany they are said to be
substituted for tobacco. In the N. F. they are used in a pectoral tea. Cullen used the
fresh juice in scrofula, several ounces daily. Dose, of the dried leaves, one to two
drachms (3.9-7.5 Gm.), which may be conveniently given in decoction.

Colubrina.—Mabèe bark, yielded by the Ceanothus reclinatus L'Herit. (Colubrina
redinata, Brongn.) (Fam. Rhamnaceae) of South America, has been analyzed by
Elborne and Wilson, who find in it a glucoside. It is used in the West Indies as a
stomachic. (See P. J., April 11, 1885.)

Falsche Senna, G.—A leguminous shrub growing spontaneously in the southern and
eastern parts of Europe, and cultivated in gardens. The leaflets are purgative, and in
some parts of Europe are used as a substitute for senna, which is said to be
sometimes adulterated with them. Barbey (P. J.: 1895, 261) isolated coluteic acid,
which occurs in white crystals, insoluble in water, soluble in alcohol, chloroform,
and carbon disulphide. Bladder senna is comparatively very feeble. It is administered in
infusion or decoction, of which the dose is about half a pint, containing the virtues of
from one to three ounces of the leaves.
Combretum. Jungle-weed.—The roasted leaves and stalks of the Combretum sundaicum (Miquel) have been used in China in the treatment of the opium habit. Harrison (P. J., lxxx, 52) was unable to find any alkaloid or glucoside in the plant, and Stanislaus (J. A. Ph. A., 1912) confirmed the absence of active principle, but found a considerable proportion of tannic acid. The method of taking is as follows: Fifty Gm. of the dried herb is macerated with 4 liters of water, the filtrate evaporated to 1 liter. To one-half of this is added the accustomed daily dose of opium. Of this mixture the patient is given one fluidounce (30 mils) every three or four hours, the equivalent amount of combretum decoction being added after each dose is removed.

Heffner has reported favorably upon its use, but H. C. Wood, Jr., (J. A. Ph. A., 1912), was unable to note any beneficial action from it which might not be justly ascribed to the tannic acid which it contains.

The Combretum Raimbaultii is a shrub native to West Africa, where it is known under the name of Kinkelibah and is used by the natives in the treatment of black-water fever and was introduced a number of years ago into Europe by a missionary, Father Raimbault. Dammermann has reported favorably on its value in this condition (D. M. W., 1906, p. 921), but Heckel was unable to find any active constituent except a tannin. (Jahrèsber. d. Pharm., 1891, p. 64.) Other species of the combretum appear also to have been used for the same purpose, notably the C. Altum Guill. et Perr. (C. micranthum, G. Don).

Commelina. Day-flower.—Under the name of Yerba del Pollo, Commelina tuberosa L. is said to be very largely used in Mexico in the treatment of internal hemorrhage, especially from the womb. From thirty to sixty grains (2.0-3.9 Gm.) of the extract may be taken in the course of one day. (See A. J. P., 1897, 290.) The North American species, Commelina communis L., has also had hemostatic properties attributed to it. For chemical and microscopical study, see A. J. P., July, 1898.

Commiphora. Commiphora Berryi Engl. (Fam. Burseraceæ.) Mulzi Kilivary.—This Indian thorn yields a gum resin in abundance. (P. J., Aug., 1899.)

Comptonia. Myrica asplenifolia. (Comptonia peregrina L., Coulter). Sweet Fern. Fernale. Meadow-fern. (Fam. Myricaceæ.)—A shrubby indigenous plant, named from the resemblance of its leaves to the spleenwort fern. It grows in sterile soil, from Nova Scotia to North Carolina and Michigan. All parts of it possess a resinous, spicy odor. R. T. Chiles has found in it tannic and gallic acids, volatile oil, extractive, gum, resin, and a substance resembling saponin. (A. J. P., xlv, 306.) H. K. Bowman found it to contain 8.20 per cent. of tannin. (A. J. P., 1869, 193.) It is said to be tonic and astrigent; its decoction is used in diarrhea.

Condurango. N. F. IV. Cundurango. Cortex Condurango, P. G.—This drug some years ago attracted a great deal of attention as a reputed remedy in cancerous disease, but further experience has demonstrated its uselessness. It appears, however, to be used largely in South America as an alterative in chronic syphilis, has
been recognized by the German Pharmacopoeia, and so merits a brief notice here. According to an official investigation (A Report on the Origin and Therapeutic Properties of Cundurango, by Ruschenberger, Washington, 1873) made by Passed Assistant Surgeon Joseph G. Ayers, U. S. N., there are at least ten different plants known in the republic of Colombia as condurango. The variety which has been used in cancer, and which may be considered as genuine condurango, is the condurango blanco, the product of an asclepiadaceous vine from ten to thirty feet in length and from one to two inches in diameter. The plant is the Marsdenia Condurango of G. H. Reichenbach. The bark is prepared by pounding the stem with a mallet, to separate it, and then drying it in the sun. In the N. F. it is described as "the dried bark of Marsdenia Condurango (Triana) Reichenbach films (Fam. Asclepiadaceae). In quills or transversely curved pieces, usually from 4 to 13.5 cm. in length; bark 1 to 6 mm. in thickness; outer surface light gray-ish-brown to dark brown, nearly smooth and with numerous lenticels, or more or less scaly and considerably roughened; the scales soft, occasionally with brownish-black apothecia of a fungus; inner surface grayish-white or light brown, longitudinally striate; fractureshort-fibrous and granular. Odor slightly aromatic, especially marked in the fresh drug; taste bitter and aromatic. Under the microscope, sections of Condurango show a corky layer consisting of several rows of thin-walled cells, frequently with yellowish-brown contents; a layer of phelloderm of eight to ten rows of cells, containing starch grains and membrane crystals of calcium oxalate, the latter in prisms, from 0.01 to 0.035 mm. in length; a primary cortex of collenchyma containing chloroplastids, starch grains, or rosette aggregates of calcium oxalate, from 0.015 to 0.04 mm. in diameter; a pericycle or pericambium of tangentially elongated parenchyma cells, with groups of bast fibers and laticiferous vessels in an interrupted circle; middle bark with large groups of stone cells varying from nearly isodiametric to elongated, sometimes very irregular in form; inner bark with medullary rays one or two cells in width, numerous laticiferous cells accompanied by small groups of sieve cells, parenchyma containing either starch grains or rosette aggregates of calcium oxalate, and an occasional isolated bast fiber or small group of stone cells. The powder is light yellowish-brown, consisting chiefly of groups of stone cells and parenchyma containing calcium oxalate crystals and starch grains; stone cells chiefly in large groups, the individual cells being more or less irregular in shape and with very thick porous walls, the lumina being usually filled with air; calcium oxalate chiefly in rosette aggregates, occasionally in single prisms, mostly from 0.015 to 0.02 mm. in diameter; starch grains mostly simple, frequently two- to four-compound, the individual grains being from 0.003 to 0.015 mm. in diameter; bast fibers non-lignified; very long and from 0.01 to 0.035 mm. in width; fragments of thin-walled latex tubes from 0.015 to 0.025 mm. in diameter and filled with a granular substance; fragments of cork grayish or light yellowish-brown. Macerate 1 Gin. of the powdered bark in 5 mils of cold water; filter and heat the filtrate in a test tube; it becomes cloudy, but on cooling assumes its original transparency. Condurango yields not more than 12 per cent. of ash." N. F. Thomas Antisell (A. J. P., xliii, 289) found in it tannin, extractive matter, and a yellow resin, to which he attributes whatever of virtue the plant may possess. Vulpius (P. J., 1885, 1066) found in it condurangin, a glucoside, very closely allied to vincetoxin of Tanret, and, like it, converted by warming when in concentrated solution into a tolerably stiff jelly. For Barthe's method of isolating it, see A. J. P., 1892, 640. Merck gives the
following constituents of condurango: Alpha-condurangin, $C_{20}H_{32}O_6$; Beta-condurangin, $C_{18}H_{24}O_7$; Conduransterin, $C_{30}H_{50}O_2$, and also a trace of an alkaloid resembling strychnine in action. Carrara (A. J. P., 1892) obtained from the so-called condurangin of commerce two principles: One insoluble in water, soluble in benzene, a light, almost white, powder, melting at from 60°-61° C. (140°-141.8° F.), and of the composition $C_{20}H_{32}O_6$. Both compounds are decomposed by acids, yielding a brown pitchy substance, insoluble in water. Boehm (M. M. W., lv, p. 1775) regards condurangin as a derivative of cinnamic acid. According to Firbas, condurangin in solution can be recognized by freeing from alcohol with gentle warmth, precipitating with a saturated solution of sodium chloride, dissolving the precipitate in chloroform, and adding a liquid composed of equal parts of sulphuric and hydrochloric acids and alcohol. On warming, the mixture assumes a green color, which turns a beautiful greenish-blue on the addition of a trace of ferric chloride. This Lafon reaction is given also by adonidin, oleandrin, sapotoxin and digitoxin. Brunton (J. P., vol. v) reached the conclusion that Condurangoblanco was inert, but Kobert found condurangin to be a violent poison, causing convulsions followed by paralysis; he believes it to be a mixture of several principles, (S. Jb., 1889, No. 9.) H. Chiriboga states that three drachms of the bark taken by himself in the form of decoction produced considerable activity of the circulation, copious diaphoresis, increased secretion of urine, and even some vertigo and disturbance of vision. Under the name of Guayaquil condurango a drug has appeared in the European markets composed of pieces of bark and fragments of woody branches, believed to be derived from an asclepiadaceous plant closely related to the genus Gonolobus. Mexican condurango is composed of split stems or thin adherent bark, and is thought to be yielded by an Aristolochia. For full description, see Ph. Rund., May, 1888. Prof. P. E. Hoinmell recommends Mistura condurango et ulmi and Fluidglycerate of condurango for the internal administration of the drug. (See Proc. N. Jersey Pharm. Assoc., 1913, 80; also M. R., 1913, 231.) Fluidextract of condurango is official in the National Formulary. Dose, one fluidrachm (3.9 mils).

CONFECTIONS PIPERIS. Br.

Electuarium Piperis; Electuaire de Poivre, Fr.; Pfeffer-latwerge, G.

"Black pepper of commerce, in powder, 100 grammes; Caraway Fruit, in powder, 150 grammes; Purified Honey, 750 grammes. Mix." Br.

This preparation was intended as a substitute for Ward's Paste, which acquired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To be of service, it must be continued, according to Brodie, for two, three, or four months. Its stimulating properties render it inapplicable to cases attended with much inflammation.

Dose, from one to two drachms (3.9-7.7 Gm.), repeated two or three times a day.
CONFECTIO ROSAE GALLICAE Br.

CONFECTION OF ROSES

Conerva Rosarum; Conserve de Rose, Fr. Cod.; Conserve de Rose rouge, Fr.; Rosen-Conserve, G.

Confection of Rose was unfortunately dropped from the U. S. P. IX, but was introduced into the National Formulary IV. (See Part III.)

"Fresh Red-Rose Petals, 250 grammes; Refined Sugar, 750 grammes. Beat together in a stone mortar," Br.

"Red Rose, in No. 60 powder, eighty grammes [or 2 ounces av., 360 grains]; Sugar, in fine powder, six hundred and forty grammes [or 22 ounces av., 252 grains]; Clarified Honey, one hundred and twenty grammes [or 4 ounces av., 102 grains]; Stronger Rose Water, one hundred and sixty cubic centimeters [or 5 fluid-ounces, 197 minims], to make about one thousand grammes [or 35 ounces av., 120 grains]. Rub the Red Rose with the Stronger Rose Water previously heated to 65° C. (149° F.), then gradually add the Sugar and Clarified Honey, and beat the whole together until a uniform mass results." U. S. VIII.

In the British process the unblown petals only are used, and these should be deprived of their claws; in other words, the rose-buds should be cut off a short distance above their base, and the lower portion rejected. In the last four editions of the U. S. Pharmacopoeia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that confection of rose is still made in Philadelphia on a large scale from the fresh petals of the R. centifolia and others, by beating them into a pulp with sugar, as in the British process. An excuse for this deviation from the official formula is, that the confection thus made has greater adhesiveness than the official, and is therefore better fitted for the formation of pills. Confection of Rose is slightly astringent; it is used almost exclusively as a vehicle, and is admirably adapted as an excipient and to impart consistence to the pilular mass.

Off. Prep.—Pilula Hydrargyri, Br
CONFECTIO SENNAE. Br.

CONFECTION OF SENNA

Electuarium Sennae Compositum; Electuarium Lenitivum; Electuaire de Sene compose, Fr. Cod.; Electuaire lenitif, Fr.; Electuarium e Senna, P. G.; Sennalatwerge, G.; Elettuario lenitivu. It.

Confection of Senna was improperly dropped from the U. S. P. IX, but the National Formulary IV introduced the U. S. P. VIII preparation.

"Senna Leaves, in powder, 100 grammes; Coriander Fruit, in powder, 40 grammes; Figs of commerce, 160 grammes; Tamarinds, 120 grammes; Cassia Pulp, 120 grammes; Prunes of commerce, 80 grammes; Extract of Liquorice, 15 grammes; Refined Sugar, 400 grammes; Distilled Water sufficient to produce 1000 grammes. Boil the figs and prunes gently with three hundred and fifty grammes of Distilled Water in a covered vessel for four hours; add more Distilled Water to make up the quantity to its original weight, and then incorporate the Tamarinds and Cassia Pulp; digest for two hours; rub the softened pulp of the fruits through a hair sieve, rejecting the seeds and other hard parts; to the pulp thus obtained add the Refined Sugar and Extract of Liquorice, dissolving them by the aid of gentle heat; while the mixture is still warm, add to it gradually the mixed Senna and Coriander powders; mix the whole thoroughly; make the weight of the resulting Confection one thousand grammes, either by evaporation or by the addition of more Distilled Water." Br.

"Senna, in No. 60 powder, one hundred grammes [or 3 ounces av., 231 grains]: Cassia Fistula, bruised, one hundred and sixty grammes [or 5 ounces av., 282 grains]; Tamarind, one hundred grammes [or 3 ounces av., 231 grains]; Prune, sliced, seventy grammes [or 2 ounces av., 205 grains]; Fig, bruised, one hundred and twenty grammes [or 4 ounces av., 102 grains]; Sugar, in fine powder, five hundred and fifty-five grammes [or 19 ounces av., 252 grains]; Oil of Coriander, five grammes [or 77 grains]; Water, a sufficient quantity, to make one thousand grammes [or 35 ounces av., 120 grains]. Digest the Cassia Fistula, Tamarind, Prune and Fig with five hundred cubic centimeters [or 17 fluid-ounces] of Water in a covered vessel, by means of a water-bath, for three hours. Separate the coarser portions and rub the pulpy mass, first through a coarse hair sieve, and then through a muslin cloth. Mix the
residue with one hundred and fifty cubic centimeters [or 5 fluidounces] of Water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy mass first obtained. Then, by means of a water-bath, dissolve the Sugar in the pulpy liquid, and evaporate the whole in a tared vessel, until it weighs eight hundred and ninety-five grammes [or 31 ounces av., 250 grains]. Lastly, add the Senna and the Oil of Coriander, and incorporate them thoroughly with the other ingredients while they are yet warm." U. S. VIII.

Confection of Senna, when correctly made, is an elegant preparation, and keeps well if properly protected. The U. S. P. VIII process differed from that of 1860 in preparing the pulps, as suggested in former editions of this Dispensatory, instead of taking them already prepared. An improvement was made in the process of the U. S. P. 1890 by replacing the coriander seed of the former Pharmacopoeias with oil of coriander; it is almost impossible to powder coriander fine enough to avoid hard particles except by drying it to such an extent as to deprive it injuriously of its volatile oil, and the plan of using the oil directly has therefore been adopted. The oil of coriander should be dropped upon a portion of the powdered senna contained in a mortar or suitable vessel and this lightly triturated with the rest of the powdered senna so as to distribute it uniformly; the mixture should then be added to the pulpy mass and the official directions then carried out. It was formerly not uncommon to omit the cassia pulp in this preparation, as the pods were not always to be found in the market; but, as this is next to the senna the most active ingredient, the omission was to be regretted. Cassia fistula is now readily procured in commerce, and there can be no excuse for its omission. It has also been proposed to substitute the fluidextract of senna for the crude drug- (A. J. P., xliii, 123); but, as the fluidextract is of such uncertain quality, the leaves themselves are preferable.

A very good, pleasant laxative, admirably adapted to cases of habitual costiveness, especially in pregnant women, and in persons affected with piles.

Dose, one to two drachms (3.9-7.7 Gm.), at bedtime.
CONFECTIONES

CONFECTIONS

Electuaries; Conserves, Electuaires, Saccharoles mous, Fr.; Conserven, Latwergen, G.; Elettuario, It.; Electuaria, Sp.

Under the general title of Confections, the Pharmacopoeias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. But two confections, Rose and Senna, were retained in the Eighth Revision of the U. S. Pharmacopoeia and in the Ninth Revision both were dropped and relegated to the National Formulary IV. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division before proceeding to the consideration of the individual preparations.

Conserves consist of undried vegetable substances and refined sugar beaten into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now used are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be in fine powder.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for official direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice
their weight, gum-resins two-thirds of their weight, resins somewhat
less, mineral substances about half their weight, and deliquescent salts
not more than one-tenth. Should the electuary become dry and hard,
more syrup should be added, so as to give it the requisite consistence. If
the dryness result from the mere evaporation of the aqueous part, water
should be added instead of syrup, and the same remark is applicable to
the conserves. To prevent the hardening of electuaries, the French
writers recommend the use of syrup prepared from brown sugar, which
is less apt to crystalline than that made from the refined. Molasses
would answer the same purpose, but its taste might be objectionable.
Some employ honey, but this is not always acceptable to the stomach.
Glycerin and syrupy glucose might sometimes be used with advantage.

Confectio Aromatica, Aromatic Confection, Electuarium Aromaticum;
Electuaire (Confection) aromatique, Fr.; Aromatische Latwerge,
Getwurzlatwerge, G.—" Take of Aromatic Powder four troyounces;
Clarified Honey, four troy-ounces, or a sufficient quantity. Rub the
Aromatic Powder with Clarified Honey until a uniform mass of the
proper consistence is obtained." U. S., 1870.

This confection affords a convenient means of administering' the spices
contained in it, and an agreeable vehicle for other medicines. The
confection is given in debilitated states of the stomach. The dose is from
ten to sixty grains (0.65-3.9 Gm.).

Confectio Aurantii Corticis, Confection of Orange Peel, Conserva
Aurantii; Conserve d'Ecorce d'Orange, Fr.; Apfelsinenschalen-Con-save,
G.—" Take of Sweet Orange Peel, recently separated from the fruit by
grating, twelve troy ounces; Sugar [refined], thirty-six troyounces. Beat
the Orange Peel with the Sugar, gradually added, until they are
thoroughly mixed." U. S., 1870.

This confection is not used as frequently as it deserves to be. It is, when
well made, a grateful aromatic vehicle or adjuvant for tonic and
purgative powders.

Confectio Opii, Confection of Opium, which was the modern substitute
for the mediaeval preparations known as theriaca and mithridate, has
been finally dropped from both Pharmacopoeias. One grain of opium
was contained in about thirty-six grains of the former United States
confection, and in about forty grains of the British. The following is the
U. S. Pharmacopoeia (1870) formula: "Take of Opium, in fine powder, two hundred and seventy grains; Aromatic "Powder, six troyounces; Clarified Honey, fourteen troyounces. Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed." U. S., 1870.

Conium. N. F. IV (U. S. P. VIII). Hemlock. Poison Hemlock. Spotted Hemlock or Parsley. Fool's Parsley. St. Bennett's Herb. Spotted Cow-bane. Herba Cicuta (Majoris). Cigue officinale, ou Grande Cigue (Feuille). Fr. Cod. Feuilles de grande Cigue, Fr. Herba Conii, P. G. Schierlingskraut, Schierlingsblatter, Schierling, Gefleckter Schierling. G. Foglied di cicuta maggiore, It. Cicuta major, Sp.—Formerly the fruit of the Conium maculatum was official in both the United States and British Pharmacopoeias and the leaves in the British Pharmacopoeia. The fruit has now been introduced into the National Formulary IV, where it is described as "the full grown, but unripe fruit of Conium maculatum Linne (Fam. Umbelliferae), carefully dried and preserved, and yielding not less than 0.5 per cent. of confine. After being kept for more than two years, Conium is unfit for use. Broadly ovoid, greenish-gray, the two mericarps of most of the fruits separated, each about 3 mm. in length and about 1.5 mm. in diameter, ovoid, somewhat curved, the inner, flattened side marked by a deep longitudinal groove, the outer, convex side with five, pale yellow, somewhat crenate ribs, the intervening surfaces wrinkled but otherwise smooth; pericarp without oil tubes. Odor slight, but when triturated with a solution of potassium hydroxide, strong, disagreeable, and mouse-like; taste characteristic, disagreeable, afterwards somewhat acid. Transverse sections of the mericarp, when examined under the microscope, exhibit a pentangular outline, the angles projecting and forming the ribs, four of the sides being almost equal in length, the fifth or commissural side being about twice as long as one of the dorsal sides and usually concave near the middle; a distinct fibro-vascular bundle at each angle composed of thick-walled fibers about 0.013 mm. in diameter and a few tracheae; epidermis consisting of one layer of cells which are sometimes slightly cen-trifugally developed, hairs are absent; pericarp thin, without vittae, enclosing a single seed and extending inwardly on the commissural side for about one-third the diameter of the section; the inner epidermis of the pericarp composed of two layers of cells with yellowish-brown walls, the outer layer with cells from 0.06 mm. to 0.12 mm. in tangential length and with thickened radial and inner walls, the inner layer with thin-walled cells from 0.03 to 0.06 mm. in tangential length and about 0.03 mm. in radial diameter; the seed coat composed of small, thick-walled cells about 0.015 mm. in radial diameter; often obliterated; a large endosperm or central portion being somewhat pentangular-rounded in outline, with a deep channel on the commissural side and composed of polygonal parenchyma cells; the latter contain globules of fixed oil and aleurone grains with rosette aggregates of calcium oxalate. The powdered drug is greenish-gray and, when examined under the microscope, exhibits numerous angular or rounded, light colored fragments of endosperm tissue, composed of parenchyma cells containing fixed oil, aleurone grains and rosette aggregates of calcium oxalate, the latter from 0.002 to 0.006 mm. in diameter; a few more or less curved groups of lignified fibers; fragments of the seed coat with yellowish-brown walls; a few rounded starch grains about 0.005 mm. in
diameter; spiral or annular tracheae few; numerous oil globules on mounting the powder in hydrated chloral T.S. Conium yields not more than 8 per cent. of ash." N. F. Conium fruit (Conii fructus) is sometimes incorrectly called coniumseed. The hemlock leaves (Conii folia) were described as "the fresh leaves and young branches of Conium maculatum Linn., collected when the fruit begins to form." Br., 1898.

Conium maculatum is an umbelliferous plant, having a biennial spindle-shaped whitish root, and an herbaceous branching stem, from three to six feet high, round, hollow, smooth, shining, slightly striated, and marked with brownish-purple spots. The lower leaves are tripinnate, more than a foot in length, shining, and attached to the joints of the stem by sheathing petioles; the upper are smaller, bipinnate, and inserted at the division of the branches; both have channelled footstalks, and incised leaflets, which are deep green on their upper surface and paler beneath. The flowers are very small, white, and disposed in compound terminal umbels. The general involucre consists of from three to seven lanceolate, reflected leaflets, whitish at their edges; the partial involucre of three or four leaflets, oval, pointed, spreading, and on one side only. There are five petals, cordate, with their summits inflected, and nearly equal. The stamens are spreading, and about as long as the corolla; the styles diverging.

Conium is a native of Europe, and has become naturalized in America from Quebec to Pennsylvania, where it is also cultivated for medicinal purposes. The term cicuta, which has often been applied to this plant, belongs to a different genus. It grows usually in clusters along the roadsides or in waste grounds, and is found most abundantly near old settlements. It flowers in June and July. The whole plant, especially at this period, exhales a fetid odor, compared by some to that of mice, by others to that of the urine of cats, and narcotic effects result from breathing for a long time air loaded with the effluvia. The plant varies in narcotic power according to the weather and climate, being most active in hot and dry seasons and in warm countries. The hemlock of Greece, Italy, and Spain is said to be much more energetic than that of the north of Europe. As a rule, those plants are most active which grow in a sunny exposure. The proper season for gathering the leaves is when the plant is in flower, and Fothergill asserts, from experiment, that they are most active about the time that the flowers begin to fade. The footstalks should be rejected, and the leaflets quickly dried, either in the hot sun, or on tin plates before a fire, or by a stove-heat not exceeding 48.8° C. (120° F.). They should be kept in boxes or tin cases, excluded from the air and light, by exposure to which they lose their fine green color and become deteriorated. The same end is answered by pulverizing them, and preserving the powder in opaque and well-stoppered bottles. But little reliance can be placed on the dried leaves, as, even when possessed of a strong odor and a fine green color, they may be destitute of the narcotic principle. When rubbed with potassium hydroxide they should exhale the odor of conine. The fruit retains its activity much longer than the leaves. Commercial conium occasionally contains other umbelliferous plants, or it may be almost wholly composed of such plants, and even anise has been used as an adulterant to the fruit. (See Anise)

The dried leaves of conium have a strong, heavy, narcotic odor, less disagreeable than that of the recent plant. Their taste is bitterish and nauseous; their color a dark
green, which is retained in the powder. A slight degree of acridity possessed by the fresh leaves is said to be dissipated by drying. Water distilled from the fresh leaves has the odor of conium, and a nauseous taste, but does not produce narcotic effects. Upon destructive distillation, the leaves yield a very poisonous empyreumatic oil. Geiger first obtained the active principle in a separate state, the volatile alkaloid coniine or conine. As it exists in the plant in combination with an acid it is not readily volatilized, but it freely comes over with the distillate when an alkali has been previously added. The acid of conium, Peschier believed to be peculiar, and named conic acid, but other observers assert that it is malic acid. For methods of isolating conium, see U. S. D., 19th ed., p. 393. The seeds contain most of this principle; but even in these it exists in very small proportion. From six pounds of the fresh or nine of the dried seeds, Geiger obtained about an ounce of conine, while from 100 pounds of the fresh herb only a drachm, and from the dried leaves none. Farr and Wright (P. J., 1896, 273) confirm the views of Harley and Manlius Smith and affirm that green fruits are alone reliable. The volatility and tendency to undergo decomposition of coniine probably has its effect even in the dried unripe seed, otherwise it is difficult to explain the fact that in thirteen analyses of commercial conium fruit made by Fan- and Wright, the average alkaloidal contents were 0.674; while the average of sixteen analyses of samples collected by themselves was 2.13. (P. J., Feb., 1904.) For a method of assaying conium fruit, by Schwickerath, see Ph. Rec., 1893, 282. The N. F. IV adopted the following assay process, requiring that conium should yield not less than 0.5 per cent. of coniine:

Assay.—" Place 15 Gm. of Conium, in No. 40 powder, in a 250 mil Eriemeyer flask, add 150 mils of purified petroleum benzin and then 15 mils of solution of sodium hydroxide, insert the stopper securely, and shake the flask vigorously at frequent intervals during six hours. Allow the mixture to settle and decant 100 mils of the clear benzin solution (representing 10 Gm. of the drug) into a separator; extract the alkaloid by shaking with successive portions of weak hydrochloric acid until a few drops of the last washing gives no precipitate with iodine T.S. Collect the acid washings and concentrate by evaporation on a water bath to 10 mils, cool and transfer the liquid to a separator, then cautiously add sodium carbonate in excess. Extract the alkaloid by shaking out with successive portions of 15 mils each of purified petroleum benzin. Separate the benzin washings and filter into a beaker. Then add exactly 10 mils of tenth-normal sulphuric acid V.S. and stir thoroughly for two minutes so as to mix the acid and benzin solution. Evaporate the benzin layer in a current of warm air, at a temperature not exceeding 60° C. (140° F.), and as soon as the benzin has disappeared, cool, add five drops of cochineal T.S. or methyl red T.S. and titrate the acid solution with fiftieth-normal potassium hydroxide V.S. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 0.0126 Gm. of coniine. Calculate the amount of coniine neutralized by the acid, and multiply the result by ten to obtain the percentage of coniine in the drug." N. F.

Harley has found in the root three proximate principles, one a very bitter resin, which he names conamarine, and the two others crystallizable bodies, named respectively rhizoconin, and rhizo-conolein. They are all neutral, and, so far as known, medicinally inert. (See P. J., Aug., 1867.)
Coniine, C₈H₁₇N, has been thoroughly studied by Hofmann (1881), who established the correct formula as given, instead of C₈H₁₅N, as it was formerly assumed, and Ladenburg (1886) effected its synthesis from allyl pyridine by reduction with sodium in alcoholic solution:

\[ C₅H₄(C₃H₅)N + 8H = C₅H₁₀(C₃H₇)N. \]

This reaction gives a-normal propyl piperidine, which is optically inactive, but by the crystallization of its tartrate splits into coniine (dextrorotatory) and a very similar laevorotatory coniine, just as racemic acid splits into dextrorotatory and layvorotatory tartaric acid.

Coniine is in the form of a yellowish oily liquid, of sp. gr. 0.862, of a very acrid taste, and a strong penetrating odor, compared to that of the urine of mice, and recalling the odor of fresh hemlock, though not identical with it. In volatility it resembles the essential oils, readily rising with the vapor of boiling water, but when unmixed requiring for ebullition a temperature of 166° C. (330.8° F.). It is freely soluble in alcohol, ether, and the fixed and volatile oils, and slightly so in water. It unites with about one-fourth of its weight of water to form a hydroxide. It reddens turmeric, and neutralizes the acids, forming with them soluble salts, some of which are crystallizable. With tannic acid it forms an insoluble compound. Like ammonia, it occasions a white cloud when approached by a rod moistened with hydrochloric acid; and the resulting hydrochloride is crystallizable, and not in the least deliquescent. The hydrochloride may also be obtained as a brilliant crystalline mass by dissolving coniine in anhydrous ether and passing dry hydrochloric acid gas through the solution. The salt is very soluble in water and alcohol, but insoluble in ether. It can be heated to 90° C. (194° F.) without decomposition, and melts at 218° C. (424.4° F.). Coniine coagulates albumin, and precipitates the salts of aluminum, copper, zinc, manganese, and iron. It also precipitates silver nitrate, but in excess redissolves the precipitate. Most of its salts are decomposed by evaporation. When exposed to the air, it speedily assumes a deep brown color, and is ultimately converted into a resinous matter, and into ammonia, which escapes. Under the influence of heat this change takes place with much greater rapidity. The presence of coniine may be detected in an extract or other preparation of hemlock by rubbing it with potassium hydroxide, which instantly develops its peculiar odor. It is a most energetic poison.

In association with coniine in the hemlock are found also the following bases: Ethyl-piperidine, C₇H₁₅N or C₅H₁₀(C₂H₂)N; Methyl-coniine, C₉H₁₂N or C₅H₉(C₃H₇)N(CH₃); Conhydrine, C₈H₁₇NO or C₅H₉(CHOH.CH₂CH₃)NH; Pseudo-conhydrine, C₈H₁₇NO or C₅H₉(CH₃.CH₂OH.CH)NH. Methyl-coniine, first obtained by Kekule and von Planta in commercial coniine, is of minor importance.

Conhydrine is crystallizable, fusible below 100° C. (212° F.), and volatilizable at a higher temperature, diffusing an odor much like that of coniine. Water dissolves it considerably, ether and alcohol freely; and the solution has a strong alkaline reaction. Its formula is given as C₈H₁₇NO. By the action of P₂O₅ or fuming hydrochloric acid
upon conhydrine, is obtained coniceine, \( \text{C}_8\text{H}_{15}\text{N} \), and water. It may be separated from coniine by exposing the mixed alkaloids to a freezing mixture, expressing, and then repeatedly crystallizing from ether. (Gmelin, xiii, 169.) E. Merck obtained a small quantity of a new alkaloid from the high boiling portion of crude coniine. The isolation was accomplished by fractional distillation in vacuo and recrystallization. The alkaloid crystallizes in needles, is easily soluble in water, alcohol, ether, benzene, and chloroform, fuses at about 98° C. (208.4° F.), and boils at 230° to 232° C. (446°-449.6° F.). According to Ladenburg, the alkaloid is an isomer of conhydrine, having the formula \( \text{C}_8\text{H}_{27}\text{NO} \), and for this reason the name pseudo-conhydrine was selected. (Chem. Cb., 1891, 414; see also P. J., 1891, 1170.)

Paraconiine.—Coniine was supposed to have been artificially produced by Hugo Schiff. From the reaction of butyric aldehyde with an alcoholic solution of ammonia, he obtained two bases, one of which, dibutyraldine, yielded, on distillation, first a neutral oily substance, and afterwards a strong alkaline base, which proved to have the physiological properties of natural coniine, but was optically inactive, while true coniine is dextrorotatory. Since the change in the formula of true coniine it will be seen that the base paraconiine, which is \( \text{C}_8\text{H}_{15}\text{N} \), is not even isomeric with coniine.

Uses.—Hemlock or conium is supposed to be the narcotic used by the Athenians to destroy the life of condemned individuals, and by which Socrates and Phocion died. It was also used by the ancients as a medicine, but fell into entire neglect until Storck employed and extravagantly praised it. Though fatal to some animals, hemlock is eaten with impunity by others, as horses, goats, and sheep.

The alkaloids of conium all have the same physiological properties, although there is a difference in the degree of their power. Their most important effect is a paralysis of the peripheral endings of the motor nerves. In the account of the death of Socrates reference is made to loss of sensation as one of the prominent symptoms of his poisoning and there is evidence that the drug has an effect upon the sensory as well as upon the motor nerves, but the dominant action is certainly upon the motor system. Hayashi and Muto (A. E. P. P., 1901, xlviii) have shown that the phrenic nerve is more susceptible to the drug than the other motor nerves of the body. It is evident, therefore, that if given in sufficient dose to control spasms, conium would stop the movements of the diaphragm and therefore cause death through asphyxia.

The drug has, however, been used in spasmodic disorders, such as whooping cough, paralysis agitans, and acute mania and by some with asserted good results. It was in the days of superstitious medicine believed to exercise an alterative effect in scrofulous and similar diatheses, but was long ago abandoned for this purpose.

Coniine acts precisely as does hemlock, and may be used for the same purposes. The dose is from one-fortieth to one-twelfth of a grain (0.0015-0.005 G-m.). Its solution has been used locally in the spasmodic contraction of the orbicularis oculi and ophthalmia, with photophobia in scrofulous children. For these purposes from one-half to one per cent. may be employed.
Various salts, including the hydrochloride and the benzoate have been prepared, but the hydro-bromide is the one most frequently used. This occurs in colorless prismatic needles, soluble in water and alcohol, less so in ether and chloroform, inodorous and almost tasteless, and are not deliquescent. It should, be kept in the dark, otherwise it assumes a red tint. The salt has been used in the treatment of whooping cough. The usual dose of this salt is from one-sixtieth to one-twelfth of a grain, but in tetanus as high as one-sixth of a grain (0.01 Gm.) has been given. In sciatica it has been employed hypodermically in quantities of one-twelfth of a grain (0.005 Gm.) with good results. (Report, de Pharm., 1876, p. 369; 2v. R., 1876, 1879, pp. 18, 178.) For an account of Harley's experiments to determine the relative value of different preparations of conium, see U. S. D., 18th ed., p. 451. He concluded that the green fruit, as the basis of tinctures and extracts, is superior to any other part of the plant, and the spirituous extract of the green fruit should be substituted for the almost worthless extract of the former Br. Pharm. (P. J., 1871, p. 585.)

Dose of conium, three to five grains (0.2 to 0.32 Gm.).

**Connarus.** Connarusguianerisis Lamb. Seribele.—The seeds and root bark of this plant (Fam. Connaraceae), from French Guinea, are used as taenifuges; two ounces of the seeds in decoction, without straining. (Malaud, P. J., 1896, 243.)

**Contrayerva.** Contrayerba. Contrayerve, Fr. Bezoarwurzel, Giftwurzel, G.—The root of Dorstenia Contrajerva L. (Fam. Urticaceae), a native of Mexico, the West Indies, and Peru. The term contrayerba, in the language of the Spanish Americans, signifies counterpoison or antidote, and was applied to this root under the impression that it had the property counteracting all kinds of poison. The probability is that the root sold as contrayerva is derived from several species of Dorstenia, among which, besides D. Contrajerva, two others are mentioned by Houston, D. Houstoni L. and D. Drakena L., the former growing near Campeachy, the latter near Vera Cruz. According to Pereira and Martius, the contrayerva of the shops is the product of D. brasiliensis Lam., and is brought from Brazil.

The root, as found in commerce, is oblong, an inch or two in length, of varying thickness, very hard, rough, and solid, of a reddish-brown color externally, and pale within; and has numerous, long, slender, yellowish rootlets attached to its inferior part. The odor is aromatic; the taste warm, slightly bitterish, and pungent. The rootlets have less taste and odor than the tuberous portion. The sensible properties are extracted by alcohol and boiling water. The decoction is highly mucilaginous. The tincture reddens infusion of litmus, and precipitates on the addition of water. Mussi (L'Orosi, 1894, 259) investigated this plant and found two substances, which he called provisionally cajapine and contrayerbine. Contra-yerva is a stimulant tonic and diaphoretic, and has been given in low fevers, typhoid dysentery, and diarrhea, and other diseases requiring gentle stimulation. Dose of powdered root, half a drachm (2 Gm.). In the root of the Gabbon ivy (Dorstenia klaineans?) Heckel and Schlagdenhauffen have found a coumarin-like body, pseudocoumarin. (Ph. Cb., xliii.)
**Convallaria Flowers.** N. F. IV. Convallariae Flores. Lily-of-the-Valley Flowers.—It is described in the N. F. as "the dried inflorescence of Convallaria majalis Linne (Fam. Liliaceae), without the presence of more than 5 per cent. of foreign matter. From 15 to 25 cm. in length, peduncle dull-green or suggesting purplish-green, and more or less angled; flowers white, when old drying to a brownish color, usually from ten to twenty in number, borne in a more or less second raceme on recurved pedicels which are usually from a half longer than their flowers to twice their length, each pedicel subtended by a whitish, ovate, acute bract about half its length; flowers from 6 to 8 mm. in length and rather broader, bell-shaped, six-parted, the segments ovate, obtuse, and slightly recurved; stamens six, included, adnate to the base of the corolla; style columnar, three-grooved. Odor agreeable; taste sweetish, then somewhat acrid. The powdered drug is light yellowish-brown and, when examined under the microscope, exhibits ellipsoidal or nearly spherical pollen grains with a smooth exine layer and occasionally with a convex rupture through the walls; calcium oxalate in raphides up to 0.04 mm. in length; fragments of tissue from the corolla composed of nearly isodiametric parenchyma cells with broadly elliptical stomata up to 0.04 mm. in length; fragments from the anther lobes, many of the coils having reticulate walls; few fragments of the short filaments with cells containing calcium oxalate; fragments of the stigma, rough and warty, with adhering pollen grains; portions of the bracts composed of thin-walled elongated cells, a few vascular bundles and stomata; tissue of the peduncle and pedicel composed of fragments of the epidermis with cells tapering at each end about 0.20 mm. in length and 0.03 mm. in breadth with elliptical stomata between the ends; sub-epidermal cells with yellowish-green plastids; tracheae about 0.021 mm. in width, spiral and with simple pores; sclerenchymatous fibers few, with lignified walls and simple pores. Convallaria Flowers yield not more than 12 per cent. of ash." N. F. For constituents and uses, see Convallaria Root.

**Convallaria Root.** N. F. IV. (U. S. P. VIII.) Convallariae Radix. Lily-of-the-Valley Root. Lilium Convallium. Muguet, Fr. Cod. Maiblumen, G. Convallaria, Muggetto, It. Convalaria, Lirio delos valles, Sp.—It is described by the N. F. as "the dried rhizome and roots of Convallaria majalis Linne (Fam. Liliaceae). Rhizome horizontal, elongated, usually branched, cylindrical, variable in length, from 1 to 3 mm. in diameter; externally yellowish-white or pale brown, with a few circular stem. scars, and from the under and side portions at the nodes usually arise from three to five thin, tortuous, dark brown, branching root's; fracture short or fibrous; internally whitish. Odor faint; taste sweetish, becoming bitter and acrid. Under the microscope, transverse sections of the rhizome of Convallaria Root show an epidermal layer with a thick outer layer of cutin; a hypodermal layer of a single row of collenchyma; a cortex made up of about twenty rows of parenchyma cells, some of which contain starch and raphides of calcium oxalate; a prominent endo-dermis, the radial and inner walls of which are strongly thickened and lignified; inside the endo-dermis is an interrupted circle of collateral fibro-vascular bundles, the woody portion of which has in cross section the shape of the letter V; inside the circle of bundles is another interrupted circle of fibro-vascular bundles of the concentric type, the sieve tissue being surrounded by the. xylem; the parenchyma cells of the pith separated by large intercellular spaces. Under the microscope, transverse sections of the root of Convallaria show a hairy epidermal layer, a hypodermis of a single row of cells; a
cortex of about six rows of cells, some of which contain starch, raphides of calcium oxalate, and oil; the cells of the endodermal layer resemble those of the rhizome; fibro-vascular bundles mostly five. The powder is dark brown, tending to cake on standing, consisting chiefly of cellular fragments and a few starch grains and raphides of calcium oxalate; cells of endodermis with slightly oblique ends and considerably thickened, lignified porous walls; fragments of tracheae with spiral and scalariform thickenings, or with porous walls; starch grains single or compound, mostly nearly spherical, and from 0.003 to 0.012 mm. in diameter; raphides of calcium oxalate few, from 0.02 to 0.045 mm. in length. Convallaria Root yields not more than 10 per cent. of ash."

The ordinary lily of the valley of the gardens is primarily a native of Europe, but may be found in America escaped from gardens, and a plant which grows wild in the higher Alleghenies from Central Virginia to South Carolina seems to be identical with it. G. F. Walz found in lily of the valley convallarin and convallamarin. (A. J. P., 1859, p. 5,77.) Convallarin is in colorless, rectangular prisms, scarcely soluble in water, but sufficiently so as to render the solution acrid and to cause it when shaken to foam like soap and water. It is easily dissolved by alcohol. Its composition is represented by the formula $C_{34}H_{62}O_{11}$, and it is a glucoside, decomposed by long boiling with diluted acids into sugar and convallaretin. Convallamarin is a white powder, very bitter and afterwards sweetish, soluble in water and alcohol, but not in ether. This also is a glucoside. Its composition is $C_{23}H_{44}O_{12}$, and it is decomposed by heating with diluted sulphuric acid into sugar and convallamaretin, the formula of which is $C_{20}H_{36}O_{8}$. For preparing convallamarin, Tanret modifies Waiz's method, as follows. An alcoholic tincture made from the whole plant is precipitated with lead subacetate and filtered; the excess of lead is removed with diluted sulphuric acid, avoiding the use of more than is necessary, and, after neutralizing, the tincture is distilled, the last portion of alcohol being driven off in the open air; then the cooled and filtered liquor is treated with tannin, care being taken to keep the liquid neutral by cautiously adding a diluted solution of sodium carbonate. A compound of tannin and convallamarin is precipitated, which, after washing, is dissolved in 60° alcohol, the solution decolorized with charcoal, decomposed with zinc oxide, filtered, and evaporated to dryness. In this way convallamarin is obtained nearly white, and having the appearance of ordinary digitalin. To free it from the salts that are sometimes carried down by the tannin precipitate, it is a good plan to redissolve it in 90° alcohol, filter, and then evaporate. One kilo-gramme of the fresh plant collected in the first days of August yielded two grammes of convallamarin. (P. J. 1882, p. 423.) Taken internally the flowers are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in epilepsy and against worms. The root, which is also bitter, has similar purgative properties, and in powder is said to be sternutatory. Haensel obtained 0.058 per cent. of an aromatic volatile oil from the leaves of Convallaria majalis. (Ph. Centralh., 1901, 495.)

Convallaria has long been used in Russia as a popular remedy for the relief of dropsy. While there is considerable divergence of statements as to the exact effects of this drug upon the circulation, it seems to be well established that it arrests the frog's heart in systole and produces the other phenomena characteristic of the digitalis
group of drugs. Dose of either the flowers or root, five to ten grains (0.32-0.65 Gm.).

Convallaria Polygonatum L. (Polygonatum uniflorum Gilib.; now P. officinalis (L.) All.) Sealwort. Solomon's Seal. Sceau de Salomon, Genouillet, Fr. Weisswursel, Salomon's Siege, G. (Fam. Liliaceae)—A perennial, herbaceous European plant, whose root is inodorous. It is said to be emetic. In former times it was used externally in bruises, especially those about the eyes, in tumors, wounds, and cutaneous eruptions, and was highly esteemed as a cosmetic. At present it is not employed. The berries and flowers are said to be acid and poisonous. Polygonatum uniflorum L. (All.) (C. multiflora L.), which grows in Europe and Asia, is analogous to the preceding in properties. (See John H. Rauch, In. Dis., 1849.)

Convolvulus. Convolvulus panduratus L. (Now Ipomœa fastigiata, Sweet) Wild Potato. Man-root. Man of the Earth. Wild Jalap.—This native climber has a perennial root, which is very large, two or three feet in length, about three inches thick, branched at the basal portion, externally of a brownish-yellow color, and with numerous longitudinal fissures, internally whitish and milky, and of a somewhat acrid taste. It is feebly cathartic and diuretic (N. Y. Journ. of Med., x, 375), and was formerly used in strangury and calculous diseases. Forty grains (2.6 Gm.) of the dried root are said to purge gently.

**COPAIBA. U. S., Br.**

**COPAIBA Copaiba. [Balsam of Copaiba, Copaiva]**

"An oleoresin derived from South American species of Copaiba (Fam. Leguminosae)." U. S. "Copaiba is the oleo-resin obtained by incision from the trunk of various species of Copaifera, Linn." Br.

Balsamum Copaiferarum; Balsam Copaiba, Balsam Capivi; Copahu, Fr. Cod.; Oleoresine (Baume) de Copahu, Fr.; Balsamum Copaivae, P. G.; Copaiva; Copaivabalsam. G.; Balsamo di Copaive, It.; Copaiba, Balsamo de Copaiva, Sp.

Copaiba was first noticed in a work published by Purchas, in England, in 1625. The next reference to it was by Cristoval d'Acuna, in 1638. In 1648, Maregraf and Piso gave a detailed account of the tree which produces it, and the methods of gathering it. Jacquin in 1763 described a species of Copaifera, growing in Martinique, which he named C. officinalis. As this was believed to be the same plant with the one observed by Marcgraf in Brazil, it was adopted in the Pharmacopoeias, but their identity was denied; and Desfontaines proposed for Jacquin's species the title of C. Jacquinii, in honor of that botanist. It is now known that many species of Copaiba (Copaifera) exist in South America, and all of them, according to Martius, yield copaiba. Besides C.
Copaiba officinalis (L.) Jacquin, the following yield Copaiba: C. guianensis (Deaf.) O. Kuntze, C. Langsdorftii (Desf.) O. Kuntze, and C. coriacea (Mart.) O. Kuntze.

The juice is obtained by making a square chamber in the stems of the trees, reaching to the very center; and the operation is said to be repeated several times during the same season. It is asserted that a single tree will yield about forty liters. As it flows from the wound, it is clear, colorless, and very thin, but it soon acquires a thicker consistency, and a yellowish tinge. It is most largely collected in the provinces of Para and Maranham, in Brazil, and is brought to this country from the port of Para, in small casks or barrels. Large quantities of it come from Maracaibo, in Venezuela, and from other ports on the Caribbean Sea, whence it is brought in casks, demijohns, cans, jugs, etc. The drug is also exported from Angostura, Cayenne, Rio Janeiro, and some of the West India islands.

C. officinalis is a native of Venezuela, and grows in the province of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique. This is the source of the Maracaibo or Venezuela Copaiba, which is also obtained in part from C. guianensis. This variety of Copaiba is distinguished by being dextrogyrate, more viscid and darker in color.

Numerous varieties of true South American copaiba exist in commerce, known under the name of the various ports of shipment. The most important of these varieties besides Maracaibo is the Para or Maranham Copaibo, which is derived from C. Langsdorffii and C. coriacea, which is characterized by being optically laevo-gyrate. The other varieties are Bahia, Carthagena, Maranham, and Cayenne. Each one of these varieties has been referred (see P. J., 1901, Ixvi, 325) to a special species of the genus Copaiba, but there is little reason for supposing that this reference is accurate, and there is much reason for believing that various trees contribute to a single variety of copaiba. The following table, according to the researches of Umney and Bennett, shows the specific gravities and percentage of oil of the five most important of these copaibas:
All of the above varieties answered to the solubility and Gurjun balsam tests.

It will be noticed that the Para and Bahia specimens examined by Umney failed to comply with the tests of the U. S. Pharmacopoeia (1890), and yet, supposing that the oil represents the chief therapeutic principle of copaiba, these varieties lead all the others. The German Pharmacopoeia requires that the specific gravity shall be 0.98 to 0.99, and that the acid number shall fall between 75.6 and 84, and the ester number be not more than 8.4. Dieterich. (P. J., April, 1899, and March, 1900.) Surinam copaiba is a yellowish or brownish-yellow liquid, of varying' consistence; it may be distinguished from Maracaibo copaiba by the fact that one drop of it dissolved in 1 mil of acetic anhydride gives a fine blue color on the addition of a drop of sulphuric acid. (P. J., Nov., 1904.)

According to E. Keto, copaiba of Maracaibo has a density of 0.999; a coefficient of acidity of 85.4; of etherification of 6.7; while that of Para has a density of 0.92; a coefficient of acidity of 19.4; of etherification of 7.4.

**Properties.**—Copaiba is a clear, transparent liquid, usually of the consistence of olive oil, of a pale yellow color, a peculiar not unpleasant odor, and a bitterish, hot, nauseous taste. Its sp. gr. varies ordinarily from 0.950 to 1.000, but has been known to be as low as 0.916. (Procter, A. J. P., xxii, 292.) It is insoluble in water, but entirely soluble in absolute alcohol, ether, and the fixed and volatile oils. Strong alkaline solutions dissolve it perfectly; but the resulting solution becomes turbid when largely diluted with water. With the alkalies and alkaline earths it forms compounds, in which the resin of the copaiba acts the part of an acid. It dissolves magnesia, especially with the aid of heat, and even disengages carbon dioxide from the magnesium carbonate. If triturated with a sixteenth of its weight of magnesium oxide and a little water and set aside, it gradually assumes a solid consistence, and a similar change is produced with calcium hydroxide. Solid Copaiba or Mass of Copaiba was official in the U. S. P., 1890, and is now official in the National
Formulary IV, Part III. See also U. S. Dispensatory, 19th edition, p. 398. The essential constituents of copaiba are volatile oil and resin, with at times small quantities of acids. As it contains no benzoic acid, it cannot properly be called balsam of copaiba. The substances which it most closely resembles, both in composition and in properties, are the turpentines. (See Oleum Copaiba.) For a description of an apparatus for distilling the volatile oil, see a paper by R. A. Cripps in C. D., 1892, 282. Cripps found commercial copaiba to contain the following percentages of volatile oil: 40.95, 45, 45.3, 46.4, 47.8, 48.2, 49.6, 50.4, 50.8, 53.3, 59.6. J. C. Umney (A. J., P., 1893, 544) found in African copaiba 39 per cent. of an oil of 0.918 specific gravity and with a rotation of +20° 42', the last character distinguishing it from the other varieties which yield laevorotatory oils.

The official description of Copaiba is as follows: "A pale yellow to brownish-yellow, more or less viscid liquid, either without fluorescence or with only a slightly greenish fluorescence; having a peculiar, aromatic odor, and a persistent, bitter, and acrid taste. It is insoluble in water and partly soluble in alcohol. Soluble, showing not more than a slight opalescence, in dehydrated alcohol, carbon disulphide, or in fixed or volatile oils; completely soluble in chloroform or ether and also soluble in an equal volume of petroleum benzin, a further addition of the solvent producing a flocculent precipitate. Specific gravity: 0.940 to 0.995 at 25° C. (77° F.). When heated on a water bath, no odor of oil of turpentine is evolved; and when all of the volatile oil has been driven off, a hard and brittle resin remains, weighing not less than 36 per cent. of the original weight of the Copaiba taken (paraffin or fatty oils). To about 1 G-m. of Copaiba, accurately weighed, add 50 mils of alcohol and 1 mil of phenolphthalein T.S., then titrate the solution with half-normal potassium hydroxide V.S. It shows an acid value of not less than 28 nor more than 95. Dissolve 3 or 4 drops of the volatile oil separated from Copaiba by distillation with steam, in 3 mils of glacial acetic acid, mix the solution with 1 drop of a freshly prepared aqueous solution of sodium nitrite (1 in 10), and carefully underlay this with 2 mils of sulphuric acid. The acetic layer is not colored pink (gurjun balsam). Shake 5 mils of Copaiba with 15 mils of alcohol and then heat the mixture to boiling for one minute; no oil separates after cooling and allowing it to stand for one hour (paraffin oils). The volatile oil separated from Copaiba by distillation with steam does not boil below.
250° C. (482° F.), and shows an angle of rotation in a 100 mm. tube of not less than -7° at 25° C. (77° F.). (African Copaiba); U. S.

"A more or less viscous liquid, generally transparent and occasionally fluorescent, yellow to golden brown. Specific gravity 0.975 to 0.995. Entirely soluble in absolute alcohol; soluble in four times its volume of petroleum spirit, the solution yielding only a slight filmy deposit on standing. Aromatic, characteristic odor; taste acrid, somewhat bitter, persistent. Loses about 45 per cent. of its weight when heated for forty-eight hours to 100° C. (212° F.). Forms a transparent solution with one-third of its volume of solution of ammonia. Four drops carefully added to a mixture of 5 millilitres of glacial acetic acid with four drops of nitric acid do not yield a purplish or violet color (absence of gurjun balsam). 1 gramme dissolved in 25 millilitres of absolute alcohol requires for neutralisation not less than 2.7 millilitres of N/2 alcoholic solution of potassium, hydroxide, solution of phenolphthalein being used as indicator (presence of a due proportion of acid resins). The volatile oil distilled from it responds to the tests described under 'Oleum Copaibae.'" Br.

The resinous mass which remains after the distillation of the oil is hard, brittle, translucent, greenish-brown, and nearly destitute of odor and taste. By mixing it with the oil in proper proportion, we may obtain a liquid identical or nearly so with the original juice. This resinous mass is of an acid character, and yields a series of amorphous salts; it may be obtained pure by exposing a mixture of 9 parts of copaiba and 2 parts of aqueous ammonia (sp. gr. 0.95) to a temperature of 10° C. (50° F'). In this way crystals of copaivic acid, C₂₀H₃₀O₂, are obtained. This acid agrees with the abietic acid of rosin in composition, but not in properties. Copavic acid is readily soluble in alcohol, and especially in warmed copaiba itself; much less soluble in ether. When recrystallized from alcohol, copavic acid fuses at 116° to 117° C. (241°-242.6° F.). (A. J. P., 1879, p. 305.)

An analogous substance, oxycopavic acid, C₂₀H₂₈O₃, was found in 1841 by H. von Fehling in Para copaiba, and Strauss, in 1865, extracted meta-copaivic acid, C₂₂H₃₄O₄, from Maracaibo copaiba. Copavic acid forms crystallizable salts with alkalies, and sodium copaivate, NaC₂₀H₂₉O₂, made by combining molecular quantities of the acid and soda, is asserted by Zlamal and Roquette to be more efficient.
than any other preparation of copaiba. Tschirch (Harze und Harzbehalter, 1900, p. 297) obtained from Maracaibo balsam a crystalline resin acid corresponding in many respects with Strauss's metacopaivic acid, to which, however, he gave the formula C_{11}H_{16}O_{2}, finding a melting point 89° to 90° C. (192.2°-194° F.) as against 205° to 206° C. (401°-402.8° F.) for Strauss's acid. Para balsam was found by Tschirch to contain two crystallizable resin acids together with several uncrystallizable ones. African copaiba balsam he found to contain a characteristic acid to which he gave the name illurinic acid and the formula C_{14}H_{20}O_{2} or possibly C_{21}H_{30}O_{3}. Keto, who worked out the preceding results jointly with Tschirch, has since published some additional results. (J. P. C., 1902, p. 381.) He finds in Para balsam the two crystallizable acids referred to above, one of which he names para-copaibic acid with the formula C_{20}H_{32}O_{3} and fusing point 142° to 145° C. (287.6°-293° F.), and the other homoparacopaibic acid, C_{18}H_{28}O_{3}, fusing at 111° to 112° C. (231.8°-233.6° F.). To illurinic acid mentioned by Tschirch he gives the formula C_{20}H_{28}O_{3} and the melting point 128° C. (262.4° F.).

Copaiba, upon exposure to the air, acquires a deep color, a thicker consistence, and greater density, and, if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization and partly to the oxidation of the essential oil. As it is the soft resin that results from the oxidation of the oil, it follows that the proportion of this resin increases with age. Considerable diversity must, therefore, exist in the drug, and in its physical properties and in the proportions of its ingredients, according to its age and degree of exposure. Similar differences also exist in the copaiba procured from different sources. Thus, that of the West Indies, when compared with the Brazilian, which is the variety above described, and in common use, is of a thicker consistence, of a deeper or darker yellow color, less transparent, and of a less agreeable, more terebinthinate odor. They differ also, as observed by Buignet, in their action on polarized light, in which they differ not only in degree, but sometimes also even in direction. (J. P. C., Oct., 1861, pp. 266-7.) It is not impossible that differences may exist in the drug according to the circumstances of its collection. The species of Copaifera from which the oleoresin is collected, as well as the age of the tree, its position, and the season of collection, must also have influence over the
product. It is highly probable that the resinous matter results from the oxidation of the oil in the cells of the plant, and that the less elaborated the oleoresin may be, the larger proportion it will contain of the oil. It is said that a volatile oil flows abundantly from a tree near Bogota, which is employed to adulterate the copaiba collected in that vicinity and shipped from Maracaibo and other neighboring ports. African Copaiba, or Balsam of Illurine, which reached the London market first in 1891, from West Africa, is a brownish substance, having a consistency similar to the Maracaibo copaiba, and a greenish fluorescence. Its aromatic odor is entirely different from that of copaiba; its taste is biting, with an after-taste of bitterness. According to Keto (/. P. C., 1902, 381), its density is 0.9905; its coefficient of acidity 55.5; of etherification 8.3. It is soluble in chloroform and petroleum benzin, also in ether, with which it makes an opalescent liquid. Its solution in absolute alcohol, or alcohol of 95 per cent. is not limpid. From it Keto separated illurinic acid. Its volatile oil is of a pale yellow color, with a strong odor entirely different from that of copaiba. The residue which remains after the distillation consists of two resins, one soluble, the other insoluble, in alcohol. This oleoresin probably shares the medicinal properties of true copaiba, and is the product of Hardwickia Mannii Oliver, a tree closely allied to the true copaibas. (See Apoth. Zeit., 1894, p. 9.)

**Adulterations.**—Copaiba is often adulterated with a fixed oil, especially castor oil, which, in consequence of its solubility, cannot, like the others, be detected by alcohol. Various plans have been proposed for recognizing the castor oil. The simplest is to boil a drachm of the copaiba in a pint of water until the liquid is wholly evaporated. If the copaiba contains a fixed oil, the residue will be more or less soft, according to the quantity present; otherwise it will be hard. Magnesium carbonate, potassium hydroxide, and sulphuric acid have also been proposed as tests. In the old Edinburgh Pharmacopoeia it was stated that copaiba "dissolves a fourth part of its weight of magnesium carbonate, with the aid of a gentle heat, and continues translucent." The presence of a small proportion of any fixed oil renders the mixture opaque. One part of potassium hydroxide dissolved in two of water forms a clear solution with nine parts of pure copaiba, and the liquid continues clear when moderately diluted with water or alcohol; but the presence of one-sixth of fixed oil in the copaiba occasions more or less opacity in the liquid, and half the quantity causes the precipitation of white flakes in a few hours. (Stolze.) Turpentine, which is said to be sometimes added to copaiba, may be detected by its odor, especially if the copaiba be heated.
According to Redwood, most of the proposed tests of the purity of copaiba are liable to fallacy, and the best measure of its activity is the quantity of volatile oil it affords by distillation. Castor oil, Venice turpentine, linseed oil, or gurjun balsam may be detected by means of petroleum benzin, which makes a clear solution with pure copaiba, but if either of the substances mentioned be present a milky mixture, which soon settles into two layers, is formed, the copaiba solution being on top. (A. J. P., July, 1873; Proc. A. Ph. A., xxiv, 191, xxvi, 286.) Maisch has found that ten volumes of petroleum benzin, instead of three as proposed by Wayne, must be added to one of copaiba to get the best results from this test. Indeed, it has been shown that pure copaiba will sometimes show turbidity when mixed with petroleum benzin. (A. J. P., 1877, p. 131.) Some years since, a substance was imported into New York, under the name of red copaiba, which did not possess a single characteristic of the genuine drug. It was of a thick, semi-fluid consistence, not unlike that of balsam of Tolu, as it often reaches us, of a brown color similar to that of the same balsam, though darker, and of an unpleasant yet somewhat aromatic odor, recalling that of liquidambar, but less agreeable. Its origin is unknown. Hager recommends the use of absolute alcohol, which he says completely dissolves, without turbidity, all the varieties of copaiba except the Para, whose solution on standing clears itself by the deposition of a few white flakes. J. M. Fulton asserts that some pure copaibas are not entirely dissolved by absolute alcohol. (A. J. P., 1877.) For additional tests and criticisms by Beckurts and Brueche, see A. Pharm., 1891, p. 90; also Proc. A. Ph. A., 1892, 635. For Hager's test, see C. D., 1894, 740. Dodge and Olcott (Am. Drug., 1895, 5) describe a test to detect gurjun balsam in copaiba, which Keble regards as the most reliable yet proposed; it is as follows. Four drops of the suspected sample, dissolved in half a fluidounce of glacial acetic acid, will, if pure, remain colorless and clear, or but slightly cloudy, if from four to six drops of pure nitric acid be dropped into the solution. If the sample be pure gurjun balsam, the mixture will have a deep purple color; if a mixture of the two balsams, the depth of color will vary according to the amount of the adulterant, as small a proportion as 2 per cent. being discoverable; a modification of this test is now official. (See also A. J. P., 1896, 143, and 1897, 394.) For a valuable paper on Copaiba by A. R. L. Dohme, see Proc. A. Ph. A., 1904, 322.

Uses.—Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of
heat in the throat and stomach, and extends an irritant action not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to the whole mucous membrane, for which it appears to have a strong affinity. The urine acquires a peculiar odor during its use, and its odor may be detected in the breath. It sometimes occasions an eruption upon the skin resembling that of measles, and attended with disagreeable itching and tingling, or even violent pemphigus. (N. Y. M. J., Jan., 1873, p. 416.) Nausea and vomiting, painful purgation, strangury and bloody urine, and a general state of fever are caused by excessive doses. As a remedy it has been found useful in catarrhs, particularly those of a chronic character. Thus, it is given with occasional advantage in leucorrhea, chronic cystitis, chronic diarrhea, hemorrhoids, and chronic bronchitis. The complaint, however, in which it is most employed is gonorrhea. It should not be administered in the first stages, when the inflammation is severe and acute, nor is it applicable to very chronic forms of the disorder, such as gleet. It was formerly much esteemed as a vulnerary and as an application to ulcers, but it is now seldom used externally. Ruschenberger recommends it locally in chilblains. (Med. Examiner, i, 77.)

Both the volatile oil and the resin are eliminated by the kidneys in an altered condition; if to the urine of a person taking the drug, nitric acid be added, a precipitate is thrown down, which may be mistaken for albumin. The volatile oil is more active than is the resin, which is not, however, inert. Wilks, of Guy's Hospital, London, speaks of the resin with great confidence as a hydragogue diuretic in obstinate dropsy, given in the dose of fifteen or twenty grains three times a day.

It may be given dropped on sugar, but in this form is often so exceedingly offensive as to render some concealment of its nauseous qualities necessary. A less disagreeable form is that of emulsion, prepared by rubbing the copaiba first with mucilage, or the yolk of an egg, and sugar, and afterwards with some aromatic water, as that of mint or cinnamon. The volatile oil, which is official in the British Pharmacopoeia, may be given in the dose of ten or fifteen minims (0.6-0.9 mil) in emulsion, or, as is almost universally preferred, in capsules.

Dose, of copaiba, from fifteen minims to a fluidrachm (1.0-3.75 mils) three times a day, or a smaller quantity repeated more frequently.

Copal.—The copals are a class of hard resins used principally in varnish manufacture. They are of various origins, both geographically and botanically. Their principal characteristics are their hardness, high melting point and comparative insolubility unless subjected to destructive distillation. There are three chief varieties: (1) Fossil copal, found in the ground in localities where the trees yielding it have entirely disappeared. (2) Semi-fossil copal, collected from the ground in the neighborhood of living copal trees. (3) Fresh copal, found on living trees, either as the result of natural exudation or from artificial incisions. The fresh copal is of least value and the fossil copal is most highly prized.

East African copals, known in commerce as Animi gum or resin, are fossil varieties coming from Zanzibar, Madagascar and along the East African Coast. American copals are collected in South America and probably originated from trees related to those which produced the East African copals, although the product is softer. Kauri or cowrie copal or Kauri gum, as it is often called, is found in New Zealand exclusively. M. Kahan has investigated Acera copal and Benin copal (Arch. d. Pharm., 1910, ccxivii, p. 443) and gives the percentages of the various constituents found.

A study of South American varieties of copal has been made by S. Machenbaum (Arch. d. Pharm; 250, Nos. 1-6 and 13), in which the constituents are stated to be copalic acid, copalolic acid, copalo-resene, copalmic acid, volatile oil and ash.

Fossil copal from Guiana has been studied by J. C. Essner (Annal. Chim. Anal., xvii, p. 166), who gives the following constants: Sp. gr. 1.089; colorless portion, acid value 118, saponification value 127, iodine value 84.3; yellow portion, acid value 125, saponification value 151, iodine value 81.5.

Zanzibar copal is obtained from several species of Trachylobium. The trunk and limbs are covered with a clear resinous exudation, portions of which, after solidifying, drop to the ground and are collected, while other portions are broken from the tree. This kind of resin is always smooth, and is exported to India. Another variety, with an indented, goose-flesh surface, known in the English market as anime, is dug from the earth, and though the product of forests now extinct, originated probably from the same tree. (P. J., 1869, G54.) It is in roundish, irregular, or flatfish pieces, sometimes several pounds in weight, often rough over the surface, probably from the impression of sand in its soft state, colorless, or brownish-yellow, more or less transparent, very hard, with a shining, conchoidal fracture, inodorous and tasteless. By heat it melts and emits gases, loses from 15 to 20 per cent. of weight, and is altered so as to become more soluble in ether, alcohol, or oil of turpentine, and in this way copal varnishes are usually made. It is not a proximate principle, but consists of various resins united in different proportions. According to Unverdorben and Filhol, some five different resins can be obtained by the successive action of solvents. Sierra Leone copal comes from Western Africa. According to Daniell (P. J., xvi, p. 369), this is derived from the Copaifera Guibourtiana Benth., a large tree growing preferably in
mountainous regions. The drug is mostly collected, not from the tree itself, but from the beds and borders of streams, into which it is washed down, during the rains, from the hillsides, in the soil of which it had been deposited.

The Sierra Leone copal is described by Daniell as occurring "in small round tears, or irregular conical and smooth nodulated masses, seldom exceeding in size an ordinary duck egg. They are covered, to a greater or less extent, by a peculiar white efflorescence, which increases by age. Their color graduates from a pale green to a lemon or dull yellow."

Inhambane copal has been shown to be the product of Copaifera Gorskiana Benth. and seeds sent to Kew Gardens in 1886 germinated, and the plant has been widely introduced into both the East and West Indies, and into Australia. (P. J., xix, 508.)

A variety of copal comes from the East Indies. This has been ascribed to Vateria acuminata Hayne (Fam. Dipterocarpaceae), but is probably the product of a Trachylobium; at least a specimen of this resin was collected by Perottet from the Trachylobium Hornemannianum Hayne, which he found growing in the Isle of Bourbon. This tree is a native of Madagascar, and probably of the neighboring parts of Africa, and Perottet was informed that the copal of India is taken thither by the Arabs of Muscat, who obtain it from the east coast of Africa. (J. P. C., 3e ser., i, 406.) It is described by Schindler as of a globular form, softer and more transparent than the other varieties, with a surface always clear, and having an agreeable odor when heated. It is readily and freely dissolved by the oils of turpentine and rosemary when pure, but not by these fluids when rendered resinous by age. It is more readily fusible than the others, and makes the best varnish.

The West India copal is in flat pieces, seldom weighing more than three ounces, rarely containing insects, very hard, of a rough appearance, of a yellowish color, and without odor or taste. It is much less readily dissolved by oil of turpentine than the East India variety, swells but does not dissolve in oil of rosemary and is slightly soluble in absolute alcohol. Another kind, probably also American, is in convex or concave pieces, about a pound in weight, often containing insects and other impurities. In solubility it resembles the last mentioned variety, in fusibility is intermediate between it and the East Indian, and is altogether inferior. (P. J., 1850.) For an account of the present views on the nature of copal resins, see Tschirch, Die Harze und die Harsbehalter, Leipzig, 1900.

For descriptions of the so-called Manila copal and Kauri copal which are derived from the conifers, see p. 1417.

Copal lotion.—Under the trade name Adhaesol there appears on the market a lotion containing: Copal, 350 parts; benzoin, 30 parts; tolu, 30 parts; ol. thyme, 20 parts; alpha-naphthol, 3 parts; ether, q. s., 1000 parts. It is used as an antiseptic varnish in diphtheritic affections of the throat.

"The dried plant of the Coptis trifolia (Linne) Salisbury (Fam. Ranunculaceae)." N. F. This plant inhabits the northern region of this continent and of Asia, and is found in Greenland and Iceland. It delights in the dark shady swamps and cold morasses of northern latitudes and alpine regions, and abounds in Canada and in the hilly districts of the Northern United States.

Dried goldthread, as brought into the market, is "in loose, matted masses consisting of long, much branched rhizomes and their small roots together with the leaves. Rhizomes orange or golden-yellow; leaves evergreen, long and slenderly petioled, trifoliate, the segments broadly obovate-cuneate, crenately lobed and toothed with sharp-pointed teeth, prominently veined, smooth, coriaceous, dark green and shining but often drying to a dull brownish hue; flowers, if present, small, solitary, terminating slender scapes, sepals five to seven, oblong, obtuse, deciduous; petals five to six, pale yellow, small club shaped; stamens numerous. Odor faint; taste purely bitter without astringency. The powdered drug is yellowish-green and, when examined under the microscope, exhibits numerous, mostly simple, starch grains, somewhat rounded, up to 0.007 mm. in diameter; fragments of leaf epidermis, composed of cells with wavy vertical walls and broadly elliptical stomata, the latter up to 0.024 mm. in length; fragments of the nerved scales from the nodes, composed of cells with yellow walls; leaf parenchyma cells containing chloroplastids; few, simple, thick-walled hairs from the midrib of the leaf, from 0.035 to 0.075 mm. in length; elongated, epidermal cells from the roots having yellow walls and filled with reddish contents; fragments of epidermal and sub-epidermal cells from the rhizome, similar to those from the root, but without reddish contents, often filled with a yellowish content; groups of elongated parenchyma cells about 0.06 mm. in length and about 6.01 mm. in width, many being filled with starch grains; tracheae with bordered pores or spiral markings, about 0.02 mm. in width; narrow thin-walled, porous sclerenchyma fibers. Coptis yields not more than 8 per cent. of ash." N. F. It imparts a bitterness and yellow color to water and alcohol, but most perfectly to the latter, with which it forms a bright yellow tincture. The infusion is precipitated by silver nitrate and lead acetate. (Bigelow.) It affords no evidence of containing either resin, gum, or tannin. The plant undoubtedly contains berberine, which, according to F. F. Mayer (A. J. P., 1863) and E. Z. Gross (A. J. P., 1873), is associated with another alkaloid. Gross states that coptine differs from berberine in its colorless crystals, and by forming with mercuric potassium iodide (Mayer's reagent) a crystalline instead of flocculent precipitate. (See also John J. Schuiz, A. J. P., 1884, 261.)

Goldthread is a simple tonic bitter. In New England it is employed as a local application in aphthous ulcerations of the mouth, but it probably has no other virtues in flits complaint than such as are common to the simple bitters. It may be given in substance, infusion, or tincture. The dose of the powder is from ten to thirty grains (0.65-2.0 Gm.); of a tincture made with an ounce of the root to a pint of diluted alcohol, one fluidrachm (3.75 mils), and of the N. F. fluidextract thirty minims (2 mils).

The Coptis Teeta of Wallich, which grows in the mountainous regions bordering on Assam, is much used as a tonic by the natives and by the Chinese. It is analogous in United States Dispensatory - 1918 - Botanicals Only - C - Page 177 The Southwest School of Botanical Medicine http://www.swsbm.com
properties to \textit{C. trifolia} Salisb., and is said to contain $8\frac{1}{2}$ per cent. of berberine. It has been brought into use in British India. It is highly commended by Twining as a stomachic tonic. (P. J., 1870, 161.) \textit{Coptis anemonifolia} Sieb. and Zucc. also contains berberine, and has been used in Japan in intestinal catarrh. (Sei-i-Kwai, 1892.)

\textbf{Corallorhiza.} Corallorhiza odontorhiza(Willd.) Nutt. Coral-root. (Fam. Orchidaceae)—This is a parasitic leafless herb, sending up from a coral-like rhizome a simple scape or flower stem, from six to sixteen inches high, furnished with sheaths instead of leaves, of a light brown or purplish color, and bearing small, greenish-brown flowers in a long spike. The plant grows throughout the United States east of the Mississippi. The rhizome is the part used. It is much branched and toothed, and of a brown color, and its resemblance to coral gave name to the plant. It has a strong peculiar odor, and an astringent bitterish taste. It is much valued by the eclectics as diaphoretic in fevers; dose, of powder, thirty grains (2 Gm.) every two hours.

\section*{CORIANDRUM. U. S. (Br.)}

\textbf{CORIANDER} Coriand. [Coriander Seed]

"The dried ripe fruit of \textit{Coriandrum sativum} Linne (Fam. Umbelliferae), without the presence or admixture of more than 5 per cent. of other fruits, seeds, or foreign matter." U. S. "Coriander Fruit is the dried ripe fruit of \textit{Coriandrum sativum}, Linn." Br.

Coriandrum sativum is an annual plant, with an erect branching stem rising about two feet, and furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnae cut into irregular serrated lobes like those of parsley. The flowers are white or rose-colored, and in compound terminal umbels; the fruit globular, and composed of two concavo-convex mericarps. \textit{C. sativum} is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extended cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact that all parts of the fresh plant are extremely fetid when bruised, while the fruit becomes fragrant by drying. This is the official portion. The chief supplies come from Russia, Morocco, Holland, and Hungary. Attempts have been made to cultivate the plant in Vermont. The amount annually imported into the United States is over 1,000,000 pounds. The drug not infrequently contains a
large admixture of earthy and stony substances as well as stems and similar inert matter. Bloine reports finding a sample of Coriander that contained 20 per cent. of flaxseed. LaWall has found leguminous starch in a specimen of powdered Coriander, probably from vetch seed which is sometimes accidentally present.

The fruit is officially described as follows: "Mericarps usually coherent; cremocarp nearly globular, from 3 to 5 mm. in diameter; externally light brown or rose colored; summit with 5 calyx teeth and a short stylopodium, each mericarp with 5 prominent, straight, longitudinal, primary ribs and 4 indistinct, undulate secondary ribs; mericarps easily separated, deeply concave on the inner or commissural surface and showing in transverse section 2 vittae (oil tubes) on the inner surface of each. Under the microscope, sections of Coriander show an epidermis of small cells with thick walls; a layer of several rows of thin-walled more or less collapsed parenchyma separated from a broad zone of strongly lignified, sclerenchymatous fibers which extend as a continuous ring in the mesocarp of each of the mericarps; 2 or 3 layers of large, tangentially elongated, thin-walled parenchyma cells, frequently with numerous large lysigenous intercellular spaces; inner epidermis of large tabular cells, the inner yellowish walls being considerably thickened and closely coherent to the brownish cells of the seed-coat; commissural surface with 2 large, elliptical vittae; the cells of the pericarp separated from the seed-coat and forming a large elliptical cavity; endosperm distinctly reniform in outline and consisting of tabular or polygonal thick-walled cells containing numerous large aleurone grains each with a rosette aggregate or prism of calcium oxalate. The powder is light brown, consisting chiefly of fragments of endosperm and lignified tissues of the pericarp; calcium oxalate crystals numerous, from 0.003 to 0.01 mm. in diameter, mostly in rosette aggregates, either isolated or in aleurone grains; sclerenchymatous fibers irregularly curved, having thick, yellowish, lignified walls and numerous simple pores; numerous globules of fixed oil; fragments of light yellow vittae few, associated with elongated polygonal epidermal cells. Coriander yields not less than 0.5 per cent. of volatile extractive, soluble in ether (see Part II, Test No. 12). Coriander yields not more than 7 per cent. of ash." U. S.

"Nearly globular, about five millimetres in diameter, uniform brownish-yellow in color, and glabrous. Mericarps usually closely united, and
crowned by the calyx teeth and stylopod. Primary ridges wavy and inconspicuous; secondary ridges straight and more prominent. In transverse section, two vittas on the commissural surface of each mericarp. Aromatic odor, especially when bruised; taste agreeable. 

The aromatic taste and odor of coriander depend on a volatile oil, which may be obtained separate by distillation. One pound of the seeds yields forty-two grains of the oil. (Zeiler.) This is colorless or pale yellow, with an agreeable odor of coriander, a mild aromatic taste, and a sp. gr. varying from 0.87 to 0.88. Its main constituent, according to Semmler (Ber. d. Chem. Ges., xxiv, 206), is what was first called coriandrol, but is now recognized as right rotatory linalool, C_{10}H_{18}O, boiling between 194° and 198° C. (381.2°-388.4° F.). Besides this, about 5 per cent. of dextro-pinene was isolated, boiling between 156° and 160° C. (312.8°-3200 F.). It is one of the most permanent volatile oils, long resisting oxidation. The fruit's virtues are imparted to alcohol by maceration, and less readily to water.

**Uses.**—Coriander is a rather feeble aromatic. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. It was well known to the ancients.

Dose, twenty to sixty grains (1.3-3.9 Gm.).

**Coriaria.** Coriaria myrtifolia L. Currier's Sumach. Redoul, Sumach des Corroyeurs Fr. Gerberstrauch; G. (Fam. Coriariaceae).—This is a shrub growing wild in Southern Europe, which is sometimes cultivated in gardens on account of its handsome foliage. The leaves, which are used for dyeing black, were at one time employed to a considerable extent in France in the adulteration of senna. They have recently been reported both in Europe and in America as an adulterant of sweet marjoram, the coriaria leaves being finely broken to facilitate admixture. The presence of coriaria in marjoram may be inferred by strewing a specimen of the broken up leaves upon the surface of a dilute ferric chloride solution, which does not affect the fragments of marjoram but which quickly stains the coriaria fragments a deep greenish-black, owing to their high tannin content. The fruit, resembling berries in form, are black, and about the size of a pea. Both these and the leaves are poisonous in large doses, and several instances of death are on record from eating the fruit. (Merat and De
Lens.) Riban (J. P. C., 1864, p. 487) separated from the fruit a glucoside coriamyrtin. He obtained it by treating the juice with lead acetate, precipitating the lead with hydrogen sulphide, concentrating the lead with a nitrate to a syrupy consistency and extracting with ether. It occurs as extremely bitter, white crystals, fusing at 220° C. (428° P.), sparingly soluble in water but freely so in alcohol and other organic solvents. Its empirical formula is C_{30}H_{36}O_{10}. Marshall (J. P. Ex. T., 1912, iv, p. 135) studied the substance supplied by Merck under the name of coriamyrtin which, however, he believed to be different from that described by Reban, because it was soluble in water. The lethal dose was 1 mgm. per kilo. He found that it was a stimulant to the medullary centers, increasing the blood-pressure and respiration and slowing the pulse; in large doses it caused cerebral convulsions. Coriamyrtin has been employed as a stimulant in collapse in doses of one-sixtieth of a grain (0.001 Gm.).

Tlolocopetale, a Mexican drug, is said to be the product of a Coriaria, probably C. myrtifolia, containing coriarin and coriamyrtin, and to be actively poisonous.

Toot-poison. Tu-tu.—In New Zealand a poisonous plant, known as the toot-plant, has proved very destructive to the domestic animals. W. Lauder Lindsay found it to resemble either Coriaria ruscifolia of Linneus or C. sarmentosa Forst., and in its action on the system to be an irritant narcotic. For an elaborate account of the toot-plant, and its poisonous effects, see Brit. and For. Med. Chir. Rev., 1865, 153, and 1868, 465. From these it appears that more than one species of Coriaria inhabit New Zealand, C. thymifolia Humb. et Bonpl. and C. angustissima Hook. f., besides the ruscifolia; though Lindsay appears to think that the two former may be merely varieties of the third. It is not only cattle that are poisoned by the plant, but not infrequently also children, and occasionally even an adult. The cattle are probably, in general, poisoned by eating the young shoots. W. S. Key attributes poisonous qualities to an oil (Chem. News, 1890, xxii), but it has been shown by T. Hill Easterfield and B. C. Aston that the three New Zealand species of coriaria contain a glucoside, tutin; C_{17}H_{20}O_{7}, which is not identical with coriamyrtin, and which, according to Marshall, is toxic, especially to the medulla oblongata and the basal ganglia of the brain. (Proc. Chem. Soc., xvi, 213.) It is affirmed by T. H. Hartwick (P. J., vol. xv, 22) that goats are not poisoned by the tu-tu, and that they have even been used to eradicate the plant by browsing, also that the berries when ripe are not only not poisonous to man, but, if care is taken to reject the seeds, are a grateful and refreshing fruit. The prominent symptoms of the poisoning in man are giddiness, stupor, and coma, without delirium or convulsions. Occasionally the delirium resembles that of alcoholic intoxication, in other instances approaches that of acute mania, and is attended with violent muscular action. Loss of memory is a characteristic of the convalescence. The toxicity of tutin, which was demonstrated by Marshall, has been confirmed by Ford (J. P. Ex. T., 1910, ii).

Cork. Suber. Liege, Fr. Kork, G.—The great use made of this substance in pharmacy and the arts justifies a brief notice of it. It is chiefly produced by Quercus Suber L. (Fam. Cupuliferae), but is obtained also from the Q. occidentalis F. Gay. It consists of the exterior layers of the bark beneath the epidermis, which acquire in these species an extraordinary development, becoming thick, and of that peculiar spongy
consistence which characterizes cork. The tree begins to yield cork when fifteen or sixteen years old, and every six or eight years—the interval requisite for the renewal of the suberose layers by the living portions of the bark beneath—furnishes a fresh supply, even for a century and a half, before it perishes. There are four constituent layers of the bark: the epidermis, the cork, the cellular envelope, and the bast which lies upon the wood. Each of these increases year by year; but the cork thus naturally produced is not valued. The commercial product is the result of an artificial injury to the bark. The exterior layers are removed, and the bast exposed. In the interior of this, at a variable distance from the surface, a layer of the proper cork is now formed, apparently by a change in the substance of the bast, the outer portions of which perish, while annually a new layer is added to the cork already existing, until it acquires a thickness which will justify its removal. Incisions are made in such a way that the cork is removed in large concave plates, which are then flattened under pressure, and dried. At present cork comes into commerce from Portugal, Spain, France, Italy, Tunis, Algeria, and Morocco. About one million of quartels of it are said to be produced annually. The value of the cork imported into the United States in 1914 was $3,851,794, and in 1915 $2,761,895.

A cork has recently come into the United States commerce from Nicaragua. It has been found by E. F. D. Baker to be obtained from the roots of the Anona, a tree closely resembling in appearance the ordinary cottonwood of the United States.

In selecting cork for use, those parts should be preferred which are soft and of uniform consistence, and in the choice of the larger plates those should be selected which are thick, flexible, elastic, finely porous, and of a reddish color. Boiling hot alcohol extracts from rasped cork tissue some 10 per cent. of soluble principles. From the hot alcohol solution a substance crystallizes which was first noticed by Ghevreui under the name of cerin. According to Kugler (Dissertation on Suberin, Halle, 1884), besides cellulose and lignocellulose, cork contains two constituents, cerin, to which he gives the formula C20H32O, and suberin, which is a fat, and contains stearic acid and phellonic acid, C22H42O3. This constituent, suberin, prevents the penetration of liquid into the cork, and is only extracted by alcoholic alkali solutions. When treated with nitric acid, cork yields a peculiar acid, which has been denominated suberic acid. This is a dibasic acid homologous with oxalic acid, and has the formula C3H14O4. It is formed by the oxidation of many other substances, such as the oils from linseed, castor bean, cocoa, nut, almond, spermaceti, etc.

Stanislaus Martin has called attention in France to the use of refuse corks in Paris, where they are collected by the scavengers, and sold to persons whose business it is to revive them, recutting such as are of unsuitable shape, filling up the interstices with mastic, and covering them over with some powder which may give them a fresh appearance. Corks are sometimes bleached with sulphurous acid, and the odor of hydrogen sulphide has been noticed in prescriptions which have been compounded, when such corks have been used in the dispensing bottle. (P. J., 1881, 1080.) Mohr has found that old corks may be regenerated by allowing them to soak for twenty-four hours in hot water, washing well several times, allowing to stand for a few hours in a mixture of one part of hydrochloric acid and fifteen parts of hot water, and finally
washing well in pure water. (See also A. J. P., 1875, 467.) It is easy to conceive that a cork at one time used to enclose arsenical or other deadly solution may become saturated with the poison, and afterwards impart enough of it to another liquid, if not to produce dangerous effects on the health, at least to give to tests evidence of its presence, and thus lead to serious suspicions. No cork, therefore, which has been used in a bottle containing a poisonous substance should be employed a second time.

**Cornus.** N. F. IV. Dogwood Bark. Ecorce de Cornouiller a grandes fleurs, Fr. Grossbluthige Cornelrinde, G.—This drug, which was at one time official in the U. S. P., is described by the N. F. as "the dried bark of the root of Cornus florida Linne (Fam. Cornaceae). In irregular, chip-like pieces, or portions of quills, usually less than 5 cm. in length and from 1 to 4 mm. in thickness; externally of a dingy-brown color, lightly fissured and thinly scaly, or reddish where the corky layer has been removed; inner surface varying from pinkish-brown to red-purple, usually harsh to the touch from numerous short striae; fracture short, the surface whitish with yellow striae, except the inner layer, which is light purple. Odor slight; taste bitter and astringent. Cornus yields not more than 10 per cent. of ash," N. F.

The barks of two other indigenous dogwoods are sometimes substituted for that of C. florida L. Each of these is a shrub with opposite leaves, the flowers in flat spreading cymes, and the fruit globular and bright red. C. circinata L’Her. is further distinguished by its branches being greenish and warty; its leaves round-oval, abruptly pointed, and woolly underneath. C. Amomum Mill. (C. sericea L.), Silky cornel or Swamp Dogwood, is to be recognized by its purplish branches, and by the fact that the branchlets, stalks, and lower surface of the elliptical pointed leaves are silky and downy. (See also Chem. News, 1908, 191.)

These dogwoods are found in all portions of the United States east of the Mississippi.

Dogwood bark was used many years ago as an antiperiodic in intermittent fever, but it is only a feeble, astringent tonic. Formerly from one to two ounces of the powder were given in the interval between the paroxysms of intermittent fever. The N. F. IV also recognizes its fluidextract. The dose of this fluidextract is from half a fluidrachm to a fluidrachm (1.8-3.75 mils).

**Coronilla.** Coronilla scorpioides Koch (Fam. Leguminosae).—In 1886 Cardot, in a thesis (Nancy) announced that the Coronilla scorpioides (Medic.) Koch, a papilionaceous plant of Southern France, is an active cardiac poison. In 1889 Schlagdenhauffen and Reeb (Rev. Gen. de Clin. et de Therap., July, 1889) isolated a glucoside, coronillin, to which they assigned the formula C₇H₁₂O₅. It was a yellowish powder, soluble in water, acetone, and amyl alcohol; slightly soluble in chloroform and ether. Heated with diluted hydrochloric acid an amorphous resin was separated, coronil. This also occurs as a yellow powder, but is not bitter to taste. It is insoluble in water, but dissolves in alcohol, acetone, and chloroform. The physiological studies by Gley, by Schlagdenhauffen and Reeb, and by Maramaldi (R. T; cxxxvi) have demonstrated that coronillin acts upon the heart in a manner similar to digitalis. In small doses it slows the pulse through stimulation of the inhibitory ganglia, and in
larger quantity increases the tonicity and contractility of the heart, eventually leading to systolic spasm of the ventricle. This action upon the heart is accompanied by increase in the arterial pressure, followed after a time by lowering of the pressure, which apparently is the result of failure of diastole, causing the amount of blood forced out of the heart at each systole to be insufficient to fill the arteries. The drug also depresses the spinal cord, and lowers the respiratory movements by an action which is believed by Maramaldi to be partly centric and partly peripheral. Death is produced by cardiac arrest.

Locally, coronillin appears to be actively irritant. In Maramaldi’s experiments it failed to assert its physiological action when administered to the dog by the mouth, a result believed by the investigator to be due to its decomposition by the acid in the stomach. As it has been found by various clinicians to be active in man when given by the mouth, it is probable that the comparative feebleness of human gastric juice permits of its absorption unchanged. The dose given by various clinicians has varied greatly, probably because of differences in purity of the various samples used; of the commercial coronillin the dose is commonly stated at present to be one and one-half grains (0.096 Gm.) from four to six times a day, but it must be noted that Schlagdenhauffen affirms that three-fourths of a grain (0.048 Gm.) is a toxic dose. Coronilla varia of Europe also probably contains coronillin. (V. Poulet, B. G. T., 1891.)

*Corylus.* Corylus rostrata Ait. Beaked Hazel.—This is a small indigenous shrub of the Fam. Betulaceae, growing especially in mountainous districts. The nut is invested with a scaly involucre, projecting beyond it like a beak, and thickly covered with short spicules like those of Mucuna pruriens DC. (Fam. Leguminosae.) These spicules have been employed by Huebener as an anthelmintic. They operate in the same way as cowhage, and may be administered in the same manner and dose. (See A. J. P., xiv, 280.)

According to Baruttan and Davidson (M. M. W., 1909, p. 2482), the hazel-nut contains an alcoholic soluble substance which acts as a stimulant to the uterine muscle. An alcoholic extract is placed upon the market under the name of mensan which these authors have found useful in the treatment of uterine hemorrhages due to chronic endometritis. The dose employed was a tablespoonful twice a day.

*Corydalis.* N. F. IV. Turkey Corn. Squirrel Corn. Bicuculla.—"The dried tubers of Bicuculla canadensis (Goldie) Millspaugh, usually somewhat mixed with the dried bulb-like portions of Bicuculla Cucullaria (Linne) Millspaugh (Fam. Fumariaceae), and without the presence of more than 5 per cent. of other parts of the plants or other foreign matter." N. F. It is described in the N. F. as "the tubers are spheroidal and frequently vertically depressed, the flattened surface more or less concave, up to 15. mm. in diameter; usually single, rarely two or more in a cluster; externally, minutely pitted or nearly smooth; grayish-brown, grayish-black, or amber-colored and more or less translucent; one of the flattened surfaces with a triangular scar from detached roots, the other usually with remains of the slender rhizome; fracture, hard and horny, exhibiting a yellowish, waxy interior, or somewhat tough and granular, exhibiting a yellowish-white interior. The grains of the granulate bulb of Bicuculla Cucullaria are
ovoid or triangular-ovoid and up to 12 mm. in length; the larger grains distinctly concave on one surface, with a scar at the apex from the detached petiole, and usually attached to the short root-stock in clusters of three; the smaller grains usually separated from the root-stock, with an acute apex, and a scar at the base; externally, yellowish or grayish-brown, usually translucent; fracture hard and horny, exhibiting a grayish, waxy interior, or granular and tough, exhibiting a whitish interior. Nearly odorless; taste slightly bitter." N. F. It is said to yield its active properties to water and alcohol. It contains corydaline, corycavine, bulbocapnine, and corydine, all alkaloidal principles. Corydaline, C₂₂H₂₇O₄N, is a tertiary base; corycavine, C₃₃H₂₃O₄N, is a difficultly soluble base; bulbocapnine, C₁₉H₁₉O₄N, which is present in largest amount, was originally called corydaline; corydine is a strong base found in the mother liquor of bulbocapnine. The total amount of alkaloids in the dried bulbs is about 5 per cent. according to Gadarner, who found in addition to the foregoing crystalline alkaloids, corybulbine and several amorphous bases which were not named. The chemistry of these numerous bases is somewhat confused and needs further research work. It is used in the N. F. Compound Elixir of Corydalis, the Fluidextract of Corydalis, and the Compound Fluidextract of Stillingia.

"The powdered drug is light yellow or yellowish-gray and, when examined under the microscope, exhibits numerous oval, ovoid or oblong, simple starch grains, the broad end of the grain sometimes truncate, up to 0.06 mm. in length and frequently with a cleft or horseshoe-shaped fissure in the small end of the grain; occasionally in two-compound grains; altered starch grains up to 0.09 mm. in length; numerous angular or rounded parenchyma cells isolated or in groups and containing more or less altered starch grains the outlines of which are indistinct; tracheae few with reticulate, simple pores, annular or spiral markings; fragments of epidermal cells with thin brownish walls; sclerenchyma fibers very few or absent; few characteristic sclerotic cells from the root-stock of Bicuculla Cucullaria, irregular in outline, mostly elongated up to about 0.75 mm. in length and 0.1 mm. in width, walls heavily lignified and about 0.02 mm. in thickness and porous, occurring isolated or in groups of from two to four; very few sclerotic cells from the rhizome of Bicuculla canadensis, mostly isodiametric, uniformly smaller than in Bicuculla Cucullaria and with walls about 0.012 mm. in thickness, not distinctly irregular in outline; very few rosette aggregates of calcium oxalate, up to 0.02 mm. in diameter, from the portions of rhizome of Bicuculla canadensis. An infusion prepared by placing 5 Gm. of powdered Corydalis in 100 mils of hot distilled water, stirring occasionally during ten minutes and then filtering, is of a light amber color, and gives a precipitate with potassio-mercuric iodide T.S. and a dark blue color with iodine T.S. Corydalis yields not more than 8 per cent. of ash." N. F.

For further information concerning the composition of corydalis, see U. S. D., 19th ed., p. 1414.

The tubers of bicuculla are asserted to be tonic, diuretic, and alterative, and are given in syphilitic, scrofulous, and cutaneous affections, in the dose of from ten to thirty grains (0.65-2.0 Gm.). They are also used in the form of tincture and decoction. Corydalin or corydalia, of the eclectics, is an impure resinous mixture. Fischer and
Svell have found that the Dicentra Cucularia Torr., a plant closely resembling B. canadensis, but producing no tubers, contains three alkaloids, one of which is protopine (Ph. Archiv, No. 7, 1903.)

Makoshi has found in Corydalis ambiguа, which is employed as a medicine in China, a number of the same alkaloids as occur in the above species, and others closely allied to them. (A. Pharm., 1908, ccxvi, p. 387.) According to Heyl (P. J., 1910, lxxv, p. 325) the alkaloid protopine occurs in several species of corydalis, although it is not found in C. cappa.

**Coscinium.** Br. Add.—The dried stem of Coscinium fenestratum Colebr. The stem of this menispermaceous plant has long been used in Ceylon and Southern India as a yellow dye and bitter tonic, and has found its way into Europe under the names of false columba and tree turmeric. It almost certainly contains berberine and is an efficient stomachic. The Br. Add. recognized an infusion (Infusum Coscinii. Br. Add.), dose one-half to one fluidounce (15-30 mils); a concentrated solution (Liquor Coscinii Concentratus, Br. Add.), dose, one-half to one fluidrachm (1.8-3.75 mils); and a tincture (Tinctura Coscinii, Br. Add.), dose one-half to one fluidrachm (1.8-3.75 mils).

**Coto Bark.**—In the years 1873 and 1874 a bark bearing this name appeared in the London drug market, coming from Bolivia. Its botanical origin still remains unknown. Under the name of coto-coto, the bark of a rubiaceous plant (Palicourea densiflora) is employed in Brazil in rheumatism. Whether this be the Bolivian plant or not is uncertain. (See also Paracoto)

Coto bark occurs in pieces 3 dm. or more long, from 3 to 6 cm. wide, and from 5 to 15 mm. thick. The outer surface is irregular, often looking as though it had been shaved or split off, and in other parts covered with a fine adherent corky layer free from lichens; the inner surface also is irregular, with numerous rather closely placed, longitudinal projecting bark bundles.

The general color approaches cinnamon-brown; upon fresh cross-section the bark is seen to be filled with yellowish spots, except in the outer portions. The odor is aromatic, and much more apparent if bruised; the taste hot, and somewhat aromatic; the powder is very pungent to the nostrils. The microscope shows the outer bark to be composed of thin-walled, colorless, parenchymatous cells, containing starch granules, with numerous yellowish sclerenchymatous cells joined into groups. The inner bark contains numerous yellow bark cells, mostly joined into bundles of from twenty to fifty. For microscopic structure, see P. J., vi, 301, also Ph. Era, May, 1888. The coto bark which we have seen in the American market conforms with the original description, but other barks are said to pass under the name. The most important of these is the so-called Paracoto bark, which is stated to differ from the true coto bark chiefly in its having a less pungent but more agreeably spicy taste, and being marked with deep whitish furrows upon its surface. Wittstein found in coto bark a volatile alkaloid, a pungent aromatic volatile oil, yellowish-brown soft resin, brown hard resin, starch, gum, sugar, calcium oxalate, tannin, and formic, butyric, and acetic acids. (A. Pharm., iii, 4, 219.) Jobst and Hesse obtained a crystallizable body, cotoin, from true
coto bark, by making an ethereal extract from the powdered bark, treating this with warm petroleum benzin, and allowing the mixture to stand until clear. The clear liquid yields cotoin in crystals on spontaneous evaporation. The oily resinous residue contains considerable cotoin, which may be obtained by boiling with milk of lime and adding to the solution hydrochloric acid. After twenty-four hours the clear liquid will be found studded with large, glistening, laminated crystals of cotoin, of a pale yellow color. Cotoin (methyl-trioxy-benzophenone), C\(_{14}\)H\(_{12}\)O\(_4\), is sparingly soluble in cold water, more soluble in hot water, insoluble in petroleum benzin, very soluble in alcohol, chloroform, benzol, acetone, and carbon disulphide. Nitric acid becomes blood-red in contact with cotoin, sulphuric acid is colored brownish-yellow, and ferric chloride blackens a dilute solution of cotoin. O. Hesse described a coto bark which did not contain cotoin but cotellin, C\(_{20}\)H\(_{20}\)O\(_6\). (Ph. Ztg., 1905, 845.)

Paracotoin, C\(_{12}\)H\(_8\)O\(_4\), is extracted from paracoto bark, in which it exists associated with hydrocotoin, C\(_{15}\)H\(_{14}\)O\(_4\), protocotoin, C\(_{16}\)H\(_{14}\)O\(_6\), methyl-hydrocotoin, C\(_{16}\)H\(_{16}\)O\(_4\), and methylprotocotoin, C\(_{16}\)H\(_{16}\)O\(_4\). Paracotoin may be distinguished from cotoin by giving no reaction with ferric chloride. Piperonylic acid (methyleneprotocatechuic acid), C\(_{8}\)H\(_6\)O\(_4\), is present in both barks.

Coto bark is decidedly irritating: its powder, rubbed upon the skin, is said to produce heat and redness, and, according to Burkart, fifteen grains (1.0 Gm.) taken into the stomach produce persistent burning pain, followed by repeated vomiting. The remedy was first introduced as serviceable in diarrhea, and seems to have established its reputation. Although observers are not explicit upon this point, it is evident that when there is a tendency to acute inflammation it must be used with great caution. Ippens (D. M. W., 1913, 1827) from his physiological studies concludes that it acts by lessening intestinal peristalsis. The paracoto hark is said to resemble it in its action, but to be much less powerful. The fluidextract and tincture are very eligible preparations, the former made with alcohol in the usual way, and the tincture 1 part in 10 of alcohol, which may be given in from five-to fifteen-minim (0.3-0.9 mil) doses every two or three hours.

The active principle, cotoin, is given by Dr. Burkart in doses of three-quarters of a grain (0.048 Gm.) every two or three hours. He states that he could detect it in the urine from four to six hours after the ingestion of the dose. Balz (Tokio, Japan) is said to have treated cholera successfully by hypodermic injections of three grains (0.2 Gm.) of paracotoin. The value of cotoin in the treatment of diarrhea has been confirmed by various clinicians. It has been used in catarrhal diarrheas and the diarrheas of tubercular ulceration, of typhoid fever, and of other conditions. (See B. G. T., vol. xi, 167.) It does appear to have some special effect upon the alimentary canal, as, according to Pribram (Prager Med. Wochens., 1880) and Albertoni (A. E. P. P., xvii, 293), it markedly lessens the excretion of indican. Albertoni also believes that it actively dilates the abdominal vessels and thereby hastens absorption, and Bibran, that it is an antiseptic. It is not probable that cotoin has any general action upon the system, and Jobst found that even fifteen grains (1.0 Gm.) injected hypodermically into the rabbit produced no other than local symptoms. Dose of cotoin, from one to three grains (0.065-0.2 Gm.); of fluidextract of coto, from five to twenty minims (0.3-
1.3 mils), four to six times a day.

**Cotula.** U. S. 1870. Mayweed. Wild Chamomile. Dog Chamomile. Camomille puante, Maroute, Herbe de camomille puante, Herbel de maroute, Fr. Hunds-Kamille, Hundskamillen-kraut, StinkendeKamille, G. Camomilla fetida, Cotula, It. Manzanilla loca, Sp. Herba Chamomillae Foetidae. Anthemis Cotula L.—Mayweed is an annual composite plant, which grows abundantly both in the United States and in Europe. In this country it is found in the vicinity of inhabited places, growing among rubbish, along the sides of roads, and in waste grounds. W. H. Warner found in the flowers volatile oil, oxalic, valeric, and tannic acids, coloring matter, acrid fatty matter, bitter extractive, and salts of potassium, calcium, magnesium, and iron. (A. J. P., 1858, 390.) Pattone (1859) claimed to have found an alkaloid, anthemidine, and a crystallizable bitter acid, anthemidic acid, but his results have not been confirmed. The whole plant has a strong, disagreeable odor, and a warm, bitter taste, and imparts these properties to water.

The medicinal properties of this species of Anthemis are essentially the same as those of chamomile, for which it may be substituted, but its disagreeable odor is an obstacle to its general use. On the continent of Europe it has been given in hysteria as an antispasmodic. It has also been thought to be emmenagogue. It is said to have the property of vesicating, if applied to the surface fresh and bruised. The whole plant is active, but the flowers, being less disagreeable than the leaves, are preferred for internal use. The remedy is best administered in the state of infusion.

**Cotyledon Umbilicus** L. Navelwort. Pennywort. Cotylet, Nombril de Venus, Fr. Nabelkraut, G.—This is a perennial, herbaceous, succulent plant, of the fam. Crassulaceae. The plant is a native of England, where it grows upon old walls and rocks, and dry sandy banks.

According to Flettet, it contains trimethylamine, combined with an unknown acid. When the powder of the plant is exposed to the air, it attracts moisture, and exhalas a disagreeable odor strikingly analogous to that of fish, and an extract treated with a fixed alkali disengages, even in the cold, an odor which, at first ammoniacal, soon acquires the fishy character referred to. The plant contains cellulose, starch, glucose, mucilage, chlorophyll, yellow coloring matter, a volatile oil of a sandarac-like odor, tannin, iron, and salts of potassium, sodium, calcium, and iron, with 0.9 per cent. of nitre, and 95 per cent. of water. (Ann. Ther., 1865, 125.) It has been highly lauded in epilepsy (for references, see 16th edition U. S. D.); but it has very feeble and uncertain therapeutic properties. Dose, of fresh juice, from one-half to one fluidounce (15-30 mils), two or three times a day; of fluidextract, one fluidrachm (3.75 mils); of dry extract, five grains (0.32 Gm.); to be increased and given steadily for months.

**Cow Tree.** Palo de Vaca. Palo de Leche.—The milky juice of the Brosimum Galactodendron, D. Don (fam. Urticaceae) is much used in South America instead of cream in tea and coffee, etc. It is obtained by making incisions in the tree, is white and viscous, turns sour on exposure to the air, and deposits a caseous substance. According to the analysis of Boussingault, its composition varies very much, but it
always contains a large percentage of fatty matters (32.2 per cent.), and much less casein, albumen, sugar, and phosphates. (P. J., ix, 67-9.)

**Cranberries.** Fruit of Vaccinium macrocarpon Aiton. (Fam. Ericaceae)—These familiar berries, so well known as an article of diet, have come into notice as a source of citric acid. For method, see J. P. C., 4e ser., xviii, 439. The leaves of the Vaccinium Vitis-idaea (L.) have been studied by Edo Claassen (A. J. P., 1886) and A. M. Karger (P. J., vol. lxx). They contain arbutin, hydroquinone, and tannin. Benzoic acid has also been recognized as normally present in small amounts. In the cranberry, Edo Claassen found an uncrystalizable glucoside, oxycccin.

**Crescentia.** Crescentia Cujete L.—The fruit of this West Indian and South American plant (fam. Bignoniaceae) has been found by Gustav Peckoldt to contain crescentinic acid and a blue coloring matter allied to indigo. (Ph. Rund., Aug., 1884.)

**Crocus.** N. F. IV. Saffron. Stigmata, Croci. Spanish Saffron, Safran, Fr. Cod. Crocus, P. G. Safran, G. Zafferano, It. Azafran, Sp.—"The stigmas of Crocus sativus, Linne (Fam. Iridaceae), without the presence of more than 10 per cent. of the yellow styles or other foreign matter." N. F. IV. "The dried stigmas and tops of the styles of Crocus sativus, Linn." Br., 1898. Crocus was dropped at the 1914 revision of the British Pharmacopoeia and the ninth U. S. P. revision. It has been recognized by the National Formulary IV.

Crocus sativus is a perennial plant, with a rounded and depressed bulb or corm, from which the flower rises a little above the ground, upon a long, slender, white, and succulent stem. The flower is large, of a beautiful lilac or bluish-purple color, and appears in September or October. The leaves are radical, linear, slightly revolute, dark green upon their upper surface, with a white longitudinal furrow in the center, paler underneath, with a prominent flattened midrib, and enclosed at their base, together with the tube of the corolla, in a membranous sheath, from which they emerge soon after the appearance of the flower. The style hangs out on one side between the two segments of the corolla, and terminates in three long convoluted stigmas, which are of a rich orange color, highly odorous, rolled in at the edges, and notched at the summit. The stigmas of the Crocus orientalis are used in the East.

C. sativus, or autumnal crocus, is believed to be a native of Greece and Asia Minor, where it has been cultivated from the earliest ages. There are three main varieties of it, the French, the Grecian, and the Chinese. The first of these is superior in color and flavor, the second in the amount of yield, while the third is said to unite these qualities. Saffron is also cultivated for medicinal use in Sicily, Spain, France, England, and other temperate countries of Europe. Large quantities of saffron are raised in Egypt, Persia. We cultivate the plant in this country chiefly as a garden flower, although some of the drug of very fine quality has been produced in Pennsylvania; the high cost of labor in America will probably prevent the possibility of its coming into commerce. Wild saffron is found growing in uncultivated fields in Southern Russia; Tichomirow believes that these are varieties of C. sativus and C. speciosus Marsh. Biebr., var. ß-Pallassii (C. Palassii Marsh. Biebr.). He further states that wild saffron from these
In England the flowers appear in October, and the leaves continue green through the winter; but the plant does not ripen its seed, and is propagated by offsets from the bulb. The flowers are gathered soon after they show themselves, as the period of flowering is very short. The stigmas, or summits of the pistils, together with a portion of the style, are separated from the remainder of the flower, and carefully dried by artificial heat, or in the sun. During this process they are sometimes made to assume the form of a cake by pressure; but the finest saffron is that which has been dried loosely. The two forms are distinguished by the names of cakesaffron and hay saffron. Five pounds of the fresh stigmas are said to yield one pound of the dried. The English saffron, formerly most highly esteemed in this country, has disappeared from our market; what may be sold under the name is probably derived from other sources. For an account of the cultivation in England, see P. J., June, 1887. The Spanish saffron is generally considered the best in the United States, although most European writers on Materia Medica give the preference to the French saffron. The better grades of Spanish saffron are known as Valencia saffron, while Alicante saffron was said by Maisch to contain scarcely more than 50 per cent. of genuine saffron. According to Landerer, the stigmas of several other species besides those of C. sativus are gathered and sold as saffron in Greece and Turkey.

Properties.—Saffron has a peculiar, sweetish, aromatic odor, a warm, pungent, bitter taste, and a rich deep orange color, which it imparts to the saliva when chewed. It is described in the N. F. as follows: "Stigmas 3, united or separate, attached to the summit of the style; usually about 25 mm. in length, cornucopia-shaped, of a dark, rich red color, the margin dentate or fimbriate; styles about 10 mm. in length, more or less cylindrical, solid, yellowish. Odor strong, peculiarly aromatic; taste bitterish, aromatic. When chewed it colors the saliva orange-yellow. Under the microscope, the upper end of the stigma shows numerous cylindrical papillae about 0.15 mm. in length, among which occur a few spherical pollen grains, the latter being nearly smooth, and sometimes up to 0.07 mm. in diameter; occasionally some of the pollen grains have germinated and show pollen tubes. When placed in sulphuric acid, the stigmas are immediately colored blue, gradually changing to violet, and finally become a deep wine-red color. Add 0.01 Gm. of finely powdered Crocus to 100 mils of cold water, allow it to macerate for several hours and filter; on adding 10 mils of this filtrate to 100 mils of water, it gives a distinctly yellow-colored solution. Macerate 0.01 Gm. of Crocus in 5 mils of methyl alcohol; a deep orange color is imparted to the liquid. Macerate 0.01 Gm. of Crocus in 5 mils of acetone, alcohol, or dehydrated alcohol; a distinct lemon-yellow color is produced. With corresponding quantities of Crocus and ether a very light lemon-yellow color is produced. With corresponding quantities of Crocus and chloroform a very slight, yellow tinge is imparted; and with corresponding portions of Crocus and xylene, benzene, carbon disulphide, or carbon tetrachloride, the solvents remain colorless. When Crocus is pressed between filter paper, the paper does not display transparent spots due to the absorption of oil. It loses not more than 14 per cent. of its weight when dried at 100° C. (212° F.). Crocus yields not more than 7.5 per cent. of ash and the ash is not fusible." N, F. The following tests were given in the Br., 1898: "Incinerated with free access of air, dried Saffron does not deflagrate (absence of nitrates), and yields about 7 per cent. of ash. It should not lose more than 12.5 per
cent. of moisture when dried at 212° F. (100° C.)."

Analyzed by Vogel and Bouillon-Lagrange, saffron afforded 65 per cent. of a peculiar extractive matter, which they named polychroite, but later researches have shown that it is a mixture of the glucoside crocin, sugar, and essential oil. (Planchon, Drogues Simples, vol. i, 210.) Kayser obtained (Ber. d. Chem. Ges., 1884, 2228) pure crocin, having the formula $\text{C}_{44}\text{H}_{70}\text{O}_{28}$ as a yellow powder, easily soluble in water and diluted alcohol, only slightly soluble in absolute alcohol, and giving with concentrated sulphuric acid a deep blue color, which turns violet, then cherry-red, and finally brown. It is easily decomposed by lime or baryta water into crocetin, and a dextro-rotatory sugar which Kayser calls crocose. The crocetin is a red powder, not soluble in water, but easily soluble in alcohol and ether. Its solution in alkalies shows an orange-yellow color, from which solution acids separate it again in orange-colored flecks. Its formula is $\text{C}_{34}\text{H}_{46}\text{O}_{9}$, or, according to Schmuck and Marchlewski, $\text{C}_{15}\text{H}_{20}\text{O}_{4}$; Kayser also found a colorless bitter principle, to which he gave the name picro-crocin or saffron bitter, and the formula $\text{C}_{38}\text{H}_{66}\text{O}_{17}$ which is also of glucoside character. Saffron contains, according to Henry, about 10 per cent. of essential oil. This has the formula $\text{C}_{10}\text{H}_{14}\text{O}$, boils at 208° to 210° 0. (406.4°-410° F.), is yellow, of a hot, acrid, bitterish taste, and heavier than water.

The high price of this medicine gives rise to frequent adulterations. Water is said to be very often added in order to increase its weight. Oil or glycerin is also added for the same purpose, or to improve the appearance. In some specimens the dyed corolla of the crocus with the attached stamens is abundant. Sometimes the flowers of other plants, particularly Carthamus tinctorius, or safflower, Calendula officinalis, or marigold, and arnica are fraudulently mixed with the genuine stigmas. They may be known by their shape, which is rendered obvious by throwing a portion of the suspected mass into hot water, to expand them. (See Carthamus.) A specimen of this adulteration was at one time introduced into the American market, by the name of African Saffron. (Maisch, A. J. P., March, 1872, p. 110.) Other adulterations are the fibers of dried beef, the stamens of the crocus, distinguishable by their yellow color, the stigmas previously exhausted in the preparation of the infusion or tincture, and various mineral substances, easily detected upon close examination. The flowers of a Brazilian plant named Feminella, or Feminelle, have, according to M. J. L. Soubeiran, been employed for the adulteration of saffron. They may be detected by shaking, gently but repeatedly, a large pinch of the suspected saffron over a piece of paper. The flowers of Feminella, being smaller and heavier, separate and fall, and may be seen to consist of very short fragments, with a color like that of saffron, but a rusty tint which the latter does not possess. (See Ph. Rev., 1898, 258.) The name Feminelle is also applied in commerce to the dyed styles of crocus or ligulate flowers of Calendula. J. Muller recommends concentrated sulphuric acid as the most certain test of saffron. It instantly changes the color of pure saffron to indigo blue. (Chem. Gaz., May, 1845.) An adulteration which has been largely practised appears to consist of yellow-colored chalk or barium sulphate, made into a thin paste, probably with honey, and attached to the stigmas, sometimes isolated, sometimes in groups of five or six, enveloping them almost completely. If this saffron be kept in a dry place, and often handled, the paste becomes partly broken up, and the colored powder
spreads itself in the mass and the envelope. The chalk can at once be detected by shaking the suspected saffron with water, and treating the precipitated powder with hydrochloric acid, when effervescence will occur. A less than the ordinary brightness of color in the saffron should lead to suspicion of this adulteration. Much can be told as to the purity of saffron by agitating the suspected flowers in distilled water; if the drug be pure the liquid will remain clear, slowly assuming a fine pure yellow tint; the saffron also will retain its red color for hours. Another excellent plan is to scatter a pinch of the flowers upon the surface of warm water, when the stigmas should spread out and display their proper form. Minute fragments of red saunders, which are often added to saffron, may be separated by agitating with water. For an elaborate discussion of adulteration, see article by Kraemer, A. J. P., 1898, p. 386.

Adulterations of crocus may sometimes be detected by remembering that the pollen grains are spheroidal, nearly smooth, and from 0.040 to 0.075 mm. in diameter. In various European markets there has been offered a saffron largely adulterated with borates, chlorides, and other salts of sodium and potassium, and yet retaining the physical properties of saffron of high character. These and other adulterations with inorganic salts can be detected by the amount of ash left on burning, genuine saffron leaving from five to seven per cent. This saffron also yielded immediately to water an orange-yellow color. Further, some of it at least was hygroscopic, so that when rubbed up between the fingers into a ball it retained that form instead of being elastic as is true saffron.

Attention has been called to a product of the Cape of Good Hope, named Cape saffron, which has a remarkable resemblance to genuine saffron, having a similar odor, and yielding a similar color to water, though the flowers themselves are differently colored. It is the flower of a small plant very abundant at the Cape, belonging to the family of Scrophulariaceae, and is said by Pappe of Cape Town, to possess medicinal virtues closely resembling those of true saffron. The flowers have been used successfully in the convulsions of children. (P. J., vi, 462, 1865.)

Choice of Saffron.—Saffron should not be very moist, nor very dry, nor easily pulverized; nor should it emit an offensive odor when heated upon a porcelain dish. The freshest is the best, and that which is less than a year old should, if possible, be selected. It should possess in a high degree the characteristic properties of color, taste, and odor. When agitated with water it should color it bright yellow, and it should not effervesce in the presence of a diluted acid. If it does not color the fingers when rubbed between them, or if it has an oily feel, or a musty flavor, or a black, yellow, or whitish color, it should be rejected. In the purchase of this drug in cakes, those should be selected which are close, tough, and firm in tearing; and care should be taken to avoid cakes made up of safflower.

As its activity depends, partly at least, on a volatile ingredient, saffron should be kept in well-stoppered vessels. Some recommend that it should be enclosed in a bladder and introduced into a tin case.

Saffron was extensively used by the ancients and by medieval physicians, as a highly stimulant antispasmodic and even narcotic emmenagogue, and is still employed to some extent upon the Continent; but in Great Britain and the United States it has been...
fallen into well deserved and almost complete desuetude. In domestic practice saffron tea is occasionally used in exanthematous diseases, to promote the eruption. At present it is chiefly used to impart color and flavor. Saffron should be preserved in tightly-closed containers protected from light.

A tincture of saffron is recognized in the N. F. and it is also an ingredient of several compound pills and tinctures.

Dose, from ten to thirty grains (0.65 to 2.0 Gm.).

Cryptocarya. Cryptocarya australis Bentham. (Fam. Lauraceae) —From the bark of this Queensland tree, T. L. Bancroft (Austral. Journ. Pharm., March, 1887) has separated an alkaloid which is said to be a powerful respiratory poison.

**CUBEB. U. S. (Br.)**

**CUBEB Cubeb. [Cubebs]**

"The dried, full-grown, unripe fruits of Piper Cubeba Linne filius (Fam. Piperaceae), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." U. S. "Cubebs are the dried full-grown unripe fruits of Piper Cubeba, Linn. fil." Br.

**Cubebae Fructus**, Br.; Fructus (s. Baceae) Cubebæ, Piper Caudatum; Cubeba, Tailed Pepper; Cubebe, Cubebe ou Poivre a Queue, Fr. Cod.; Cubebæ, P. G.; Kubeben, G.; Pepe Cubebe, Cubebe, It.; Cubeba, Sp.; Kebabeh, Ar.

Piper Cubeba is a climbing perennial plant, with a smooth, flexuous, jointed stem, and entire, petiolate, oblong or ovate-oblong, acuminate leaves, rounded or obliquely cordate at the base, strongly nervèd, coriaceus, and very smooth. The flowers are dioecious and in spikes, with peduncle's about as long as the petioles. The fruit is a globose, pedicelled drupe. This species of Piper is a native of Java, Penang, and probably other parts of the East Indies. It is extensively grown in the coffee plantations, supported by the trees which are used for shade, and has been introduced into Ceylon. The dried unripe fruit is the official portion. Our knowledge of the false cubeb of commerce up to 1894 was epitomized in the 17th edition of the U. S. D., p. 457. To this account the reader is referred for historical details. (See also U. S. D., 19th ed., p. 410.)

**Properties.**—Cubeb is officially described as follows: " Upper portion globular, from 3 to 6 mm. in diameter, with a straight, slender stem-like
portion, from 5 to 7 mm. in length; pericarp externally grayish, brownish, or bluish-black; coarsely reticulate; about 0.3 mm. in thickness, easily cut, 1-locular, 1-seeded; the immature seed attached at the base of the pericarp; odor aromatic, characteristic; taste strongly aromatic and pungent. Under the microscope, sections of Cubeb show an epidermal layer of tabular cells with thickened, undulate outer walls, the contents being olive-green; 1 or 2 rows of parenchyma cells, the contents resembling those of the epidermal cells; a continuous layer of radiately elongated, thick-walled stone cells having numerous pores; a few layers of collapsed cells near which may occur an occasional small group of bast-fibers; a middle layer of 10 rows of cells composed chiefly of parenchyma, scattered among which are numerous secretion cells containing a volatile oil and occasionally crystals in the form of short rods, the contents of the secretion cells being colored a deep crimson upon the addition of sulphuric acid; an endocarp of small, somewhat isodiametric or polygonal stone cells with very thick porous walls; seed-coat of several rows of reddish-brown, tangentially elongated, more or less collapsed cells; perisperm of numerous thin-walled parenchyma, the cells being more or less polygonal in shape and containing either small compound starch grains, or globules of a fixed oil or occasionally a crystal of calcium oxalate. The powder is light brown to blackish-brown, consisting of a more or less even distribution of starch-bearing cells of the pericarp and fragments of the pericarp with stone cells; starch grains numerous, single or compound, from 0.002 to 0.012 mm. in diameter; stone cells numerous in palisade-like groups, in surface view rounded or polygonal with rather prominent dark lumina and yellowish porous walls; secretion cells with a yellowish, oily content, becoming reddish on the addition of sulphuric acid; fragments of stalk few, with spiral trachea and groups of sclerenchymatous fibers from 0.05 to 1 mm. in length with blunt, rounded, or very much attenuated ends, the walls strongly lignified and with numerous oblique pores. Cubeb yields not less than 10 per cent. of volatile extractive, soluble in ether (see Part III, Test No. 12). Cubeb yields not more than 8 per cent. of ash."

"Nearly globular, about four millimetres in diameter, greyish-brown or nearly black. Pericarp reticulately wrinkled, thin, brittle, and abruptly prolonged at the base into a slender, rounded stalk about one and a half times as long as the globular portion. Seed almost spherical, sometimes much shrivelled, attached by the base. In the transverse section of the pericarp two layers of sclerenchymatous cells, one near the outer, the other near the inner surface, those of the latter being radially elongated
and usually arranged in a single row. Strong, aromatic, and characteristic odor; taste warm, aromatic, and somewhat bitter. When 2 grammes of powdered Cubebs are macerated with 20 millilitres of ether for twenty-four hours, and shaken occasionally, 10 millilitres of the clear ethereal solution, allowed to evaporate in a flat-bottomed dish, yield a residue which, dried for one hour in a desiccator over sulphuric acid, weighs not less than 0.200 gramme." Crushed Cubebs impart a crimson color to sulphuric acid. Ash not more than 8 per cent." Br.

Commercial cubebs are not infrequently admixed with and entirely substituted by other fruits, some of which contain volatile oils which possess very different properties from the genuine oil of cubeb, being in some instances highly toxic. Hartwich (Arch. d. Pharm., 1898, Heft 3; also p. 172) gives the following classification for the identification of spurious fruits:

I. Fruits of the Piperaceae having slender stalks.

   A. STONE CELLS IN EPICARP, ENDOCARP AND DISTRIBUTED IN THE MESOCARP:
      Piper ribesiioides Wallich (identical with Padang Cubeb). Fruits not colored red with sulphuric acid.

   B. STONE CELLS ONLY PRESENT IN THE EPICARP AND ENDOCARP:
      (a) Stone cells of the endocarp radially elongated.
          Piper Cubeba L.f. Seed attached only at the base of the pericarp.
          a Rinoe Katoentjor, the official variety, which is colored red with sulphuric acid.
          ß Rinoe badak, distinguished by not being colored red with sulphuric acid.
      (b) Stone cells of the endocarp of iso-diametric form.
          Piper crassipes Korthals. Sections not colored red with sulphuric acid.
      (c) Stone cells of the endocarp thickened like a. horseshoe.
          Piper a court pedicelle. Origin unknown.

   C. STONE CELLS PRESENT ONLY IN THE EPICARP:
      (a) Fruit with stem 3 cm. in length, the stem-like portion being alone 17 mm. long.
          Piper mollissimum Blume (Keboe Cubeb. Karbauw berries) sections
not colored red with sulphuric acid.
(b) The fruits and stems much smaller, but distinguished by having radially elongated stone cells.
Piper venosum DC. colored red with sulphuric acid.

D. STONE CELLS ABSENT IN THE PERICARP:
(a) African varieties:
1. Fruit without stem 5 to 6 mm. long, stem-like portion equally long.
   a. Piper clussi DC., sections colored red with sulphuric acid.
   ß. Piper guineense Schum. sections not colored red with sulphuric acid.
2. Fruits 4 mm. long, 2 to 3 mm. thick and stems 6 mm. long.
Piper borbonense DC. (Cubebe du pays) sections not colored red with sulphuric acid.
(b) Indian varieties: None of which are colored red with sulphuric acid.
a. Stems flattened.
Piper Lowong Blume. Secretion cells colored bluish-green with sulphuric acid.
Ceylon pepper. Secretion cells colored yellow with sulphuric acid.
ß. Stem-like portion cylindrical.
Piper canium Blume and P. phyllostitum DC.

II. Fruits of the Piperaceae without stalks.

A. STONE CELLS PRESENT IN EPICARP AND ENDOCARP:
1. Piper nigrum L. Stone cells of epicarp radially elongated and sections colored red with sulphuric acid.
2. Cubebe de Jaba sauvage. Stone cells of the epicarp not radially elongated.

B. STONE CELLS ONLY IN THE EPICARP:
   Dangdang boeroeng. A fruit obtained from Java, the origin of which is unknown.

C. STONE CELLS ABSENT IN PERICARP.
   Cubeb from Bangil, origin unknown. Sections at first colored red with sulphuric acid, then becoming brown.

III. Fruits obtained from plants belonging to other families than the
Piperaceae.
1. Xanthoxylum Budrunga Wall. (Fagara Budrunga Roxb.) (Rutaceae).
2. Bridelia tomentosa Bl. (Euphorbiaceae).
3. Tetranthera citrata N. v. Esenbeck (Litsea citrata Bl.) (Lauraceae).
4. Daphnidium Cubeba Nees. (Lauraceae).
5. Pericampylus incanus Miers. (Menispermacæae).
7. Helicteres hirsuta Bl. (Sterculiaceae).

** Constituents.**—The most obvious constituent of cubeb is the volatile oil, the proportion of which yielded by the drug varies from 4 to 13 per cent. It is, as shown by Oglialoro, a mixture of a terpene, C\(_{10}\)H\(_{16}\), boiling at 158° to 163° C. (316.4°-325.4° F.), which is present in very small amount, and is probably pinene or camphene, some dipentene, and two oils of the formula C\(_{15}\)H\(_{24}\), boiling at 262° to 265° C. (503.6°-509° F.). One of these, known as cadmene, is strongly laevogyrate, and yields a crystallized compound having the formula, C\(_{15}\)H\(_{24}\)HCl, and melting at 118° C. (244.4° F.), while the other is less laevogyrate, and does not combine with HCl.

The oil distilled from old cubeb on cooling at length deposits large transparent inodorous octahedra of camphor of cubeb, C\(_{15}\)H\(_{25}\)O. E. Schmidt found that this camphor melts at 66.5° C. (152° F.); simply by standing over sulphuric acid, more rapidly on heating, it gave up water and passed into that fraction of cubeb oil which boils at 260° C. (500° F.), of which it is, therefore, simply the hydroxide. Another constituent of cubeb is cubebin. This is an inodorous substance, crystallizing in small needles or scales, melting at 125° C. (257° F.), having a bitter taste in alcoholic solution, it dissolves freely in boiling alcohol, but deposits on cooling, and is abundantly soluble in chloroform. Its composition, according to Weidel (1877), is C\(_{10}\)H\(_{10}\)O\(_3\), and its structural formula,
sium hydroxide it yields proto-catechuic acid. The resin extracted from cubeb consists of an indifferent portion, nearly 3 per cent., and of cubebic acid, $C_{13}H_{14}O_7$, amounting to about 1 per cent. (Pharmacographia, 2d ed., p. 587.)

The formula of cubebic acid as just given is that of Schmidt. Schultze (Jahresbericht, 1873, p. 863), on the other hand, gives to it the formula $C_{28}H_{30}O_7+H_2O$. According to Capitaine and Soubeiran, cubebin is best obtained by expressing cubeb from which the oil has been distilled, preparing from the marc an alcoholic extract, treating this with a solution of potassium hydroxide, washing the residue with water, and purifying it by repeated crystallizations in alcohol. In the official oleoresin of cubeb a deposit takes place consisting chiefly of cubebin, which may be obtained by washing the deposit with a small quantity of cold alcohol to remove adhering resin and oil, and then dissolving repeatedly in boiling alcohol, and crystallizing until the product is white. E. Schaer calls attention to the similarity in reaction between cubebin and veratrine, aconitine, morphine, and digitalin. (A. Pharm., 1887, p. 531.) The volatile oil is official. (See Oleum Cubebae.) By practical trial Bernatzik has satisfied himself that the peculiar virtues of cubeb as a remedy in gonorrhoea depend not on the cubebin or the volatile oil, but on the cubebic acid. When the ethereal extract of cubeb is deprived of its volatile oil by evaporation on a water bath, and of cubebin and wax by deposition, a soft resin is left, the cubebic acid of Bernatzik, in which, according to F. V. Heydenreich, who experimented with it as a physiological agent, the diuretic properties reside, the cubebin being without apparent effect, and the volatile oil, though stimulant and carminative, having no diuretic action. The soft resin, which was of the consistence of honey, of a dark olive-green color, and some remaining odor of cubeb, when taken in the dose of ten grains every two hours for six hours, acted as a laxative, and gave the urine a peculiar odor, without increasing its quantity; but in the dose of a drachm, once repeated at an interval of three hours, while it produced the same effects as the smaller dose, it considerably augmented the urine. In still larger doses it produced decided irritation of the urinary passages. (A. J.
Heydenreich's experiments are confirmatory of Bernatzik's conclusion as to the peculiar active principles of cubeb. Cubeb gradually deteriorates by age, and in powder becomes rapidly weaker, in consequence of the escape of its volatile oil. It should be kept whole, and pulverized when dispensed. The powder is said to be sometimes adulterated with that of pimenta.

**Uses.**—Cubeb is generally stimulant, with a special direction to the urinary organs. In considerable quantities it excites the circulation, increases the heat of the body, and sometimes occasions headache and giddiness. At the same time it frequently produces an augmented flow of the urine, to which it imparts a peculiar odor. Among its effects are also occasionally nausea and moderate purging, and it is said to cause a sense of coolness in the rectum during the passage of the feces. We have no evidence that it was known to the ancients. It was probably first brought into Europe by the Arabians, and was formerly employed for similar purposes as black pepper, but it was found much less powerful and fell into disuse. In India it has long been used in gonorrhea and gleet, and as a grateful stomachic and carminative in disorders of the digestive organs, and it is at present very frequently given both in this country and in Europe in gonorrhea, after the subsidence of the first active inflammatory symptoms. It has been given also in leucorrhœa, cystorrhea, the urethritis of women and female children, abscess of the prostate gland, piles, and chronic bronchitis. In connection with copaiba it has been especially recommended in affections of the neck of the bladder and the prostatic portion of the urethra.

It is best administered in powder, of which the dose in gonorrhea is from one to three drachms (3.9-11.6 Gm.) three or four times a day. The volatile oil may be substituted, in the dose of ten or twelve minims (0.6-0.7 ml), suspended in water by means of sugar, although the oleo-resin is generally preferred. (See Oleoresina Cubebae.) An infusion, made in the proportion of an ounce of cubeb to a pint of water, has been employed as an injection in discharges from the vagina.

Dose, of powdered cubeb, ten grains to one drachm (0.65-3.9 Gm.).

Pilulas Antiperiodicæ sine Aloes, N. F.; Tinctura Antiperiodica, N. F.; Tinctura Antiperiodica sine Aloes, N. F.; Tinctura Cubebæa, N. F.

**Cucurbita.** Citrullus vulgaris Schrad. Watermelon.—The seeds of the watermelon are employed, to a considerable extent, as a domestic remedy in strangury and other affections of the urinary passages. Power and Salway(-P. J',. Ixxxiv, 760) found in watermelon seeds a fixed oil very similar to that which is found in pumpkin seeds. The Russian peasants are said to employ watermelon in the treatment of dropsy, urino-genital affections, chronic hepatic congestion, and chronic intestinal catarrh. Manassein (Vratch, Nov., 1881), found that the melon honey acts upon the lower animals as a very powerful diuretic, and causes, when in sufficient dose, fall of the arterial pressure, rapid pulse, and death from cardiac paralysis. A resin, extracted in the amount of 0.3 per cent. from the press cake of watermelon seed, when administered to a dog in doses of 1 gramme exhibited no physiological activity. A chemical examination of this resin led, however, to some results of interest, inasmuch as it yielded, besides a little phytosterol, a new crystalline alcohol, $C_{24}H_{40}O_4$, which has been designated cucurbitol.

The pulp of the root of Lagendaria vulgaris, or gourd, is said by Chapin to be a powerful and even drastic purgative, and to be used by the natives of the Sandwich Islands successfully in the treatment of dropsy. (See N. Y. Journal of Med., 1855, 203.)

**Cudbear.** N. F. IV. Persia. Orsell de terre, Fr.—"A purplish-red powder prepared from species of Roccella De Candolle, Lecanora Acharius, or other lichens." N. F. IV. Cudbear is described in N. F. IV as follows: "An aqueous or alcoholic preparation of Cudbear is of a deep red color which is rendered lighter in tint by the addition of acids and changed to purplish-red on the addition of alkalies. Agitate 2 Gm. of Cudbear occasionally with 200 mils of water during thirty minutes and then filter; the deep red-colored filtrate conforms to the following tests: Add to 5 mils of the filtrate 5 drops of glacial acetic acid and boil for one minute; then add 5 drops of stannous chloride T. S., and boil again for one minute; the liquid is only faintly pink (brazilwood or logwood which produce solutions of a deep red color); add 25 Gm. of kaolin to 100 mils of the filtrate in an Erlenmeyer flask, shake frequently during one hour and then filter; the filtrate is almost entirely decolorized in comparison with some of the original filtrate (a number of coal tar colors). Cudbear yields not more than 35 per cent. of ash, consisting mainly of sodium chloride." N. F. IV.

Cudbear was introduced into the National Formulary solely for coloring liquids. Two preparations were made official, Tinctura Persionis, N. F. IV (Tincture of Cudbear) and Tinctura Persionis Composita (Compound Tincture of Cudbear). Both tinctures are used to give a deep red color to syrups, tinctures, solutions, and elixirs of the National Formulary. George M. Beringer has given much attention to cudbear with a view of securing a uniform product. (See Proc. New Jersey Pharm. Assoc., 1912, 56.) He declares that all of the ordinary methods, as color charts, colored yarns, threads, glass, etc., are unsatisfactory and inapplicable to pharmacy. He advocates the preliminary purification of cudbear by washing it with water to remove the sodium.
chloride so largely used as a diluent and the ammonium salts with their empyreumatic odor. He states that if the washing is properly done the cudbear loses scarcely any of its tinctorial power. He gives a table showing comparative values of eight tinctures prepared with various menstrua. He believes that the best results, however, would follow the preparation and use of a standard extract. Alexander Gardner gives the name persionin to an acetone extract of cudbear made as follows: The process consists in percolating commercial cudbear with purified benzine until free from wax, then drying the drug, repacking it in a percolator and percolating it with acetone to exhaustion—about 2500 mils being required for 1000 Gm. of cudbear. The acetone is recovered by distillation, the residual extract heated for thirty minutes to 98.8° C. (210° F.) in a porcelain capsule, then pulverized and placed in a sulphuric acid desiccator for three days, during which it loses about 25 per cent. of its weight. So obtained, "persionin" is a black, lustrous powder with an aromatic odor, soluble in alcohol, glycerin, chloroform, ether, and hydro-alcoholic liquids, but is only sparingly soluble in water. Five different lots of cudbear yielded, respectively, 6.5, 7, 6, 5, and 5.5 per cent. of persionin. Each sample of "persionin" was tested by dissolving 1 part in 100 parts of alcohol and 3 parts of glycerin. One mil of this was added to 99 mils of distilled water, and in each particular the color was the same. (J. A. Ph. A., 1913, 51-52.) H. V. Arny (J. A. Ph. A., 1913, 47) proposes to remove a brown pigment present in cudbear (which interferes with the tinctorial power) by macerating an alcoholic extract with chloroform and extracting the residue with acetone. The final product is then "scaled."

Because of the difficulty of completely extracting cudbear the liquid preparations are rarely uniform in color value. For this reason the N. F. uses powdered cudbear in several preparations, allowing it to macerate until all color is extracted. This plan results in more uniform coloring than if the tincture was directed.

**Culilawan.** Cortex Culilaban.—An aromatic bark, produced by Cinnamomum Culilawan, Blume (Laurus Culilawan. L.), (Fam. Lauraceae), a tree of considerable size, growing in the Molucca Islands, Cochin-China, and other parts of the East. It is usually in flat or slightly quilled pieces, 5 to 10 cm. long, 2.5 to 3.5 cm. wide, and 2 to 4 mm. thick. Sometimes the bark is thinner and more quilled, bearing considerable resemblance to cinnamon. The periderm is for the most part removed, but when present is of a light brownish-gray color, soft to the touch, and somewhat spongy. The color of the bark itself is a dull, dark, cinnamon brown, the odor highly fragrant, the taste agreeable, aromatic, and not unlike that of cloves. The active constituent is a volatile oil, smelling like a mixture of the oils of cajuput and cloves. Culilawan has the medicinal properties of the aromatics, but is rarely used. (See Cortex Caryophyllata.)

**Cumin.** Cyminum Lond. Cuminum Ed. Cumin, Fr. Kreuzkummel, Mutterkummel, Romischer (langer, scharfer) Kummel, G.—The so-called cumin seeds are the fruit of the Cuminum Cyminum L., an annual umbelliferous plant, which is a native of Egypt, but is cultivated for its fruit in Sicily, Malta, and other parts of Europe.

The cumin fruits (seeds) are elliptical, flat on one side, convex, furrowed, and rough on
the other, from 5 to 6 mm. in length and about 1.5 mm. in thickness, and of a light brown color. Each has seven longitudinal ridges. Two mericarps are sometimes seen united. Their odor is peculiar, strong, and heavy; their taste warm, bitterish, aromatic, and disagreeable. They contain about 2.5 per cent. of an essential oil, which is lighter than water, yellowish, and has the sensible properties of the fruits. It consists of three distinct oils, one a hydrocarbon, cymene, C\textsubscript{10}H\textsubscript{14}, recognized now as isopropyl-p-methyl-benzene, another cuminol, C\textsubscript{10}H\textsubscript{12}O, which may be regarded as cuminic aldehyde, C\textsubscript{10}H\textsubscript{11}OH, and the third a terpene, C\textsubscript{10}H\textsubscript{16}. Dumas, a long time since, obtained a cymene identical with that of oil of cumin seeds, by dehydrating camphor, and Paterno prepared it in a similar way from oil of turpentine. (J. P. C., 4e ser., xx, 409.) In his discovery Paterno seems, however, to have been preceded by seven chemists, O. R. A. Wright apparently having the priority. (A. J. P., xlvi, 117; see especially A. J. P., xlv, 452.) Cumin aldehyde has also, together with cymene, been obtained from the fruits of Cicuta virosa L. (Trapp, Ann. Ch., Ph., cviii, 386; see also Schim. Rept., 1909, 49.) In medicinal properties cumin fruits resemble the other aromatic umbelliferous fruits. Dose, fifteen to thirty grains (1-2 Gm.).

**Cunila.** Cunila origanoides (L.) Britt. (C. Mariana L.) (Fam. Labiatae), American or Common Dittany. Sweet Horsemint. Stonemint.—A small indigenous perennial herb, growing on dry, shady hills, from New York to Georgia, and Illinois and Arkansas westward, and flowering in June and July. The whole herb has a warm, pungent taste and a fragrant odor, dependent on an essential oil. This, according to Philip Milleman, of Chicago, is of reddish-amber color, becoming light yellow by exposure to light, of a delicate, fragrant odor, very similar to that of oil of monarda, of a warm pungent taste, and of the sp. gr. 0.920. It is readily soluble in alcohol, ether, and chloroform. On spontaneous evaporation, it leaves a small crystalline residue. Iodine decomposes it, producing white vapors; by sulphuric acid it is reddened and decomposed, by nitric acid resinified, and by hydrochloric acid decolorized, though its color returns on exposure. It is slightly rubefacient; in the dose of five or ten minims (0.3-0.6 mil) it is carminative, and of from fifteen to twenty minims (0.9-1.3 mils) diaphoretic. The same author found in the dried herb tannic acid, a trace of glucose, gum, bitter extractive, resin, and salts of potassium, calcium, magnesium, and iron. (A. J. P., Nov., 1866, 495.) American dittany is a gently stimulant aromatic, analogous to the mints.

**Curare.** Woorari. Woorara. Woorali. Urari. —This powerful South American arrow poison was first brought to Europe by the celebrated traveller Waterton; it was in the form of a thick syrup, but as it now occurs in commerce it is a blackish extract, brittle, somewhat resinoid in appearance, encrusting the sides of gourds or little rude earthenware jars, into which it has been poured in a liquid state. The drug varies much in strength. It has been variously described. According to the researches of Planchon (P. J., xi, 491), there are really four distinct varieties of curare.

1. That from the Upper Amazon, obtained from the Strychnos Castelnaei Wedd., and possibly from S. Yapurensis G. Planch.

2. That from the Upper Orinoco, extending towards the Rio Negro, yielded by S.
Gubleri G. Planch.; this is the variety spoken of by Humboldt.

(3) That of British Guiana, obtained from S. toxifera Schomb., associated with S. pedunculata Benth. and S. cogens Benth.

(4) That of French Guiana, made out of S. Crevauxiana Baill. (S. Crevauxii G. Planch.).

These varieties are, however, commercially indistinguishable. The preparation of woorari has been witnessed by various travellers and variously described. (See P. J., xvi, 502; B. F. M. R., Oct., 1865; P. J., x, 1881.)

The method followed in the Upper Amazon region is to make a decoction of the bark of Strychnos castelnaei, to which one-tenth of the stem of another liane is added. This is then concentrated by evaporation. To this concentrated juice then is added the leaves of Petiveria alliacea, the stems of Dieffenbachia Seguine, the root barks of two plants of the Piperaceae and a species of Marcgravia. The fluid extract is then evaporated until it is in the condition of an extract, and poured into small vessels. Joubert asserts that the Tecuma Indians use, besides S. Castelnaeana Weddell, Cocculus toxiferus and an arum (Taya), which he found to be very poisonous. According to Kobert (Ph. Ztg., June, 1885), Malouetia nitida Spruce (fam. Apocy-nacece), or Guachamaca, a plant which is abundant in the Orinoco and Rio Negro districts, enters largely into the composition of curare. The alkaloid, guachamacine, isolated by T. Schiffer in 1883, is very closely allied to, if it be not identical with, curarine, in both its chemical and its physiological activity. It is entirely possible that the varieties of woorari vary in their alkaloid and their physiological properties.

Allied, it may be, to the third variety of woorari are the arrow poisons brought by W. S. W. Ruschenberger from Colombia, and studied by W. A. Hammond and S. Weir Mitchell. (Am. J. M. S., July, 1859.) Corroval was in dark brown lumps, having the appearance of a vegetable extract, and of an intensely bitter and persistent taste. They found its activity to depend upon the presence of a peculiar alkaloid, corrovaline. It resembles curare in that it produces general paralysis without previous spasm, but diners, in paralyzing also the heart. Vao or Bao appears to be a dilute and adulterated form of corroval. It would seem, therefore, that there is a variety of "woorari" used in South America which is more closely allied to strophanthus than to the true curares.

The term "curare" has no specific meaning, but according to Whiteford is simply the Indian word for poison, and it is evident that there are a considerable variety of arrow poisons used in South America under the same name.

In 1898 Boehm classified the curares of the markets as Tubocurare, originating from the Amazon, preserved in hollow bamboo canes, and said to contain about 9 to 11 per cent. of tubocurarine as its poisonous constituent; Gourd curare, derived from Strychnostoxifera, very rarely met with, and having curarine and a second alkaloid soluble in ether for its active principle; Jor curare, obtained from Strychnos castelnouei, also exceedingly rare in the European markets, containing three alkaloids—protocurine, having a feeble curare action; the non-poisonous proto-
curidine, and protocurarine, which is more actively poisonous than is curarine. (Ph. Ztg., xlii, 41.)

R. Boehm has isolated the two bases, curarine (also called tubocurarine from its source in the curare packed in bamboo tubes), C_{19}H_{26}Na, and curine, C_{19}H_{28}O_{3}N. The free tubocurarine forms an amorphous brown-red mass. Boehm (Ber. d. Chem. Ges., xx, 143) states that curine exists in many specimens of curare; it may also be obtained from the aqueous extract of curare. It is much less poisonous than the accompanying curarine. Curine is a crystalline powder fusing at 161° C. (321.8° F.), slightly soluble in cold water, freely soluble in alcohol, chloroform, and dilute acids. It forms a voluminous white precipitate with meta-phosphoric acid.

Woorari is one of those poisons whose active principle passes through animal membranes with difficulty, and hence when given by the stomach or rectum it acts very slowly, and in some cases elimination may proceed so rapidly that no marked influence is exerted, because not enough of the alkaloid is in the blood at any one time. There is also reason for believing that the alkaloid is destroyed in the liver. When injected into a vein, or introduced by the hypodermic needle or the poisoned arrow into the cellular tissue, it acts with great promptness. The symptoms caused are progressive loss of muscular power, the animal growing weaker and weaker, the respirations becoming more and more feeble, until death by asphyxia results.

The action of curare is to paralyze the peripheral ends of the motor nerves, the muscles, when directly stimulated, retaining their irritability. In mammals, as a result of the paralysis of the phrenic nerves, there is failure of respiration, and consequent death from asphyxia. The heart usually continues beating after cessation of the breathing, only very large doses affecting the arterial pressure directly. If, however, the dose be sufficient, the drug paralyzes the peripheral ganglia, thereby causing a dilation of the blood vessels with consequent fall of pressure, increased rate of the pulse through lack of inhibitory control, loss of irritability in the secretory nerves, and other modifications of functions of less importance. Tillie (A. E. P. P., xxvi) has brought forward evidence to show that there is a primary excitation of the spinal cord which, however, in ordinary poisoning, is masked by paralysis of the motor nerves. The sensory apparatus does not seem to be affected, unless by enormous doses. Glycosuria has been frequently noticed in animals as the result of curare poisoning. According to Morishima (A. E. P. P., 1889, xlii), this is apparently independent of the amount of glycogen in the liver or muscles.

Voisin and Lionville describe two types of poisoning in human beings. In the milder type the pulse is increased in force and frequency, respirations somewhat rapid, the temperature a little elevated, and the urine contains sugar. After larger quantities symptoms begin with severe chill, tremors, small pulse, and early loss of power in the lower extremities, later the cold skin becomes hot, the pulse rapid and full, there is marked reduction of the body temperature, with redness of the skin, and frequently profuse sweating. In non-fatal cases, the paralysis of the extremities rarely lasts for an hour, but the fever may continue for several days.
In cases of poisoning from the injection of woorari, a ligature around the limb between the place of injection and the heart, the free exhibition of diluents and evacuants, and artificial respiration when required, are the measures recommended. (Ed. M. J., 1867, 667.)

According to the experiments of Joseph Tillie, curine has no influence upon the motor nerves, but acts both in the frog and in the mammal upon the heart, belonging physiologically to the digitalis group. Boehm states that the presence of curine in curare can be recognized by the white precipitate made by metaphosphoric acid.

Although curare has in the past been used as an anti-convulsant in tetanus and hydrophobia, it is a remedy of no practical value, because the phrenic nerve is no less susceptible than the other motor nerves of the body, and if given in sufficient doses to control the spasm, will likely lead to fatal asphyxia. According to the elaborate experiments of Du Cazal (A. G. M., Sept., 1869), from one-fourteenth to one-seventh of a grain (0.005-0.01 Gm.) daily were borne by a dog without inconvenience; at the dose of ten milligrammes the characteristic phenomena began to show themselves, but disappeared in a few hours; with fourteen milligrammes the animal perished. For man the doses administered by subcutaneous injection were from one-twelfth to one-third of a grain (0.005-0.02 Gm.) of the crude curare. According to Bernard, curarine is at least twenty times as strong as curare.

Curcuma. U. S. 1870. Turmeric. Curcuma longa L. (Fam. Zingiberacea)—The rhizome of this plant is perennial, ovate or pear-shaped, and internally of a deep yellow or orange color. The plant is a native of Southern Asia, and is cultivated particularly in China, Bengal and Java, whence the root is exported to London, about 2,400,000 Kg. being shipped annually. The best is said to come from China.

The dried rhizome (Safran des Indes, Souchet des Indes, Fr.; Kurkuma, Gelbwurzel, G.; Curcuma, It., Sp.; Zirsood, Arab.; Huldie Hindoo) is in cylindrical or oblong pieces (Curcuma longa), from 0.5 to 1.5 cm. in thickness, distinctly annulate, tuberculated, somewhat contorted, externally yellowish-brown or greenish-yellow, internally deep orange-yellow, hard, compact, breaking with a fracture like that of wax, and yielding a yellow or orange-yellow powder. Another variety, Curcuma rotunda, or round turmeric is ovate or pear-shaped, about the size of a pigeon's egg, and marked externally with numerous annular wrinkles. Sometimes it comes cut into two tranverse segments. The two varieties have a close resemblance in sensible properties, and are derived from the same plant, though formerly ascribed to different species. The odor of turmeric is peculiar; the taste warm, bitterish, and feebly aromatic. It tinges the saliva yellow. Analyzed by Pelletier and Vogel, it was found to contain lignin, starch, a peculiar yellow coloring matter called curcumin, a brown coloring matter, gum, an odorous and very acrid volatile oil, and a small quantity of calcium chloride. Curcumin was obtained, mixed with a little volatile oil (about 1 per cent.), by digesting the alcoholic extract of turmeric in ether, and evaporating the ethereal tincture. It has been obtained by F. A. Daube, in deep yellow crystals, of a high luster, by a process which may be found in the A. J. P. (1871, 308). C. L. Jackson and Menke have submitted turmeric root to a thorough examination, and give the following results:
The turmeric oil was first removed from the ground root by treatment with ligroine, then the curcumin mixed with a large quantity of resin is extracted with ether, and finally purified by crystallization from alcohol. The oil extracted by ligroine was dark yellow, and amounted to 11 per cent. of the root. The purified curcumin amounted to 0.3 per cent., and melted at 178° C. (352.4° F.). Analyses of the pure curcumin, of several of its salts, and of derivatives, show its formula to be \( \text{C}_{10}\text{H}_{10}\text{O}_3 \). It is brown in mass, but yellow in the state of powder, without odor or taste, insoluble in benzoin, scarcely soluble in water, but very soluble in alcohol, ether, and the oils. It is a diatomic monobasic acid. When treated with weak oxidizing agents it yields vanillin. The alkalies rapidly change its color to a reddish-brown, and paper tinged with tincture of turmeric is employed as a test of their presence. The paper is rendered brown also by boric acid, which it thus serves to detect. When treated with a mixture of sulphuric acids and boric acids it yields a product called rosocyanin, because it dissolves in alcohol with a fine red color, and is turned blue by alkalies. Its alcoholic solution produces colored precipitates with lead acetate, silver nitrate, and other salts. Turmeric is used for dyeing yellow, but the color is not permanent. James Cook has found in turmeric an alkaloid, which forms crystallizable salts with sulphuric and nitric acids, and, separated from these acids by ammonia, yields a semi-crystalline precipitate. He observed also indications of a second base. (P. J., Nov., 1870.) Ivanow Gajewaky also states that there is an alkaloid in the root. (Pharmacographia, 641.)

This root is a stimulant aromatic, bearing some resemblance to ginger in its operation, and is much used in India as a condiment, the so-called curry powder. It is a constant ingredient in the curries so generally employed in the East. In former times it had some reputation in Europe as a remedy in jaundice, but its medicinal action was purely imaginary, based on the old doctrine of signatures, and at present it is employed only to impart color to ointments and other preparations.

Turmeric, when used as an adulterant, may be detected by means of a mixture of boric and sulphuric acids, but according to A. E. Bell, a much better test is afforded by the use of the reagent made by dissolving 1 gramme of diphenylamine in 20 mils of 90 per cent. alcohol, carefully adding 25 mils of pure sulphuric acid. To a little of the suspected powder, placed on a slide, a drop of the reagent is added with a glass rod. Spots of a fine purple color immediately develop, which may be readily recognized with the microscope.

Turmeric paper, used as a test, is prepared by the method described in the appendix of the U. S. P.

**Curry Leaves.** Currie—The leaves of the Murraya Koenigii Spreng. (fam. Rubaceae), a tree of India, are very largely used in that country as an aromatic, stomachic stimulant; when powdered and mixed with spices and other substances it forms currypowder, which is much used for seasoning food, rice, cooked dishes, etc.; it is also employed in dyspepsia, diarrhea, and even dysentery. According to J. Gr. Prebble (Pharmacographia Indica, vol. i), curry leaves yield to distillation a small quantity of volatile oil, and also contain a greenish-black resin, and a glucoside, koenigin. The clear oil extracted from the seeds is known as sima-bolee oil.
**Cusparia Bark.** Cuspariae Cortex. Br. 1898. Angustura, U. S. 1870. Angustura (Angostura) Bark. Carony Bark. Cortex Angusturiae. Angusturae, Angosturae. Angosturae. Cortex Angusturae. Cortex Angusturiae, Fr. Cod. Angustura, Fr. Angosturaninse, G. Corteceia del’Angustura, It. Corteza de Angostura, Sp.—"The dried bark of Cusparia febrifuga, DC." Br., 1898. This bark was dropped from the U. S. Pharmacopoeia at the revision of 1880 and from the British in 1914. The subject of Angostura bark in its botanical relations has been involved in some confusion. Humboldt and Bonpland were the first to throw light upon its true source. Unable to attach it to any known genus, they erected it into a new one with the title of Cusparia, a name of Indian origin, to which they added the specific appellation of febrifuga. On their authority, Cusparia febrifuga was generally believed to be the true source of the medicine, and was recognized as such by the London College. But it appears from the researches of Hancock, who resided for several months in the country of the Angostura bark tree, that it is doubtful whether the plant described by Humboldt and Monpland is that which yields the drug, and not another species of the same genus. Hancock proposed for the plant of the Orinoco the title of Galipea officinalis, which was adopted in the U. S. P., 1870. This name was afterward changed by Hancock to Cusparia officinalis, which is now generally accepted as the correct origin for true Angostura bark.

Cusparia febrifuga is a small tree, irregularly branched, with an erect stem from three to five inches in diameter, and covered with a smooth gray bark. The leaves are alternate, petiolate, and composed of three leaflets, which are oblong and pointed at each extremity. They are very smooth and glossy, of a vivid green color, marked occasionally with small whitish round spots, and, when fresh, of a strong odor resembling that of tobacco. The flowers are numerous, white, arranged in axillary and terminal peduncled racemes, and of a peculiar unpleasant odor. The fruit consists of five two-valved capsules, of which two or three are commonly abortive. The seeds, two of which are contained in each capsule, one often abortive, are round, black, and of the size of a pea. The tree grows abundantly on the mountains of Carony, between the 7th and 8th degrees of N. latitude, at the height of from six hundred to one thousand feet above the level of the sea.

The bark is generally brought from the West Indies packed in casks; but, according to Brande, the original package as it comes from Angostura consists of the leaves of a species of palm, surrounded by a net-work of sticks.

Cusparia bark "occurs in flattened or curved pieces, or in quills, generally about 10 to 12 Cm. long, 2.5 Cm. wide, and 2 mm. thick. The outer layer usually consists of a gray or yellowish cork which is often soft and easily removed, disclosing a hard, dark brown inner layer; the inner surface is light brown and frequently laminated. The fracture is short and resinous; on the fractured surface many white points are visible. A transverse section exhibits numerous cells filled with acicular crystals of calcium oxalate and small oil glands, but seldom any sclerenchymatous tissue other than small isolated groups of bast fibers. Odor musty; taste bitter." Br., 1898. Calcium oxalate raphides are abundant in the bark, but the
most characteristic peculiarity is the presence of numerous cells a little larger than
the other parenchyma-tous cells and completely filled with oil or a yellowish resin. The
odor of Angustura bark is peculiar and disagreeable when fresh, becoming fainter with
age; the taste is bitter and slightly aromatic, leaving a sense of pungency at the end
of the tongue. According to Fischer, it contains volatile oil, bitter extractive, a hard
and bitter resin, a soft resin, a substance analogous to caoutchouc, gum, lignin, and
various salts. Oberlin and Schlagdenhauffen (1878) found in the bitter extractive an
alkaloid, angosturine, $C_{10}H_{40}O_{14}N$, which melts at 85° C. (185° F.), is crystallizable,
and is turned red by pure sulphuric acid, and green by sulphuric acid with admixture
of nitric acid. The volatile oil, which may be obtained by distillation with water, is of a
pale yellowish color, lighter than water, of an acrid taste, and with the odor of the
bark. Beckurts and Froeger (Gildemeister and Hoffman, AetherischeOele, p. 601)
found as its essential ingredient a sesquiterpene alcohol, $C_{15}H_{26}O$, to which they give
the name galipol. It $H_{17}O_{3}N$. Korner), melting at 89° C. (192.2° F.) and is optically
inactive. Cadinene, $C_{15}H_{24}$, is also present and gives left rotatory character to the oil.
A small quantity of an inactive sesquiterpene, galipene, is also present, as well as
traces of a terpene which is probably pinene The cusparine of Saladin has not been
found by other investigators. Beckurts and Nehring (A. J. P., 1892, 410) announced
the discovery of four alkaloids in Angustura bark—viz., galipine, $C_{20}H_{21}O_{3}N$, melting at 115.5° C. (240° F.) and crystallizing in slender lustrous needles of white
color; galipidine, $C_{19}H_{19}O_{3}N$, melting at 111° C. (231.8° F.) and crystallizing in silky
lustrous plates of white color; cusparine, $C_{20}H_{19}O_{3}N$ (C$_{19}$H$_{17}$O$_{3}$N, Korner), melting at
90° C. (192.2° F.) and readily soluble in alcohol, ether, chloroform, acetone, and
benzene, more sparingly in light petroleum; and cuspadine, $C_{19}H_{17}O_{3}N$, melting at
78° C. (172.4° F.) and crystallizing in minute slender white needles. Its salts are less
soluble than those of galipine and galipidine, but more readily than those of cusparine.
The four alkaloids are tertiary bases. (See also A. Pharm., 233 (1895, No. 6), 410.)
Beckurts and Nehring also extracted the essential oil, amounting to 1.5 per cent. It
had a sp. gr. at 15° C. (59° F.) of 0.956. Distilled under a pressure of 35 mm. it
commenced to boil at 153° C. (307.4° F.) and the greater part distilled between 200°
and 220° C. (392°-428° F.) the last portions becoming solid when artificially chilled.
(See also A. Pharm., 1897, 518.) They found the bitter principle angosturine, which
when purified was white and melted at 58° C. (136.4° F.). A glucoside was also found,
the solution of which fluoresced; but it was not investigated. Troeger and Beck assert
that angostura bark contains cusparine, $C_{19}H_{17}ON_{3}$ (thus confirming Korner's
formula) galapoidine, $C_{19}H_{15}ON_{4}$, and a new alkaloid of the formula $C_{16}H_{13}O_{2}N$. (A.
Pharm., 1913, cdi, 246.) For a description of false Angustura barks, see U. S. D.,

Angustura bark has long been used by the natives of South America and the West
Indies as a stimulant tonic. In large doses it also evacuates the stomach and bowels,
and is often employed for this purpose in South America. It is said to be peculiarly
efficacious in bilious diarrheas and dysenteries, and has been recommended in
dyspepsia and other diseases requiring a tonic treatment. The testimony, however, of
practitioners in Europe and the United States, is not strongly in its favor.
The Br., 1898, Infusion, of Cusparia was prepared as follows: "Cusparia Bark, in No. 20 powder, 1 ounce (Imperial) or 5.0 grammes; Distilled Water, boiling, 1 pint (Imp. meas.) or 1000 mils. Infuse in a covered vessel for fifteen minutes; strain." Br., 1898. Under the name of Infusum Angusturae this preparation was official in the U. S. Pharm., 1870, made in the proportion of half a troyounce of Angustura bark in a pint of water. Dose, two fluidounces (60 mils), repeated every two, three, or four hours.

It may be given in powder, infusion, tincture, fluidextract, or extract. Dose, of the extract, five to fifteen grains (0.32 to 1 Gm.), which, however, according to Hancock, is inferior to the powder or infusion. To obviate nausea, it is frequently combined with aromatics. Dose in substance, ten to thirty grains (0.65 to 2.0 Gm.). In larger quantities it is apt to produce nausea. It is known best in the proprietary preparation called "Angustura Bitters."

CUSSO. Br.

KOUSSO [Brayera]

"Kousso consists of the dried panicles of pistillate flowers of Brayera anthelmintiea, Kunth." Br. "The dried panicles of the pistillate flowers of Hagenia abyssinica (Bruce) Gmelin (Fam. Rosaceae), without the presence of more than 10 per cent. of the staminate flowers, other parts of the tree, or other foreign matter. Reject any portions of the stems over 3 mm. in diameter and any binding material, before the drug is powdered or used." N. F.

Kousso was dropped from the U. S. P. IX but has been introduced into the N. F. IV and is retained in the Br. Pharm., 1914.

Hagenia abyssinica Willd. (Syn. Brayera anthelmintiea Kunth) is a beautiful tree about twenty feet high, growing on the table-land of Abyssinia, at an elevation of from three thousand to eight thousand feet. The branches exhibit circular cicatrices, left by the fallen leaves. The latter are crowded near the ends of the branches, are large, pinnate, sheathing at the base, with opposite, lanceolate, serrate, leaflets, villose at the margin, and nerved beneath. The unisexual flowers are tinged with purple, pedicelled, with an involucre of four roundish, oblong, obtuse, membranous bracts, and are arranged in fours, upon hairy, flexuous, bracteate peduncles, with alternate
branches. They are small and of a greenish color, becoming purple. These and the unripe fruit are the parts of the plant employed. The petals are apt to be wanting in the dried flowers. They are brought from Abyssinia packed in boxes, reaching Europe chiefly by way of Aden and Bombay. The Abyssinian name of the medicine has been variously spelled by European writers kosso, kossedo, cossos, cossos, etc. The fruit of the tree is said to be used as an anthelmintic in Abyssinia, but Dragendorff failed to detect any active principle in it. It is stated that in Abyssinia, honey gathered directly after the flowering season from beehives in gardens planted with kousso plants, is used in doses of a teaspoonful as a very effective tenicide.

Properties.—The dried flowers are in unbroken though compressed clusters. The male flowers are usually collected, so that ordinarily the general color of the mass is greenish-yellow or light brown; sometimes the female flowers constitute the bulk of the drug, which then has a distinct reddish tint, and is often known in commerce as red kousso. In accordance with our Pharmacopoeia, this commercial variety should alone be used. The male flowers are often found mixed with the female flowers, when loose (not in bundles), as high as 12 per cent. of this adulteration having been noticed by Meyer and Sandlund. (Ph. Ztg., 1893, No. 99.) The description in the Br. Pharm. is as follows: "Usually in more or less cylindrical rolls from three to six decimetres long, composed of reddish panicles of pistillate flowers. Panicles mush branched, the branches arising from the axils of large sheathing bracts; more or less covered with hairs and glands. Flowers numerous, small, shortly stalked, mostly unisexual, with two roundish, membranous, veined bracts at the base of each. Calyx with reddish veins, hairy externally, and consisting of two alternating whorls each of five segments, the inner whorl being curved inwards over the young fruit and shrivelled. No marked odor; taste bitter and acrid."

Br.

The N. F. describes the drug as "usually in rolls or flattened bundles from 25 to 50 cm. in length, reddish-brown, or occurring more or less loose and stripped from the larger portions of the panicles. Panicle branches cylindrical, somewhat flattened, longitudinally furrowed or wrinkled, externally light brown to yellowish, tomentose, glandular; internally, cork brownish, bast- and wood-fibers yellow, fibro-vascular bundles in wedges, pith large and yellowish-brown; nodes distinct, each with a scar or branch and subtended by a sheathing bract; internodes mostly from 1 to 2 cm. in length; flowers subtended by two ovate,
reddish, pubescent and glandular bracts; pedicel short; calyx turbinate, pubescent below, subtended by four or five rigid, spreading, obovate, purple-veined bractlets which are persistent and elongated in fruit, alternating with and larger than the five usually shriveled, reflexed calyx lobes; petals five, caducous, and usually absent in the drug; carpels two; styles exserted, stigmas broad and hairy with prominent papillae; fruit an ovoid akene about 2 mm. in diameter, enclosed by the remains of the calyx. The staminate flowers are greenish-yellow, with about twenty fertile stamens. Odor slight; taste bitter. The powdered drug is light brown or reddish-brown and, when examined under the microscope, exhibits numerous simple, non-glandular, straight or curved hairs, up to about 1 mm. in length, with thick, strongly lignified walls, usually enlarged at the base; glandular hairs with one- to three-celled stalks, the glandular head unicellular or consisting of one or two pairs of cells; tracheae spiral, annular, scalariform, or with bordered pores, up to 0.05 mm. in width; sclerenchymatous fibers long, thick-walled, strongly lignified and with numerous, simple, oblique pores; parenchyma of pith more or less lignified and with large simple pores; fragments of epidermal tissue from the bracts and calyx with elliptical stomata up to 0.03 mm. in length; groups of thin-walled, somewhat branching parenchyma cells with large intercellular spaces; tissue from the inner surface of the pericarp consisting of numerous, elongated, porous, strongly lignified cells; calcium oxalate in rosette aggregates up to 0.04 mm. in diameter; occasionally fragments of tissue containing prisms of calcium oxalate, the latter about 0.014 mm. in length; pollen grains few, nearly spherical, from 0.025 to 0.04 mm. in diameter, with three pores. The larger branches of the panicles exhibit simple, non-glandular hairs up to about 5 mm. in length; tracheae up to 0.125 mm. in width and rosette aggregates of calcium oxalate up to about 0.075 mm. in diameter. Brayera yields not more than 9 per cent. of ash." N. F.

As the medicine, from its high price, is apt to be adulterated, it should be procured in the unpowdered state, in which the botanical characters of the flower will sufficiently test its genuineness. It has a fragrant balsamic odor, and the taste, slightly perceptible at first, becomes in a short time somewhat acrid and disagreeable. Analyzed by Wittstein, it was found to contain, in 100 parts, 1.44 of fatty matter and chlorophyll, 2.02 of wax, 6.25 of bitter acrid resin, 0.77 of tasteless resin, 1.08 of sugar, 7.22 of gum, 24.40 of tannic acid, < ? > of lignin, 15.71 of ashes, with 0.14 part of loss. It has also been studied by Clemens Willing (Ch. Cb., 1855, 224), and by Pavesi (Viertelj. f. Prak. Pharm., 1858, viii, 505)
but we are chiefly indebted to Bedall, of Munich, for determining that the bitter acrid resin of Wittstein is equivalent to the taeniin of Pavesi, and for the name of kosin. This may be obtained by treating kousso repeatedly with alcohol to which calcium hydroxide has been added; the residue is boiled with water, the liquids are mixed, filtered, and distilled, and the residue treated with acetic acid, which precipitates the kosin in a white flocculent form, soon becoming denser and resin-like, and, on drying, yellowish, or, at a higher temperature, brown. The product is 3 per cent. In bulk, kosin has an odor like that of Russian leather, a persistent bitter and acrid taste, a yellowish or yellowish-white color, and an indistinct crystalline appearance under the microscope. It is very sparingly soluble in water, but freely so in alcohol, ether, and alkaline solutions. (A. J. P., 1872, 394.) Its formula, according to Fluckiger, is C_{31}H_{38}O_{10}. It fuses at 142° C. (287.6° F.), and remains after cooling an amorphous yellow mass, but if touched with alcohol it immediately assumes the form of stellate tufts of crystals. This may be repeated at pleasure, kosin not being altered by cautious fusion. (Pharmacog. 2d ed., 258.) Leichsenring (A. Pharm., 1894, 50) has reexamined kousso, and finds an inactive crystalline principle to which he gives the name protokosine, and an amorphous substance, kossotoxine, which he considers the active principle of the drug; the latter is a yellowish powder, fusing at 80° C. (176° F.), and not obtainable in a crystalline state. It is easily soluble in alcohol, ether, benzene, carbon disulphide, and insoluble in water.

Sodium kosinate has been recommended by Pavesi as a very eligible preparation for obtaining the virtues of kosin; a process is given in Am. Drug., 1884, 96; A. J. P., 1885.

Uses.—Kousso is highly valued in Abyssinia as a vermifuge. Bruce speaks of it in his travels, and gives a figure of the plant. Brayer, a French physician practising in Constantinople, published a treatise on it at Paris in 1823. It was in his honor that Kunth adopted the generic title of the plant. Much attention has been attracted to this valuable medicine, and trials made with it have proved its efficacy in the destruction and expulsion of the tape-worm. Its effects when taken internally are not very striking. In the ordinary dose it sometimes produces heat of stomach, nausea, and even vomiting, and shows a tendency to act on the bowels, though this effect is not always produced. It appears to act exclusively as a poison to the worms, and has been found equally effectual in both kinds of tape-worm. The medicine is
taken in the morning upon an empty stomach, a light meal having been made the preceding evening. A previous evacuation of the bowels is also recommended. The flowers are given in the form of powder, mixed with half a pint of warm water, the mixture being allowed to stand for fifteen minutes, then stirred up, and taken in two or three draughts at short intervals. The medicine may be preceded and followed by lemonade. The medium dose for an adult is half an ounce (15.5 Gm.), which may be diminished one-third for a child of twelve years, one-half for one of six years, and two-thirds for one of three years. Should the medicine not act on the bowels in three or four hours, a brisk cathartic should be administered. One dose is said to be sufficient to destroy the worm. Should the quantity mentioned not prove effectual, it may be increased to an ounce (31 Gm.).

Pure kosin has been considerably used in Germany in doses of thirty grains (2 Gm.), taken in two or four powders; but Buchheim found pure kosin less powerful as an anthelmintic than that which was not pure, while Arena (Ph. Z. R., 1879, 655) believes that kosin is not the active principle at all, but that the activity of kousso resides exclusively in the green, slightly bitter resin, which is soluble in alcohol and ether. If this view be correct, it explains the greater efficacy of freshly powdered kousso, for the green resin turns yellow by age and loses its power, and Arena’s investigations further indicate that the amorphous kosin of commerce is preferable to the pure principle. It is a yellowish-brown mass, which may be given in doses of from seven to fifteen grains (0.45-1.0 Gm.), repeated every half hour until four doses are taken, to be followed in an hour by a full dose of castor oil. So far as we know, no cases of poisoning by kousso or its active principle are on record, but it has been found by Rochebrune to be capable of causing centric convulsions in the lower animals.

Dose, of kousso, half an ounce (15.5 Gm.); of kosin, seven to fifteen grains (0.45-1.0 Gm.).

**Cyclamen.** Cyclamen europoeum L. Pain de Porceau, Arthanite, Fr. Erdscheibe, Erdbrod, Schweinbrod, G. Sowbread.—This is an herbaceous, perennial, stemless plant, of the subalpine mountainous regions of Europe. Some of the species of Cyclamen are among the most popular of winter plants on account of their beautiful foliage and exquisite flowers. The corm is globular, with many branched rootlets, almost black without, and white within, inodorous, and, when fresh, of a bitter, acrid, burning taste. By drying it loses much of its acridity, and is said to be rendered edible by roasting. Hogs are said to root it up from the ground and to eat it with impunity,
and hence the common name "Sow Bread." The corm is a drastic cathartic, and is used to cause abortion, but has in such cases produced fatal gastro-enteritis. Its active principle appears to be arthanitin of Saladin, the cyclamin of S. De Luca. This is a poisonous glucoside, which, when boiled with diluted acids, splits into cyclamiretin, $C_{15}H_{22}O_2$, and glucose. It is white, amorphous, inodorous, and, when held a short time in the mouth, intensely acrid, extending its action even to the throat. With cold water it swells and becomes gelatinous, but is readily dissolved, and form a solution which froths like soap and water, and is coagulated by a heat of about 65.5° C. (150° F.). Alcohol dissolves it with difficulty when cold, but freely when hot; it is soluble in glycerin with the aid of heat; and is insoluble in ether, chloroform, carbon disulphide, and the essential oils. Its formula, according to an analysis by Klinger, is $C_{20}H_{34}O_{10}$, although Robert (Chem. Ob., 1893, i, 32) makes it one of the class of saponins, and gives it the formula $C_{20}H_{32}O_{10}$, which is the same as that of sarsaparilsaponin and smilacin. T. W. C. Martius recommends the following method of preparing it. The tubers, collected in the autumn, dried and powdered, are mixed with animal charcoal, and exhausted at a boiling heat by alcohol of 0.825; the tincture is filtered, concentrated, and set aside for six or eight weeks, when the cyclamin is deposited. This should be washed on a filter with alcohol till it passes colorless, and if the filtrate be concentrated, and set aside, it will deposit a further quantity in a few weeks. The whole is then mixed with animal charcoal and treated with boiling alcohol, which will slowly deposit the pure cyclamin on cooling. Dose, of powdered root, is said to be from twenty to forty grains (1.3-2.6 Gm.).

**Cydonium.** U. S. 1880. Quince Seed. Semen Cydonus. Semeneses (Pepins) de Coing, Fr. Quittenkerne, Quitzensamen, Gr. Semi di Cotogno, It. Semiente de Membrillo, Sp.—Cydonia vulgaris, Pers. (Fam. Rosaceae), or common quince tree, has been under cultivation since very remote times. It is supposed to be a native of Crete, but grows wild in Austria, on the banks of the Danube, and in Northern Africa, is extensively cultivated for its fruit. The fruit is yellow, downy, of an agreeable odor, and a rough, astringent, acidulous taste, and in each of its five cells contains from eight to fourteen seeds. Though not eaten raw, it forms a very pleasant confection, and a syrup prepared from it may be used as a grateful addition to drinks in sickness, especially in looseness of the bowels, which it is supposed to restrain by its astringency. The seeds, which were formerly official, are ovate, angled, reddish-brown externally, whitewithin, inodorous, and nearly insipid, being slightly bitter when long chewed. Their coriaceous envelope abounds in mucilage, which is extracted by boiling water. They were officially described as follows: "About 6 mm. in length, oval, or oblong, triangularly compressed, brown, covered with a whitish, mucilaginous epithelium, causing the seeds of each cell to adhere. With water the seeds swell up, and form a mucilaginous mass. The unbroken seeds have an insipid taste." U. S., 1880. The seeds which are still extensively imported and used in the preparation of Bandoline and cosmetic lotions are frequently adulterated with fragments of bark or other vegetable tissue of the same size and color as the seeds and only detected by a close examination of the drug. Two drachms of the seeds will render a pint of water thick and ropy. (A. J. P., 1876, 35.) It has been proposed to evaporate the decoction to dryness, and powder the residue. Three grains of this powder form a sufficiently consistent mucilage with an ounce of water. According to Garot, one part communicates to a thousand parts of
water a semi-syrupy consistence. (J. P. C; 3e ser., iii, 298.) Pereira considers the mucilage as peculiar, and proposes to call it cydonin. It differs from arabin in not yielding a precipitate with potassium silicate, and from bassorin and cerasin in being soluble in water both hot and cold. Tollens and Kirchner (Ann. Ch. Phys., clxxv, 205-226) assign to it the formula \( C_{18}H_{28}O_{14} \), regarding it as a compound of gum, \( C_{12}H_{20}O_{10} \) and cellulose, \( C_6H_{10}O_5 \), less one molecule of water. Quince mucilage (Mucilago Cydonii, U. S., 1880) may be used for the same purposes as other mucilaginous liquids. The U. S. P., 1880, gave the following formula for its preparation. "Cydonium, two parts [or thirty-six grains]; Distilled Water, one hundred parts [or four fluidounces]. Macerate the Cydonium for half an hour, in a covered vessel, with Distilled Water, frequently agitating. Then drain the liquid through muslin, without pressure. This preparation should be freshly made, when required for use." U. S., 1880.

**Cynara.** Cynara. Scolymus L., (Artichoke).—This is a composite plant, indigenous in the south of Europe, and cultivated as a culinary vegetable. The receptacle and the lower portion of the fleshy leaflets of the flower-heads are eaten. When young, the heads are cut up raw and eaten as salad; when older, they are boiled, and dressed variously. The flowers are said to curdle milk, and the plant to yield a good yellow dye. The leaves and their expressed juice are very bitter, and have been thought to be actively diuretic. Cynara Cardunculus, the cardoon of the garden, very much resembles the artichoke. The stalks of the leaves are used as a vegetable in France. Artichoke leaves have been used in dropsies and rheumatic affections.

**Cynoglossum.** Cynoglossum officinale L. Hound's-tongue. Langue de Chien, Fr. Hundszunge, G.—A biennial plant of the fam. Boraginaceae, common both in Europe and in this country. The leaves and root have been employed, but the latter has been generally preferred. The fresh plant has a disagreeable narcotic odor, resembling that of mice, which is dissipated by drying. The taste is nauseous, bitterish, and mucilaginous. Although hound's-tongue has been believed by some to be nearly inert, there can be little doubt that it is a dangerous poison. The experiments of Diederilin (M. S. Rep., 1868) many years ago demonstrated that the extract paralyzes motor nerves in vertebrate animals, and K. Greimer has found in it a poisonous alkaloid, cynoglossine, which acts upon the animal organism similarly to curare; also a toxic glucoside, consolidin, and a notable amount of choline (P. J., vol. lxv.) Consolidin, a derivative of consolidin, like consolidin, paralyzes the central nervous system. Cynoglossum has been used as a demulcent and sedative in coughs, catarrh, spitting of blood, dysentery, and diarrhea. The piluiae de cynoglosso owe their properties chiefly to opium.

**Cypress Oil.** N. N. R. 1917. Oleum Cupressi. —A volatile oil distilled from the leaves and young branches of Cupressus sempervirens. It has a specific gravity of 0.88 to 0.89 at 15° C. (59° F.) and an optical rotation of +4° to +18°. It contains furfural, d-pinene, d-camphene, cymene, d-sylvestrene, d-terpineol, and esters of the same, l-cadinene and cypress camphor. It is used as an inhalant in whooping cough by sprinkling on the pillow and coverlet of the patient.
**Cypripedium.** N. F. IV (U. S. VIII). Lady Slipper. Rhizoma Cypripedii. Yellow Lady Slipper Root. Yellow Indian Shoe. Yellow Moccasin Flower. Yellow Noah's Ark. Venus' Shoe. Male Nervine. American Valerian. Racine de Cypripede jaune, Valeriane americaine, Fr. Gelbfrauenschuhwurzel, G.—"The dried rhizome and roots of Cypripedium hirsutum Miller, Cypripedium pubescens Wildenow, or of Cypripedium parviflorum Salisbury (Fam. Orchidaceae), without the presence of more than 5 per cent. of other parts of the same plants or other foreign matter." N. F. IV.

Under the common name of lady's slipper, or mocassin plant, several species of Cypripedium inhabit the woods in different parts of the United States. They are small plants, with large, many-nerved, plaited leaves, sheathing at the base, and large, often beautiful flowers, of a shape not unlike the Indian mocassin, whence they derive one of their common names. Several of them have been used by American physicians, the root being the part employed. R. P. Stevens of Ceres, Pennsylvania, says of them that he has found the C. reginae Walt. (C. spectabile Salisb.), and C. acaule Ait., especially when growing in dark swamps, to be possessed of narcotic properties, and to be less safe than the C. parviflorum Salisb., which is gently stimulant with a tendency to the nervous system, and is quite equal to valerian. He has employed it advantageously in hysteria, and in the pains of the joints, following scarlet fever. (N. Y. Journ. Mod., iv, 359.) E. Ives considers C. hirsutum Mill. and C. reginaeWalt. identical in their effects, but C. reginaemore powerful. (Trans. Am. Med. Assoc., iii, 312.) The roots of the two species, C. hirsutum and C. parviflorum are indiscriminately found in commerce and sold under the same name.

Cypripedium parviflorum var. pubescens or large yellow lady's slipper, has a simple, often flexuous, pubescent, leafy steam, from one to two feet high. The leaves are pubescent, ovate-lanceolate, acuminate, narrowing at the base, about four or five inches long by two in breadth, alternate, sessile, and sheathing. The flower is usually solitary and terminal, with four divisions of the perianth, the two outer cohering nearly to the apex, the inner longer, narrower, undulatory or twisted, and the lip an inch or two in length, swelling sac-like, and of a yellow color. The fruit is an oblong capsule, tapering at each end, recurved, pubescent, and pedundled. The plant is indigenous, growing abundantly in rich, moist woods throughout the United States.

Cypripedium parviflorum. Small-flowered Yellow Lady's Slipper, is a perennial plant with a leafy stem, a foot or two in height, and comparatively small yellowish-green flowers, appearing in May. The specific character of the flower, which is that also of the plant, ia that the lobe of the style is triangular and acute; the outer petals are oblong-ovate and acuminate; the inner linear and contorted; the lips shorter than the petals, and compressed. This species grows extensively through the United States, south of the Potomac, east and west of the Alleghanies, and in several of the Northern States, particularly New York, Michigan, Connecticut and Vermont.

It is described by the N. F. IV as a "rhizome of horizontal growth, curved, from 3 to 10 cm. in length, and from 2 to 6 mm. in thickness, orange-brown to dark-brown, the upper side showing numerous circular, cup-shaped scars, closely covered below with simple, wiry roots, varying from 3 to 15 cm. in length; fracture of rhizome short, white, that of roots somewhat fibrous. Odor distinct, heavy; taste sweetish, bitter,
and somewhat pungent. The powdered drug is yellowish-brown and, when examined under the microscope, exhibits numerous rounded or somewhat angular, simple and compound starch grains up to 0.014 mm. in diameter; calcium oxalate in raphides up to 0.065 mm. in length and occurring isolated or in bundles, occasionally imbedded in a. mucilage-like plasma; tracheae spiral, scalariform, or with simple or bordered pores; a few tracheids; sclerenchyma fibers, long, thin-walled and lignified; a few non-lignified, thick-walled fibers; fragments of epidermal tissue composed of elongated cells with reddish-brown walls; groups of thick-walled parenchyma cells with numerous simple pores. Cypripedium yields not more than 12 per cent. of ash. N. F. Maisch gave a distinctive description of the roots of the two species. (A. J. P., 1872, 297.) Poisonous properties have been attributed to C. reginae Salisb. and C. parviflorum var. pubescens (see Geol. Nat. Hist. Survey, Minnesota, Bull., 9, part i), but it has been shown that the secretion from the glandular hairs simply exerts an irritant action. Senega and hydrastis roots are sometimes found accidentally mixed with those of cypripedium, probably from the plants having a common habitat.

Cypripedium has a somewhat aromatic odor, which diminishes by time, and a bitter, sweetish, peculiar, and in the end somewhat pungent taste. Henry C. Blair found it to contain a volatile oil, a volatile acid, tannic and gallic acids, two resins, gum, glucose, starch, and lignin. (A. J. P., 1866, p. 494.) The eclectic preparation cypripedin is said to be a resinoid, obtained by precipitating with water a concentrated tincture of the rhizome. The substance thus obtained is complex, and has no claim to the name given it, which ought to be reserved for the active principle when discovered. It is probable that the virtues of the rhizome reside in a volatile oil and a bitter principle.

Cypripedium appears to be a gentle nervous stimulant or antispasmodic, and has been used for the same purposes as valerian, though less powerful. E. Ives of New Haven, Conn., commends the remedy in hypochondriasis and neuralgia. It may be used in powder, infusion, or tincture.

Dose of the powder, fifteen grains (1.0 Gm.), three times a day. The resinoid, obtained by precipitating the tincture, has been given in doses varying from half a grain to three grains (0.032 to 0.20 Gm.).

**Cytisus.** Cytisus Laburnum, L. (Fam. Leguminosae)—Laburnum is a small hardy tree, indigenous in the higher mountains of Europe and cultivated throughout the civilized world for its flowers, which appear early in the spring in rich pendant yellow clusters. All parts of the plants are probably poisonous. In fifty-eight boys poisoned simultaneously by the roots, the symptoms were intense sleepiness, vomiting, convulsive movements, coma, slight frothing at the mouth, and unequally dilated pupils. (M. T. G., vol. ii, 875.) In some cases the diarrhea has been severe. The convulsions have at times been markedly tetanic; wide-spread anesthesia has been noted, and also excessive mydriasis, with loss of the pupillary reflex, elevation of temperature, delirium, and cyanosis. After death there have been found erosion of the colonic mucous membrane, extreme hyperemia of the brain, and nephritis. (D. M. W., xxi, 1895.) For cases, see also previous editions of the U. S. D.; Le Mouvement
Husemann and Marme isolated in 1864 an alkaloid, cytisine, a white, crystalline solid, of a bitter, somewhat caustic taste, soluble in water and alcohol, but scarcely at all soluble in ether, chloroform, benzene, or carbon disulphide. The same alkaloid has been isolated from the seeds of several plants of the Papilionacaeous group. A second alkaloid, laburnine, was also announced by them. (Chem. News, July 16, 1869, 36.) Partheil (A. Pharm., 1892, 448) has since studied cytisine, and gives it the formula $C_{11}H_{14}ON_2$, which has been adopted by other authorities. Ferric chloride colors cytisine and its salts blood-red, which color, however, disappears on diluting with water or on addition of hydrogen dioxide. If after the addition of this latter reagent the mixture is heated gently in the water bath an intense blue color is developed. When cytisine is distilled with soda lime, pyrrol is obtained, besides a base, $C_9H_{13}N$, which is possibly a hydroquinoline. A. Kannerda purified crude cytisine, obtained from the seeds of Cytisus Laburnum L., by the well known shaking out process with chloroform, by distilling it in a partial vacuum. Under a pressure of 2 mm. and a temperature of $228^\circ$ C. ($442.4^\circ$ F.), the alkaloid distils over as a colorless liquid and congeals in the receiver in the form of fine crystalline needles. It separates from absolute alcohol in the form of small transparent rhombic crystals, which have the sp. gr. 1.0046. (Ap. Ztg., July, 1900, 486.)

According to the researches of P. C. Plugge (A. Pharm., 1895), cytisine is a very widely distributed alkaloid. He has found it in eight species of the genus Cytisus, two of the genus Genista, two of the genus Sophora, two of the genus Baptisia, and in other plants. He asserts that ulexine of Gerrard, from Ulex europeus L., sophorine of H. C. Wood, from Sophora secundiflora (Gav.) DC. (S. speciosa Benth.), and baptitoxine of von Schroeder, from Baptisia tinctoria K. Br., are identical with cytisine. Plugge also believes that the alkaloid of Euchestra Horsfieldii Benn. (fam. Leguminosae), a Javanese pea, whose seeds are used as a contra-poison by the natives, is identical with cytisine. Kober and Kadziwillowicz (Arb. d. Pharm. Inst. Dorpat., 1888, ii) found that cytisine caused in lower animals, spinal convulsions, followed, if the dose were large enough, by paralysis, vomiting of central origin, primary stimulation, and secondary paralysis of respiration and a marked reduction in the ozonizing powers of the red corpuscles. The blood pressure was at first elevated and later depressed and there was a paralysis of the motor nerves similar to that produced by curare. Dale and Laidlaw (J. P. Ex. T., 1912, hi) find that the rise and secondary fall of the blood pressure is due to effects upon the sympathetic ganglia and that cytisine closely resembles nicotine in its physiological action. Gray (J. P. C., 1862) found laburnum to produce in man narcotic effects, and commends it in vomiting, bronchitis, whooping cough, and asthma.

Of late years several salts of cytisine have made their appearance. The hydrochloride, hydro-bromate and nitrate have all been used as diuretics and nervines in one-twentieth to one-tenth grain doses (0.003-0.006 Gm.).
Damiana. N. F. IV. Turnera. — "The leaves of Turnera diffusa Wildenow or of Turnera aphrodisiaca Ward (Fam. Turneraceae), without the presence of more than 10 per cent. of stems and other parts of the same plants or other foreign matter." N. F. There are 57 species of Turnera which are mostly indigenous to tropical America. The 2 species which yield damiana are small shrubs indigenous to Southern California, Mexico and the Antilles. These leaves are "obovate to lanceolate, from 10 to 25 mm. in length and from 4 to 10 mm. in width, shortly petiolate, obtuse or acute at the apex, and with a short, cuneate base; sharply two- to ten-toothed on each side; the veins ascending, generally strong, straight and simple, and running to the sinuses of the teeth, but sometimes branched and sending the branches into the teeth; the upper surface smooth and pale green, the lower glabrous or with a few hairs on the ribs (Turnera aphrodisiaca) or densely tomentose over the entire surface (Turnera diffusa). Intermixed with the leaves are frequently found some reddish twigs, the young tips and buds of which are grayish with appressed pubescence (Turnera aphrodisiaca) or white floccose (Turnera diffusa), also flower buds, yellowish flowers, and globose pods. Odor aromatic; taste characteristic, aromatic and resinous. The powdered drug is light yellowish-green and, when examined under the microscope, exhibits numerous rough simple hairs, up to 0.8 mm. in length and 0.03 mm. in width at the base, with a narrow lumen usually distinct at the base only and with heavy, mostly non-lignified walls, often curved near the base so that the major portion of the hair lies nearly parallel to the surface of the stem or leaf; fragments of the epidermis from the stems composed of somewhat rectangular cells up to about 0.07 mm. in length and about one-half as broad, with square or somewhat pointed ends, with few broadly elliptical stomata about 0.03 mm. in length; sub-epidermal cells from the stem resembling those of the epidermis in shape but with lignified walls; tracheae, spiral, up to 0.02 mm. in width, with bordered pores up to about 0.035 mm. in width; tracheids from stem few; strongly lignified, thick-walled sclerenchyma cells or fibers few; lignified pith-parenchyma with large simple pores; fragments of epidermal cells and mesophyll of leaf; the former with somewhat wavy, vertical walls and associated with stomata up to 0.024 mm. in length; numerous crystals of calcium oxalate in rosette aggregates up to 0.03 mm. in diameter and occasionally in prisms; starch grains few, simple, up to 0.005 mm. in diameter. Damiana yields not more than 10 per cent. of ash." N. F.

Parsons (Arch. d. Pharm., 1881, p. 133) obtained 0.2 per cent. of a volatile oil; 8.06 of
a soft resin, fixed oil and chlorophyll; 3.46 per cent. of tannin; 7.08 per cent. of a bitter
principle; 6.39 per cent. of a hard brown resin; 10 per cent. of extractive; 13.5 per
cent. of a gum; 6.15 per cent. of starch, etc.

The leaves of the composite plant Aplopappus discoideus DC. (Bigelovia Veneta Gray)
were, formerly, also sold under the name of damiana.

Although damiana has achieved some repute in the treatment of sexual impotence, it
is worthy of note that it is always given in conjunction with strychnine, phosphorus or
some other stimulant; it is probably nothing more than a feeble tonic. Dose, one-half
to one drachm (2-4 Gm.) of the leaves, either in the form of infusion or fluid-extract.

Danais. Danais fragrans, Commerc. (Fam. Rubiaceae)—In this Madagascar plant,
the root of which is said to be tonic and antiperiodic, Heckel and Schlagdenhauffen
found a glucoside, danain. (A. J. P., 1886.)

Daphnandra.—The bark of Daphnandramicrantha (Tul.) Benth., an Australian tree
(fam. Monimiaceae), is asserted to be rich in poisonous alkaloid. (P. J., Oct., 1887.)
Bancroft states that the active alkaloid is soluble in water, and to some extent is
antagonistic to strychnine.

DATURAE FOLIA. Br.

DATURA LEAVES

"Datura Leaves are the dried leaves of Datura fastuosa, Linn., var. alba, Nees and also of Datura Metel, Linn." Br.

DATURAE SEMINA. Br.

DATURA SEEDS

"Datura Seeds are the dried seeds of Datura fastuosa, Linn. var. alba, Nees." Br.

The genus Datura consists of fifteen species, which are distributed throughout the warmer portions of the whole world, the greatest
number being found in Central America. Nearly all of them are used locally in medicine. The plants vary from herbs to shrubs and even
trees. The leaves of Datura Stramonium are official in the U. S. Pharmacopoeia. (See Stramonium.) The leaves and seeds of Datura
fastuosa alba are used in India and the Eastern and West Indian Colonies as an equivalent of Belladonna and Stramonium leaves.
Tincture of Datura seeds is used in India as an equivalent of Stramonium seeds.

Datura fastuosa is a small shrub, indigenous to tropical India. There is said to be several varieties of this species and it is very generally conceded to be the most toxic of the Indian Daturas. The leaves are ovate and more or less angular, the flowers being white or purplish. Datura Metel is also an Indian plant and resembles D. fastuosa. It differs in that the leaves are cordate, almost entire, and pubescent. The flowers being white. Pyman and Reynolds (P. J., 1908, lxxxii) have found in the D. meteloides a new alkaloid, which they call meteloidine.

Of the varieties of D. fastuosa, the British Pharmacopoeia recognizes that known as alba. From it the Thugs prepared the poison Dhat (whence is derived the generic name), which they used to stupefy their victims. The leaves and seeds are recognized by the Br. Pharm. 1914, and the leaves are described as "Brownish or yellowish-green, attaining twenty centimetres in length and thirteen centimetres in breadth; ovate, acuminate, with sinuate-dentate margins and long petioles; often unequal at the base; bearing scattered glandular or simple hairs. Characteristic odor; taste bitter." Br.

The trumpet-shaped corolla, together with the stamens, is sometimes found mixed with the leaves. The drug has a slight unpleasant odor, and a bitter taste.

The seeds are "yellowish-brown, somewhat wedge-shaped, flattened, with rounded, thickened, furrowed, wavy margins; from four to five millimetres broad and about one millimetre thick. Hilum large, extending from about the middle to the acute end of the seed. Surface finely pitted and reticulated. Endosperm narrow and translucent, enclosing a curved embryo. No odor; taste slightly bitter." Br.

They contain the alkaloid hyoscine, a resin, a fixed oil and traces of hyoscyamine and atropine.

Uses.—While this drug produces effects more or less similar to those of belladonna its precise action has not been clearly determined. It is used in India to a considerable extent as a criminal poison. Banerja (Indian Med. Gaz., 1885, xx, p. 209) has reported 32 cases. The symptoms are not given in sufficient detail to allow of definite statement but seem to
differ somewhat from those of either atropine or scopolamine. Gimlette (B. M. J., 1903, i, p. 1137) also records several cases of poisoning and states that the nature of the active principle of the drug has not been determined. In India the Datura fastuosa leaves have been used for the same purposes as the stramonium leaves.

Off. Prep.—Tinctura Daturae Seminum, Br.

DECOCTA. U. S.

DECOCTIONS

Tisanes par decocction, Decoctions, Fr.; Abkochungen, G.; Decotti, It.; Cocimiento, Sp.

Decoctions are solutions of vegetable principles, obtained by boiling the substances containing these principles in water. Vegetable tissues generally yield their soluble ingredients more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapor over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a rule, be long continued, as the ingredients are apt to react on one another, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fiber. Should the physician not happen to prescribe this preliminary comminution, the pharmacist should not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavorable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cold water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively
injure, the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place and the liquid is rendered turbid, and this constitutes the greatest objection to this class of preparations. When the active principle is thus dissolved in excess, the decoction should always be strained while hot, so that the matter which separates on cooling may be mixed again with the fluid by agitation at the time of administering the remedy. In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a rule, glass or earthenware vessels should be preferred, as those made of metal are sometimes corroded by the ingredients of the decoction, which thus become contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those made of copper, brass, or zinc; but iron pots should not be used where astringent vegetable substances are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, when the "weather is warm, for a longer period than forty-eight hours.

The tendency of modern medicine and pharmacy has been decidedly against the employment of decoctions; their nauseous taste, bulky dose, repulsive appearance, and non-permanent character have been powerful reasons for causing their retirement, while the use of tinctures and fluidextracts has largely increased. In the 1880 revision of the U. S. Pharmacopoeia the number of official decoctions was reduced to two, and a general formula was appended for the guidance of the pharmacist. The U. S. P., 1890, reduced the strength of the general formula for decoctions from 10 per cent. to 5 per cent., and this strength was retained in the U. S. P. VIII and IX, as will be seen from the following: "Decoctions must be freshly made from the drugs, and, when the strength of decoctions is not otherwise directed, they are to be prepared by the following general formula:
“The Drug, coarsely comminuted, fifty grammes [or 1 ounce av., 334 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]. Introduce the drug into a suitable vessel provided with a cover, pour upon it one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms] of cold water, cover it well, and boil for fifteen minutes. Then allow it to cool to about 40° C. (104° F.), express, strain the expressed liquid, and pass enough cold water through the strainer to make the product measure one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms]."

"Caution.—The strength of decoctions of energetic or powerful substances should be specially directed by the physician." U. S.

The two decoctions of the U. S. P., 1890, Decoctum Cetrariae and Decoctum Sarsaparillae Compositum, were both dismissed in the Eighth Revision and only the general formula for decoctions retained. See Decoction of Cetraria and Zittman's Decoction.

**DECOCTUM ACACAE CORTICIS. Br.**

**DECOCTION OF ACACIA BARK**

“Acacia Bark, bruised, 60 grammes; Distilled Water sufficient to produce 1000 millilitres. Boil the Acacia Bark with twelve hundred millilitres of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." Br.

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used in India as an astringent gargle, lotion, or injection. The dose is from four fluidrachms to two fluidounces (15-60 mils).

**DECOCTUM AGROPYRI. Br.**

**DECOCTION OF COUCH GRASS [Decoction of Triticum]**

"Couch Grass, cut small, 50 grammes; Distilled Water sufficient to produce 1000 millilitres. Boil the Couch Grass with twelve hundred millilitres of Distilled Water, in a suitable vessel, for ten minutes; strain;
if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." Br.

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used in cystitis and urinary diseases. Dose, four fluidrachms to two fluidounces (15-60 mils).

DECOCTUM GOSSYPIII RADICIS CORTICIS. Br.

DECOCTION OF COTTON ROOT BARK

“Cotton Root Bark, bruised, 200 grammes; Distilled Water sufficient to produce 1000 millilitres. Boil the Cotton Root Bark with two thousand millilitres of the Distilled Water, in a suitable vessel, until the volume is reduced to one thousand millilitres; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." Br.

This decoction was transferred from the British Addendum (1800) to the British Pharm. (1914). It is used as an emmenagogue and in uterine hemorrhage. Dose, from four fluidrachms to two fluidounces (15-60 mils).

DECOCTUM ALOES COMPOSITUM. Br.

COMPOUND DECOCTION OF ALOES

Tisane (Decocte) d'Aloes composee, Fr.: Zusammengesetztes Aloedecoc.t. G.

"Extract of Aloes, 10 grammes; Myrrh, Potassium Carbonate, of each, 5 grammes; Extract of Liquorice, 40 grammes; Compound Tincture of Cardamoms, 300 millilitres; Distilled Water sufficient to produce 1000 millilitres. Reduce the Extract of Aloes and the Myrrh to coarse powder, and boil them and the Potassium Carbonate and the Extract of Liquorice with four hundred millilitres of Distilled Water in a covered vessel for five minutes; cool; add the Tincture of Cardamoms; set aside for two hours; strain through flannel; pass sufficient Distilled Water through the strainer to produce the required volume." Br.

This is essentially the former process of the British Colleges. The effect of the alkaline carbonate is, by combining with the resin of the myrrh
and the insoluble portion of the aloes, to render them more soluble in water, while the licorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (P. J., xiv, 491.) J. F. Brown proposes to prepare a concentrated decoction which keeps for a long time unchanged. (C. D., 1896, 425.)

Long boiling impairs the purgative property of aloes, and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself; it is also more tonic and cordial, from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the potassium carbonate. It is given as a gentle cathartic, tonic, and emmenagogue, and is especially useful in dyspepsia, habitual constipation, and atonic amenorrhea. The decoction should not be combined in prescription with acids, acidulous salts, or other bodies incompatible with the alkaline carbonate.

Dose, from one-half to two fluid ounces (15-60 mils).

**DECOCTUM HAEMATOXYLI Br.**

**DECOCTION OF LOGWOOD**

Tisane (Decocte) de Bois de Campeche, Fr.; Blauholz-Abkochung, G.

"Logwood, in chips, 50 grammes; Cinnamon Bark, bruised, 10 grammes; Distilled Water, sufficient to produce 1000 millilitres. Boil the Logwood with twelve hundred millilitres of Distilled Water in a suitable vessel for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." Br.

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt much whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the Br. formula is in general a very suitable addition, but there might
be circumstances under which it would be better omitted, and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in diarrheas of relaxation.

Dose, for an adult, two fluidounces (60 mils); for a child about two years old, two or three fluidrachms (7.5-11.25 mils).

**DECOCTUM ISPAGHULAE. Br.**

**DECOCTION OF ISPAGHULA**

"Ispaghula, bruised, 15 grammes; Distilled Water, sufficient to produce 1000 millilitres. Boil the Ispaghula with twelve hundred millilitres of Distilled Water, in a suitable vessel, for ten minutes; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." Br.

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used as a demulcent drink in India for diarrhea. Dose, four fluidrachms to two fluidounces (15-60 mils).

**DECOCTUM SAPPAN. Br.**

**DECOCTION OF SAPPAN**

"Sappan, in chips, 50 grammes; Cinnamon Bark, bruised, 10 grammes; Distilled Water, sufficient to produce 1000 millilitres. Boil the Sappan with twelve hundred millilitres of Distilled Water, in a suitable vessel, for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; if necessary pour sufficient Distilled Water over the contents of the strainer to produce the required volume." Br.

This decoction was transferred from the British Addendum (1900) to the British Pharm. (1914). It is used like logwood decoction in India as an astringent in diarrhea in doses of four fluidrachms to two fluidounces (15-60 mils).

**Dianthus.** Dianthus Caryophyllus L. Clove Pink. (Fam. Caryophyllaceae)—Of the ordinary garden pink those specimens should be selected for medicinal use which have the deepest red color and the most aromatic odor. The petals should not be collected
until the flower is fully blown, and should be employed in the recent state. They have a fragrant odor, said to resemble that of the clove. Their taste is sweetish, slightly bitter, and somewhat astringent. Both water and alcohol extract their sensible properties, and they yield a fragrant essential oil by distillation. In Europe they are employed to impart color and flavor to a syrup, used as a vehicle. The Edinburgh Pharmacopoeia directed this to be made by macerating one part of the flowers, without their claws, in four parts of boiling water for twelve hours, then filtering, and adding seven parts of sugar.

**Dicentra.**—The *Dicentra pusilla* Sieb. et Zucc. is a Japanese plant belonging to the Fumariaceae which is used in that country as a folk remedy in dysentery. Asahina (A. Pharm., 1909, ccxvii) has found it in an alkaloid, $C_{20}H_{21}NO_4$, which is isomeric with papaverine. It has been studied physiologically by K. Iwakawa (A. E. P. P., 1911, lxiv), who finds that it produces in both cold and warm blooded animals a light narcosis, followed, if the dose be large, by convulsions. It also caused a fall in the blood pressure with slowing of the heart and depression of the respiratory center.

**Dichondra Brevifolia.**—An extract of this plant dissolved in glycerin is used as an application in the treatment of diphtheritic ulcers. It is applied direct to the mucous membrane and is claimed to possess specific action on the diphtheritic bacilli.

**Diervilla.** *Diervilla Lonicera Mill.* (D. trifida Moench.) Bush Honeysuckle.—A low, erect, indigenous shrub, growing in dry woods and rocky places throughout the Eastern Northern States and Canada. L. E. Dawson (Chem. News, 1912) examined the fruit of D. Florida, the dark-red berries contain fructose, fixed oil, tartaric and citric acids and an alkaloid which he believes to be narcine. Charvaux found a glucoside identical with fraxin in D. lutea. (J. P. C., 1911, -2,4:8.) The whole plant is supposed to be possessed of diuretic and astringent properties, and is given in infusion by the eclectics in diseases of the urinary passages.

**Dioscorea.** N. F. IV- Wild Yam Root. Colic-root. Rheumatism-root.—" The dried rhizome of *Dioscorea villosa* Linne (Fam. Dioscoreaceae)." N. F. IV. An indigenous, perennial, twining plant, with long, knotty, matted, contorted, ligneous root stocks. It grows from Ontario to Wisconsin, and south to Florida and Texas. The rhizome is used by the eclectics, who consider the drugs efficacious in bilious colic, and by the Southern negroes in rheumatism. The rhizome is described by the N. F. as "knotted and woody, elongated, from 6 to 12 mm. in thickness, often compressed, bent and branched, bearing scattered nodular projections at the sides, slender, tough roots underneath and stem-scars on their upper surface; externally pale brown, surface more or less scaly from the partly detached, thin outer layer; fracture short but tough, the fractured surface whitish or pale-brown, with numerous small, scattered, yellowish wood bundles. Odorless; taste starchy, insipid, afterwards acrid. Dioscorea yields not more than 7 per cent. of ash." N. F.

W. C. Kalteyer found abundant saponin in the roots. (A. J. P., 1888; see also M. R., 1913, 311.) A substance, improperly called *dioscorein*, obtained by precipitating the tincture with water, is used in the dose of from one to four grains (0.0065-0.26 Gm.).
Dose, one-half to one drachm (1.9-3.75 mils), which may be given either in the form of
decocion or a fluidextract.

Dioscorea hirsuta, Bl. grows in the island of Java, where it is known as Gadoeng. In
1894 W. G. Boorsma (Mededelingenwuit's LandsPlanten-tuin, xiii) separated from it
an alkaloid to which he gave the name of dioscorine. This alkaloid has been studied by
Plugge and Schutte (A. J. P., iv, 1897) who assigned to it the formula C₁₃H₁₉NO₂, and
found it to be a convulsant poison, resembling closely in its action picrotoxin, but
much more feeble. Dioscorea bulbifera L. grows in the Gaboon country of tropical
Africa. Heckel and Schlagden-hauffen found in the tuber a glucoside, together with
wax, chlorophyll, saccharose, and resin.

The root of Dioscorea rhizopogonoides (?) Oliver, under the names of Cunao, Shu-lang,
faux gambier, is exported in enormous quantities from Indo-China to Southern China
for use as a dye-stuff.

Diospyros. Persimmon. Date-plum. Fruits de Plaqueminier de Virginie, Fr.
Persimmon-fruchte, Dattelpflaumen, G.—The Diospyros virginiana L., or persimmon
(fam. Ebenaceae), is a small indigenous tree, occurring in woods and old fields from
Connecticut, southward. The flowers appear in May or June, but the fruit is not ripe
until the middle of Autumn. The fruit is a globular berry, dark yellow when ripe, and
containing numerous seeds in a soft yellow pulp. The seeds, dried, roasted, and ground,
are used in some parts of Georgia as a substitute for coffee. (M. S. Rep., 1873, 437.)

While green, the fruit is excessively astringent, and in this form was formerly included
in the U. S. Secondary List; but, when perfectly mature, and after being touched by
the frost, it is sweet and palatable. The unripe fruit, according to B. "R. Smith of
Philadelphia, contains tannic acid, pectin, sugar, malic acid, coloring matter, and
lignin. (A. J. P., xviii, .167.) The persimmon has been used by Mettauer in diarrhea,
chronic dysentery, and uterine hemorrhage. The dose of the vinous tincture (an ounce of
the fresh green fruit to two fluidounces of dilute alcohol) is half a fluid-drachm (1.9 mils)
or more for infants, and half a fluidounce (15 mils) or more for adults. The bark is
astringent and very bitter. For further information concerning this drug, see U. S. D;

Dirca. Dirca palustris L. Leather Wood. (Fam. Thymelceaceae) —A shrub growing
widely in the Northeastern United States. The berries, which are small, ovoid, and of
an orange or reddish color, are said to be narcotic and poisonous. The tough bark, in
the fresh state, has a peculiar, rather nauseous odor, and an unpleasant acrid taste,
and when chewed excites a flow of saliva. It yields its acridity completely to alcohol,
but imperfectly to water even by decoction. Six or eight grains of the fresh bark
produce violent vomiting, preceded by a sense of heat in the stomach, and often
followed by purging. Applied to the skin it slowly excites reddness and ultimately
vesicating. It is analogous to mezereon in its medicinal as well as botanical
characters.

Doundake Dundaki. Quinquina Africaine. Kina du Rio Nunez.—Sarcocephalus
esculentus Afzel (fam. Rubiaceæ) of Africa yields & bark which is said to be an astringent and tonic febrifuge. For a description of the bark and its chemical characteristics, see P. J., vol. xvi, 49. Heckel and Schlagdenhauffen do not believe that doundake contains an alkaloid, but attribute its power to three distinct principles of a resinous nature, the first of which is of an orange-yellow color and very bitter, soluble in water, alcohol, and potassium hydroxide; the second light yellow in color, soluble in potassium hydroxide but not in water; the third soluble in potassium hydroxide, insoluble in water and in alcohol. (J. Soc. Chem. Ind., 1886, 435.) The wood of the Sarcoccephalus Diderrichii (?) (fam. Rubiaceæ), which is used for making shuttles, has been found by Gibson to contain an alkaloid, which is a cumulative cardiac poison. Workers in the wood frequently suffer and even die from cardiac disturbances. [Bio-Chem, J., 1906, i, p. 39).

**Dracontium.** Symlocarpus Foetidus (L.) Nutt. (Spathyema foetida (L.) Raf. Dracontium Foetidum L. Ictodes foetidis Bigelow.) Skunk Cabbage. Skunk Weed. Polecat Weed. Racine des Pothos foetide, Fr. Stinkende Drachenwurssel, G — The plant of the Fam. Araceæ is abundant in wet places throughout the Northern and Middle United States. All parts of it have a fetid odor, dependent upon an extremely volatile principle, which is rapidly dissipated by heat. The rhizome should be collected in the autumn, or in the early spring.

The rhizome occurs either whole or in transverse slices. When entire, it is cylindrical or in the shape of a truncated cone, 5 to 10 cm. long and 2 to 4 cm. thick, externally dark brown and very rough from the insertion of the radicles, internally white and amylaceous. The rootlets are of various lengths, 2 to 4 mm. thick, coarse, simple, and very strong, very much flattened and wrinkled, white within, and covered by a yellowish or reddish-brown epidermis, considerably lighter colored than the body of the rhizome. The odor is fetid, the taste acrid; both are lessened by drying and progressively diminish with time, so that the dried rhizome should not be kept longer than a single season. This acridity is entirely absent in the decoction. The seeds are very acrid, and, though inodorous when whole, give out, when bruised, the peculiar odor of the plant.

The rhizome is affirmed to be antispasmodic and narcotic; occasioning nausea and vomiting, with headache, vertigo, and dimness of vision. It has been used with alleged success in asthma, chronic catarrh, chronic rheumatism, chorea, hysteria, and dropsy. Dose, of powder, from ten to twenty grains (0.65-1.3 Gm.), increased pro re nato.

**Dragon's Blood.** Sanguis Draconis. Sang-dragon, Fr. Drachenblut, G. Sangre de drago, Sp.—Dragon's blood, of which there are several commercial varieties, is a resinous exudation obtained from the fruits of a number of palms. East Indian dragon's blood ia obtained from a number of species of Daemonorops, a genus which was previously ascribed to Calamus. Malay dragon's blood is obtained from Daemonorops didynophylllos, D. micranthus and D. propinquis; Sumatra dragon's blood from Daemonorops Draco Blume (Calamus Draco Willd.). In Borneo a dragon's blood is obtained from Daemonorops draconcellus and other species of Daemonorops. On the surface of the fruit, when ripe, is an exudation, which is separated by rubbing,
or shaking in a bag, or by exposure to the vapor of boiling water, or finally by decoction. The finest resin is procured by the two former methods. It comes in two forms: sometimes in small oval masses (tear dragon's blood) of a size varying from that of a hazelnut to that of a walnut, covered with the leaves of the plant, and connected in a row like beads in a necklace; sometimes in cylindrical sticks, eighteen inches long and from a quarter to half an inch in diameter, thickly covered with palm leaves, and bound round with slender strips of cane. See paper by E. M. Holmes in P. J., 1905, 933.

Dragon's blood is inodorous and tasteless, insoluble in water, but soluble in alcohol, ether, and the volatile and fixed oils, with which it forms red solutions. According to Herberger, it consists of 90.7 parts of a red resin, which he calls draconin, 2.0 of fixed oil, 3.0 of benzoic acid, 1.6 of calcium oxalate, and 3.7 of calcium phosphate. Tschirch (Harze und Hambehalter, 1900, p. 189) has made an elaborate study of dragon's blood, and finds 2.5 per cent. of draco-alban, C_{20}H_{4}O_{4}, a white substance melting with decomposition at about 200° C. (392° F.); 13.58 per cent. of draco resen, a yellow resinous substance of the formula C_{26}H_{4}O_{4}, and 56.86 per cent. of draco resin, a resin ester or mixture of esters, benzoic dracoresinotannol ester and benzoylacetidraco-resinotannol ester, and 18.4 per cent. of insoluble substances. It was formerly employed in medicine as an astringent, but is nearly or quite inert, and is now never given internally. It is sometimes used to impart color to plasters. For further information concerning this drug, see U. S. D., 19th ed., p. 1475.

**Drosera.** Sundew. N. F. IV. Herba Rorelle. Rosollis. Roseed du Soleil, Fr. Sonnenthalau, G. —It is described by the N. F. as "the air-dried flowering plant of Drosera rotundifolia Linne (Fam. Droseraceae), frequently mixed with the closely allied species Drosera intermedia- Hayne and Drosera longifolia Linne, or at times wholly replaced by these. A delicate plant of a reddish color throughout, with few fibrous, blackish rootlets; leaves all in a basal rosette, blade orbicular, about 15 mm. in diameter, abruptly contracted into a slender, pubescent petiole, upper surface covered with prominent glandular hairs; scape filiform, smooth, from 10 to 20 cm. in length, bearing a few, five-parted, small, white fugacious, flowers in a curved, one-sided raceme. Drosera intermedia is identified by its spatulate leaves with blades two or three times as long as they are wide and glabrous petioles. Drosera longifolia is identified by its elongated spatulate obovate leaves with blades six to eight times as long as they are wide, and its slender smooth petioles and scape, declinate at base. Odorless; taste faintly bitter and acidulous. Drosera yields not more than 30 per cent. of ash." N. F. Drosera has been employed in phthisis, but is probably of no value. (See Proc. A. Ph. A., xxvii, 225.) Under the name of droserin an extract of various plants of this species has been recommended in whooping cough. It is marketed in the form of tablets of which there are two strengths; number one being intended for children, number two for adults. The dose of the crude drug is one drachm (4 Gm.).

**Duboisia.**—D. myoporoides R. Br. (fam. Solanaceae) is a tall, glabrous shrub or small tree, which is a native of Australia, New South Wales, New Caledonia, and Queensland. The medicinal properties of this plant were made known by Baron von Mueller, who received the leaves from J. Bancroft. The alkaloid duboisine was
discovered in the leaves by A. W. Gerrard. (P. J., viii, 787). For his method, see 16th ed., U. S. D.; also, for an account of the chemical and medicinal properties of this alkaloid, and its relations to atropine, see Belladonna.

According to the researches of Jos. Lanterer (L. L., 1896), the old leaves and twigs of Duboisia myoporoides, contain hyoscyamine, the fresh young leaves scopolamine, the dried leaves being stronger than are belladonna leaves, and yielding 0.97 per cent. of alkaloid. Duboisia Leichhardtii F. v. Muell. is said to be still richer in alkaloid, which is chiefly amorphous scopolamine; while the leaves of Datura arborea L. (Brugmansia arborea Steud.) and of D. cornigera Hooker (Brugmansia Knightii Hort.), natives of South America, acclimatized in Queensland, contain a mixture of hyoscyamine and atropine.

D. Hopwoodii F. v. Muell., pitury plant, is the source of pituri, a narcotic stimulant largely used by the natives of Central Australia. The drug itself is a fine powder, composed of the leaves and twigs which are gathered during the month of August, while the flower is in bloom, and are put up in various forms of circular mats about 7.5 cm. in diameter. The natives smoke and chew pituri, and it is alleged to have a powerfully stimulating effect, assuaging hunger, and enabling those who are its devotees to perform much labor and go long journeys with but little food. Pituri yielded to A. W. Gerrard minute quantities of an alkaloid which he believed to be identical with nicotine, but Liver-sidge has shown that the liquid, acrid alkaloid, piturine, C\textsubscript{12}H\textsubscript{16}N\textsubscript{2}, is distinct from nicotine. (Proc. Roy. Soc. N. S. W., 1880.) Pituri contains from 1 to 2\frac{1}{2} per cent. of the alkaloid.
Echinacea. N. F. IV. Nigger-head. Sampson-root. Pale Purple Cone-flower.—"The dried rhizome and roots of Brauneria pallida (Nuttall) Britton (Echinacea angustifolia De Candolle) (Fam. Compositae)." N. F. IV. This composite plant, a native of the prairie region of America west of Ohio, has been introduced by the so-called eclectic physicians as a remedy in divers dissimilar diseases. The root is described by the N. F. as "nearly entire, cylindrical, very slightly tapering and sometimes slightly spirally twisted, from 10 to 20 cm. in length and from 4 to 13 mm. in diameter, externally grayish-brown, light brown or purplish-brown, slightly annulate in the upper portion, with occasional V-shaped stem scars, somewhat longitudinally wrinkled, or furrowed; fracture short, fibrous, bark less than 1 mm. in thickness, wood thick and composed of alternate light yellowish and black wedges; the rhizome with a circular pith. Odor faint, aromatic; taste sweetish, followed by a tingling sensation suggesting aconite, but lacking the persistent and benumbing effect produced by that drug. Under the microscope, sections show the presence of intercellular (schizogenous) oil and resin cavities or reservoirs in both the wood and bark, numerous stone cells distinguished by the presence of a blackish, resinous substance in the intercellular spaces between them and some of the adjoining parenchyma, the latter containing masses or aggregates of inulin. The walls of the tracheae or vessels are marked with simple slit-like pores or annular and reticulate thickenings; bast fibers occur in the stem, and in some specimens true libriform or wood fibers are found. Echinacea yields not more than 6 per cent. of ash." N. F. Kraemer and Sollenberger (A. J. P., 1911, p. 315) have described the physical characteristics of the drug. Lloyd (Eclectic Med. Journ., 1897) obtained minute quantities of an inert alkaloid and believed that the active substance was a resin. Heyl and Hart (J. Am. C. S., 1915, xxxvii, p. 1769) found the drug to contain inulin, 5.9 per cent.; inuloid, 6; sucrose, 7; vulose, 4; betaine, 0.1, and resins, 1.9 per cents.; the latter consisting of two isomeric phytosterols, phytosterolin, and the following fatty acids, oleic, linolic, cerotic and palmitic, but could find no physiologically active substance. Echinacea has been attributed with the property of increasing the resistance of the body to infection and is consequently used in boils, septicemia, cancer, and other infective conditions. It is also attributed with aphrodisiac and analgesic powers, but is probably without therapeutic value. The recommended dose of the fluidextract is from ten to thirty minims (0.6-1.8 mils). Hale (Lancet Clinic, March, 1901) injects an extract into the rectum in the treatment of hemorrhoids.
Brauneria purpurea D.G. Britton (Rudbeckia purpurea L., Echinacea purpurea Moench), Black Sampson, Purple Cone-flower (Virginia to Illinois and southward to Louisiana), has similar properties to B. pallida, and is similarly used.

Elaterium. Br. 1898. Extractum Elaterii. Elaterium, Elaterion, Fr. Elaterium, G. Elaterio, It., Sp.—"A sediment from the juice of the fruit of Ecballium Elaterium, A. Richard." Br., 1898. Ecballium Elaterium (L.) A. Eich., commonly known as the wild or squirting cucumber, is a perennial plant, with a large fleshy root, from which rise several round, thick, rough stems, branching and trailing like the common cucumber, but without tendrils. The leaves are petiolate, large, rough, irregularly cordate, and of a grayish-green color. The flowers are yellow and axillary. The fruit has the shape of a small oval cucumber, about an inch and a half long, an inch thick, of a greenish or grayish color, and covered with stiff hairs or prickles. When fully ripe, it separates from the peduncle, and throws out its juice and seeds with considerable force through an opening at the base, where it was attached to the footstalk. The name of squirting cucumber was derived from this circumstance, and the scientific and official title is supposed to have had a similar origin, though some authors maintain that the term elaterium was applied to the drug rather from the mode of its operation upon the bowels than from the projectile property of the fruit. The word elaterium was used by Hippocrates to signify any active purge. Dioscorides applied it to the medicine of which we are treating. It is a native of the south of Europe, and is cultivated in Great Britain, where, however, it perishes in the winter. (For description of the culture in England, see U. S. D., 19th ed., p. 432.)

Elaterium is the substance spontaneously deposited by the juice of the fruit, when separated and allowed to stand. Strong expression of the juice injures the product. When the fruit is sliced and placed upon a sieve, a perfectly limpid and colorless juice flows out, which soon becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white color, slightly tinged with green. It is the genuine elaterium, and was found by Clutterbuck to purge violently in the dose of one-eighth of a grain. But the quantity contained in the fruit is very small. Clutterbuck obtained only six grains from forty cucumbers. Commercial elaterium is often a weaker medicine, owing in part, perhaps, to adulteration, but much more to the fact that in order to increase the product, the juice of the fruit is often expressed with great force, and there is reason to believe that it is sometimes evaporated so as to form an extract, instead of being allowed to deposit the active matter. The French elaterium is prepared by expressing the juice, clarifying it by rest and nitrature, and then evaporating to a suitable consistence. As the liquid remaining after the deposition of the sediment is comparatively inert, it will be perceived that the preparation of the French Codex must be relatively feeble. The following are the directions of the British Pharm. (1885): "Cut the fruit lengthwise, and lightly press out the juice. Strain it through a hair sieve, and set aside to deposit. Carefully pour off the supernatant liquor; pour the sediment on a linen filter, and dry it on porous tiles, in a warm place. The decanted fluid may deposit a second portion of sediment, which can be dried in the same way. " The slight pressure directed is necessary for the separation of the juice
from the somewhat immature fruit employed. The perfectly ripe fruit is not used, as, in consequence of its disposition to part with its contents, it cannot be carried to market.

The best elaterium is in thin flat or slightly curled cakes or fragments, often bearing the impression of the muslin upon which it was dried, of a greenish-gray color becoming yellowish by exposure, of a feeble odor, and a bitter, somewhat acrid taste. It is pulverulent and inflammable, and so light that it floats when thrown upon water. When of inferior quality, it is sometimes dark-colored, much curled, and rather hard, breaking with difficulty, or presenting a resinous fracture. "In light, friable, flat or slightly curved, opaque cakes, about one-tenth of an inch (two and a half millimetres) thick; pale green, grayish-green, or yellowish-gray in color; fracture finely granular; odor faint, tea-like; taste bitter and acrid. It should not give the characteristic reactions with the tests for carbonates or for starch, and should yield half its weight to boiling alcohol (90 per cent.). When exhausted with chloroform, the solution evaporated, the residue washed with ether, and the process of solution, evaporation, and washing repeated, Elaterium should yield 25 per cent., or not less than 20 per cent., of Elaterin." Br. For an assay of elaterium by Jones and Ransom, see U.S. Dispensatory, 19th ed., p. 432. The Maltese elaterium is in larger pieces, of a pale color, sometimes without the least tinge of green, destitute of odor, soft, and friable, and not infrequently gives evidence of having been mixed with chalk or starch. It sinks in water, and usually contains so little elaterin that it should be employed only as a source of that principle. In the analyses of T. A. Elwood, the average yield of English elaterium was 21.5 per cent., of Maltese elaterium 15.3 per cent. (P. J., Nov., 1891.)

Clutterbuck first observed that elaterium resided in the portion of it soluble in alcohol and not in water. The subsequent experiments of Hennell, of London, and Morries, of Edinburgh, which were nearly simultaneous, demonstrated the existence of a crystallizable matter in elaterium which is the active principle, and has been named elaterin. (See Elaterinum.) According to Hennell, 100 parts of elaterium contain 44 of elaterin, 17 of a green resin (chlorophyll); 6 of starch, 27 of lignin, and 6 of saline matters.

Uses.—Elaterium is a powerful hydragogue cathartic, and in a large dose generally excites nausea and vomiting. If too freely administered, it operates with great violence upon both the stomach and bowels, producing inflammation of these organs, which has in some instances eventuated fatally. It also increases the flow of urine. The fruit was employed by the ancients, and is recommended in the writings of Dioscorides as a remedy in mania and melancholy. It is at present employed only for its purgative effects. It is one of the most efficient hydragogue cathartics in the treatment of dropsy, especially valued when edema is due to disease of the kidney. It should be used with the greatest caution, or not at all, in the old or feeble or those prostrated by disease. Two-fifths of a grain (0.025 Gm.) of elaterium proved fatal by purging in an ill and feeble lady of 70 years. (A. J. P., 1868, p. 373.) Because of its variability elaterium should never be employed, preference always being given to the official elaterin.
**Elder Flowers.** Sambucus, N. F. IV. Elder. Sambuci Flores, Br. 1898. Sweet Elder, Black Elderberry. Sureau, Fr. Cod. Fleurs de Sureau, Hollunder, Fliederblumen, G. Sambuco, It. Sauco (Flor de), Sp.—“The air-dried flowers of 8am-bucus canadensis Linne or of Sambucus nigra Linne (Far., Caprifoliaceae), separated from the peduncles and pedicels.” N. F. The common elder, Sambucus nigra, of Europe, differs from the American most obviously in its size, the former approaching in height that of a small tree. The stem is much branched towards the top, and has a rough whitish bark. The leaves are narrower. The flowers are small, whitish and in five-parted cymes. The ovary consists of but three carpels, there being five cells in S. canadensis L. The berries are larger in the European elder, globular, and blackish-purple when ripe. A fungus growing on this plant, called fungus sambuci, has been used as a local application in conjunctivitis. According to Steckel, it is capable of taking up from 9 to 12 times its weight of water. (N. R. Pharm., xiii, 476, 1864.) G. De Sanctis (Gazz. Chim. Ital., 1895, xxv, 1, vol. xlix) obtained coniine from the leaves and stems of Sambucus nigra.

The indigenous common elder, Sambucus canadensis, is a shrub from six to ten feet high, with a branching stem, covered with a rough gray bark, and containing a large spongy pith. The small branches and leaf-stalks are very smooth. The leaves are opposite, pinnate, sometimes bipinnate, and composed usually of five to nine oblong-oval, acuminate, smooth, shining, deep-green leaflets; the veins of the under surface are somewhat pubescent. The flowers are small, white, and disposed in loose cymes; the cream-colored corolla is wheel-shaped, with five stamens on the tube. The berries are small, globular, and deep purple when ripe. The shrubs grow in low, moist grounds, along fences, and on the borders of small streams, throughout the United States, from Canada to the Carolinas, and westward as far as Arizona and Texas. It flowers from May to July, and ripens its fruit early in autumn. The flowers were official in the U. S. P., 1890, and Br. Pharm., 1898, and are now recognized by the N. F. IV. They have an aromatic though rather heavy odor. The berries as well as other parts of the plant are employed, in domestic practice, for the same purposes as the corresponding parts of the European elder, to which this species bears a close affinity.

They are described by the N. F. as follows:

"Small, from 2 to 3 mm. in breadth, shrivelled; calyx superior, five-lobed; corolla cream-colored to brownish-yellow, rotate, flat or slightly cam-panulate, regularly five-lobed; stamens five inserted at the base of the corolla, and alternating with its lobes, filaments slender, anthers oblong, yellow; pollen ellipsoidal or tetrahedral and rounded, covered with finely punctate markings and having three pores. Odor faintly sweet and aromatic; taste slightly bitter. Sambucus yields not more than 8 per cent. of ash." N. F.

The flowers yield their active properties to water by infusion, and when distilled give over a small proportion of volatile oil, which on cooling assumes a butyricaceous consistence and contains an appreciable portion of ammonia. The berries are nearly inodorous, but have a sweetish, acidulous taste, dependent on the presence of saccharine matter and malic acid. Their expressed juice is susceptible of fermentation, and forms a vinous liquor used in Northern Europe. It is colored violet...
by alkalies, and bright red by acids, and the coloring matter is precipitated blue by lead acetate. The inner bark is without odor. Its taste is at first sweetish, afterwards slightly bitter, acrid, and nauseous. Both water and alcohol extract its virtues, which are said to reside especially in the green layer between the liber and the epidermis. According to Simon, the active principle of the inner bark of the root is a soft resin, which may be obtained by exhausting the powdered bark with alcohol, filtering the tincture, evaporating to the consistence of syrup, then adding ether, which dissolves the active matter, and finally evaporating to the consistence of a thick extract. Of this, twenty grains produce brisk vomiting and purging. (Ann. Ph. Ch., xxxi, 262.) The bark, analyzed by Kramer, yielded an acid called by him viburnic acid (which has proved to be identical with valeric acid), traces of volatile oil, albumen, resin, fat, wax, chlorophyll, tannic acid, grape sugar, gum, extractive, starch, pectin, and various alkaline and earthy salts. (Chem. Gas., May, 1846; from A. Pharm.) C. G. Traub found in the bark valeric acid, volatile oil, fat, resin, tannin, sugar, and coloring matter. (A. J. P., 1881, p. 392.) J. B. Metzgar made a partial examination of the fruit and found sugar, gum, tannin, fat, and a resinous body. (A. J. P., 1881, p. 553.) It was also examined by F. F. Lyons (A. J. P., 1892, p. 1), who found 0.5 per cent. of a volatile oil, an amorphous yellow compound of a glucosidal character, and a tannin. The volatile oil of elder flowers was examined by W. J. Bush & Co. (C. D., 1897, 53.) It has the sp. gr. 0.827, and is solid at ordinary temperatures like oil of rose. The liquid portion possesses the fragrance of fresh elder blossoms.

The flowers are gently excitant and sudorific, but are seldom used. The berries are diaphoretic and aperient, and their inspissated juice has been used as an alterative in rheumatism and syphilis in doses of from one to two drachms (3.9-7.7 Gm.) also as a laxative in doses of half an ounce (15.5 Gm.) or more. The inner bark is a hydragogue cathartic, and in large doses emetic. It has been employed in dropsy, epilepsy, and as an alternative in various chronic diseases. An ounce may be boiled with two pints of water to a pint, and four fluidounces (118 mils) given for a dose. It is also used in vinous infusion. The leaves are not without activity, and the young leaf-buds are said to be a violent and even unsafe purgative. The juice of the root has been highly recommended in dropsy as a hydragogue cathartic, sometimes acting as an emetic, in the dose of a tablespoonful, repeated pro re nata. The fruits of the California species S. glauca and S. racemosa are said to be used as food by the Indians. According to Combemale, confirmed by Lemoine, the aqueous solution of the European elder, S. nigra, is a very active diuretic, also causing in the lower animals, when given in sufficient amount, a pronounced fall of temperature, pulse, and respiration. It was found very useful in cardiac and renal dropsies. The drug itself sometimes caused vomiting and purging, but this effect never followed the use of the decoction. Elder-flower water was official in the Br., 1898, and was made by distilling one-fifth of the volume from a mixture of 10 pounds (Imperial) or 500.0 Gm. of fresh elder flowers, and 5 gallons (Imp. meas.) or 25 liters of water. In the N. F. they are an ingredient in compound fluidextract of stillingia and laxative species. Dose, from one to two drachms (3.9-7.7 Gm.) ; as a laxative, half an ounce (15.5 Gm.) or more.

**Elemi.** Gum Elemi. Elemi, Fr.—This concrete resinous exudation is official in several of the European Pharmacopoeias. The variety which is mostly used is known as
Manila or ø and is derived from Canarium commune L. and probably also from C. lusonicum Gray (Fam. Burseraceae). The name elemi is applied commercially to a large number of resins. The true elemi varieties contain from 20 to 25 per cent. of amyrin. These are further distinguished as "hard" or "soft" elemi, which are differentiated by the fact that the "soft" elemi contains from 20 to 25 per cent. of volatile oil. There are a number of other commercial varieties of elemi. The so-called carana-elemi is obtained from Protium Carana (Humb.) L. March., a tree growing in Venezuela and Northern Brazil. Brazilian Almesseya-elemi is obtained from Protium heptaphyllum March., var. Brasiliense Engl. East African elemi is probably obtained from Boswellia Frereana Birdwood. Yucatan elemi is derived from Amyris Plumieri DC. All these plants belong to the Burseraceae. The elemi is obtained by incisions into the trees, through which the juice flows and concretes upon the bark.

Carana-elemi occurs in masses of a greenish-yellow color, externally hard, internally soft, with a peculiar fennel-like aromatic odor. It is insoluble in water, soluble in sulphuric ether, chloroform, and benzene. According to Tschirch and Saal, carana-elemi contains 20 per cent. of exceedingly acrid resin. (A. Pharm., Bd. 241, 1903.)

Elemi is in masses of various consistence, sometimes solid and heavy like wax, sometimes light and porous; unctuous to the touch; diaphanous; of diversified colors, generally greenish with intermingled points of white or yellow, sometimes greenish-white with brown stains, sometimes yellow like sulphur; fragile and friable when cold; softening by the heat of the hand; of a terebinthinate somewhat aromatic odor, diminishing with age, and resembling to some extent that of lemon and fennel; of a warm, slightly bitter, disagreeable taste; entirely soluble, with the exception of impurities, in boiling alcohol; and affording a volatile oil by distillation. "Moistened with rectified spirit, it breaks up into small particles, which, when examined by the microscope, are seen partly to consist of acicular crystals." Br., 1885. Elemi is sometimes adulterated with rosin and turpentine.

According to Bacon (Philippine Journal of Science, 1909, iv, p. 93), the Manila elemi is derived from the Canarium luzonicum Miq. When first collected it is soft, but later becomes hard on exposure to the air and light, which has given rise to the belief that there were two varieties of the Manila gum. It is collected by incising the tree at the time when it is developing new leaves, the juice exuding through the bark and collecting in lumps at the point of the incision.

The two varieties of elemi that have been investigated chemically are the Manila, or soft elemi, and the Brazilian, or hard elemi. The Manila elemi contains 10 per cent. of an ethereal oil (made up of phellandrene and dipentene), amyrin, \( C_{30}H_{50}O \), of which, according to Vesterberg, the isomeric varieties \( a \)- and \( b \)-amyrin are present, an amorphous resin, small amounts of \( a \)-mandemic acid, \( C_{37}H_{56}O_{4} \), \( \beta \)-mandemic acid, \( C_{44}H_{80}O_{4} \), bryoidin, \( C_{20}H_{38}O_{4} \), and a bitter principle. The Brazilian elemi (protium elemi) contained protomyrin, 30 per cent.; protolaminic acid, 25 per cent.; and protolaresine, 37.5 per cent. The protomyrin has the same melting point and formula as the amyrin from Manila elemi.
Elemi has properties analogous to those of the turpentine, but is exclusively applied
to external use. In the United States it is rarely employed even in this way, except as
a constituent of plasters prepared upon the large scale. In the pharmacy of Europe it
enters into the composition of numerous plasters and ointments. Unguentum Elemi
(Br. Ph., 1885) was of the strength of about 20 per cent.

ELIXIR AROMATICUM. U. S.

AROMATIC ELIXIR Ellx. Arom. [Simple Elixir]

Elixir aromatique, Fr.; Aromatisches Elixir, G.

“Compound Spirit of Orange, twelve mils [or 195 minims]; Syrup, three
hundred and seventy-five mils [or 12 fluidounces, 326 minims];
Purified Talc, thirty grammes [or 1 ounce av., 25 grains]; Alcohol,
Distilled Water, each, a sufficient quantity, to make one thousand mils
[or 33 fluidounces, 6½ fluidrachms]. To the Compound Spirit of Orange
add enough Alcohol to make two hundred and fifty mils [or 8
fluidounces, 218 minims]. To this solution, add the Syrup in several
portions, agitating after each addition, and afterwards add, in the same
manner, three hundred and seventy-five mils [or 12 fluidounces, 326
minims] of Distilled Water. Mix the Purified Talc intimately with the
liquid, and then filter through a wetted filter, returning the first
portions of the filtrate until a transparent liquid is obtained. Lastly,
wash the filter with a mixture of one volume of Alcohol and three
volumes of Distilled Water, until the product measures one thousand
mil [or 33 fluidounces, 6½ fluidrachms].” U. S.

This is justly one of the most popular vehicles of the Pharmacopoeia.
The flavor which is agreeable to nearly all palates is enhanced by its
sweetness. If desired it can be colored with cochineal or caramel.

Off. Prep.—Elixir Aromaticum Rubrum, N. F.

ELIXIR GLYCRRHIZAE. U. S.

ELIXIR OF GLYCRRHIZA Elix. Glycyrrh. [Elixir Adjuvans. U.
S. VIII Elixir of Licorice]

Adjuvant Elixir, Elixir adjuvant, Fr.; Gewurzhaftes Lakritzenelixir, G.

“Fluidextract of Glycyrrhiza, one hundred and twenty-five mils [or 4
fluidounces, 109 minims]; Aromatic Elixir, eight, hundred and seventy-five millilitres [or 29 fluidounces, 282 minims], to make one thousand mils [or 33 fluid-ounces, 6\(\frac{1}{2}\) fluidraehms]. Mix and filter." U. S.

**Uses.**—This elixir is used as a vehicle for the administration of various medicinal preparations; it was introduced into the U. S. Pharmacopoeia (8th Rev.) mainly to furnish an alternative elixir to aromatic elixir which is similarly used. The presence of the glycyrrhiza aids in disguising or obtunding the taste of bitter or disagreeable substances and the proportion might advantageously be increased.

**ELIXIRIA**

**ELIXIRS**

Cordials; Elixirs, Fr.; Elixire, G.

Elixirs as they are known in modern American pharmacy are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. They differ greatly from the liquids formerly termed elixirs, from the fact that the first object sought for in the modern elixir is an agreeable taste, and usually this is attained only by such sacrifices as to render the effect of the medicine almost nil, while the principal activity is due to the alcohol, which has proved in many cases very injurious. These considerations have prevented an extensive official recognition of elixirs, and the U. S. Pharm., 1890, recognized but two, one of which, the Aromatic Elixir, has been introduced merely as a vehicle. In the U. S. P. (8th Rev.) two elixirs were introduced, Adjuvant Elixir and Elixir of Iron, Quinine and Strychnine Phosphates. In the U. S. P. IX Elixir of Iron, Quinine and Strychnine Phosphates was dropped and Aromatic Elixir and Elixir of Glycyrrhiza (formerly named Adjuvant Elixir) were alone retained.

A number are, however, included in the N. F. IV. Elixir of Orange, official in the U. S. Pharm., 1880, may be made by the formula on page 435, U. S. Dispensatory, 19th edition.

**EMBELIA. Br.**

**EMBELIA**
"Embelia is the dried fruit of Embelia Ribes, Burm. fil., and also of Embelia robusta, Roxb." Br.

Embelia was introduced into the Br. Pharm. (1914) from the British Addendum (1900). It is officially described as "globular, about four millimetres in diameter, varying in color from dull red to nearly black; warty or striated longitudinally; superior, minutely beaked and often attached to a 5-partite calyx and slender pedicel. Pericarp brittle, enclosing a single seed surrounded by a delicate membrane. Seed reddish, marked with lighter spots. Endosperm horny and slightly ruminated. Taste slightly astringent and aromatic." Br.

The genus Embelia (Fam. Myrsinaceæ) includes a large number of creeping or almost climbing tropical shrubs. They possess petiolate leaves, small white flowers and are especially abundant in tropical Asia, Embelia Eibes extending as far as southern China. The fruits of this plant somewhat resemble pepper and have been used as an adulterant of it.

Embelia contains 2.5 per cent. of embelic acid, C₉H₁₄O₂, which occurs in golden yellow crystals, which are insoluble in water and soluble in alcohol, ether, chloroform and benzene.

Uses.—Embelia, under the names of viranga, vayvirang or birang-i-kabuli, has long been employed in India as an anthelmintic and has found its way into European commerce. It has but slight laxative properties, so that it is better to follow it by a purgative. It is especially tenicidal, the tape worm being expelled dead. The powdered drug may be given in milk early in the morning. Warden has found that ammonium embelate is an effective tenicide in dose of three grains (0.2 Gm.) for children and six grains (0.4 Gm.) or more for adults. As it is nearly tasteless and soluble it may be readily administered in syrup.

Dose, of embelia, one to four drachms (3.9-15.5 Gm.).

EMPLASTRA

PLASTERS

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Spread plasters having rubber in their composition are most largely used; they are usually perforated. Some plasters have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the Pharmacopoeias. Others owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and fats.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change color and to become hard and brittle, and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be excluded as much as possible. The defect may usually be remedied by melting the plaster with a moderate heat and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheepskin, or the kind known commercially as "hemlock splits." A margin about one-fourth or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper so cut as to leave in the center a vacant space of the required dimensions, and removing the paper when no longer needed. The spreading of the plaster is most conveniently accomplished by the use of a spatula or plaster iron. This may be heated by means of a spirit lamp or gas jet. Care must be taken that the instrument be not so hot as to
discolor or decompose the plaster, and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if this has become so hard as to crack, the iron should be drawn over the line of junction.

The spreading of plasters has become to a great extent a lost art to the pharmacists of this country, owing to the introduction of machine-spread plasters, which contain India-rubber in the adhesive composition. These are reasonably permanent, and do not require the application of heat. When made by reliable manufacturers they are in many cases to be preferred, but the introduction of immense quantities of worthless ones by unscrupulous makers has caused many practitioners to direct plasters to be spread by the pharmacist from official plaster. The perforation, or "porousing," of plasters is usually accomplished on a large scale by expensive apparatus. J. J. Edmondson read a paper before the Pennsylvania Pharmaceutical Association in 1887 giving the process for manufacturing rubber-mass plasters as carried on by Johnson & Johnson, of New York. It is as follows: The ingredients employed are—rubber, two parts; Burgundy pitch, one part; 'gum olibanum, one part. This may vary with some special plasters, but they constitute the component parts of the mass used for the majority.

The crude rubber is at first steeped in hot water, to cleanse and soften it, then the rubber is passed through the washer and crusher, where it is subjected to severe pressure between two corrugated rolls, eight inches in diameter and one foot wide, while a stream of water falling continually washes it thoroughly, and it comes out in sheets somewhat softened. After these sheets are dried, which requires a number of days, they are passed through the grinder, where they are crushed between two smooth rollers, fourteen inches in diameter and thirty-six inches across. This thoroughly softens the rubber and makes it plastic, so that it can be readily worked up with the other ingredients. The principal operation, the mixing, then takes place. The medication must be carefully combined, and the whole manipulation so managed that the plaster will be uniform, so that age or varying temperature shall not
affect it. This operation is performed by means of rollers, sixteen inches in diameter, arranged so that one revolves at twice the speed of the other. Between these large rollers the mass is passed with whatever medication is required: e.g., when a belladonna mass is to be made, a certain amount of the stock mass is taken and extract of belladonna in the proportions corresponding to the formula in the Pharmacopoeia. These are repeatedly passed through the rollers until the extract of belladonna is thoroughly mixed with the mass, care being taken to keep the temperature from rising high enough to decompose or affect the alkaloids. The spreading is also done by rollers, into which the thoroughly mixed mass is fed at the same time that the cloth is fed, the thickness of the plasters being governed by the adjusting of screws on the side of the machine.

The rubber base is pliable, adhesive, it will not become too hard or too soft, but will yield up the medication to the absorbents of the skin, and its properties will be retained indefinitely. For formulas for plasters of former Pharmacopoeias, see U. S. D., 19th edition, p. 436.

**EMPLASTRUM CAPSICI. U. S.**

**CAPSICUM PLASTER Emp. Capsic.**

Sparadrapum Capsici; Sparadrap de Capsique, Fr.; Capsicumpflaster, G.

“Oleoresin of Capsicum, Rubber Plaster, spread on fabric, each, a sufficient quantity. Apply oleoresin of capsicum to the surface of rubber plaster so as to form a thin, even coating, leaving a margin around the edges. Each fifteen square centimeters of spread plaster contains 0.25 Gm. of oleoresin of capsicum." U. S.

The oleoresin should be laid on very evenly with a camel's-hair brush.

This affords a convenient way of obtaining the rubefacient effects of capsicum; of course, the practice will be for the pharmacist to employ machine-spread adhesive plaster as the base; although, with a little experience, very good work can be done by hand.

**EMPLASTRUM MENTHOL. Br.**

**MENTHOL PLASTER**
Emplatre de Menthol, Fr.; Mentholpflaster, G.

"Menthol, 150 grammes; Yellow Beeswax, 100 grammes; Resin, 750 grammes. Melt the Beeswax and Resin together; when the mixture has cooled to about 70° C. (158° F.), add the Menthol, and stir until dissolved." Br.

This is an official plaster of the British Pharmacopoeia, having been introduced in the additions in 1885. It is a mild counter-irritant, intended especially for relief in localized neuralgia and rheumatic pains.

EMPLASTRUM RESINAE. U. S., Br.

ROSIN PLASTER Emp. Res. [Rosin Adhesive Plaster, Adhesive Plaster]

"Rosin, in fine powder, one 'hundred and forty grammes [or 4 ounces av., 411 grains]; Lead Plaster, eight hundred grammes [or 28 ornees av., 96 grains]; Yellow Wax, sixty grammes [or 2 ounces av., 51 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Melt the lead plaster and yellow wax together with a gentle heat, then add the rosin and, when melted, mix thoroughly, strain, and allow the product to cool, stirring until it stiffens." U. S.

"Resin, 100 grammes; Lead Plaster, 850 grammes; Hard Soap, 50 grammes. Melt each ingredient separately at as low a temperature as possible; mix." Br.

The name of this plaster was changed in the U. S. P. IX to rosin plaster, it was formerly termed adhesive plaster. It differs from lead plaster in being more adhesive and somewhat more stimulating. It resembles the common adhesive plaster of commerce, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other and a firm support is given to the granulations. The U. S. P. IX formula differs from that official in U. S. P. VIII in that the use of rubber and petrolatum in place of yellow wax and rosin was abandoned and the old process has been restored. As prepared by the
Dublin College it contained soap, which gave it greater pliability, and rendered it less liable to crack in cold weather, without impairing its adhesiveness, and the process of that College has been adopted in the British Pharmacopoeia. It is usually spread upon muslin, and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept ready spread by the pharmacist; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. Adhesive plaster originally employed by Baynton contained only six drachms of rosin to the pound of lead plaster. To obviate the possibility of irritating the skin, Herpin recommends the addition of lead tannate, the proportion of which, when adhesiveness is required in the plaster, should not exceed one-twentieth, but under other circumstances may be increased to one-twelfth.

The addition of Burgundy pitch or turpentine is objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.

The most popular and widely used forms of adhesive plaster used at the present time are those containing zinc oxide as one of the constituents.

**EMPLASTRUM SINAPIS. U. S.**

**MUSTARD PLASTER** Emp. Sinap. [Charta Sinapis, U. S. VIII, Mustard Paper]

"A uniform mixture of powdered black mustard (deprived of its fixed oil), and a solution of rubber, spread on paper, cotton cloth or other fabric. Preserve it in tightly-closed containers. A square of 100 square centimeters contains not less than 2.5 Gm. of black mustard deprived of its fixed oil. When moistened thoroughly with tepid water and applied to the skin, the Plaster produces a decided warmth and reddening of the skin within five minutes. Before Mustard Plaster is applied, moisten it thoroughly with tepid water." U. S.

"Black Mustard, in No. 60 powder, one hundred grammes [or 3 ounces
av., 231 grains]; Rubber, ten grammes [or 154 grains]; Petroleum Benzin, Carbon Bisulphide, each, a sufficient quantity. Pack the Black Mustard in a conical percolator, and gradually pour Petroleum Benzin upon it until the percolate ceases to produce a permanent, greasy stain upon blotting paper. Remove the powder from the percolator, and dry it by exposure to the air. Having meanwhile dissolved the Rubber in a mixture of one hundred cubic centimeters [or 3 fluidounces, 183 minims], each, of Petroleum Benzin and Carbon Bisulphide, mix the purified Mustard with a sufficient quantity of the solution to produce a semi-liquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather thick, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of sixty square centimeters should contain about 4 Gm. of Black Mustard deprived of oil. Before it is applied to the skin, Mustard Paper should be dipped in warm water for about fifteen seconds." U. S. VIII.

"Black and White Mustard Seeds, equal proportions by weight; Benzol, Solution of India-rubber, of each, a sufficient quantity. Bruise the Mustard Seeds and extract the fixed oil by percolation with the Benzol. Dry the residue by exposure to the air in a warm closet, and reduce to No. 60 powder. Mix seventy-five grains (or five grammes) of the purified mustard with five fluid drachms (or eighteen cubic centimetres) of Solution of India-rubber, and spread by means of a suitable brush over about 30 square inches (or about two square decimetres) of one side of a piece of cartridge paper. Allow it to dry by exposure to the air." Br., 1898.

The name of this preparation was changed in the U. S. P. IX from mustard paper to mustard plaster; from a pharmaceutical point of view this was a mistake, for mustard leaves as they are often called are very different from either mustard plasters or mustard poultices. The U. S. P. IX and the British Pharm. (1914) no longer admit a process for making Charta Sinapis, the U. S. P. IX merely describing the preparation as found in commerce. The U. S. P. VIII and the Br. Pharm., 1898, processes are given above.

The formula for this preparation was greatly improved by the U. S. P. in 1890 and Br., 1898. The British preparation (1885) was at fault in not providing for the extraction of the fixed oil by previously percolating with petroleum benzin or carbon disulphide; otherwise the paper will be greasy, giving to the plaster an untidy appearance and soiling the linen of the patient. Solution of gutta-percha is unsuited for use in this
preparation, on account of want of adhesiveness, and the tendency of
the mixture, when dry, to crack and peel off. We have used instead a
solution of 1 part of pure rubber in 30 of equal parts of carbon
disulphide and petroleum benzine. On the large scale, by means of a
plaster spreading apparatus a uniform coat of this solution may be
applied to paper. As the latter passes out from under the apparatus, a
sieve containing the powdered mustard is shaken over it; this is fixed by
the adhesive coat and firmly retained after the evaporation of the
volatile liquids in a warm place. The application of the powdered
mustard must be properly regulated according to the speed with which
the machine delivers the coated paper. The paper is cut into pieces of
convenient size, and needs only to be wetted with tepid water to be
ready for use. Owing to the fact that the large manufacturers can put
mustard paper upon the market at such low rates that it pays the
apothecaiy better to buy than to prepare it, Charta Sinapis, so far as we
can learn, is rarely made in the retail stores.

Uses.—For the uses of the mustard plaster, see Sinapis.

Experience has shown that the ready-made mustard papers err rather
from too much than from too little activity. Moreover, their action cannot
be regulated with the same nicety as can that of the mustard poultice.
Unless in the case of travellers, and of others who must wait upon
themselves, the domestic application is preferable. The mustard leaves
can rarely be borne for more than ten or fifteen minutes. Care should be
observed to protect the leaves, as they are popularly called, from the
action of moist air by keeping them in well closed containers.

EMULSA.

EMULSIONS

Emulsions, Fr.; Emulsiones, G.; Emulaiones It; Sp

Under this head are included in the U. S. Pharmacopoeia liquid
preparations in which oleaginous substances are suspended in aqueous
fluids by the intervention of gum or other viscid matter. The
preparations forming the present class of emulsions were termed
Mixtures in earlier pharmacopoeias, and it is to be regretted that under
this indefinite term are still grouped liquids of many kinds; the
separation of these into proper classes is only a question of time, and the
introduction of this new class into the Pharmacopoeia of 1890 marked
the first step in the direction of greater accuracy in defining
pharmaceutical preparations, and more system in classification. The
object of emulsions is usually to facilitate the administration, to conceal
the taste, or to obviate the nauseating effects of unpleasant medicines,
and their perfection depends upon the intimacy with which the
ingredients are blended. Some skill and care are requisite for the
production of uniform and perfect emulsions. As a rule, the body to be
suspended should be thoroughly mixed by trituration with the
substance intended to act as the intermedium, before the aqueous
vehicle is added. In the case of the liquid balsams and oils, if gum arabic
is employed as the intermedium it should be previously brought to the
state of mucilage of the consistence directed in the U. S. Pharmacopoeia.
When a fixed oil, oleoresin, or balsam is to be made into an emulsion,
the method most employed abroad is to add one part of gum to two or
three of the oil, in a mortar, triturate until the mixture is complete, and
then add at once twice as much water as gum used, and triturate
rapidly until the oil is completely emulsified, then gradually add the
remainder of the vehicle with constant trituration. Agitation in a bottle
is sometimes substituted for trituration. The plan most largely used in
this country is to make the emulsion with mucilage. Having a broad flat
pestle and a mortar perfectly free from grease, put in a little mucilage,
rub it around the mortar, add about half as much oil, triturate from the
center so as to emulsify this, then add more mucilage, then oil, and so
on until the operation is completed. Care is required never to get the oil
in excess of the mucilage. This plan seems to accord with the principle
laid down by R. Bother, that the most perfect and rapid emulsifier is a
perfect emulsion. The proportion of gum and water necessary to make a
good emulsion with the fixed oils varies with the oil. Thus, while castor
oil requires only two drachms of the gum and three drachms of water to
the ounce, most other fixed oils require half their weight of gum, and a
weight of water equal to half that of the oil and gum united. These
quantities being well rubbed together, any desirable amount of water
may afterwards be gradually added, and will readily incorporate with
the other ingredients. The white of egg has been frequently ordered by
physicians as the suspending substance, but it is inferior for this
purpose to the yolk, or to gum arabic. When the white is used it should
be well beaten, and incorporated with the oleaginous or balsamic
substances before the water is added. When volatile oils are to be
emulsified they should be mixed with an equal volume of inert fixed oil
to promote stability. Quillaja, saponin, and other substances having
similar properties have been proposed as emulsifying agents, but they are objectionable on account of their medicinal activity. Emulsifying agents should be inert.

Leo Boon (J. A. Ph. A., 1916, v, 496) gives an extensive review of the literature on emulsification and Roon and Oesper have made an important contribution to the theory of emulsification (J. I. & E. C. 1917, p. 156). The authors agree with Fischer (Science 1916, p. 468) that emulsification is due to, or accompanied by, the formation of a hydrated colloid compound. Both the English and Continental methods of emulsification were studied carefully. The unsatisfactory results obtained by the majority of workers with the English method, are alleged to be due to the fact that the hydration of the emulsifying agent occurs progressively and not all at one time and for the greater part is not accomplished in the presence of the internal phase (oil). In the Continental method all of the emulsifying agent (colloid) is hydrated at one time and in the presence of the internal phase (oil). After experimenting with various proportions of materials, it is stated by the authors that the best and quickest results are obtained by the use of the following proportions in the preparation of the original nucleus: oil 4, water 3, gum 2.

Experimental emulsions were produced of the following substances: hexane, sp. gr. 0.691; chloroform, sp. gr. 1.526; carbon tetrachloride, sp. gr. 1.597; benzene, sp. gr. 0.877; oil of turpentine, sp. gr. 0.85; mineral oil, sp. gr. 0.853; cottonseed oil, sp. gr. 0.921. Gum emulsions and soap emulsions were made of all these and the conclusions, in part, were as follows:

1. The presence of a hydrated colloid is necessary for emulsification.

2. This hydration compound is most efficiently used if formed at the moment of dispersion of the internal phase—in other words, the three constituents, internal phase, emulsifier and water, in critical proportions, must all be mixed at one time in order to form a properly hydrated nucleus.

3. Slight variations from the proper procedure or from the critical proportions yield either less stable emulsions or none at all.

4. No emulsion results if the emulsifier is diluted before the dispersion of
the internal phase.

**EMULSUM AMYGDALAE. U. S. (Br.)**

**EMULSION OF ALMOND Emuls. Amygd.**

[Milk of Almond]

**Mistura Amygdalae**, Br.; Almond Mixture; Mistura Amygdalae, U. S. 1880; Emulsio Amygdalae, s. Amygdalarum, Emulsio Simplex; Milk of Almonds; Simple Emulsion; Emulsion d’Amande, Fr. Cod.; Lait d’Amande, Fr.; Mandelemulsion, Mandelmilch, G.; Emulsione di mandorle doici, It.; Emulsion comun, Sp.

"Sweet Almond, sixty grammes [or 2 ounces av., 51 grains]; Acacia, in fine powder, ten grammes [or 154 grains]; Sugar, thirty grammes [or 1 ounce av., 25 grains]; Water, a sufficient quantity to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Having blanched the almonds, add the acacia and sugar, and beat them, in a mortar, until they are thoroughly mixed. Then rub the mass with nine hundred mils [or 30 fluidounces] of water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with enough water to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly. This preparation must not be dispensed unless it has been recently prepared." U.S.

"Compound Powder of Almonds, 125 grammes; Distilled Water, sufficient to produce 1000 millilitres. Triturate the Powder with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water; strain through fine muslin." Br.

These preparations are essentially the same, the gum and sugar which enter into the U. S. formula directly being ingredients of the compound powder of almonds of the British. The gum arabic in these formulas is introduced not so much for its demulcent properties as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an emulsion of bitter almonds from bitter almond or peach kernels. The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water, and
with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when pure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The emulsion is not permanent and compound powder of almonds often has a taint of rancidity when kept too long. Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation is closely analogous to milk in chemical relations and appearance. In warm weather it soon becomes sour.

Uses.—Emulsion of almond has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections and irritation of the urinary passages. To be of service it must be freely employed. It is occasionally employed as an emollient lotion, and as a vehicle for less agreeable medicines, but should not be used with any considerable quantity of tinctures, acidulous salts, or other acid substances.

Dose, two to eight fluidounces (60-240 mils).

**EMULSUM ASAFOETIDAE. U. S.**

**EMULSION OF ASAFOETIDA** Emuls. Asafoet.  
[Milk of Asafoetida]

"Asafoetida, in tears or selected masses, forty grammes [or 1 ounce av., 180 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Rub the Asafoetida, in a warmed mortar, with nine hundred mils [or 30 fluidounces] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and rinse the mortar and strainer with enough Water to make the product measure one thousand mils [or 33 fluidounces, 6¹/₂ fluidrachms]. Mix the whole thoroughly." U. S.

The present 4 per cent. official emulsion slightly exceeds in strength the mixture of the U. S. P., 1870, which contained but 3 per cent. of asafoetida. This emulsion is less stimulating than the tincture, and more
prompt in its action than the pill. Its excessively disagreeable odor and taste are, however, objections, which induce a frequent preference for the last mentioned preparation. It is very often employed as an enema. From two to four fluidounces (60-120 mils) may be given by the rectum. D. Ackerman prepares a concentrated emulsion of asafetida, which will keep if excluded from the light, by using a mixture of three-fourths of pure water and one-fourth of diluted acetic acid as the menstruum. For cleaning mortars in which asafetida has been rubbed, he recommends solution of potassium hydroxide, followed by soap and water.

Dose, one-half to one fluidounce (15-30 mils).

**EMULSUM OLEI TEREBINTHINAE. U. S.**

**EMULSION OF OIL OF TURPENTINE Emuls. Ol. Tereb.**

Emulsion d'Essence de Terebenthine, Fr.; Terpentintol-emulsion, G.

"Rectified Oil of Turpentine, fifteen mils [or 243 minims]; Expressed Oil of Almond, five mils [or 81 minims]; Syrup, twenty-five mils [or 406 minims]; Acacia, in fine powder, fifteen grammes [or 231 grains]; Water, a sufficient quantity, to make one hundred mils [or 3 fluid-ounces, 183 minims]. Introduce the acacia into a perfectly dry bottle of sufficient capacity, add the rectified oil of turpentine and the expressed oil of almond and shake the bottle thoroughly. Then add thirty mils [or 1 fluid-ounce, 7 minims] of "water and incorporate it by vigorous shaking. When the oil has been completely emulsified add first the syrup, in several portions, shaking after each addition, and then enough "water, in divided portions, shaking after each addition, to make the product measure one hundred mils [or 3 fluid-ounces, 183 minims]." U. S.

The U. S. P. VIII introduced this emulsion with the view of providing a simple and fairly permanent preparation. Rectified oil of turpentine should be used exclusively. The process is much like the one recommended by J. Winchell Forbes, and a mortar and pestle are not needed to produce a perfect emulsion.

Dose, one-half to one fluidrachm (1.9-3.75 mils).

**Ephedra.** Ephedra vulgaris Eich. (Fam. Gnetaceae)—Nagai has extracted from this Japanese plant an alkaloid, ephedrine, which, according to Kinnossuke, produces in the lower animals acceleration of the pulse, with lowering of the blood pressure,
elevation of the rectal temperature, dilatation of the pupils, convulsions, and death by arrest of the heart and respiration. (B. K. W., 1887.) Scriba found that a 10 per cent. solution dilates the pupil with certainty, in from forty to sixty minutes, without irritation, the dilatation not being complete, and the accommodation not at all or only slightly affected, and the pupils returning to normal in from five to twenty hours. An alkaloid has also been discovered in Ephedra distachya L., a shrub whose branches and root are used in Siberia as a remedy in gout and syphilis. According to Robert, this alkaloid is essentially different from, ephedrine, in not being mydriatic or poisonous. P. Spehr (A. J. P., 1892, 234) considers that E. vulgaris contains two alkaloids, ephedrine and pseudo-ephedrine, isomeric and of the formula C_{10}H_{15}ON, while E. monostachya contains a crystalline base melting at 112° C. (233.6° F.) and having the formula C_{13}H_{19}ON. This latter, as stated by Kober, is not mydriatic or poisonous. See paper by E. Schmidt, A. Pharm., cd, 1912, Nos. 2 and 3, 154, 161. According to Gunsberg, pseudo-ephedrine is a powerful mydriatic, its 10 per cent. solution causing in fifteen minutes dilatation of the eye through excitement of the sympathetic nerve.

Ephedra nevadensis S. Wats and E. antisyphilitica C. A. Meyer, which grow abundantly in the extreme Western United States, are used under the names of caynote, canutilo, whorehouse tea, as a remedy in gonorrhrea. Loew thinks that their virtues reside in a peculiar tannin. Dose, of fluid-extract, from one to two fluidrachms (3.75-7.5 mils). In Texas E. trifurca Torr. is similarly employed.

Epigaea. Epigaea repens L. Trailing Arbutus. Ground Laurel. Mayflower. Gravel Plant.—This is a small prostrate or trailing ericaceous plant, having bristly woody stems; evergreen, entire, cordate-ovate leaves, and small, very fragrant dimorphic, subdioecious flowers, which appear early in the spring. It is found in the sandy woods or rocky soil, and grows on the sides of hills with a northern exposure. Darlington states that the plant has been supposed to be injurious to cattle, when eaten by them. (Flora Cestrica, 259.) Jefferson Oxiey has found in this plant arbutin, C_{12}H_{16}O_{7}, urson, C_{20}H_{32}O_{2}, ericolin, C_{34}H_{56}O_{21} (the same constituents as are in uva ursi), tannic and formic acids, and a principle allied to gallic acid. (A. J. P., xliv, 253.) Thal gives the simpler formula C_{26}H_{30}O_{3} to ericolin. Eli Ives of New Haven, Connecticut, in 1849, highly commended epigaea as a substitute for uva ursi, and we now know that the two drugs contain the same active principles. The decoction of the leaves and stem may be used freely.

Epilobium. Epilobium angustifolium L. (Chamaenerion angustifolium Scop.) Willow-herb. Herbe de St. Antoine, Fr. Weidenröschen, Antonskraut, G. (Fam. Onagraceae)—There are several indigenous species of Epilobium, which have the common name of willow-herb, from the resemblance of their leaves to the willow, all of which probably have nearly identical properties. The E. angustifolium is the largest of them. Its leaves and roots are said to be demulcent, tonic, and astringent, and yield their virtues to water and alcohol. They are used by the eclectics, generally and locally, in decoction, infusion, or cataplasm, as astringents. Oliver reports (B. M. J., ii, 1897) violent poisoning with epileptiform convulsions caused by E. hirsutum L. Under the name of Kaporietea, the leaves of E. angustifolium and of E. hirsutum are largely
used in Russia as a beverage.

**Equisetum.** Equisetum hyemale L. Horsetail. Scouring Rush. Prele, Fr. Schachtelhalm, G. (Fam. Equisetaceae)—An indigenous plant, with slender annual stems from 3 to 9 dm. high, growing abundantly throughout the United States, and preferring wet places, as the banks of streams, etc. The plant derives its name of scouring rush from its use in scouring, for which it is fitted by the silicious character of the stems. Examined by F. J. Young (A. J. P., 1886, 419), it yielded to petroleum benzine as a solvent 1.4 per cent. of a brownish-green, semi-liquid, fixed oil, which was readily saponified. It also contained a green semi-solid resin, sugar, and mucilage. The infusion of the whole plant is used sometimes in dropsical and renal diseases, but Cow (A. E. P. P., 1912, lxx, p. 393) has shown that the diuretic action of equisetum is very feeble.

**Erechthites.** Erechthites hieracifolia (L.) Raf. Fire-weed.—An annual indigenous composite plant, growing in moist woods and recent clearings, and having a rank, somewhat aromatic odor. Its taste is bitterish, slightly acrid, and disagreeable. It yields its virtues to water. It has been especially recommended in dysentery. It is prone to infest the peppermint fields of Michigan, and its oil is said sometimes to deteriorate the oil of peppermint from that region. It has been shown however, that Erigeron (Leptilon) canadensis L. is far more injurious (see Erigeron).

**Erigeron.** Fleabane. Scabious. Sweet Scabious. Daisy Fleabane. Herbe d’erigeron, HerbedeVergerette, Fr. Berufkraut, Gr.—Under this name the U. S. Pharmacopoeia of 1870 recognized the herbal portions of Erigeron annuus (L.) Pers. and E. philadelphicus L. (Fam. Compositae)

The two species are abundant in the middle portions of the United States, grow in open fields, and are probably of identical medicinal value. They are popularly known as fleabane. The whole herb is used, and should be collected while the plants are in flower. It has a feebly aromatic odor and bitterish taste, and imparts its properties to boiling water.

Canada fleabane is very common throughout the northern and middle sections of the United States, and has become naturalized over the world. It abounds in neglected fields, and is reported to be a very troublesome weed on the peppermint plantations of the West. It blooms in July and August. The plant, all parts of which are medicinal, should be collected while in flower. The leaves and flowers are said to be the most active parts. It has a characteristic odor, and a bitterish, acrid, somewhat astringent taste. Among its constituents, according to De Puy, are bitter extractive, tannin, gallic acid, and volatile oil. Both alcohol and water extract its virtues. Its acrimony is diminished by decoction, in consequence, probably, of the escape of the oil, upon which its virtues in part depend. All of the erigerons are reputed to be diuretic, tonic, and astringent: and useful in dropsical complaints and diarrhea. They have been given in
substance (dose, a drachm, or 3.9 Gm.), infusion, tincture, or extract (dose ten grains, or 0.65 Gm.), but the oil is the only proper preparation. The oil is of value in uterine, pulmonary, and other internal hemorrhages, in doses of from five to fifteen minima (0.3-0.9 mil), every two hours. (See p. 1519.)

For further information concerning these drugs see U. S. D., 19th cd., p. 1479.

**Eriobotrya.** Eriobotrya japonica Lindl. Loquat. Loquat. Bibader. Neflier du Japon. Nestolédi Giappone. (Fam. Rosaceae)—A small tree, indigenous to Japan and extensively cultivated. The fruit closely resembles the apricot and has a sweetish acid pulp. The seeds of this tree are said to contain amygdalin and emulsin, and to yield hydrocyanic acid in poisonous quantities. (P. J., Aug., 1885.) Herissey, in 1907, stated that Lehmann was incorrect in his conclusions that the glucoside was identical with laurocerasin, and states that the glucoside is amygdalin. (A. Pharm., coxiv, 1907.)

**ERIODICTYON. U. S.**

**ERIODICTYON Eriodict. [Yerba Santa]**

"The dried leaves of Eriodictyon californicum (Hooker and Arnott) Greene (Fam. Hydrophyllaceae), without the presence or admixture of more than 5 per cent. of stems or other foreign matter." U. S.

Mountain Balm, Consumptive's Weed, Bear's Weed, Gum Bush.

Eriodictyon californicum is a low evergreen shrub growing abundantly upon dry hills in California. It is glabrous, resinous, having short petiolate, long lanceolate leaves, irregularly more or less serrate, sometimes entire, whitened beneath, between the reticulations, by a minute and close tomentum, above glabrous. The corolla is tubular funnel-form; the calyx being sparsely hirsute. The leaf structure has been studied by F. W. Ritter. (See A. J. P., 1895, 565.)

E. tomentosum, which grows often along with E. californicum, especially in the southern part of California, is readily distinguished by its dense coat of short villous hairs, whitish or rusty-colored with age. It is also a larger shrub than E. californicum, has its corolla somewhat salverform, and its leaves oblong or oval, and obtuse.

**Properties.**—The leaves of eriodictyon are characterized by the U. S. Pharmacopoeia as "Usually in fragments; when entire, laminae lanceolate, from 5 to 15 cm. in length, and from 1 to 3 cm. in breadth;
summits acute; bases slightly tapering into short petioles; margins irregularly serrate or crenate-dentate; upper surfaces yellowish-brown, covered with a more or less glistening resin; under surfaces grayish or yellowish-white, conspicuously reticulate with greenish-yellow veins; minutely tomentose between the reticulations; thick, brittle; odor aromatic; taste balsamic, bitter, becoming sweetish. Under the microscope, transverse sections of the laminas of Eriodictyon show upon the upper surface large epidermal cells, the outer walls being very uneven, owing to indentations which appear as striations in surface view; glandular hairs numerous, with short 1-celled stalks and 6- to 8-celled glandular heads; palisade cells very narrow, from 2 to 6 rows deep, containing numerous chloroplastids; cells of dorsal-pneumatic tissue (loose mesophyll) very few; fibro-vascular tissues not strongly developed except in the midrib and more prominent veins; numerous 1-celled, much twisted, thick-walled, non-glandular hairs occurring on the lower surface between the veins. Under the microscope, sections of the stems of Eriodictyon show the epidermis usually replaced by strongly lignified cork; cortex of from 10 to 20 rows of more or less rounded cells; bast-fibers deep-seated with thick, more or less strongly lignified walls and occurring in small groups forming a more or less interrupted circle; sieve tissues in a narrow zone; wood-wedges consisting of tracheae with spiral thickenings, simple or bordered pores and numerous strongly lignified wood-fibers, separated by medullary rays 1-cell in width; pith very large, the walls of the cells being strongly lignified and with numerous simple pores."

U. S.

Tunmann (Ph. Centralh., 1908, p. 159) describes and illustrates the pharmaeognostic and microscopic characteristics of Eriodictyon californicum, and discusses the morphological importance of the oil glands of eriodictyon. H. S. Wellcome (The Pharmacist, 1876, p. 33) found the drug to contain two aromatic resins, while an aqueous infusion of leaves which had been exhausted by alcohol yielded an intensely bitter extract. According to the analysis of Chas. Mohr (A. J. P., 1879, 549), it contains tannic acid and 8 per cent. of an acrid, bitter, resin, upon which its activity is believed to depend, also a minute quantity of volatile oil. R. Rother describes (A. J. P., 1887, p. 225) an acid resin which forms with bases quite soluble salts. The acid resin was obtained at the conclusion of the spontaneous volatilization of the several solvents as a green-yellow transparent mass. Thai (Ph. Z. R., 1883, p. 209) affirmed the presence of ericolin, C_{34}H_{56}O_{22}. Power and Tutin deny that ericolin is present but find besides volatile oil and resin, triacontane, C_{30}H_{62},
penta triacontane, \(C_{35}H_{72}\), eriodictyol, \(C_{15}H_{12}O_{6}\), homoeriodiciyol, 
\(C_{16}H_{14}O_{6}\), and a phenol, \(C_{16}H_{41}O_{6}\).

**Uses.**—Eriodictyon has long been used in California as a bitter tonic, and also as a stimulant balsamic expectorant. There is considerable testimony to its usefulness in asthma, chronic bronchitis, and allied conditions; also in chronic inflammation of the genito-urinary tract. Attention has been called by Kier to its remarkable power of disguising the taste of quinine, and Meyer (Ph. Ztg., 1905) found that it will also mitigate the unpleasantness of hydrastis or aspidium. It is best exhibited in the form of the official fluidextract, the dose of which is one-half to one fluidrachm (1.8-3.75 mils); a solid extract has been made, which may be given in doses of from five to fifteen grains (0.32-
1.0 Gm.). In cases of asthma, eriodictyon is often used by smoking. The aromatic syrup is well adapted as a vehicle for quinine.

Dose, fifteen to sixty grains (1.0-3.9 Gm.).

**Off. Prep.**—Fluidextractum Eriodictyi, U. S.; Elixir Eriodictyi Aromaticum (from Fluidextract), N. F.; Syrupus Eriodictyi Aromaticus (from Fluidextract), N. F.

**Erodium.** Erodium cicutarium L. Stork's- oil. —An annual hairy plant belonging to the Geraniaceae. It grows in Europe, Asia, Northern Africa and is widely cultivated, being found naturalized about cities in the United States. It is highly recommended by W. Abbots Smith in dropsy. (See Am. J. M. S., 1865.)

**Eryngium.** Eryngium aquaticum L. Button Snakeroot. Corn Snakeroot. Rattlesnake's Master.—The button snakeroot or water eryngo is an indigenous umbelliferous plant which grows in low wet places, from New Jersey as far south as Florida and Texas. The root, which is the medicinal portion, has a bitter, pungent aromatic taste, provoking, when chewed, a flow of saliva. It is said to be diaphoretic, expectorant, in large doses emetic, and the plant has been used as a substitute for senega.

**Erythrina.**—The bark of the Australian species of this genus, Erythrina Broteroii, is said to contain an alkaloid, erythrinine, while the Mexican species, Erythrina coralloides DC., bears poisonous seeds in which Altamirano has found erythroidine, a powerful paralyzant of the motor system, erythroresin, an emetic, coralin and erythric acid. The extract has been suggested as a substitute for curare. (B. S. Ph. Br., 1900) Langham obtained from the seeds of E. zeyheri (which have a scarlet pesta), erythrine, 15 per cent. (C. D., 1911, 134.)

Erythrina lithosperma Blume. (Hypaphorus subumbra Hassan.)—From the seeds of
this beautiful leguminous tree, largely grown for shade in the coffee gardens of Java, P. C. Plugge has obtained hypaphorine, a tetanizing alkaloid. (A.E. P. P., xxxii.)

**Erythronium.** Erythroniumi americanum Ker. Scrofula Root. Yellow Snowdrop. Rattlesnake Violet. Dogtooth Violet. Yellow Adder's Tongue. —This is an indigenous, perennial, lilaceous plant, sometimes called, after the European species, dog's-tooth violet. It grows in rich woods from New Brunswick to Florida and west to Ontario and Arkansas. It flowers in the latter part of April or early in May. All parts of it are active. In the dose of twenty or thirty grains (1.3 or 2.0 Gm.) the recent bulb is emetic. The leaves are said to be more powerful. The activity of the plant is diminished by drying.

**Eschscholtzia.** Eschscholtssia californica, Chamisso. California Poppy.—Attention has been brought to this Californian member of the Papaveraceae, as a powerful soporific and analgesic, which is free from the disadvantages of opium. The plant is extensively cultivated and there are now a number of garden varieties. Bardet and Adrain (G. H. M. C., Nov., 1888) assert that they have obtained a glucoside, an alkaloid, and morphine in the proportion of from five to six grains in two pounds of the dried product. According to Fischer and Tweeden, there are seven alkaloids in Eschscholtzia californica; protopine β- and µ-homochelidonine, "alkaloid a," "alkaloid b," sanguinarine and chelerythrine. As far as could be determined from the small quantities obtained, the alkaloids designated as a and b differ from any other alkaloids thus far known. (Ph. Archiv., 1902, No. 7.) The narcotic power of the drug seems to be very weak, since, according to Bardet, three drachms were necessary to kill a rabbit. Ter-Zakariant (G. M. P., Feb., 1889) states that the alcoholic extract acts as a respiratory depressant and narcotic, affecting in toxic dose also the spinal cord. Dujardin-Beaumetz has used the extract in commencing doses of twelve grains (0.78 Gm.), increasing to one hundred and eighty-five grains (12 Gm.) a day, and affirms that it is a harmless soporific and analgesic.

**EUCALYPTUS. U. S.**

**EUCALYPTUS Eucalypt. [Blue Gum Leaves]**

"The dried leaves of Eucalyptus Globulus Labillardiere (Fam. Myrtaceae), collected from the older parts of the tree, without the presence or admixture of more than 3 per cent. of the stems, fruits or other foreign matter." U. S.

The genus Eucalyptus was named by L'Heritier in 1788, from the two Greek words meaning ("I cover well," in allusion to the operculum or
lid which covers the calyx until the stamens are fully formed." The plants, which are known as Gum trees, Woolly butts, Iron barks, etc., by the natives of Australia and Tasmania, are evergreen and vary from shrubs to trees of enormous height, some of them probably being the highest trees known. Kerner gives the height as 140 to 152 meters. They form, it is stated, about three-fourths of the whole vegetation of those countries. At least one hundred and forty species have been described. The leaves frequently vary in shape and in position on both young and mature trees; they are fixed vertically, and not horizontally as the leaves of our trees, the petiole being twisted. The leaves furthermore contain large oil-secreting reservoirs. The flowers are arranged in cymes or axillary umbels and are devoid of petals; the usually whitish stamens are inflexed in the bud and expand when the operculum is removed, giving the name as already stated to the genus. The fruit is a 3- to 6-celled truncated capsule, or pyxis. The seeds are small and very numerous, the sterile ones predominating; this is no doubt one reason why there has been so much difficulty in producing seedlings.

Most of the species do not require excessive heat for their perfecting, and some of them are able to resist moderate frosts. Over forty species are being grown successfully in the United States, and in the neighborhood of Los Angeles and other points in California a pure oil is said to be commercially produced. On account of the rapidity of their growth and the hardness and indestructibility of their timber, many of the species are very valuable for economic purposes. A number of the species are said to be cultivated in the Southwest as a source of honey. (See Bulletin No. 35 of the U. S. Bureau of Forestry.)

With a genus of so many species and numerous varieties it was to be expected that there would be considerable confusion in regard to the accurate determination of its members. Tate and Luehman give prominence to the fruit for purposes of classification. Maiden, however, says that all of its characters display a puzzling amount of variation, and concludes that for herbarium work the best characters are afforded by the anthers and fruits; whereas the scientific forester will be largely guided by the nature of the bark and timber. Baker and Smith, in addition to morphological characters, base their deductions on the chemical properties and physical characters of oils, dyes, kinos, etc. See Bentham, Flora Australiensis; Baron F. von Mueller's Eucalyptographia, 1879 to 1884. Baker and Smith (A Research on the
Eucalypts, Sydney, 1902), arrange the species in seven different groups, according to the chemical characteristics of the oils which they produce. It is stated that the leaves of the E. rebaudianum, of Paraguay, are used in that country in place of sugar, which they exceed in sweetening power.

Eucalyptus globulus is one of the largest known trees, attaining sometimes a height of 300 or even 350 feet, with a smooth, ash-colored bark. The leaves attain a foot in length, and vary, according to age, from a glaucous white to a bluish-green color. The flowers are large, pinkish-white, axillary, occurring singly, or in clusters. Although its wood is very resinous, hard, and durable, the tree is remarkable for the rapidity of its growth, reaching, under favorable circumstances, fifty feet of height in five or six years. It flourishes best in valleys having a rich, moist soil, and has very largely been naturalized in semi-tropical countries, partly on account of its economic value, but chiefly because of the reputation it enjoys as a means of overcoming malaria. Its sanitary powers appear to be established, numerous notoriously miasmatic stations and districts having been rendered healthful by its growth. It is probable that the destruction of the miasma is due not so much to emanations from the tree as to the fact that it evaporates water so rapidly from its innumerable large leaves as to drain the swamps and marshes in which it is planted. It is possible, however, that the large amount of volatile oil which must escape from it has some effect, and it is even affirmed (A. J, P., 1875, p. 423) that the parasitic phylloxera will not attack grape-vines growing near it.

The eucalyptus oil of commerce is, indeed, composed chiefly of the oils of E. amygdalina and E. dumosa, which yield a very much larger product than does the official species. The oils of E. piperita and E. haemastoma have a peppermint odor, and that of E. citriodora a citron-like odor, while the oil of E. staigeriana exactly resembles the oil of verbena; it is probable that these oils will come into commerce for the purposes of the perfumer.

Properties.—The leaves are the official portion of the plant and are officially described as follows: "Laminas lanceolately scythe-shaped, from 8 to 30 cm. in length and from 2 to 7.5 cm. in breadth; summits when present acute or acuminate; bases unequal, obtuse or more or less rounded and connected with a twisted petiole from 5 to 35 mm. in length; margins slightly uneven, revolute; coriaceous; both surfaces
varying from pale yellowish-green to grayish-green and more or less
glaucous, glabrous, glandular-punctate and with numerous small,
circular, brown dots of cork; veins of the first order anastomosing with
each other and forming a line nearly parallel with the margin; odor
slightly aromatic; taste aromatic, bitter, and cooling. Under the
microscope sections of Eucalyptus show the upper and lower surfaces
with nearly similar cells, the outer walls being strongly cuticularized;
stomata occur on both surfaces, a region of palisade cells made up of
from 3 to 4 rows of cells occurring beneath each surface; among the
palisade cells occur large oil-secretion reservoirs, with a yellowish or
orange colored oily content; calcium oxalate crystals in cells of the loose
mesophyll in the form of rosette aggregates or monoclinic prisms
varying from 0.015 to 0.025 mm. in diameter. At the periphery of the
fibro-vascular bundles of the midrib and petiole occurs a more or less
interrupted circle of small groups of slightly lignified bast-fibers."

Hans Kramer (B. P. G., 1907, p. 319) presents an anatomical study of
Eucalyptus with the characteristics of the drug in a powdered form.

In March, 1870, Cloez (J. P. C., 4e ser., xii, 201) reported an elaborate
chemical study of the eucalyptus leaves, and his results have been
substantially confirmed by Debray (De l'Eucalyptus Globulus, Paris,
1872), Rabuteau (Mem. de l'Académie, Nov., 1872), and Broughton (P.
J., 3d ser., iii, 463). Cloez found, besides chlorophyll, resin, tannin, and
inert substances, an essential oil, upon which the virtues of the drug
appear to depend. Of this oil the fresh leaves afforded 2.75 parts per
hundred, the recently dried leaves 6 parts; leaves which had been kept
some time yielded a much smaller percentage. In the distillation, the oil
for a time comes over freely at from 170° C. (338° F.) to 178° C. (352.4°
F.); subsequently another portion of oil distils at 188° C. (370.4° F.) to
190° C. (374° F.), and finally a very minute portion does not volatilize
until the temperature reaches 200° C. (392° F.). Cloez believes the oil to
be composed of two camphors, differing in their volatility. The bulk of
the oil yielded is the portion first distilled; to this Cloez has given the
name of eucalyptol, or, as it is now also called, cineol, C_{10}H_{18}O.
Gildemeister and Hoffmann (Aetherische Oele, 1899, p. 690) divide the
eucalyptus oils into 5 groups according to their constituents, viz.:

Group 1, Cineol (or Eucalyptol) containing oils, of which group
Eucalyptus Globulus is the most important;
Group 2, Citronellal containing oils, of which group Eucalyptus maculata is the most important;

Group 3, Citral containing oils, of which E. staigeriana F. von Muell., is the typical example;

Group 4, Peppermint smelling oils, of which Eucalyptus piperita is an example;

and Group 5, Less known oils of varying odor.

Schimmel & Co. (Semi-Annual Report, April, 1897) gave a list of some fifteen varieties of eucalyptus oils from the different Eucalyptus species. In their report for October, 1904, they give the sources and state the properties and components of 109 different eucalyptus oils obtained by them from Baker and Smith, Curators of the Technological Museum of Sydney, N. S. W.

According to Duquesnel, the oil of eucalyptus is adulterated—with alcohol, to be detected by means of fuchsin, which is insoluble in the pure oil but soluble in that containing even a very small percentage of alcohol; with fixed oil, to be detected by boiling with water, when the fixed oil remains on the surface; with volatile oil of copaiba or turpentine, to be detected by means of the boiling point, that of eucalyptol being 170° C. (338° F.), that of oil of turpentine 155° C. (311° F.), that of oil of copaiba 260° C. (500° F.). (J. P. C., 4e ser., xvi, 45.)

*Uses.*—Whatever medicinal virtue eucalyptus possesses beyond a slight astringency is due to its volatile oil. Preparations of the crude drug are rarely used in this country. The leaves are occasionally rolled into cigarettes to be smoked for the relief of bronchitis or asthma. For therapeutic properties of the oil of eucalyptus, see page 762.

Dose, of eucalyptus, ten to thirty grains (0.65-2 Gm.); of the oil, five to ten minims (0.3-0.0 mil).

*Off. Prep.*—Fluidextractum Eucalypti, U. S.

**Eucalyptus Manna.** Australian Manna.—Thia substance exudes during the summer months from punctures made in the bark and leaves of the Australian tree Eucalyptus viminalis Labill. (fam. Myrtaceae). It occurs in small round opaque masses, and is said medicinally to resemble ordinary manna. It contains melitrose.
similar manna is also formed on Eucalyptus Gunnii Hook. The "blue-grass manna" of Australia occurs on the stems of Andropogon annulatus Forsk. (fam. Graminece). The latter contains 75 per cent. of mannite.

**Eugenia Cheken** Hook. et Arn. (Myrtus Cheken, Spreng.) Cheken. Chequen. Arrayan. (Fam. Myrtaceae)—The leaves of this Chilian plant have entered commerce under the name of Chekan leaves. Weiss (A. Pharm., 1888, p. 226) has found in them: (1) chekenon, $C_{40}H_{44}O_8$, a crystalline body; (2) chekenin, $C_{12}H_{11}O_3$, in yellowish rhombic tables; (3) chekenetin, $C_{11}H_7O_6+H_2O$, in olive-colored crystals; (4) cheken-bitter, an amorphous, very soluble bitter substance. (See P. J., 1889, 782, and Wein, A. Pharm., 1888, 665.) The leaves are used in their native country as a remedy in chronic respiratory catarrh, and have been strongly recommended by Murrell and others in chronic bronchitis. Their virtues appear to reside in the tannin, and especially in the volatile oil that they contain. The dose of the fluidextract is from one to three fluidrachms (3.9-11.6 mils).

**Eugenia Jambolana** Lain. (Syzygium Jambolana Lam.) Jambul. Jambol. Rose Apple. Java Plum.—This is a large tree belonging to the Myrtaceae, growing in East India and also in Queensland; well known on account of its popular edible fruit. The bark and seeds are employed in medicine. Jambul bark is a dense, hard bark, about 1.5 cm. in thickness, of a pinkish-brown or reddish-brown color, with a whitish-gray mottled cork or thick bark, the inner surface is of a somewhat silky luster, frequently coarsely marked by waving lines or ridges; the fresh fracture varies from pinkish or purplish to fawn color, sometimes distinctly but shortly fibrous, more commonly absolutely abrupt. The taste is somewhat bitter, astringent, after a time distinctly pungent. The bark contains a resin, tannin, and gallic acid. Jambul seeds are grayish-black or blackish-gray, being abruptly truncated at the base, above rounded or dome-shaped. They are from 1 to 2.5 cm. long, and 8 to 12 mm. broad; so hard and dense that they cannot be chewed, and are almost tasteless. The analysis of the seeds by Thomas Christy yields the following results. Essential oil, a trace; chlorophyll and fat, 0.37; resin soluble in alcohol and ether, 0.30; gallic acid, 1.65; albumen, 1.25; colored extractive soluble in water, 2.70; moisture, 10.00: insoluble resin, 83.73. Power and Callan (P. J., 1913, 245) found in these seeds a phenolic substance, jambulol, $C_{16}H_{3}O_4(OH)_5$, which is identical with ellagic acid.

In the experiments made by Thomas Christy of London (P. J., 1888), it was found that when sufficient of diastatic matter was mixed with fifty grains of starch to convert 45 per cent. of the latter in fifty minutes into sugar, the addition of twenty-five grains of powdered jambul seeds reduced the conversion of the starch to 12' per cent. We have no knowledge of the effect of jambul or its active properties upon the general organization, but Binz (Verhandl. der Kongr. fur Innere Med., Wiesbaden, 1886) found that when dogs were made diabetic by the administration of phlorizin, according to the method of von Mering, the exhibition of jambul reduced the excretion of sugar from 50 to 90 per cent. without the production of any evidences of poisoning by the jambul. In India, jambul has long been used as a stomachic astringent and carminative in diarrhea, and also in the treatment of diabetes. The first therapeutic trials in Europe appear to have been made by Clacus, who found that the drug
notably reduced the excretion of sugar in diabetic patients. The practice has been largely followed, and there would seem to be no doubt that in occasional cases of glycosuria jambul does good. No cases of poisoning or of disagreeable results from it have been reported.

Nevertheless jambul has failed to establish itself as a practical medicament. It may be that this has been due to the use of too small doses. The dose of the fluidextract usually recommended is ten minims (0.6 mil); but according to von Noorden (Deutsche Praxis, 1901) half a fluidounce (15 mils) of the fluidextract should be taken in eight fluidounces (240 mils) of hot water, one hour before breakfast and late in the evening.

J amrosin is a proprietary preparation asserted to be the fluidextract of jambul. It is alleged to possess marked remedial qualities in the treatment of diabetes.

**EUONYMI CORTEX. Br.**

**EUONYMUS BARK**

"The dried root bark of Euonymus atropurpureus, 'J acq." 'Br. "The dried bark of the root of Euonymus atropurpureus Jacquin (Fam. Celastraceae), without the presence of more than 3 per cent. of wood or other foreign matter." N.F.

Euonymus N. F. IV, Wahoo; Cortex Euonymi; American Indian Arrow-wood; Ecorce d'Evonymus, Fr. Cod.; Spindlebaum, Pfaffenhutchen, Spillbaumrinde, G.

Euonymus (Evonymus) atropurpureus, named variously wahoo, spindle-tree, and burning-bush, is a tall, erect shrub, with quadrangular branchlets, and opposite, petiolate, oval-oblong, pointed, serrate leaves. The flowers, which stand in loose cymes on axillary peduncles, are small and dark purple, with sepals and petals commonly in fours. The capsule or pod is smooth and deeply lobed. The plant is indigenous, growing throughout the Northern and Western States, and sometimes cultivated for the beauty of its crimson fruit.

The plants belonging to this genus are shrubs or small trees, presenting in the autumn a striking appearance from the rich red color of their fruit, which has obtained for them the name of burning-bush. E. americanus L. and E. europæus L. have been cultivated in gardens as ornamental plants. Two or more of the species have been used in medicine. Their properties are probably similar, if not identical. Grundner, who experimented with the fruit of E. europæus, found it to have no other effect than that of a diuretic. (Ph. Cb., 1847, p. 873.) An
oil expressed from the seeds is used in Europe for the destruction of
vermin in the hair, and sometimes also as an application to old sores.
(Ibid., 1851, p. 641.) Griffith says that the seeds of this and other
species are purgative and emetic, and that the leaves are poisonous to
sheep and other animals feeding on them. He states also that the inner
bark of E. tingens Wall. is beautifully yellow, and used in India for
dyeing, and in diseases of the eye. (Med. Bot., p. 220.) It is probable that
much of the wahoo of our drug stores has been obtained from E.
americanus, which is distinguished from E. atropurpureus by its rough,
warty, depressed pods, and almost sessile, thickish leaves.

Properties.—The dried bark is described in the National Formulary as
follows: "Usually in transversely curved pieces, occasionally in single
quills from 2 to 7 cm. in length; bark from 1 to 2.5 mm. in thickness;
very light in "weight; outer surface grayish or light brown, somewhat
"wrinkled, occasionally transversely fissured from the lenticels and with
scale-patches of soft cork; inner surface grayish-white, longitudinally
striate and somewhat porous; fracture short with silky, projecting elastic
fibers. Odor distinct-taste bitter and acrid. The powder is light brown,
and when examined under the microscope shows numerous starch
grains, nearly spherical, from 0.003 to 0.012 mm. in diameter; fragments
of cork with nearly colorless, thin walls; secretion cells with yellowish or
brownish amorphous contents; bast fibers very long, with thin, non-
lignified walls possessing numerous small, more or less oblique pores;
numerous fragments of starch-bearing parenchyma; calcium oxalate in
rosette aggregates from 0.015 to 0.035 mm. in diameter, the amount in
different specimens showing some variation. Euonymus yields not more
than 12 per cent. of ash." N F.

"In quilled or curved pieces, from two to four millimetres thick. Outer
layer a soft, friable, greyish cork, marked with dark patches. Inner
surface pale tawny-white and smooth. Fracture short, the fractured
surface yellowish in color. Transverse section free from sclerenchymatous cells and fibres, and exhibiting, in the secondary bast,
laticiferous cells filled with a granular, elastic substance. Faint but
characteristic odor; taste somewhat mucilaginous, afterwards bitter and
slightly acrid." Br.

The drug frequently has as much as 25 per cent. of adhering wood. The
amount of the latter with other foreign matter should not exceed 3 per
cent. Holm (Merck's Rep., 1909, p. 169) illustrates the structural
characteristics of E. atropurpureus and E. americanus. Holmes (P. J., 1905) describes the bark of Alstonia scholaris which has been used as an adulterant of Euonymus. The name of Wahoo or Waahoo (pronounced Wawhoo) was given to it by the Indians. The same name has also been applied to Ulmus alata, of the Southern States, and has thus led to mistakes.

It imparts its virtues to water and alcohol. Analyzed by Wm. T. Wenzell, it was found to contain a bitter principle which he named euonymin, asparagin, a soft resin, a crystallizable resin, a yellow resin, a brown resin, fixed oil, wax, starch, albumen glucose pectin, and various salts of organic and inorganic acids. Euonymin was obtained by agitating with chloroform a tincture made with diluted alcohol, separating the chloroformic solution and allowing it to evaporate spontaneously, treating the residue with ether, dissolving what was left in alcohol, adding lead acetate to the solution, filtering, precipitating the lead with hydrogen sulphide, and evaporating. The euonymin obtained was uncrystallizable, intensely bitter, soluble in water and alcohol, and neutral in its reactions. It was abundantly precipitated from its solution by lead subacetate and phosphomolybdic acid. For an examination of commercial euonymin (the eclectic resinoid) by Paul Thibault, see N. R., 1883, 294. W. P. Clothier found the bark to yield no volatile oil on distillation. According to the same writer, if a concentrated tincture be poured into water, a dark yellow substance will be thrown down, containing resin and fixed oil, which is the euonymin of the eclectics, very improperly so named, as, though it contains a portion of the active principle, it is a very complex substance. Clothier found the bark to purge actively without griping. (Ibid., 1861, p. 491.) Frank V. Cassaday (A. J. P., 1889, p. 284) found 1.30 per cent. of volatile oil and resin, 1.48 per cent. of euonic acid and resin, 2.10 per cent. of euonymin and resin, together with the usual plant constituents. Kubel has discovered in the fresh inner bark of E. europaeus a saccharine, orystallizable substance, closely resembling mannite, but differing in its crystalline form and in its melting point. He calls it euonymite. (J. P. C., Dec., 1862, 523.)

H. Rogerson (Ph. J., 1912, p. 687) has made a complete chemical examination of this bark with the result that the following definite constituents are reported present: dulcitol; furan B carboxylic acid, C₅H₄O₃; euonymol, C₂₁H₃₀O₄ (a new crystalline alcohol, having a melting point of 248° C. [478.4° F.]); a sugar which yielded d-phenyl glucoazone; euonosteryl, C₃₁H₅₁O.ÖH; homoeuonosteryl, C₄₀H₆₉O.ÖH;
atropurol, \(C_{27}H_{44}(OH)_{2}\); citrullol, \(C_{22}H_{36}O_{2}(OH)_{2}\); and a mixture of palmitic, cerotic, oleic and linoleic acids. No glucoside was found nor could any product corresponding to the euonymin of Wenzell or of Schmiedeberg be found.

**Uses.**—This bark was first introduced into notice, as a remedy for dropsy, under the name of Wahoo, by George W. Carpenter. It exerts a digitalis-like action on the heart, but because of the irregularity of its absorption should not be employed as a systemic remedy. By virtue of its local irritant effects on the intestines it usually exerts a laxative effect but is not to be recommended because of its liability to nauseate and the possibility of circulatory effects. It was formerly used as a diaphoretic in muscular rheumatism, influenza, acute coryza, and similar conditions but it does not appear to have any advantage for this purpose over the other nauseating drugs and has been largely abandoned. The fluidextract may be given in doses of eight minims (0.5 mil).

Dose, of euonymus, five to fifteen grains (0.32-1.0 Gm.).

"Caution.—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." N. F.

**Off. Prep.**—Extraction Euonymi, Br., N. F.; Fluidextractum Euonymi, N. F.

**Eupatorium.** N. F. IV (U. S. P. VIII). Boneset. Thorough-wort. Herba Eupatorii Perfoliati. Indian Sage. Thorough-stem. Cross-wort. Thorough-wax. Sweating Plant. Herbe d'Eupatoire perfoliée, Berbe a fièvre, Herbe parfaite, Fr. Durchwachsender Wasserhanf or Wasserdost, G.—" The dried leaves and flowering tops of Eupatorium perfoliatum Linne (Fam. Compositae)." N. F. This is an indigenous perennial plant, with numerous herbaceous stems, which are erect, round, hairy, from two to five feet high, simple below, and trichotomously branched near the summit. The leaves serve to distinguish the species at the first glance. They may be considered either as perforated by the stem, perfoliate, or as consisting each of two leaves, joined at the base, connate. In the latter point of view, they are opposite and in pairs, which decussate each other at regular distances upon the stem; in other words, the direction of each pair is at right angles with that of the pair immediately above or beneath it. They are narrow in proportion to their length, broadest at the base where they coalesce, gradually tapering to a point, serrate, much wrinkled, paler on the under than on the upper surface, and beset with whitish hairs, which give them a grayish-
green color. The uppermost pairs are sessile, not joined at the base. The flowers are white, numerous, supported on hairy peduncles, in dense corymbs, forming a flattened summit. The involucre, which is cylindrical and composed of imbricated, lanceolate, hairy scales, encloses from twelve to fifteen tubular florets, having their border divided into five spreading segments. The anthers are five, black, and united into a tube, through which the bifid filiform style projects.

This species of Eupatorium inhabits meadows, the banks of streams, and other moist places, growing generally in bunches, and abounding in almost all parts of the United States. It flowers from the middle of summer to the end of October. All parts of it are active, but the herb only is official. It has a faint odor, and a strongly bitter, somewhat peculiar taste. It is described as "usually more or less broken; leaves opposite, the pair united at the base, from 8 to 20 cm. in length and from 1.5 to 5 cm. in breadth, tapering regularly from near the base to an acute summit, crenate-serrate, rugosely veined, rough and bright green above, yellowish-gray-green, tomentose and resinous-dotted beneath; flower-heads small, numerous, corymbed, with a campanulate involucre of lance-linear, imbricated scales and with from ten to fifteen tubular, yellowish-white florets having a bristly pappus in a single row. Odor faintly aromatic; taste strongly bitter. Eupatorium yields not more than 10 per cent. of ash." N. F. The virtues of the plant are readily imparted to water and alcohol. W. Peterson found it to contain a peculiar bitter principle, chlorophyll, resin, a crystalline matter of undetermined character, gum, tannin, yellow coloring matter, extractive, lignin, and salts. (A. J. P., xxiii, 210.) George Latin (A. J. P., Aug., 1880) found a glucoside, eupatorin, and a crystallizable body of the nature of wax. O. F. Dana, J r., obtained 3.80 per cent. of extract with petroleum benzoin; 4.60 per cent. with ether; 33.80 per cent. with alcohol; 24.80 per cent. with water; 5.80 per cent. with alkali. (A. J. P., 1887, p. 229.) Shamel (Am. Chem. J., 1892, p. 224) published an analysis of the nitrate of the crystalline principle giving the formula \( C_{20}H_{25}O_{36}HNO_3 \).

Eupatorium is, in large doses, emetic and aperient. Because of its nauseating action, the warm infusion tends to increase perspiration and has been used to abort attacks of muscular rheumatism or general cold. H. S. Wilkins has found the infusion useful in the expulsion of tapeworm. (A.J.P., 1874, p. 2'95.)

As an emetic and cathartic, a strong decoction, prepared by boiling an ounce with three half-pints of water to a pint, may be given in doses of from four fluidounces to a half-pint (120 to 240 mils), or more. (See Fluidextractum Eupatorii, N. F., Part III.)

Dose, twenty to thirty grains (1.3 to 2.0 Gm.).

Eupatorium purpureum L., Joe-Pye Weed, Trumpet Weed, or Gravel Root, is a perennial herbaceous plant, with a purple stem, five or six feet in height, and furnished with ovate-lanceolate, serrate, rugosely veined, slightly scabrous, petiolate leaves, placed four or five together in the form of whorls. The flowers are purple, and consist of numerous florets contained in an eight-leaved involucre. It grows in swamps and other low grounds, from Canada to Florida, and flowers in August and September. The root has, according to Bigelow, a bitter aromatic and astringent
taste, and is said to be diuretic. Its vulgar name, 'boneset, indicates the popular estimation of its virtues. J. U. Lloyd found in it an apparently new, yellow, neutral, crystalline principle, euparin. (A. J. P., 1890.) This euparin, with a number of derivatives, has been prepared by C. C. Mauger (A. J. P., 1894, 120) and analyzed. The formula $\text{C}_{12}\text{H}_{11}\text{O}_{3}$ is assigned to it.

Eupatorium verbenaefolium Michx., commonly called wild horehound, is also an indigenous perennial, with an herbaceous stem, which is about two feet high, and supports sessile, distinct, ovate, acute, scabrous leaves, of which the lower are coarsely serrate at the base, the uppermost entire. The flower-heads are small, white, composed of five florets within each involucre, and arranged in the form of a corymb. The plant grows in low wet places from New England to Georgia, and abounds in the Southern States. It is in flower from August to November. The whole herb is used. In sensible properties it corresponds with E. perfoliatum, though less bitter and disagreeable, and has been used for similar purposes and in like manner. E. incarnatum and E. aromaticum are said to contain an aromatic principle similar to, if not identical with, coumarin, obtained by Guibourt from Dipteryx odorata, or Tonka bean. (See P. J., Oct., 1874, 303.) The roots of E. aromaticum are said to be sold in the Western United States under the name of white snake-root. E. cannabinum of Europe, the root of which was formerly used as a purgative, and E. triplinerve Vahl (E. Aya-pana Vent.), of Brazil, the leaves of which at one time enjoyed a very high reputation, have fallen into neglect. The Aya-pana is an aromatic bitter, like E. perfoliatum, but weaker, and is said to be still occasionally met with in European commerce. (A. J. P., 1887, 154; Ph. Era, 1898, 293.) E. villosum is used in Jamaica, under the name of bitter-bush, in the preparation of beer, as a tonic, and as a stimulant in low zymotic diseases. (P. J., Oct., 1866; A. J. P., 1887, 155.) E. collinum is included in the Mexican Pharmacopoeia.

**Euphorbia.** Wild Ipecac. Wild Hippo. Euphorbe, Fr. Wolfsmilch, G.—The genus Euphorbia (Fam. Euphorbiaceae) contains numerous species, having the common property of yielding a milky juice. They are herbaceous or shrubby, with or without leaves, and the leafless species, which are chiefly confined to the African deserts, have fleshy, naked, or spiny stems, like those of the cactus. They nearly all afford products which act powerfully as emetics and cathartics, and in overdoses occasion dangerous if not fatal prostration, with symptoms of inflammation of the gastro-intestinal mucous membrane. Their milky juice, which concretes on exposure, usually possesses these properties in a high degree, and, in addition, that of powerfully irritating the skin when applied to it. The U. S. Pharmacopoeia formerly recognized the indigenous species E. corollata L. and E. Ipecacuanhae L. In a full dose the root of E. corollata L. acts as an emetic and cathartic and in smaller doses is a nauseating diaphoretic and expectorant. It is, however, too harsh and uncertain in its action for practical use, and has passed entirely out of vogue. The dose of the dried root as an emetic is from ten to twenty grains (0.65-1.3 Gm.), as a cathartic from three to ten grains (0.2-0.65 Gm.). The recent root, bruised and applied to the skin, produces vesication. C. Petzolt (A. J. P., 1873) found in the root of E. Ipecacuanhae fixed oil, resin, starch, glucose, and various salts. The resinous matter was a dark mass, of a taste slight at first but after a time nauseous and pungent, readily dissolved by
alcohol, but insoluble in ether and petroleum benzin, and, when swallowed, producing in half grain (0.032 Gm.) doses watery stools, and in one and a half or two grain (0.096 or 0.13 Gm.) doses nausea and vomiting. It gave no evidence of the presence of an alkaloid. The medicinal properties of *E. Ipecacuanha* resemble those of *E. corollata*, though the former is said to be somewhat milder. The indigenous *E. Preslii* Guss. (E. *hypericifolia* A. Gray) and *E. maculata* L. are said by Zollickoffer to be a valuable remedy in dysentery, diarrhea, menorrhagia, and leucorrhoea. (See 16th ed., U. S. D., also A. J. M. S., xi.) B. J. D. Irwin, U. S. A., states that, under the name of *gollindrinera*, the native Mexican uses the Euphorbia prostrata Ait. in New Mexico and Arizona as a remedy for snakes bites. (Am. J. M. S., 1861.). In Chili the juice of Euphorbia *portulacoides* L. (E. *chilensis* C. Gay) is said to be used as a drastic purgative. (A. J. P., 1866, 102.) The juice of Euphorbia Drummondii Boiss. is said in Australia to kill annually a great many sheep and cattle, and in 1886 John Reid (Australasian Med. Gaz; No. 61) announced the discovery in it of a new anesthetic alkaloid, *drummine*, which he obtained in colorless crystals almost insoluble in ether, but freely soluble in chloroform and in water. The report of Alexander Ogsden (B. M. J., Feb., 1887) throws, however, very grave doubts upon the anesthetic power of this new alkaloid. The *E. ocellata* Durand and Hilgard of the Pacific coast is used as an antidote for snake bites, and is said to contain 2.82 per cent. of resin, besides gallo-tannic acid, while Euphorbia *eremocarpus* Auct. of the same region is employed for the purpose of poisoning fish in still pools and streams, and is said to contain a volatile oil, besides acid and resins. (See Proc. California Coll. Pharm., 1885.) The oil of E. *Lathyris* L. is stated to physiologically resemble croton oil. (Proc. A. Ph. A., xxvi, 305.)

The *E. heterodoxa* Muell. Arg., *alveloz* or *aveloz*, a Brazilian species, has been used with asserted extraordinary advantage against cancerous and syphilitic ulcers. It is a powerful irritant, and even mild caustic. The milky juice, preserved with salicylic acid, or a resin obtained by precipitating with water is employed. The ointment of the resin may be made 3 parts in 100 with vaseline. For further information concerning various euphorbia species which have been used in medicine, see U. S. D., 19th ed., p. 1484.

**Euphorbia Pilulifera.** N. F. IV. Pill Bearing Spurge.—"The dried herb of Euphorbia pilulifera* Linne (Fam. Euphorbiaceae, collected while flowering and fruiting." N. F. This plant is a prostrate or ascending branched annual, found in almost all tropical countries; it is furnished with leaves which are opposite, short stalked, ovate to ovate-lanceolate or oblong, from 8 to 35 mm. long, denticate, very oblique and narrow below, or with a semicordate base. Stipules minute and linear. The flower-heads are small, numerous, crowded in head-like cymes, globular, and are borne on a short stalk in one axil, only, of each pair of opposite leaves. The involucre is small, entire, and without petal-like appendages. According to De Candolle, the seeds are reddish, acutely oblong, four-sided, and transversely wrinkled, the ridges uniting irregularly. It is to be distinguished from *E. parviflora* (L.), which is sometimes substituted for it, by the flower-head of the latter having but few flowers, by the glands of the involucre being furnished with a white, obovate-orbicular appendage, and by the seeds being minutely papillose. The N. F. describes the drug as follows: "Roots usually present, small, branched, and reddish; sternae slender, cylindrical,
obliquely erect, dichotomously branched from near the base, branches recurved at apices; branches and stem only sparsely leafed at base, pale greenish-brown, rough or hairy; stems coarsely pilose with yellow hairs which are rather dense on the upper parts but sparse on the lower; pubescence consisting of short, nearly straight, unicellular hairs, becoming almost hispid at the flowering tops; leaves opposite, obliquely oblong, acute, serrulate, rusty pale green, pubescent, especially on the prominent veins on the lower surface, becoming brittle on drying and usually much broken in the drug; flowers small, numerous, in short peduncled axillary clusters; fruits about 1 mm. in diameter, three-celled capsules; seeds about 0.9 mm. in diameter, triangular ovoid, pale brown. Odor aromatic and characteristic; taste faintly bitter, aromatic and acrid. Euphorbia Pilulifera yields not more than 12 per cent. of ash." N. F. Levison found in it (A. J. P., 1885, 147) several glucoside resins, wax, and volatile matter. Dr. F. B. Power (C. D., 1913, 544) examined E. pilulifera from the Fiji Islands and found a monohydric alcohol, euphosterol, among other constituents, none of which seem to possess value therapeutically.

A physiological study of Euphorbia pilulifera led A. Marsset (T. G., 1885) to the conclusion that the active principle acts directly upon the heart and respiration; that it is not an irritant to the skin, but in large dose it is to the gastric mucous membrane. It has been used by Dujardin-Beaumetz and a number of other clinicians with asserted excellent results in the treatment of asthma and bronchitis. The best preparation is the fluidextract (see Fluidextractum Euphorbia, Piluliferae. N. F. IV), the dose of which is from a half to one fluidrachm (1.8-3.75 mils) three or four times a day.

**Euphrasia.** E. officinalis L. Eyebright. Eye-wort. Eupraise, Fr. Augentrost, Gr. (Fam. Scrophulariaceae)—A small annual plant, native of Europe, without odor, and of a bitterish, astringent taste. Enz (Viertelj. f. Prakt. Pharm., viii, 175) obtained a little volatile oil, an acrid and bitter principle, mannite and glucose, and a tannic acid. The name "eyewort" so frequently ascribed to this drug, is derived from the practice of using it in eye affections in older medicine. It is used on the continent to-day as an astringent tonic in the treatment of jaundice. G. M. Garland (A. J. P., 1890) states that ten minims (0.6 mil) of a concentrated tincture every two hours is a specific in acute nasal catarrh.

**Evodia.**—Several species of this rutaceous genus are stated, to have medicinal properties. Evodia, febrifuga St. Hil (Esenbechia febrifuga A. Juss.) of Brazil is astringent and tonic, E. meliaefolia Benth. of Japan contains berberine, while E. longifolia A. Rich. of the Fiji Islands is used to prevent abortion.

**EXTRACTA**

**EXTRACTS**

Extracts, as the term is employed in the Pharmacopoeias, are solid preparations, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing a dried drug to the action of a solvent, or by expressing the juice from a fresh plant. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called Extracta, the latter Succi Spissati, but the distinction has been generally abandoned. There is no such essential difference between these two sets of preparations as to require that they should be separately classed, and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant with as little of the inert matter as possible, though sometimes it may be desirable to separate two active ingredients from each other when their effects upon the system are materially different; this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, coloring matter, salts, and the peculiar principles of plants, to which, when an alcoholic solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil, gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in this commentary. There is one, however, which from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to extractive, or, as it is sometimes called, extractive matter.

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid even if originally limpid, first a greenish, then a yellowish-brown, and ultimately a deep brown color, and becoming itself insoluble. This substance, originally called saponaceous matter by Scheele, afterwards received the more expressive name of extractive.
derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted, by some chemists, who consider the phenomena supposed to result from its presence as depending upon the mutual reaction of other principles. The most important property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. The name of oxidized extractive which has been given to it is incorrect, and Berzelius proposed to substitute for it that of apothem, synonymous with deposit. According to Berzelius, apothem is not completely insoluble in water, but imparts a slight color to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it, thus acquiring properties somewhat different according to the source from which it is obtained. In this way also, even when the extractive of a plant is itself medicinally inert, its conversion into apothem may be injurious by causing a precipitation of a portion of the active principle, and in practical pharmaceutical operations this change should always, if possible, be avoided. We shall treat of the subject under the several heads of (1) the extraction of the soluble principles from the plant; (2) the method of conducting the evaporation; (3) the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them.

1. Extraction of the Soluble Principles.

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract: (1) by expression alone; (2) by the agency of a solvent, with or without expression.

1. By Expression.—This method is applicable to recent vegetable substances. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active
principles with their juice. Succulent fruits, and various acrid and
narcotic plants, are proper subjects for this treatment. The plants should
be operated upon, if possible, immediately after collection. Battley, of
London, recommended that, if not entirely fresh, they should be revived
by the immersion of the stalks in water for twelve or eighteen hours,
and those only used which recover their freshness by this management.
They should then be cut into pieces, and bruised in a stone mortar till
brought to a pulpy consistence. When the plant is not very succulent, it
is necessary to add a little water during this part of the process, in order
to dilute the juice. After sufficient contusion, the pulp is introduced into
a linen or canvas bag, and the liquid parts expressed. Brande states
that light pressure only should be employed, as the extract is thus
procured greener, of a less glutinous or viscid consistence, and, in his
opinion, more active than when considerable force is used in the
expression. (See Remington's Practice of Pharmacy.) The juice thus
obtained is opaque, and usually green, in consequence of the presence
of green wax or chlorophyll, and of a portion of the undissolved
vegetable fiber in minute division. By heating the juice to about 71.1°C.
(160° F.) the albumen contained in it coagulates, and, involving the
chlorophyll and vegetable fiber, forms a greenish precipitate. If the
liquid be now filtered, it becomes limpid and nearly colorless, and is
prepared for evaporation. The clarification, however, is not absolutely
necessary, and is generally neglected. Sometimes the precipitate carries
with it a considerable portion of the active principle, in which case it
should be subsequently incorporated with the juice, when reduced by
evaporation to the consistence of syrup. Ether added to the expressed
juices of plants enables them to be kept long without injurious change.
Lepage, of Gisors, France, has kept the juice of belladonna in this way
more than ten years, and found it, at the end of that time, to yield an
extract identical in physical, chemical, and physiological properties with
that obtained from the fresh juice. If this fact is found to be of general
applicability, it will be of considerable importance, as enabling the
pharmacist to supply himself at pleasure with extracts to be relied on,
without reference to the season.

2. By Solution.—The active principles of dried vegetable substances
can be extracted only by means of a liquid solvent. The menstruum
usually employed is either water or alcohol, or a mixture of the two.
Water, on account of its cheapness, is always preferred, when
circumstances do not strongly call for the use of alcohol. It has the
advantage, moreover, that it may be assisted in its action if necessary
by a higher degree of heat than the latter. Tap water is often unfit for the purpose, in consequence of the quantity of its saline matter, which in some instances may exert an unfavorable influence on the active principle, and must always be left in the extract. Rain, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The aqueous solution requires to be quickly evaporated, as this fluid rather promotes than counteracts chemical changes, while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former is preferable, and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively than of both united.

Extracts obtained by the agency of water are called aqueous extracts; those by means of alcohol, undiluted or diluted, alcoholic or spirituous extracts. Sometimes the term hydro-alcoholic is applied to extracts obtained by the joint agency of alcohol and water.

Chloroform is frequently used to saturate the water used in making aqueous extracts to prevent fermentation during percolation.

The method of preparing the solution is not a matter of indifference. The drug should be thoroughly bruised, or reduced to a coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved or inactive portion. When water is alone employed, it has been customary to boil the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions until the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the
decomposition of many vegetable principles, or at least so modifies them as to render them inert, and the extracts prepared by decoction are usually less efficient than those made with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion, in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, maceration is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By digestion, though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. Hot infusion, therefore, is to be preferred where the vegetable substance does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without adding to its virtues. A convenient mode of performing this process is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel having a notched cork in its mouth, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated until the water comes away without any obvious impregnation.

It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it.

Sometimes filtering a turbid infusion or decoction, before evaporation, causes the resulting extract to keep better by removing substances which, beside undergoing decomposition, may act as a ferment, and
occasion the decomposition of the active matter of the extract.

When alcohol is employed as a menstruum, the vegetable substance should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration, as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger with alcohol to which strong acetic acid has been added. ([ J. P. C., 3e ser., i, 239.) Experiments have shown that strong acetic acid (60 per cent.) is a powerful solvent for the active properties of various drugs, particularly those which contain volatile oils, and in many cases a 10 per cent. acetic acid is an excellent menstruum for making extracts; for these the name acettract has been proposed. (Proc. A. Ph. A., 1897, 416.) E. R. Squibb has used acetic acid largely for extracts. (West. Drug., 1897, 123.)

Ether also is now used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation, and the ether is then allowed to escape by spontaneous evaporation, or distilled off at a very moderate heat. The oleo resinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. Several of them now rank among the official preparations, in the U. S. P., under Oleoresinae. Acetone is another solvent used much for the same purpose as ether.

The process of percolation has in this country been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages:
(1) that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion

(2) that it effects the extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and

(3) that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing the injurious effects of the subsequent evaporation.

While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed, for, though an inexpert or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. In the process of percolation the drug must first be reduced to the proper degree of fineness. The U. S. P. (8th Rev.) gives the following directions.

Fineness of Powder.—The fineness of powder is expressed, in the Pharmacopoeia, either by descriptive words (generally so in the case of brittle or easily pulverizable substances), or in terms expressing the number of meshes to a linear inch of the sieve through which the powder will pass. The corresponding values, in terms of metric measures of length, are added below in parentheses, but it has not been deemed advisable, in this revision, to substitute them in the text of the Pharmacopoeia for those at present in use. The diameter of the wire (gauge number) used in making sieve cloth has an important influence upon the size of the mesh, and it is necessary to specify in each case the thickness of the wire, and it was so specified in the U. S. P. VIII but the U. S. Bureau of Standards, owing to the different standards in use by manufacturers of wire gauze determined to standardize the diameter of the particles of the powders, and the U. S. P. IX provides the following statement: "The fineness of powders and granular substances is expressed, in the Pharmacopoeia, by numbers which originally represented only the meshes per inch of the sieve through which the powders would pass. Fineness, so used, has been redefined below in terms of the maximum diameter of the particles of the powder as
measured by the width of the opening of the meshes of the sieves from which they receive their designating numbers. A powder of a specified number must meet the requirements given below for that number of powder, but the larger proportion of it must not pass through a sieve of a lower degree of fineness.

The degree of fineness defined above shall be such as are determined by sieving tests made with sieves of the Standard Screen Scale recommended by the Bureau of Standards." U. S.

Percolation, as directed in the U. S. Pharmacopoeia IX "consists in subjecting a comminuted substance or a mixture of substances, contained in a vessel called a percolator, to the Solvent action of successive portions of a liquid termed the menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall extract the soluble constituents, and pass from the percolator free from insoluble matter:
"When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself.

"In preparations which direct the process of percolation, wherever the expression (until the drug is exhausted' or a similar phrase occurs, it is to be understood that the term 'exhausted' means the point at which the valuable constituents have been as completely extracted 'as is possible or practical, and this must be determined by the judgment and experience of the operator.

"Percolators.—The following statement with regard to percolators and the process of percolation is given in order to illustrate a method of percolation. It is not intended as compulsory and it is permissible for manufacturers and others to modify the process to suit their needs. The percolator most suitable for the quantities contemplated by this Pharmacopoeia should be nearly cylindrical, or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become wider toward the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it. The glass tube, which must not project above the inner surface of the cork, should extend from 3 to 4 cm. beyond the outer surface of the cork, and should be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby (when it is desired to interrupt the percolation) the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding the tube in position.

"The shape of a percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a feebly alcoholic or an aqueous menstruum is employed, a conical percolator is preferable. A cylindrical or only slightly tapering percolator may be used for drugs which are not liable to swell, particularly if difficult to exhaust, also when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to the quantity of drug
extracted. When properly packed in the percolator, the drug should not occupy more than two-thirds of its height. The percolator is best constructed of glass, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum. For hot percolation glass percolators are unsuited, as they are liable to fracture. Metallic percolators in such cases are required.

"The percolator is prepared for percolation by gently pressing a small tuft of purified cotton into the neck, and this may then be moistened by pouring a few drops of menstruum upon the cotton, to facilitate the passage of the first portion of percolate, which is often very dense.

"The Process.—The powdered substance to be percolated (which should be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a suitable dish, sufficient menstruum is poured on, and the powder thoroughly stirred until it is uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, and No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum, strongly alcoholic menstrua, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper, held in place by a glass stopper or percolator weight, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions are accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time for maceration specified in the formula.
"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for a quantity of liquid to be received, if the percolate is to be measured, or of a tared bottle, if the percolate is to be weighed; and by raising or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable. A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator.

"Unless otherwise directed when the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the directed menstruum should be poured on to displace the retained liquid, until the prescribed quantity has been obtained.

"Repercolation or Fractional Percolation.— Authority is given to employ, where it may be applicable, the process of repercolation, without change of the initial menstruum. This process is used in Type Process C for fluidextracts.

"Rate of Flow.—It is obvious that the success of the process of percolation largely depends upon the regulation of the flow of the percolate; if this should be too rapid, incomplete exhaustion will result, but if too slow, valuable time may be wasted. The rate of flow for fluidextracts for 1000 Gm. of powder should not exceed ten drops a minute; for official quantities of tinctures and preparations of about the same strength twenty drops a minute, and the word 'slowly' throughout the text is understood to mean a rate of flow corresponding to this; it is evident that the proper rate of flow should vary with the quantity and character of the drug employed and the density of the menstruum.

"Maceration.—Percolation is not suitable for exhausting some drugs, and the process of maceration is employed for some of the tinctures
(Aloes, Asafetida, Sweet Orange Peel, Tolu, etc.). Specific directions will be found in the text, and maceration should be conducted preferably at a temperature of from 15° to 20° C. (59°-68° F.)." U. S.

For an account of E. R. Squibb's process of repercolation, see Fluidextracta.

Some prefer the mode of expression to that of percolation. This also is applicable both to aqueous and to alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances, and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw press, or other convenient apparatus. Another portion of the menstruum may then be added, and pressure again applied, and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of the percolation, that it yields solutions of more uniform concentration, that it does not require the materials to be so carefully powdered, or otherwise so skilfully managed, in order to insure favorable results, and, finally, that it occupies less time.

2. Mode of Conducting the Evaporation.

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapor. The operator should, therefore, observe two rules: (1) to conduct the evaporation at as low a temperature as is consistent with other objects; (2) to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. The injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case, and therefore a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine
the different modes in practice. First, however, it is proper to observe that decoctions generally let fall, upon cooling, a portion of insoluble matter, and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble substance formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a rule, is to allow it to remain.

The method of evaporation formerly resorted to in the case of aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted, the better, provided the liquid is to be brought to the boiling point, for the temperature cannot exceed this, and the length of exposure is diminished. But, where this method is employed, it should never be continued until the completion of the evaporation, for when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire before it has attained the consistence of thick syrup, and completing the evaporation, either by means of a water bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions and evaporate each separately, for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. But the mode of evaporation by boiling is always objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by the method of decoction.

Evaporation by means of a water bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and, the temperature being nearly the same, when the water bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the steam bath has become very general in this country, as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, may be less than 100° C; (212° F.). The
apparatus consists of an ordinary boiler, containing water, the vapor of which is conducted through a pipe into the evaporating vessels, communicating with each other by means of iron steam pipes. These vessels have the form of an ordinary copper basin, to the inside of which is riveted a shallow tinned copper evaporating basin, intended to contain the liquid to be evaporated. The vapor from the boiler circulates between these vessels, and the water into which it condenses is allowed to escape through a steam valve attached to the bottom of each vessel. The liquid to be evaporated is first distributed in two or three basins, but when considerably concentrated, is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid can be easily regulated by the steam valves.

As the heat capable of being applied by boiling water to the evaporating liquid does not exceed 93.3° C. (200° F.), while that by steam can, by a moderate pressure, be increased to the boiling point or beyond it, the evaporation by the latter agency may be much more rapid than by the former, when the pressure is from ten to twenty pounds to the square inch; so that there is a temptation to raise the heat to a degree seriously injurious to the product. Evaporation, therefore, by steam heat always requires caution and a stirring device should be used. The water bath is much less liable to be abused. In this respect the latter method has the advantage.

A good plan of evaporation, though slow, is to place the liquid in a broad, shallow vessel, exposed in a stove or drying room to a temperature of about 37.8° C. (100° F.), or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while extracts prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid, and in reference to substances which are injured by heat and not by atmospheric air the plan will be found useful.
Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for evaporation in vacua, now largely used by manufacturing pharmacists, is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapor more rapidly, and at a comparatively low temperature.

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that in vacuo. Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water bath.

In the concentration of alcoholic solutions, distillation should always be performed, as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion and the tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat therefore, should be applied to the bottom and not to the sides of the vessel.

Inasmuch as the yield of extracts is largely dependent on the character of the menstruum used in the percolation, it follows that there must necessarily be a great variation in the strength of commercial extracts. C. H. LaWall has prepared a valuable table giving the yield of extract by various drugs. (Proc. A. Ph. A., 1897, 414.) For methods of assay, see various official processes.

"Pilular Extracts" are solid or semi-solid products prepared by
exhausting drugs with appropriate solvents and carefully evaporating the solutions to the proper consistence. These extracts preserve the useful constituents of the drug in a concentrated, relatively uniform and permanent condition, and in a form suitable for medication.

"The solvents or menstrua employed in the preparation of pilular extracts are water, alcohol, or mixtures of these in the proportions stated in the formulas. A few drugs require for their extraction the addition of an acid or an alkali to the solvent. Where alcohol is used in the extraction it may be recovered by distillation.

"In the preparation of pilular extracts the concentration of the solutions should be completed without delay, and undue exposure to heat must be avoided. The limit of temperature for the evaporation, as stated in the formulas, should not be exceeded. In the manufacture of these extracts on a large scale an apparatus for distilling and evaporating under reduced pressure should be used. It is also important that the residue be frequently stirred so as to hasten the evaporation and to obtain a uniform product.

"Pilular extracts are extensively used in pill masses and in ointments and, to facilitate their use in these preparations, the degree of concentration is commonly directed to be that of a 'pilular consistence.'

"Pilular extracts should be protected from exposure to sunlight and air by being kept in tightly-covered glass or earthen-ware containers.

"Powdered Extracts differ from pilular extracts in that they are dry, fine powders. Powdered extracts are often preferred to pilular extracts for general use, because they can be more accurately weighed, more easily dispensed, and more conveniently preserved in tightly-stoppered bottles.

"In the preparation of powdered extracts, it is necessary to use solvents that will extract the active principles of the drugs, and only a minimum amount of the inert substances. Where the drug contains an oily constituent that would be extracted by the menstruum directed, it becomes necessary to adopt in the process of manufacture a method for the separation of this oil so that the product will retain a satisfactory, pulverulent form.

"The concentration of the liquids containing the extractive should be
completed without delay and undue exposure to heat must be avoided.

"The limit of temperature as stated in the formulas should not be exceeded, and the use of apparatus for concentrating under reduced pressure is recommended. The final drying of the soft extract can be greatly facilitated by spreading it upon plates of glass or tinned metal and exposing it to currents of warm, dry air. Powdered extracts must be thoroughly dried, powdered and mixed with the diluent and preserved in tightly-stoppered, small, wide-mouthed, amber-colored bottles, and stored in a cool and dry place.

"Alkaloidal standards have been adopted for Extracts that can be reliably assayed. Assay methods are directed for the determination of their strength, and to provide for standardization. When necessary, an inert diluent is directed to reduce the product to the standard. In the official formulas glucose is directed for the diluent in pilular extracts and dried starch and magnesium oxide are directed for powdered extracts, but it is permissible for the manufacturer to use as inert diluents for the latter, sugar, sugar of milk, powdered glycyrrhiza, magnesium carbonate or the finely powdered drug or marc from which the respective extract was made. For the convenience of the prescriber, the standards of strength for the Extracts have been adjusted, wherever possible, so that each bears a definite relation to that of the respective drug of average strength, and a statement of the standard precedes the formula," U. S.

3. Condition and Preservation of Extracts.

Extracts may be prepared of three different degrees of consistence: soft, so that they may be readily made into pills, hard, in order that they may be pulverized, and in a fine, dry powder. The soft extracts always contain a notable percentage of water. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophyll, harden by time, in consequence of the escape of their moisture, and it not unfrequently happens that small crystals of saline matter are formed in their substance; sodium chloride in small cubes is sometimes found in certain old extracts, having slowly crystallized as they
hardened. John Attfield of London, has made a chemical examination of
the crystals found in numerous extracts, and ascertained that in a large
number they consisted of potassium chloride, and in a comparatively
few of potassium nitrate. Potassium chloride was detected in the extracts
of belladonna, hemlock, sarsaparilla (compound), colchicum seed,
stramonium seed, andaconite; potassium nitrate in the extracts of
belladonna, hyos-cyamus, and lettuce; and sodium sulphate in extract
of stramonium seed. (P. J., March, 1862, p. 448.) The air, moreover,
exercises an unfavorable chemical influence over the softer extracts,
which are enfeebled, and ultimately become nearly inert, by the same
changes which they undergo more rapidly in the liquid state at an
elevated temperature. If an extract be dissolved in water, and the liquid
be saturated with common salt or any other very soluble salt of difficult
decomposition, the greater part of it will be precipitated, in consequence
of the insolubility of this class of substances in saline solutions. The
precipitate may be again dissolved in pure water.

Abstracts, which were official in the U. S. P., 1880, were not re-
introduced in the U. S. P. (8th Rev.), as they did not come into general
use; this is unfortunate, as they had many advantages, and are used in
certain sections of the country. A description and a typical formula, with
comments, will be found in the U. S. Dispensatory, 19th edition, p. 466.

Extracts, in order that they may keep well, should be placed in glazed
earthenware, glass, or porcelain jars, and completely protected from the
access of the air. This may be effected by covering their surface with a
layer of melted wax, or with a piece of paper moistened with strong
spirit, then closing the mouth of the vessel with a cork, spreading wax
or rosin over this, and covering the whole with leather or a piece of
bladder. The application of alcohol to the surface has a tendency to
prevent mouldiness. Should the extract become too moist, it may be
dried by means of a water bath; should it, on the contrary, be too dry,
the proper consistence may be restored by softening it in the same
manner and incorporating with it a little distilled water. Martin proposes
to preserve extracts in a soft condition by surrounding the vessel
containing the extract by another of larger diameter, which is furnished
with a tight cover, the space between the two vessels being filled with
crystallized sodium sulphate, which gradually parts with its water of
crystallization and prevents the extract from becoming hard and dry.

When extracts which are too soft are subjected to a moderate
temperature, fermentation may set in; E. Cocardas describes the various forms of "Penicillium-ferment" which are found in such extracts, and concludes that the ferment causes them to undergo changes similar to those effected by heat—viz., the absorption of oxygen and the disengagement of carbon dioxide. (P. J., 1886, p. 590.)

It is preferable to add a definite weight of the glycerin to the percolate. If it were added to the menstruum, owing to the variation in the yield, of extracts from plants, some would be too soft, and at another time, in the case of a large yield of extract, the quantity of glycerin would be insignificant.

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; a good rule is to prepare them once a year; but the demand for extracts from fresh drugs has declined rapidly of late, as it has been found that properly dried drugs yield extracts of uniform strength.

Powdered Extracts.—These extracts are largely superseding soft extracts for reasons given in preceding paragraphs; the difficulty of making them arises from the injurious influence of heat upon concentrated percolates of organic substances, but by the use of vacuum apparatus, suitable absorptive diluents and care, they should be made successfully.

Some extracts when powdered have a tendency to cohere. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered licorice root, two or three parts of the former and one part of the latter to one of the extract being sufficient for the purpose. (Ph. Cb., 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered licorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing calcium chloride thoroughly dried by heat insufficient to melt it; then enclose the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the mixture is quite dry, powder it, and add so much of the powdered root as to make the weight double that of the original extract. This process was substantially adopted in the German Pharmacopoeia (1882). The old process of using dextrin as a diluent was found very objectionable, principally on account of the tendency of the extracts to reabsorb...
moisture. Four parts of extract are now mixed with three parts of finely powdered licorice-root, and dried in a porcelain dish at 40° to 50° C. (104°-1220 F.) until the mixture ceases to lose weight. The mass is then rubbed to powder, and sufficient powdered licorice-root added to make the whole weigh eight parts, or double the weight of extract used. In our opinion, this method is not so good as that formerly adopted for abstracts. The German powdered extracts are always half the strength of the extracts, no relation whatever with the drug is established, and the variations in the yield of extract from different drugs have been repeatedly shown to be great. Kirchmann proposes exsiccated sodium sulphate as a diluent instead of dextrin, licorice-root, etc. (Ph. Ztg., 1881, 116.) A. B. Lyons, of Detroit (1898), has introduced scale extracts. These do not, as a class, bear a definite relation to the drug; they are assayed, however, and acacia is used as a means of preserving their dry condition; they are easily pulverized, and are very convenient for dispensing.

The plan of incorporating a little glycerin with extracts has been recommended for such extracts as require it, 10 per cent. of glycerin being added to the liquid extract before evaporating to a pilular consistence. By its unchangeable liquid character, glycerin keeps the extract soft, so that it can be readily made into pills, and it also exercises a favorable influence through its chemical properties. The U. S. P. (8th Rev.) directs the use of glycerin for this purpose as follows: "When it is desired to preserve a solid extract (for instance, of Gentian, Taraxacum, etc.) in a plastic condition, suitable for making pills, or for other purposes, it is recommended that there be incorporated with it, after it has been evaporated to the proper consistence, and while it is still warm, 10 percent. of its weight of glycerin." U. S.

Eight extracts were dismissed at the last revision of the U. S. Pharmacopoeia, these were as follows: Aloes, digitalis, euonymus haematoxyln, krameria, leptandra, quassia, and scopola; five extracts were added as follows: Aconite, oxgall, gelsemium, hydrastis, viburnum pruni-folium.
EXTRACTUM ACONITI. U. S.

EXTRACT OF ACONITE Ext. Aconit. [Powdered Extract of Aconite]

"Extract of Aconite yields not less than 1.8 per cent. nor more than 2.2 per cent. of the ether-soluble alkaloids of aconite and, if assayed biologically, the minimum lethal dose should not be greater than 0.00001 Gm. for each gramme of body weight of guinea-pig. One gramme of the Extract represents about four grammes of aconite." U. S.

“Aconite, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Tartaric Acid, five grammes [or 77 grains]; Purified Petroleum Benzin, Starch, dried at 100° C. (212° F.), Alcohol, each, a sufficient quantity. Dissolve the tartaric acid in five hundred mils [or 16 fluidounces, 435 minims] of alcohol, moisten the drug with this solution and pack it in a cylindrical glass percolator; then add sufficient alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, an^,, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed very slowly, adding alcohol as required. Reserve the first one thousand mils [or 33 fluidounces, 61/2 fluidrachms] of percolate and continue the percolation, until the second percolate measures one thousand mils [or 33 fluidounces, 61/2 fluidrachms] or until the drug is exhausted. Transfer this second percolate to a suitable apparatus and distil off the alcohol at as low a temperature as practicable, until a residue measuring about one hundred mils remains then add the reserved percolate and continue distillation until the residue in the still is of syrupy consistence. Transfer this syrupy residue to a flask, using a little warm alcohol to rinse the still, and adding the rinsing to the flask. When it has cooled, add two hundred and fifty mils [or 8 fluidounces, 218 minims] of purified petroleum benzin and shake the mixture thoroughly for several minutes. Allow the liquids to separate and decant the benzin layer as closely as possible; add again to the residue two hundred and fifty mils [or 8 fluidounces, 218 minims] of purified petroleum benzin, agitate and decant the benzin layer as before. Transfer the syrupy residue to a shallow evaporating dish, rinse the flask with twenty mils [or 325 minims] of warm alcohol, adding the rinsings to the residue in the dish, and then incorporate fifty grammes [or 1 ounce av., 334 grains] of the thoroughly dried starch. Evaporate
the mixture by a very gentle heat on a water bath, frequently stirring, and, when the mass has become thick, spread it on glass plates and continue the drying in an air bath at a temperature not exceeding 70° C. (158° F.) until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 2 per cent. of the ether-soluble alkaloids of aconite. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly.

"Assay."—Introduce 3 Gm. of Extract of Aconite into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of ether and 2 mils of ammonia water, shake the mixture vigorously every few minutes during a half hour, and when the dregs have settled decant 100 mils of the clear liquid, representing two grammes of the Extract. Proceed as directed under Belladonna Radix, modifying the process there given by using ether instead of chloroform for the final shaking out of the alkaloids.

" Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 64.539 milligrammes of the ether-soluble alkaloids of aconite." U. S.

For a biological method of assaying Extract of Aconite, see Aconitum.

This extract is an undesirable addition to the U. S. P. IX and requires the utmost care in its preparation, for notwithstanding the addition of both a chemical and biological assay it is often variable in strength as found in commerce.

Dose, one-eighth to one-fourth grain (0.008-0.015 Gm.).

**EXTRACTUM ALOES. Br.**

**EXTRACT OF ALOES**

Extrait d'Aloes, Fr.; Extractum Aloes, P. G.; Aloeextract, G.; Estratto di aloe acquoso, It.

"Aloes, in small fragments, 1000 grammes; Distilled Water, boiling,
10,000 millilitres. Add the Aloes to the Distilled Water and stir well until they are thoroughly mixed; set aside the mixture for twenty-four hours; decant; strain; evaporate the strained liquid to dryness at a temperature not exceeding 60° C. (140° F.)." Br.

The object of this preparation is to afford an aloes purified from mechanical impurities. The process is based upon the British formulas for extracts of Barbados aloes and Soeotrine aloes, formerly official. With an official purified aloes, the necessity for this preparation is not obvious. The U. S. P. IX dismissed Extract of Aloes and Aloe Purificata, but added tests for Aloes which exclude inorganic impurities, gum, etc. See Aloe. A powdered extract is official in the N. F. IV. An extract made with cold distilled water was formerly official in the German Pharmacopoeia, as was also the vitriolated extract, "Extractum Aloes Acido Sulfurico Correctum," made by suspending eight parts of extract of aloes in thirty-two parts of distilled water, adding drop by drop one part of pure sulphuric acid, and evaporating in a porcelain vessel to dryness.

Dose, one to five grains (0.06-0.3 Gm.).

**EXTRACTUM CANNABIS. U. S. (Br.)**

**EXTRACT OF CANNABIS Ext. Cannab. [Extractum Cannabis Indicee, U S. P. VIII]**

"Extract of Cannabis, when assayed biologically, produces incoordination when administered to dog’s in a dose of not more than 0.004 Gm. of Extract per kilogramme of body weight." U.S.

**Extractum Cannabis Indicae**, Br.; Extract of Indian Hemp: Br.; Extrait de Chanvre de l’Inde, Fr. Cod.; Indischer Hanfextrakt, G.

"Cannabis, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, a sufficient quantity. Moisten the powder with sufficient alcohol, pack it firmly in a cylindrical percolator and add enough alcohol to saturate the powder and leave a stratum above it.
When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding alcohol, until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract, and from the result thus obtained adjust the weight of the finished Extract, by the addition of glucose, to conform to the required biological standard.

"Assay.—Proceed as directed under Biological Assays." U. S. (See under Cannabis.)

"Exhaust Indian Hemp, in coarse powder, with Alcohol (90 per cent.) by the percolation process; recover the alcohol by distillation, and evaporate the residue to a soft extract." Br.

The continuation in the Br. Pharm. of the name of Indian Hemp is unfortunate because of the possibility of its being mistaken for the root of Apocynum cannabinum, which is also called Indian Hemp. Several mistakes have occurred through this unfortunate confusion of nomenclature.

Although there is some difference in the details of the two processes, the preparations of the U. S. and Br. Pharmacopoeias are practically identical. The U. S. P. IX provides a biological test.

Great care is necessary in the manufacture of this extract not only in the selection of the crude drug, but also there is reason to believe that excessive heat in evaporating may have an injurious effect on the quality of the preparation. The only means of ascertaining its activity is by means of the biological test. The preparation varies exceedingly in strength, so that it is wisest to begin with a small dose, one-quarter of a grain (0.016 Gm.), and rapidly increase the amount given until some effect is produced.

Dose, one-fourth to three-fourths of a grain (0.015-0.045 Gm.).

Off. Prep.—Tinctura Cannabis Indicae, Br.; Mistura Chlorali et Potassii Bromidi Composita, N.F.
"One gramme of the Extract represents three grammes of cascara sagrada." U. S.

Extractum Cascarae Sagradae Siccum, Br.; Dry Extract of Cascara Sagrada;

"Cascara Sagrada, in No. 20 powder, nine hundred grammes [or 31 ounces av., 327 grains];

Magnesium Oxide, twenty-five grammes [or 386 grains]; Starch, dried at 100° C. (212° F.), Boiling Water, each, sufficient quantity, to make three hundred grammes [or 10 ounces av., 255 grains]. Mix the cascara sagrada with four thousand mils [or 135 fluidounces, 122 minims] of boiling water and macerate the mixture during three hours. Then transfer it to a metallic percolator, allow it to drain and pour on boiling water until the percolate measures five thousand mils [or 169 fluidounces, 33 minims], or the drug is exhausted. Evaporate the percolate to dryness on a water bath or steam bath, reduce the extract to a fine powder, weigh it, add the magnesium oxide and enough of the dried starch to make the product weigh three hundred grammes [or 10 ounces av., 255 grains]. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." U. S.

"Exhaust Cascara Sagrada, in No. 20 powder, with Distilled Water by the percolation process; evaporate the percolate to dryness on a water-bath;" Br.

This powdered extract was made official in the U. S. P. VIII for the first time; 1 part of the extract represented 4 parts of the drug; in the U. S. P. IX 1 part represents 3 parts of the drug.

The British preparation (1914) is a dry extract. It well represents the virtues of the bark, and furnishes a good means of administering this
purgative in pilular form.

Dose, from two to eight grains (0.13-0.5 Gm.).

**Off. Prep.—**Pilulae Aloini, Strychninas et Belladonae Compositae, N. F.

**EXTRACTUM CIMICIFUGAE. U. S.**

**EXTRACT OF CIMICIFUGA Ext. Cimicif. [Powdered Extract of Cimicifuga]**

“One gramme of the Extract represents four grammes of cimicifuga." U. S.

Extract of Black Cohosh; Extrait d'Actee a grappes, Fr.; Cimicifuga-extrakt, G.

“Cimicifuga, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Starch, dried at 100° C. (212° F.), each, a sufficient quantity, to make two hundred and fifty grammes [or 8 ounces av., 358 grains]. Moisten the drug with sufficient alcohol, pack it in a cylindrical percolator, and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue to dryness, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Weigh the residue and add sufficient of the dried starch to make the product weigh two hundred and fifty grammes [or 8 ounces av., 358 grains]. Reduce the mixture to a fine powder, mix thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." U. S.

In the U. S. P. VIII this extract was made from the fluidextract, but the U. S. P. IX gives a process. This extract was introduced for the reason that although the fluidextract and tincture represent the virtues of cimicifuga, the alcohol present in both may be therapeutically contra-indicated, and the exceedingly disagreeable taste of the drug is entirely masked if the extract be prescribed in the form of a pill, with proper additions, such as extract of licorice, or if the pill be coated or enclosed in
a capsule. It is used in the treatment of chorea.

Dose, of the extract, from three to ten grains (0.2-0.65 Gm.).

**EXTRACTUM COLCHICI CORMI. U. S. (Br.)**

**EXTRACT OF COLCHICUM CORM Ext. Colch. Conn.**

[Powerdered Extract of Colchicum Conn]

"Extract of Colchicum Corm yields not less than 1.25 per cent. nor more than 1.55 per cent. of colchicine. One gramme of the Extract represents about four grammes of colchicum corm." U.S.

Extractum Colchict, Br.; Extractum Colchici Radicis, U. S., 1890; Extrait de Colchique acetique, Fr.; Zeitlosen Esaigextrakt, G.

"Colchicum Corm, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Purified Petroleum Benzin, Starch, dried at 100° C. (212° F.), each, a sufficient quantity. Moisten the drug with sufficient alcohol, pack it in a cylindrical percolator and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required, until the percolate measures two thousand mils or until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable until a residue measuring about one hundred and fifty mils [or 5 fluidounces, 35 minims] remains in the still. Transfer this residue to a flask, using a little warm alcohol to rinse the still, and add the rinsings to the flask. When it has cooled, add two hundred and fifty mils [or 8 fluidounces, 218 minims] of purified petroleum benzin and shake the mixture thoroughly for several minutes. Allow the liquids to separate and decant the benzin layer as closely as possible; again add to the residue one hundred and fifty mils [or 5 fluidounces, 35 minims] of purified petroleum benzin, agitata and decant the benzin layer as before, repeat the washing with one hundred mils [or 3 fluidounces, 183 minims] of purified petroleum benzin and reject the benzin washings. Transfer the residue to a shallow evaporating dish, rinse the flask with a little warm alcohol, adding the rinsings to the residue in the dish, and evaporate it on a water bath to a thick extract. To this add fifty grammes [or 1 ounce av., 334 grains] of
the dried starch, mix well, spread the mixture on glass plates and continue the drying in an air bath at a temperature not exceeding 70° C. (158° F.) until thoroughly dry. Reduce the product to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloid in the remainder of the powder and add to this enough of the dried starch to make the finished Extract contain 1.4 per cent. of col-chicine. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small wide-mouthed bottles and stopper them tightly. "U. S.

"Crush fresh Colchicum Corms, deprived of their coats; press out the juice; allow the feculence to subside, decant; heat the clear liquid to 100° C. (212° F.); strain through flannel, and evaporate at a temperature not exceeding 70° C. (158° F.) to a soft extract." Br.

The U. S. VIII extract was an acetic extract of the corm, but in the I.T. S. P. IX process the acetic acid "was omitted. The British extract is made by evaporating the juice of fresh conns.

In Great Britain a preparation called preserved juice of colchicum is given in the dose of five minims (0.3 mil) or more. It is made by expressing the fresh corm, allowing the juice to stand for forty-eight hours that the starchy matter may subside, then adding one-fourth of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering.

"Assay.—Proceed as directed under Colchici Semen, modifying the process there given by using 6 Gm. of the Extract of Colchicum Corm instead of 15 Gm. of colehicum seed. The final weight will be the amount of colchicine from two grammes of Extract of Colchicum Corm." U. S.

As the fresh colchicum corm is rarely to be had in this country, the U. S. Pharmacopoeia employs the dried corm; its process, if properly conducted, will afford a very efficient extract. In preparing this extract according to the British process, by expression from the recent corm, there will be experienced some inconveniences, which would seem to render the U. S. process under all circumstances preferable. (P. J., xiii, 62.) The acetic extract of colchicum made from fresh conns was abandoned by the Br. Ph., 1898, and by the U. S. P. IX, but the acetic acid menstruum is a good solvent for colchicine.
Dose, from one-fourth to one grain (0.016-0.065 Gm.).

EXTRACTUM COLOCYNTHIDIS. U. S.

EXTRACT OF COLOCYNTH Ext. Colocynth. [Powdered Extract of Colocynth]

“One gramme of the Extract represents four grammes of colocynth." U. S.

“Colocynth, in No. 20 powder, one thousand grammes (freed from the seeds) [or 35 ounces av., 120 grains]; Diluted Alcohol, Starch, dried at 100° C. (212° F.) each, a sufficient quantity, to make two hundred and fifty grammes [or 8 ounces av., 358 grains]. Moisten the drug with two thousand mils [or 67 fluidounces, 301 minims] of diluted alcohol and macerate it in a closed vessel for twenty-four hours, then transfer the moist drug to a cylindrical percolator, shake it down evenly without packing, and gradually pour diluted alcohol upon it, allowing the percolation to proceed slowly, until the percolate measures five thousand mils [or 169 fluidounces, 33 minims]. Recover the alcohol from the percolate by distillation and evaporate the residue to dryness on a water bath or steam bath. Reduce the extract to a fine powder, weigh it, and add sufficient of the dried starch to make the product weigh two hundred and fifty grammes [or 8 ounces av., 358 grains]. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly.” U. S.

The colocynth should always be deprived of its seeds, following the directions of the U. S. Pharmacopoeia, before being submitted to the action of the menstruum. Boiling water extracts such a large amount of pectin and mucilage from colocynth that either the decoction or the hot infusion gelatinizes on cooling, and the extract made by means of it is therefore loaded with inert matter, and, besides, is liable to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence many years ago the London College, following in this respect the old French Codex, directed, in the last edition of its Pharmacopoeia, maceration with cold water; but diluted alcohol has
been found to be a much better menstruum, and has accordingly been adopted in the U. S. Pharmacopoeia process, while in the British Pharmacopoeia the simple extract has been discarded altogether. The chief, if not exclusive, use of the alcoholic extract is in the preparation of the compound extract.

This preparation should never be substituted for an extract prepared with a menstruum containing a larger percentage of water, because the water extracts a large quantity of mucilaginous and inert matter. Commercial extract of colo-cynth may be often found in the market made with an aqueous menstruum.

Dose, one-half grain (0.032 Gm.).

Off. Prep.—Extractum Colocynthidis Compositum, U. S.; Pilulae Colocynthidis Compositae, N. F.; Pilulae Colocynthidis et Hyoscyami, N. F.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. U. S., Br.

COMPOUND EXTRACT OF COLOCYNTH Ext. Colocynth. Co. [Powdered Compound Extract of Colocynth]

Estrait de Coloquinte compose, Fr.; Zusammengesetetes Koloquintenextrakt, G.

“Extract of Colocynth, one hundred and sixty grammes [or 5 ounces av., 282 grains]; Aloes, five hundred grammes [or 17 ounces av., 279 grains]; Cardamom Seed, in No. 60 powder, fifty grammes [or 1 ounce av., 334 grains]; Resin of Scammony, in No 60 powder, one hundred and forty grammes [or 4 ounces av., 411 grains]; Soap, dried and in powder, one hundred and fifty grammes [or 5 ounces av., 127 grains], to make one thousand grammes [or 35 ounces av., 120 grains]. Triturate the ingredients until the product is reduced to a No. 60 powder. Pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." U. S.

“Colocynth Pulp, 150 grammes; Extract of Aloes, 300 grammes; Scammony Resin, 100 grammes; Curd Soap, in powder, 75 grammes; Cardamom Seeds, in powder, 25 grammes; Alcohol (60 per cent.), 4000 millilitres. Macerate the Colocynth Pulp in the Alcohol for four days; press out the tincture; recover the alcohol by distillation; evaporate to
dryness; add the Extract of Aloes, Scammony Resin, and powdered Cardamom Seeds; powder; mix the powder with the Curd Soap." Br.

The Br. Pharm. (1914) directs Extract of Aloes instead of Barbados Aloes, and decreased the proportion of soap from four to three ounces. The object of the soap is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the gastric juices. It may possibly also serve the purpose of modifying the action of the aloes. In the

U. S. process the extract is in the form of powder, which is very convenient for admixture with other substances; while if given uncombined, it may be readily made into pills by suitable additions. The alternative of using the scammony or its resin, in the first British formula, which appeared to us very objectionable, has been abandoned in the present edition, and the resin only directed. The plan of having the powders simply mixed was liable to the objection that the mixture was not likely to be so thoroughly effected as to obtain a uniform result, and hence the U. S. Pharm., 1880, adopted Squibb's suggestion, to melt together all the ingredients unpowdered, except the cardamom, add a little alcohol, and, when the mixture is thoroughly made, to stir in the powdered aromatic, and finally to reduce the whole to a fine powder. The U. S. P. IX, however, relies upon trituration as an assurance of thorough commingling.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, etc., with one or more of which it is often united in prescription.

Dose, as a laxative, one to two grains (0.065-0.13 Gm.); as a purgative, five to ten grains (0.32-0.65 Gm.).

EXTRACTUM EUONYMI Br.

EXTRACT OF EUONYMUS

Dry Extract of Euonymus; Extract of Wahoo; Extrait d'Evonymus atropurpureus, Fr. Cod.; Extrait dc Fusain Americaine, Fr.; Spindelbaumextrakt, Spillbaumrindenextrakt, G.

"Exhaust Euonymus Bark in No. 20 powder with Alcohol (45 per cent.) by the percolation process. Evaporate the percolate and thoroughly dry the residue. Powder the product as far as possible and mix it with one-fourth of its weight of Calcium Phosphate, continuing the drying and powdering until a sufficiently dry preparation is obtained; transfer this to a well-closed bottle." Br.

This extract was not admitted to the U. S. P. IX, but was retained in the Br. Pharm. (1914) and introduced into the National Formulary IV which directs the percolation of euonymus in No. 40 powder with alcohol 4 volumes and water 1 volume. The percolate is evaporated or distilled and the residue dried and mixed with dried starch so that 1 Gm. of the extract represents 4 Gm. of euonymus. On account of the reports of physicians of cumulative effects the following note was inserted:

"CAUTION—It has been stated that the absorption of Euonymus in the gastro-intestinal tract is uncertain and irregular. To avoid an accumulation of the drug or toxic action, the physician should carefully guard the dosage and determine in each case the tolerance of the patient." N. F. IV. Dry and powdered extract of euonymus is frequently but erroneously termed "euonymin."

Dose, one to three grains (0.065 to 0.2 Gm.).

EXTRACTUM GELSEMII. U. S.

EXTRACT OF GELSEMIUM Ext. Gelsem. [Powdered Extract of Gelsemium]

"One gramme of the Extract represents four grammes of gelsemium." U. S.

"Gelsemium, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Magnesium Oxide, Starch dried at 100° C.
(212° F.), each, a sufficient quantity, to make two hundred and fifty grammes [or 8 ounces av., 358 grains]. Moisten the drug with sufficient alcohol, pack it in a cylindrical percolator and add enough alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required, until the drug is exhausted. Recover the alcohol from the percolate, by distillation at as low a temperature as practicable, until a residue measuring about five hundred mils [or 16 fluidounces, 435 minims] remains in the still. Transfer this residue to a shallow dish, and evaporate it to a soft extract with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Then add fifty grammes [or 1 ounce av., 334 grains] of a mixture of one part of magnesium oxide and three parts of the dried starch, mix well, spread the mass in a thin layer on glass or tinned-metal plates or in a porcelain dish and continue the drying in an air bath, at a temperature not exceeding 70° C. (158° F.), until thoroughly dry. Reduce the extract to a fine powder, weigh it, and add sufficient of the mixture of magnesium oxide and dried starch, made in the same proportion as before, to make the finished product weigh two hundred and fifty grammes [or 8 ounces av., 358 grains]. Mix the powders thoroughly, pass the extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly." U. S.

Dose, one-eighth to one-fourth of a grain (0.008-0.016 Gm.).

**EXTRACTUM GENTIANS. U. S., Br.**

**EXTRACT OF GENTIANS Ext. Gentian.**

"Gentian, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Water, a sufficient quantity. Moisten the powder with sufficient water, and allow it to macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour water upon it until the drug is exhausted. Reduce the liquid to two thousand mils [or 67 fluidounces, 301 minims] by boiling, strain it, and then evaporate it to a pilular consistence on a water bath." U. S.
“Infuse Gentian Root in ten times its weight of Distilled Water for two hours; boil for fifteen minutes; pour off; press; strain; evaporate the liquid to a soft extract." Br.

The plan of percolation with cold water is admirably adapted to the extraction of the active principles of gentian. By the use of cold water, starch and pectic acid are left behind, while any albumen that may be taken up is disposed of by the subsequent boiling and straining.

The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water, and in like manner expressing, and evaporating the united expressed liquors. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but also more transparent, more bitter, and possessing more of the color and odor of the root, than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water, while decoction favors the combination of a portion of the coloring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian has an agreeable odor, is very bitter, and of a dark brown color approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations; but the practice of some pharmacists of using it indiscriminately as a pill excipient is deserving of severe censure.

Dose, from two to eight grains (0.12-0.5 Gm.).

**Off. Prep.**—Pilulae Antiperiodicae, N. F.; Pilulae Ferri, Quininae, Aloes, et Nucis Vomicee, N. F.
EXTRACTUM GLYCYRRHIZAE. U. S.

EXTRACT OF GLYCYRRHIZA Ext. Glycyrrh, [Extract of Licorice]

"The commercial Extract of Glycyrrhiza." U. S.

Licorice is an article of export from the north of Spain, particularly Catalonia, where it is obtained in the following manner. The roots of the G. glabra, having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water until the liquor is saturated. The decoction is then allowed to rest, and, after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract, thus prepared, is formed into rolls from five to six inches long by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

The British Pharmacopoeia gives a process for making extract of licorice. The U. S. Pharmacopoeia directs that not less than 60 per cent. of it should be soluble in cold water.

Much licorice is prepared in Calabria, according to Fee, from the G. echinata, which abounds in that country. The process is essentially the same as that just described, but conducted with greater care, and the Italian licorice is purer and more valuable than the Spanish. It is in cylinders, generally somewhat smaller than the Spanish, and usually stamped with the manufacturer's brand. Most of the extract brought to this country comes from Messina and Catania in Sicily and Naples, from Seville and Saragossa in Spain, and from Smyrna in Turkey. Perhaps in no other part of the world is more licorice consumed than in the United States, from four to five thousand tons having been imported annually before 1860; but the article is now made on an extensive scale in this country, very successfully, with the best modern appliances, and of such good quality as to have almost driven the foreign article out of the market. The principal use of Extract of Licorice is in the manufacture of chewing tobacco, that in the form of rolls as sold by the druggists being a comparatively small portion of the whole amount.
Consumed.

Crude Licorice, Licorice Paste, or Licorice Mass, as it is variously termed, is found in the market in cases ranging from two hundred and fifty to four hundred pounds, of a hard pilular consistence and, as its name implies, in a mass, which has been run into the case while hot and then allowed to cool.

Licorice is usually in cylindrical rolls, somewhat flattened, and often covered with bay-leaves. We have seen it abroad and in this market in large cubical masses. When good, it is black, dry, brittle, breaking with a shining fracture, of a peculiar sweet and slightly acrid or bitterish taste, and almost entirely soluble, when pure, in boiling water.

It is described officially as "in flattened cylindrical rolls or in masses, of a glossy black color externally; fracture brittle, sharp, smooth, conchoidal; taste characteristic and sweet. When pulverized it yields a brown powder. Not less than 60 per cent. of Extract of Glycyrrhiza is soluble in cold water. The yield of ash does not exceed 6 per cent." U. S. Neumann obtained 460 parts of aqueous extract from 480 parts of Spanish licorice. It is, however, considerably less soluble in cold water. It is often impure from accidental or fraudulent addition or careless preparation. Starch, sand, the juice of prunes, etc., are sometimes added, and carbonaceous matter, and even particles of copper, are found in it, the latter arising from the boilers in which the decoction is evaporated. In different commercial specimens examined by Chevallier he found from 9 to 50 per cent. of insoluble matter. (J. P. C., xxx, 429.) This is by no means, however, always impurity. In the preparation of the extract by decoction, a portion of matter originally insoluble, or rendered so by decoction, is taken up, and is, in fact, necessary to the proper constitution of the licorice. When this is prepared with cold water, or even with hot water by simple displacement, the extract attracts moisture from the air, becomes soft, and loses the characteristic brittleness of the drug. The additional substances taken up in decoction serve to protect the extract against this change. Delondre has obtained the same result by using steam as the solvent. He prepares from the root an excellent licorice, having all the requisite qualities of color, taste, and permanence, by passing steam, in suitable vessels, through the coarse powder of the root. The vapor thoroughly penetrates the powder, and is drawn off as it condenses. With about 500 lbs. of the root, this treatment is continued for twelve hours, and repeated at the end of five days. The
liquors are collected, decanted, clarified with about 4 lbs. of gelatin, and quickly evaporated. After being put into the form of cylinders, the extract is kept for ten days in a drying room, at a temperature of 25° C. (77° F.). A bitter or empyreumatic taste is a sign of inferior quality in licorice. As ordinarily found in commerce, it requires to be purified. (See Extractum Glycyrrizae Purum; also Glycyrrhizinum Ammoniatum.)

Licorice contains glycyrrhizin, $C_{24}H_{36}O_9$, a glucoside, partly free and partly in combination with ammonia, to which combination the characteristic sweet taste of licorice is due. The glycyrrhizin when boiled with dilute acids decomposes into glycyrrhetin, $C_{18}H_{26}O_4$, and a fermentable sugar.

According to Mellor (A. J. P., 1898, 23, 54, 136) the best process for estimating glycyrrhizin is as follows: The best menstruum with which to treat the commercial powdered extract is a mixture of 40 mils ammonia water, 240 mils of alcohol, and sufficient water to make a liter. After extraction, filter, and precipitate with diluted sulphuric acid. Of twelve samples examined, the highest was a Greek licorice with 27.78 per cent., and the lowest a Spanish with 5.28 per cent. of glycyrrhizin. Of insoluble matter, the highest was a Spanish with 36.52 per cent., and the lowest a Greek with 5.95 per cent. The average yield, however, was strongly in favor of American licorice. In determining the per cent. of glycyrrhizin in the commercial extract, the tobacco manufacturers dissolve 10 Gm. in 100 mils of water, add 200 mils of alcohol, and allow it to stand over night. The insoluble matter will then have mostly settled; the filtrate may be acidulated with sulphuric acid, and the precipitated glycyrrhizin dried and weighed. For an improvement on the foregoing method see Dwier’s article in the Analyst for 1913, p. 367, translated from Ann. Falsif., 1913, p. 252; Also Evans’ Sons, Lescher and Webb method. Proc. A. Ph. A., 1911, 57 from Chem. Ztg., 1911, No. 92.

The so called refined licorice, found in commerce in small cylindrical pieces not thicker than a pipestem, is prepared by dissolving the impure extract in water without boiling, straining the solution, and evaporating. The object of this process is to separate not only the insoluble impurities, but also the acrid oleoresinous substance which is extracted from the licorice root and is necessarily mixed with the unrefined extract. It is customary to add, during the process, a portion of sugar, gum, flour, starch, or perhaps glue. These additions, or
something equivalent, are necessary to obviate the deliquescent property of the pure licorice. According to Delondre, 15 per cent. of gum is the proper proportion, when this substance is used; Geiseler has found sugar of milk to lessen the disposition of the extract to absorb moisture; but he considers the best addition, on the whole, to be very finely powdered licorice root, which should be used in the proportion of 1 part to 16 of the purified extract. (A. J. P., xxviii. 225.) The preparation is sometimes attacked by small worms, probably in consequence of the farinaceous additions. Excellent licorice is prepared in some parts of England, from the root cultivated in that country. The Pontefract cakes are small lozenges of licorice made in the vicinity of Pontefract, England. For methods of assaying extract of licorice, see A. J. P., 1896, 663; also 1898, 23, 136.

Uses.—Licorice has some demulcent property and is a popular addition to various lozenges. In large quantities it is somewhat laxative. Its most important role in medicine, however, is for the purpose of disguising the taste or covering the acrimony of various drugs such as quinine or ammonium chloride. It is also used to impart consistency to pills and troches.

Off. Prep.—Trochisci Ammonii Chloridi, U. S.; Trochisci Cubebeae, U. S.

EXTRACTUM GLYCYRRHIZAE PURUM. U. S. (Br.)

d"Glycyrrhiza, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains];

Ammonia Water, one hundred and fifty mils [or 5 fluidounces, 33 minims]; Water, Chloroform Water, each, a sufficient quantity. Mix the ammonia water with three thousand mils [or 101 fluidounces, 212 minims] of water, and, having moistened the powder with one thousand mils [or 33 fluidounces, 6½ fluidrachms] of the mixture, allow it to macerate in a closed vessel for twenty-four hours. Then pack it lightly in a cylindrical percolator, and gradually pour upon it, first the remainder
of the menstruum, and then chloroform water, until the glycyrrhiza is exhausted. Evaporate the liquid in a porcelain dish on a water bath, to a pilular consistence." U. S.

"Licorice Root, in No. 20 powder, 1000 grammes; Chloroform Water, 5000 millilitres. Mix the Liquorice Root with one-half of the Chloroform Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Chloroform Water and set aside for six hours; strain; press; mix the strained liquids; heat to 100° C. (212° F.); strain through flannel; evaporate to a soft extract." Br.

The necessity for a pure extract of licorice must be apparent to every pharmacist; the very variable quality of the commercial extract has frequently led to disappointment. The official process affords a preparation which is unexceptionable, the ammonia rendering the glycyrrhizin soluble, yet care must be taken in its evaporation, as it is very easily injured by too much heat, which gives it an empyreumatic taste, destroying at once its usefulness as an agreeable adjuvant. Extract of licorice is incompatible with acids of all kinds which precipitate the glycyrrhizin.

Off. Prep.—Mistura Glycyrrhizae Composita, U. S.; Mistura Ammonii Chloridi, N. F.

EXTRACTUM HYDRASTIS. U. S.

EXTRACT OF HYDRASTIS Ext. Hydrast. [Extract of Golden Seal, Powdered Extract of Hydrastis]

"Extract of Hydrastis yields not less than 9 per cent. nor more than 11 per cent. of the ether-soluble alkaloids of hydrastis. One gramme of the Extract represents about four grammes of hydrastis." U. S.

"Hydrastis, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Tartaric Acid, five grammes [or 77 grains]; Alcohol, Magnesium Oxide, Starch, dried at 100° C. (212° F.), each, a sufficient quantity. Dissolve the tartaric acid in one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms] of alcohol, moisten the drug with sufficient of this solution and pack in a cylindrical percolator; then add enough of the acidified alcohol, followed by alcohol if necessary, to saturate the powder and leave a stratum above it. When the liquid
begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding alcohol as required, until the drug is exhausted. Recover the alcohol from the percolate by distillation, and evaporate the residue to a soft extract, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Add fifty grammes [or 1 ounce av., 334 grains] of a mixture of one part of magnesium oxide and three parts of the dried starch, mix thoroughly and spread the mass in a thin layer on glass or tinned-metal plates or in a porcelain dish and continue the drying in an air bath at a temperature not exceeding 70° C. (158° F.), until thoroughly dry. Then reduce the extract to a fine powder and weigh it. Assay a portion of this product as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the powder and add to this enough of the mixture of magnesium oxide and dried starch, made in the same proportion as before, to make the finished Extract contain 10 per cent. of the ether-soluble alkaloids of hydrastis. Mix the powders thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly. U. S.

"Assay.—Introduce 3 Gm. of Extract of Hydrastis into a 250 mil flask, add 10 Gm. of washed sand and mix thoroughly. Then add 150 mils of ether and 5 mils of ammonia water. Shake the mixture vigorously every ten minutes during a half hour, and when the dregs have settled decant 100 mils of the clear liquid, representing two grammes of the Extract. Proceed as directed under Belladonna Radix, eleventh line of the Assay, beginning with the word "Filter," modifying the process there given by using ether instead of chloroform for the final shaking out of the alkaloids, and drying the residue to constant weight at 100° C. (212° F.), instead of titrating it. The weight will be the amount of ether-soluble alkaloids from two grammes of Extract of Hydrastis," U. S.

Uses.—This extract was introduced into the U. S. P. IX to furnish a convenient method of administering hydrastis (see Hydrastis).

Dose, five to ten grains (0.3-0.6 Gm.).
EXTRACTUM HYOSCYAMI. U. S., Br.

EXTRACT OF HYOSCYAMUS Ext. Hyosc.

"Extract of Hyoscyamus yields not less than 0.22 per cent. nor more than 0.28 per cent. of the alkaloids of hyoscyamus. One gramme of the Extract represents about four grammes of hyoscyamus." U. S. "Extract of Hyoscyamus contains in 100 grammes 0.3 gramme of the alkaloids of Hyoscyamus Leaves." Br.

Extract of Henbane; Extrait de Jusquiame (feuille), Fr. Cod.; Extractum Hyoscyami, P. G.; Bilsenkrantextrakt, G.; Estratto di giusquiamo idroalcoolico. It.; Extracto alcohólico de beleno, Sp.

"Hyoscyamus, in No. 40 powder, one thousand grammes [or 35 ounce's av., 1.20 grains]; Glucose, Alcohol, Water, each, a sufficient quantity. Moisten the powder with sufficient of a mixture of three volumes of alcohol and one volume of water, pack it firmly in a cylindrical percolator and add enough menstruum, using the same proportion of alcohol and water as before, to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol by distillation and evaporate the residue, with frequent stirring, at a temperature not exceeding 70° C. (158° F.), until it is reduced to a pilular consistence. Mix the mass thoroughly and weigh it. Assay a portion of this extract as directed below, and, from the alkaloidal content thus determined, ascertain by calculation the amount of alkaloids in the remainder of the mass and to this add enough glucose to make the finished Extract contain 0.25 per cent. of the alkaloids of hyoscyamus. Mix thoroughly." U. S.

"Hyoscyamus Leaves, in No. 40 powder, Alcohol (70 per cent.) of each, a sufficient quantity. Reduce ten grammes of the Hyoscyamus Leaves to No. 60 powder, and determine the proportion of alkaloids present by the process described under 'Belladonnas Folia.' Moisten one thousand grammes of the Hyoscyamus Leaves with two hundred and fifty millilitres of the Alcohol, pack firmly in a percolator, and percolate with more of the Alcohol until foul-thousand millilitres of percolate have been obtained. Determine the proportion of total solids in the percolate by evaporating twenty millilitres, drying the residue at 80° C. (176° F.),
and weighing. Determine also the proportion of alkaloids in the percolate by the process described under 'Tinctura Belladonnae.' Having thus determined the proportion of total solids and of alkaloids in the percolate, proceed as directed under 'Extractum Belladonnas Siccum' to prepare a dry Extract of Hyoscyamus containing 0.3 per cent. of alkaloids. Examined by the process described under 'Extractum Belladonnae Siccum,' Extract of Hyoscyamus is found to contain in 100 grammes 0.3 gramme of the alkaloids of Hyoscyamus Leaves. Limit of error 0.015 gramme in excess or defect." Br.

"This Extract may be used when the Extractum Hyoscyami of the International Agreement is required. It contains 0.3 per cent. of the alkaloids of Hyoscyamus Leaves." Br.

"Assay.—Proceed as directed under Extractum Belladonna Foliorum (Pilular), modifying the process there given by using 5 Gm. of Extract of Hyoscyamus instead of 2 Gm. of extract of belladonna leaves. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of hyoscyamus." U.S.

The U. S. P. IX introduced a special process for this extract, instead of evaporating the fluid extract as did the U. S. P. VIII. The British Pharm., 1914, discarded the process for making the extract from the fresh leaves and adopted percolation and evaporation of the percolate of dried leaves so that both pharmacopoeias are practically in accord. The strength is not quite the same, the U. S. P. IX requires not less than 0.22 per cent. nor more than 0.28 per cent. of alkaloids while the Br. Pharm., 1914, requires not less than 0.3 per cent. of alkaloids. For an account of the disadvantages of the extract from the fresh leaves see U. S. Dispensatory, 19th ed., p. 478.

Dose, from one to two grains (0.065-0.13 Gm.).

**Off. Prep.**—Pilulae Cartharticae Vegetabiles, N. F.; Pilula Colocynthidis et Hyoscyami, Br. (N. F.); Pilulae Laxativse Post Partum, N. F.

**EXTRACTUM KRAMERIAS. Br.**

**EXTRACT OF KRAMERIA**

Extract of Rhatany; Extractum Ratanhae; Extrait de Ranthia, Fr. Cod.;
Exhaust Krameria Root, in No. 10 powder, with Distilled Water by the
percolation process; evaporate the percolate to dryness." Br.

This extract was deleted from the U. S. P. IX, but has been introduced in
the N. F. IV as a powdered extract (see Part III). In the U. S. P. VIII it
was made by percolating the drug with water and evaporating the
liquid as in the British process above. The wood of the root yielded to
Procter only 6.8 per cent. of extract, while the bark separated from the
wood yielded 33 per cent. As the wood is of difficult pulverization, the
inference is obvious that, in powdering the roots, the ligneous portion
may be rejected with advantage. (A. J. P., xiv, 270.) As a prolonged
exposure of the infusion to the air is attended with the absorption of
oxygen and the production of insoluble apothem, it is desirable that the
evaporation should be conducted rapidly, or in a vacuum. There scarcely
appears to be occasion, in the case of rhatany, for heating and filtering
the infusion before evaporation as required by the U. S. P. VIII process
as the only use of which is to get rid of albumen, and this is not among
the recognized ingredients of the root.

Very inferior extracts of rhatany are often sold. Such is the South
American extract, which has been occasionally imported. As the product
obtained by decoction is greater than that afforded by the official plan,
the temptation to substitute the former is not always resisted, although
it has been shown to contain nearly 50 per cent. of insoluble matter.
Some druggists prepare the extract with an alcoholic menstruum, with a
view to the greater product, but the extract thus prepared has from 20
to 30 per cent. less of the active principle than the official.

Extract of krameria should have a reddish-brown color, a smooth
shining fracture, and a very astringent taste, and should be almost
entirely soluble in water. Its virtues may be considered as in proportion
to its solubility. It is much used for all the purposes for which the
astringent extracts are employed.

Dose, from five to twenty grains (0.32-1.3 Gm.).

Off. Prep.—Trochiscus Krameriae, Br.; Trochiscus Krameriae et
Cocainae, Br.
EXTRACTUM MALTI. U. S.

EXTRACT OF MALT Ext. Malt.

“Malt, in coarse powder, not finer than No. 12, one thousand grammes [or 35 ounces av., 120 grains]; Water, a sufficient quantity. Pour one thousand mils [or 33 fluidounces, 61/2 flui-drachms] of water upon the powder contained in a, suitable vessel and macerate for six hours, then add four thousand mils [or 135 fluidounces, 122 minims] of water, heated to 60° C. (140° F.), and digest the mixture for one hour on a water bath at a temperature not exceeding 60° C. (140° F.). Strain the mixture, express, filter the strained liquid, and, by means of a water bath or vacuum apparatus, evaporate the liquid, at a temperature not exceeding 60° C. (140° F.), until it has a specific gravity of not less than 1.350 nor more than 1.400 at 25° C. (77° F.).” U.S.

Under the name of extract of malt, two distinct preparations have been put upon the market, the one being a liquid similar to beer, the other, the official extract prepared from malt, composed chiefly of dextrin and glucose, with some albumen and phosphates. The object of the U. S. process is to obtain all of the soluble principles of malt in a permanent form. To secure this, strict attention to the details of the process is necessary. Good extract of malt should contain no starch, have the consistence of thick honey, a brown color, and should be free from empyreumatic taste. A great deal of commercial extract of malt is adulterated with glucose to a surprising extent. A dry extract of malt has come into extensive use as an infant's food, made by artificially drying the thick syrupy extract. It is in the form of a straw-colored, coarse powder, and is given dissolved in milk or water.

O. F. Romer and H. R. Randoll of Brooklyn, have patented several improvements in the process of making extract of malt,—namely, 1, the properly ground malt is treated with an alkaline solution, in order to neutralize the fatty acids which usually impart a bad taste to the product; 2, the extract is separated from the solid matters by pressing in press cloths, whereby it is obtained as a clear liquid with scarcely any loss. (N. R., 1880, 179.) Pharmaceutically, extract of malt has been used as an emulsifying agent; it makes a good basis for a cod liver oil emulsion, for which purpose it is admirably adapted therapeutically.
For therapeutic properties see Maltum.

Dose, from one to four fluidrachms (3.75 to 15 mils).

**Off. Prep.**—Emulsum Olei Morrhuae cum Malto, N. F.

**EXTRACTUM RHEI. U. S., Br.**

**EXTRACT OF RHUBARB Ext. Rhei [Powdered Extract of Rhubarb]**

"One gramme of the Extract represents two grammes of rhubarb." U. S.

“Rhubarb, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Magnesium Oxide, fifty grammes [or 1 ounce av., 334 grains]; Starch, dried at 100° C. (212° F.), Alcohol, Water, each, a sufficient quantity to make five hundred grammes [or 17 ounces av., 279 grains]. Moisten the drug -with sufficient of a mixture of four volumes of alcohol and one volume of water, pack it in a cylindrical percolator and add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same proportion of alcohol and water as before until the drug is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable, and continue distillation until a residue of syrupy consistence remains in the still. Transfer this to a shallow dish, rinse the still with a little warm menstruum, add the rinsings to the residue in the dish, and evaporate the mixture to dryness, with frequent stirring, at a temperature not exceeding 70° C. (158° F.). Weigh the dry extract and add the magnesium oxide and sufficient of the dried starch to make the product weigh five hundred grammes [or 17 ounces av., 279 grains]. Reduce the mixture to a fine powder, mix thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them tightly.” U. S.
"Exhaust Rhubarb, in No. 20 powder, with Alcohol (60 per cent.) by the percolation process. Recover most of the alcohol from the percolate by distillation, and evaporate the residual liquid to dryness." Br.

The British extract (1914) is now nearly identical with the U. S. preparation; the menstruum used for the former is, however, slightly more aqueous. Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation be performed with great care and with a moderate heat, it is certain that the purgative principle is to a greater or less extent injured or dissipated in the process, and the extract may thus become even less efficient than the root. When properly prepared, the extract has decidedly the peculiar odor of rhubarb. Dose, from two to ten grains (0.13-0.65 Gm.).

**EXTRACTUM SUMBUL. U.S.**

**EXTRACT OF SUMBUL Ext. Sumbul**

Extract of Muskroot; Extrait de Racine de Sumbul, Fr.; Sumbulwurzelextrakt, Moschuswurzelextrakt, G.

"Sumbul, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Moisten the powder with sufficient of a mixture of four volumes of alcohol and one volume of water and pack it in a cylindrical percolator; then add enough of this menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, at a temperature not exceeding 70° C. (158° F.), to a pilular consistence." U. S.

Dose, two to five grains (0.13-0.32 Gm.).

**EXTRACTUM TARAXACI. U. S., Br.**

**EXTRACT OF TARAXACUM Ext. Tarax.**

Extract of Dandelion; Extrait de Dent-de-lion, Fr.; Lowenzahnextrakt, G.; Estratto di tarassaco acquoso, It.
“Taraxacum, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, Water, each, a sufficient quantity. Mix one hundred and twenty-five mils [or 4 fluidounces, 109 minims] of alcohol with eight hundred and seventy-five mils [or 29 fluidounces, 282 minims] of water, and, having moistened the powder with a portion of the mixture, pack it in a cylindrical percolator, then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed, gradually adding menstruum of the same strength until the drug is exhausted. Recover the alcohol from the percolate by distillation and evaporate the residue with frequent stirring, on a water bath, to a pilular consistence." U. S.

“Crush Taraxacum Root; press out the juice; allow the starchy matter to subside; decant; heat the liquid to 100° C. (212° F.), and maintain the temperature for ten minutes; strain; evaporate to a soft extract." Br.

The inspissated taraxacum juice of the former U. S. Pharmacopoeias has been superseded by the present hydro-alcoholic extract, because of the very variable quality of the former; if the root is of good quality a better extract can be made by percolation and evaporation in the usual way.

The extract made from the juice is undoubtedly stronger when prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavor; in the latter part of the summer, and in autumn, thick, opaque, cream-colored, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating the juice is more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure during evaporation changes the bitterness of the juice into sweetness, which is a sign of inferiority. In the British process it is wisely directed that before the evaporation of the juice it shall be exposed for a short time to a heat sufficient to coagulate the albumen, which is then separated and
rejected as useless; it is indeed injurious, by favoring decomposition. As often found in the shops, the extract is dark-colored, sweet, and in all probability nearly inert. Houlton took more than an ounce of it in a day, without any sensible effect. (P. J., i, 421.) When prepared from the root and leaves together, it has a greenish color. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained from plants collected in November, and the least in April and May. This extract deteriorates by keeping. It is conveniently given in an aromatic water.

Dose, from fifteen grains to a drachm (1.39 Gm.) three times a day.

**EXTRACTUM VIBURNI PRUNIFOLII. U. S.**

**EXTRACT OF VIBURNUM PRUNIFOLIUM Ext. Viburn. Prun.**

[Powdered Extract of Viburnum Prunifolium]

“One gramme of the Extract represents five grammes of viburnum prunifolium." U. S.

“Viburnum Prunifolium, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Magnesium Oxide, five grammes [or 77 grains]; Starch, dried at 100° C. (212° F.), Diluted Alcohol, each, a sufficient quantity, to make two hundred grammes [or 7 ounces av., 24 grains]. Moisten the powder with sufficient diluted alcohol and pack it in a cylindrical percolator; then add enough diluted alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, adding diluted alcohol as required until the viburnum prunifolium is exhausted. Recover the alcohol from the percolate by distillation at as low a temperature as practicable and evaporate the residue to a soft extract in a shallow dish on a water bath, at a temperature not exceeding 70° C. (158° F.). Add the magnesium oxide, incorporate it thoroughly, spread the extract on glass plates and dry it by exposure to currents of warm air. Reduce the extract to a fine powder, weigh it, and add sufficient of the dried starch to make the finished product weigh two hundred grammes [or 7 ounces av., 24 grains]. Mix the powder thoroughly, pass the Extract through a fine sieve, transfer it to small, wide-mouthed bottles and stopper them.
tightly." U. S.

Dose, five to ten grains (0.3-0.65 Gm.).
Fabiana. Fabiana imbricata Ruiz and Pavon. Pichi. (Fam. Solanaceae)—This is a small shrub growing in Bolivia, Peru, Chili and the Argentine Republic. The plant somewhat resembles a juniper. The branches are brownish-gray and about 5 mm. in diameter; the wood is yellowish and tough; leaves scale-like, about 1 mm. in length, closely imbricated and bluish-green; the flowers are about 12 mm. in length and possess a white or purplish corolla; the fruit is a capsule containing a few sub-globular seeds. The odor of the drug is aromatic and the taste bitter and terebinthinate. For microscopic structure, see Ph. Ztschr. f. Russland, 1891, No. 44; Apoth. Zeit., 1892, p. 22.

A. B. Lyons obtained from it a fluorescent body resembling sesculin, a neutral crystalline principle, some volatile oil, resin, and apparently traces of an alkaloid. (A. J. P., 1886, 65.) Henry Trimble and J. M. Schroeter (A. J. P., 1889, 407) considered the crystalline principle to be a resin, and gave it the formula \( (\text{C}_{18}\text{H}_{31}\text{O}_2)x \). H. Kunz-Krause (A. J. P., 1900, p. 80) made a full study of pichi and found a tannin which he named fabiana-tannoid, a fluorescent substance proven to be chrysatropic acid (\( \beta \)-methyl aesculetin), \( \text{C}_9\text{H}_5(\text{CH}_3)\text{O}_4 \), while no alkaloids are present, the sole basic principle being choline. The volatile oil he names fabianol and gives it the formula \( \text{C}_{54}\text{H}_{90}\text{O}_2 \). The resin he calls fabiana-resin and gives it the formula \( (\text{C}_{18}\text{H}_{30}\text{O}_2)_3 \). The resin appears in microscopical crystals, melting at 280° C. The tannin proved to be like caffetannic acid, which Kunz-Krause had previously shown to be glycosyl-dioxycinnamic acid. It contains volatile oil, a characteristic soft resin and tannin.

Pichi appears to be a terebinthinate diuretic, to which also are attributed tonic and cholagogue properties. It has been used to a considerable extent in the treatment of acute and chronic vesical catarrh, giving especially favorable results in cases in which the urinary irritation is kept up by gravel. It is said even to calm the irritability and aid in the expulsion of renal, urethral, or cystic calculi. It has been further recommended in the treatment of jaundice and dyspepsia, with lack of biliary secretion. It is somewhat irritanting, and is usually said to be contra-indicated by the existence of organic disease of the kidneys; but cases have been reported in which renal hemorrhage connected with Bright's disease has been greatly benefited by the remedy. It has also been employed in gonorrhea and in gonorrheal prostatitis. The solid extract may be used in the dose of from two to ten grains (0.13-0.65 Gm.); the
fluidextract, in the dose of from ten to forty minims (0.6-2.5 mils). It is probable that the resinoid precipitate, made from a strong tincture by means of water, would be the best preparation of the drug. The fluidextract does not mix with water unless the solution be made alkaline. It may be administered in capsules.

The genus Ficus yields a number of economic products. Many species possess a milky juice containing caoutchouc, as F. elastica Roxb., of Sumatra, etc. Some of the juices are employed externally as well as internally, as that of F. indica L. Some possess anthelmintic properties, as F. anthelmintica Mart. Some yield gum lac or shellac as a result of the puncture of an insect, as F. religiosa L., F. laccifera Roxb.; and some are esteemed for their fruits, as F. Carica L., F. religiosa L., etc.

Ficus Carica, or fig tree, though often not more than twelve feet high, sometimes rises in warm climates twenty-five or even thirty feet. Its trunk, which, seldom exceeds seven inches in diameter, is divided into numerous spreading branches, covered with a brown or ash-colored bark. Its large, palmate leaves, usually divided into five obtuse lobes, are deep green and shining above, pale green and downy beneath, and stand alternately on strong, round foot-stalks. The flowers are situated within a common receptacle, placed upon a short peduncle in the axils of the upper leaves. This receptacle, the walls of which become thick and fleshy, constitutes what is commonly called the fruit; though this term is, strictly speaking, applicable to the small seed-like bodies found in great numbers on the internal surface of the receptacle, to which they are attached by fleshy pedicles. Cultivation has produced in the fig, as in the apple and peach, a great diversity in shape, size, color, and taste. It is usually, however, turbinate, or top-shaped, umbilicate at the large extremity, of the size of a small pear, of a whitish, yellowish, or reddish color, and of a mild, mucilaginous, saccharine taste. The dried figs can be partially restored to their original shape by soaking. The fig tree is supposed to have come originally from the Levant. It was introduced at a very early period into various parts of the south of Europe, and is now very common throughout the whole basin of the Mediterranean, particularly in Italy and France. Large numbers of Syrian fig trees were planted in the Pomona Valley, California, in 1890, and California figs are now commercial articles. To hasten the ripening of the fruit, it is customary to puncture it with a sharp pointed instrument covered with olive oil. Caprification consists in attaching branches of the wild fig tree to the cultivated plant. The fruit of the former contains great numbers of the eggs of insects of the genus Cynips, the larvae of which, as soon as they are hatched, spread themselves over the cultivated fruit, and, by conveying the pollen or the male organs over which they pass to the female florets, hasten the impregnation of the latter, and cause to quickly come to perfection the fig which might otherwise ripen very slowly, or wither and drop off before maturity. In California the great difficulty in cultivating figs was found to be to get a Cynips which would flourish in the climate. According to Landerer, the unripe fig contains an irritant juice, which inflames the skin, and may
even disorganize it. (See A. J, P., xxxiii, 215.) The figs, when perfectly ripe, are dried by the heat of the sun, or in ovens. Those imported into this country come chiefly from Smyrna, packed in drums or boxes. They are more or less compressed, and are usually covered in cold weather with a whitish saccharine efflorescence, which softens in the middle of summer and renders them moist. The best are yellowish or brownish, somewhat translucent when held to the light, and filled with a sweet viscid pulp, in which are lodged numerous small yellow achenes. They are much more saccharine than is the fresh fruit. Their chief constituents are grape sugar, and gum or mucilage. An average of several analyses of dried figs as quoted by Konigs (Nahrungs und Genussmittel, 3te Aufl., Ed. i, 781) gives — water, 31.20; nitrogenous material, 4.01; sugar, 49.79; ash, 2.86. Reckoned on the weight of absolutely dry material, the nitrogenous matter amounted to 5.75 per cent. and the sugar to 72.26 per cent. They are officially described as "usually compressed, of irregular rounded shapes, from 2.5 to 5 cm. in diameter, fleshy, light brown to yellow, frequently with an efflorescence of sugar; summit with a small, scaly orifice; base with a scar or short stalk; internally hollow, with numerous small, brownish-yellow, glossy, and hard achenes. Odor distinctive, fruity; taste sweet, pleasant." N. F.

Figs are nutritious, laxative, and demulcent. In the fresh state they are considered, in the countries where they grow, a wholesome and agreeable aliment, and have been employed from time immemorial. They are prone, however, when eaten freely, to produce flatulence, pain in the bowels, and diarrhea. The latex of the fig has been used as an anthelmintic against intestinal parasites. Their chief medicinal use is as a laxative article of diet in constipation. They occasionally enter into demulcent decoctions, and, roasted or boiled, and split open, are sometimes applied as a cataplasm to inflamed gums.

**Flindersia.** Flindersia maculosa (Lindl.) F. Muell. Leopard Tree—This is a tree of New South Wales, belonging to the Meliaceae. During the summer it yields large masses of a clear amber-colored gum, which has a pleasant taste and is eaten by the aborigines; it is used as a remedy for diarrhea. Leopard tree gum occurs in pieces as large as pigeons' eggs; dissolves rapidly in cold water, and has been found by J. H. Maiden to contain eighty per cent. of arabin but no metarabin. (P. J., vol. xxi, 1890.)

**FLUIDEXTRACTA. U. S. (Br.)**

**FLUIDEXTRACTS**

**Extracta Liquida,** Br.; Fluid Extracts; Extraits liquides, Fr.; Extracta fluidea, P. G.; Fluidextrakte, Flussige Extrakt. G.

"Fluidextracts are concentrated liquid preparations of vegetable dings, containing alcohol either as a solvent or as a preservative, and bearing a uniform relation to the drug used so that one mil of the fluidextract closely represents the activity of one gramme of the air-dried and powdered drug of standard quality." U. S.
The Latin title Extractum ——— Fluidum formerly used for Fluid Extracts was dropped by the U. S. P. VIII because of the confusion which resulted from the necessary bringing together of the extracts and fluid extracts due to a strict alphabetical arrangement; the name "fluidextractum " is now used for " fluidextract" and the latter made one word; this, of course, brings the fluidextract under the letter F instead of the letter E under which extracts and fluidextracts were formerly both classed.

Fluidextracts were first introduced into the U. S. P. of 1850 as a distinct class of preparations, the fluidextract of sarsaparilla being the only one previously directed, either in our own official code or by the British Colleges. Now we have one hundred and fifty-seven that are official in the U. S. P. IX, British Pharm., 1914, and National Formulary IV, besides large quantities of non-official fluidextracts annually produced. They are now perhaps the most important class of liquid preparations in use. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form, a cubic centimeter, mil, or fluidgramme of any one of them now representing a gramme of the crude drug. In addition to convenience of administration, the advantage of these preparations is that, evaporation not being carried so far as in ordinary extracts, the active principles are less liable to be injured by heat. Formerly their main difficulty was the liability of substances in the liquid state to undergo spontaneous decomposition. In the U. S. P. of 1850 this was counteracted by means of sugar and of alcohol, but in 1865 (A. J. P., 1865, p. 50) Taylor proposed the use of glycerin, which was adopted in the U. S. P., 1870, revision. Glycerin, while it exerts a powerful preservative influence, possesses the valuable property of dissolving matters deposited by some of the fluidextracts when made with sugar, as in the old official recipes. Consequently these fluid-extracts were much clearer and better preparations than were the old ones. Subsequent experience with these fluidextracts showed that the use of glycerin should be circumscribed, and that it had been employed too freely in the U. S. P., 1870, formulas. The solvent powers of glycerin are so great that the fluidextracts were frequently loaded with many inert principles, which it dissolved, giving them a dense, rich appearance, without increasing their activity. As the primary object of fluidextracts is concentration, suitable menstrua should in each case be selected with the single object of dissolving and retaining permanently the active constituents of the drug.
The present fluidextracts are of the same strength as those formerly official, and the formulas are based upon the theory that from a given weight of drug an amount of fluidextract shall be made equal in measure to the bulk of the same weight of distilled water; in other words, upon the relation of gramme to millilitre. Although the metric system is admirable in practice, some may prefer to use ordinary weights and measures; in such cases, to make 20 fluidounces of a fluidextract 19 troyounces of drug will be required, while if avoirdupois weight is preferred, the most convenient relation to recollect will be that 50 avoirdupois ounces are required to make 48 fluidounces, or three pints, of a fluidextract. It has been repeatedly proposed to make 50 per cent. tinctures or half-strength fluidextracts, the main object being 'to secure more representative preparations when made on the small scale. Experiments by Sayre, Gregory, Patch, and others prove that half-strength fluidextracts possess no advantages over those of official strength. (D. C., 1897, 119, 147.) The precipitation experienced heretofore, when the evaporated weak percolate was added to the reserved portion, is considerably diminished by causing the former to be evaporated to a soft extract. This precipitation, formerly noticed more particularly in alcoholic fluidextracts, was due to the greater volatility of the alcohol in the weak percolates, which, when evaporated, left the residue to a great extent aqueous; when this was added to the strongly alcoholic reserved portion, a precipitation of resinous and frequently active matter took place, which necessitated the storing of the fluidextract until precipitation ceased, and subsequent filtration. This is not altogether avoided by evaporating to a soft extract, but the loss of activity through precipitation is thus greatly diminished. Fluid-extracts invariably deposit insoluble matter upon standing, and those made in warm weather, owing to the greater solvent powers of the menstrua (due to the elevated temperature) are found to deposit more freely than the same kind of fluidextracts if made in the winter time with menstrua correspondingly reduced in temperature.

A useful distillatory apparatus has been contrived by Joseph P. Remington for recovering alcohol from weak percolates, and for general pharmaceutical uses. The still shown in the cut is the new form. It is made of tinned copper, the still body holding about three gallons; the condenser has seven straight tubes surrounded with the cold water introduced by a rubber tube from a hydrant or bucket of water placed higher than the still, and carried off as it becomes warmed by the tube.
shown at the upper part of the condenser.

By a siphon arrangement not shown in the cut, the still can be fed from a reservoir while distillation is in progress, thus using a three-gallon still where otherwise a much larger one would have been necessary. The joints are carefully ground, and troublesome lutes and water joints are entirely superseded. The condenser, having straight tubes instead of a spiral one, is easily cleaned, and is powerful enough to condense a gallon of alcohol in thirty minutes. The still may be set into a kettle partly filled with water and thus used as a water bath, or a shallow tinned copper dish with flat rim, which accompanies the still, may be placed between the two brass ring bands and clamped securely. (A. J. P., May, 1879.) Remington's Practice of Pharmacy, Fourth ed., page 158.

Several methods have been suggested for preparing fluid-extracts more economically. The use of acetic acid as a menstruum to replace alcohol or diluted alcohol has the merit of economy. (See Extracta, also A. J. P., 1899, 1-14; Proc. Pennsylvania Pharm. Assoc., 1898, 116; A. J. P., 1898, 543; A. J. P., 1899, 67; Ph. Era, 1898, 796; Proc. Minnesota Pharm. Assoc., 1902, 103; West. Drug., 1903, 652.)

The most important modification is the plan of repercolation, as proposed by E. R. Squibb, for this class of preparations as well as the dry extracts.

Repercolation.—In consequence of the existing high price of alcohol, it is important to adopt some plan by which, while the ends aimed at are attained, the consumption of the menstruum used in percolation may be diminished. This object has been accomplished, to a considerable extent, by E. B. Squibb, of Brooklyn, N. Y., by a modification of the process of
percolation to which he has given the name at the head of the present paragraph. As defined by the author, repercolation consists in the successive application of the same percolating menstruum to fresh portions of the substances to be percolated. The result is that the same menstruum, acting repeatedly on unexhausted portions of the substance, becomes concentrated to the greatest possible extent, so that much of the menstruum is saved, while subsequent evaporation is avoided, which is itself an object of great importance in the preparation of extracts. It is obvious that repercolation is not applicable to the preparation of infusions, decoctions, tinctures, etc., in which the object in general is less a high degree of concentration than precision in the strength of the preparation, and consequently in the dose. It is to the extracts and fluidextracts that the process is peculiarly adapted, and there now remains no doubt whatever of the great value of the improvement. One of its disadvantages is that the substance treated is less completely exhausted than when the proceeding is inverted, and fresh portions of menstruum are made to act on the same material until the latter is deprived of all its soluble matter. But the loss in this way is trifling, compared with the gain when a menstruum as high-priced as alcohol is employed.

Another practical disadvantage is the inconvenience of keeping the weak percolates, as these have to be labelled, numbered, and stored away for use until the same operation is repeated. In deciding when to adopt it, the operator will, of course, be influenced by the relative value of the drug and the menstruum. In order to secure the most favorable results in repercolation, certain methods of proceeding are advisable in various steps of the process, differing with the character of the substance to be acted on; and these can be determined only by a careful study, confirmed by repeated experiment. Squibb used repercolation exclusively on the large scale in the manufacture of extracts and fluidextracts, and applied it especially to the preparation of fluidextracts of cinchona; and since his first paper, which was reproduced in the 14th revision of the U. S. Dispensatory, p. 1164, he introduced several improvements, which are intended to make the process useful to the apothecary in his every-day work. See Type Process C.

The plan of N. Spencer Thomas consists in exposing the substance to be acted on to successive expressions, by means of a press, with the menstruum divided into different portions, so that fresh portions of liquid are brought to act on the same solid body in different stages of
exhaustion, and then mixing the expressed liquids. The due proportion between the weight of the medicine and the bulk of the ultimate fluidextract is secured by regulating the measure of the last added portion of menstruum, which, in the process as described by Thomas, is the third. Whatever may be the advantages of this method—and it is not without its recommendations—it is liable to the objection of loss of alcohol through exposure during expression. Another method of limiting the quantity of alcohol used has been proposed by S. P. Dutfield, of Detroit. It consists in macerating, for from six to ten days, the medicine to be acted on, previously deprived, by means of a vacuum apparatus, of all the air, and of all readily volatilizable matter contained in its pores, with a certain volume of the menstruum, which is forced through a tube into the vacuum pan by atmospheric pressure, and thus brought into the most intimate contact with all parts of the powder. The process is completed by submitting the mass thus impregnated to hydraulic pressure, and, after allowing the liquid to settle in glass carboys, drawing off the clear liquid into bottles. It is obviously inapplicable to substances whose virtues depend in any considerable degree upon readily volatilizable constituents. Campbell (A. J. P., xlii, 17) proposed a method for doing away with the use of heat, which, however, although in some cases it may do well, cannot be relied upon for the complete exhaustion of all drugs. Sixteen troyounccs of the powder are moistened with four to six fluid-ounces of the menstruum (usually alcohol), and packed in a glass funnel, a piece of sponge having previously been put in the beak of the funnel; the surface of the powder is covered with a disk of paper, and twelve fluidounces of menstruum poured on. When the sponge becomes saturated, the beak of the funnel is corked tightly and the whole set aside for four days, at the end of which time the percolation may be allowed to proceed without further addition of menstruum. J. W. Mill has called attention to the advantage of separating the powder into fine and coarse parts by means of sieves and packing the finer powder at the bottom.

H. Biroth (Pharm., April, 1877) proposes the method which he termed "insuccation" for making non-alcoholic fluidextracts; the advantages claimed for it are simplicity and economy. Colaz prepared fluidextracts from fresh plants by bruising and crushing them, and placing the mass in a dialyzer suspended in 90 per cent. alcohol; when the dialysis is completed, the liquid is evaporated to free it from alcohol, the remaining aqueous liquid retaining the active constituents in the proportions in which they are found in the plant. (Ph. Post, xxix, 271.) Haussmann (A.
J. P., 1895, 291), after examining a large number of commercial fluidextracts, recorded his results in tabular form, and considered that there is great variation in the quality, due to deviation from pharmacopoeial processes.

J. U. Lloyd proposes to recover the alcohol which remains absorbed by the residue after percolation, by mixing the wet residues with an equal bulk or less of dry sawdust, and then percolating this with water. (A. J. P., June, 1877.) Wm. M. Thomson, of Philadelphia, devised a very complete method of preparing fluidextracts on a large scale; the principles of his process are maceration and percolation in vacuo, and although the principles which have been applied have long been known, and similar apparatus used by Duffield and others, there are many useful practical points which merit a notice in detail. The percolators are egg-shaped, and made of tinned copper; they are capable of being tightly covered, and communicate by means of stopcocks above and below, and iron and stout rubber tubing, with a very efficient double acting air pump. The moistened powder is packed tightly in the percolator, and the cover securely bolted on. The stopcock in the cover is now opened, which communicates with the air pump and a partial vacuum created in the space above the moistened drug; the stopcock is now closed and another stopcock in the cover opened, which communicates by a tube with the reservoir containing the menstruum. The menstruum, of course, quickly penetrates the powder, taking the place of the interstitial air, and when the powder is saturated it is permitted to macerate in vacuo a sufficient length of time. To start percolation, a receiver is connected with the beak of the percolator, and, the air being exhausted from it, the percolate at once makes its appearance. When the flow slackens, air may be forced by the pump in the space above the powder, if desired, and the receiver again exhausted below. In this way, it can be seen, entire control of these powerful physical forces may be secured. The advantages are very apparent in preventing the loss of volatile principles and alcohol, while protecting from chemical change caused by exposure to the air. It is quite possible to make official fluidextracts without recourse to subsequent evaporation of weak percolate. For a cut of this apparatus, see A. J. P., 1882.

Assaying Fluidextracts.—The number of assay processes for fluidextracts was materially increased in the U. S. P. (9th Rev.) for preparations made from alkaloidal drugs. The process in each case
differs but slightly from the process used for the corresponding drug; they will be found in the succeeding pages under their appropriate headings.

A new method of assay for alkaloidal fluid-extracts, especially adapted to the mydriatic leaf drugs in that the interfering chlorophyll is removed, making only one shaking out operation necessary, was proposed by LaWall (J. A. Ph. A., 1912, 29), as follows: Place 25 Gm. of sodium chloride in a 100 mil graduated cylinder, with water sufficient to make 85 mils. Agitate well for 1 minute, then pour upon a dry filter and collect 50 mils of clear filtrate, which can be shaken out as directed in the final shake out of the ordinary assay process, using the solvent directed for the particular drug which is being assayed. The method does not work with cinchona, guarana or other drugs containing large amounts of alkaloids in the form of cincho-tannates.

Fluidextracts U. S. P. IX.

"The fluidextracts of this Pharmacopoeia, with few exceptions, may be classified according to the menstrua used in the extraction of the drugs and the processes of manufacture employed. Several drugs require special manipulation to obtain satisfactory fluidextracts, and for these appropriate formulas have been devised and are printed in full in the text. The following type processes are described, and in each formula the process to be used is designated by reference to the type process:

"Type Process A—In this class are included those fluidextracts that are made with a menstruum of alcohol or a mixture of alcohol and water by the usual process of percolation. Moisten one thousand grammes [or 35 ounces av., 120 grains] of the powdered drug directed with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to maintain it so, after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more menstruum until the drug is exhausted. Reserve the first eight hundred and fifty mils [or 28 fluidounces, 356 minims] of the percolate (unless otherwise specified in the formula);
recover the alcohol from the remainder and concentrate the residue to a soft extract at a temperature not exceeding 60° C. (140° F.); dissolve this in the reserved portion, mix thoroughly, and finally add a sufficient quantity of the menstruum to obtain one thousand mils [or 33 fluidounces, 6½ fluidrachms] or the volume determined by calculation from the assay.

'Type Process B—In this class are included those fluidextracts in which glycerin or an acid is used in the extraction and two menstrua are successively employed. Menstruum I contains the glycerin or acid in definite proportion to the amount of the drug, and Menstruum II, a mixture of alcohol and water intended for completing the exhaustion of the drug. Moisten one thousand grammes [or 35 ounces av. 120 grains] of the powdered drug directed with a sufficient quantity of the prescribed Menstruum I, to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator, add the remainder of Menstruum I, and, when this has just disappeared from the surface, gradually add Menstruum II, constantly maintaining a stratum of liquid above the drug. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours, and then allow the percolation to proceed slowly, gradually adding Menstruum II until the drug is exhausted. Reserve the first eight hundred and fifty mils [or 28 fluidounces, 356 minims] of the percolate (unless otherwise specified in the formula); recover the alcohol from the remainder and concentrate the residue to a soft extract at a temperature not exceeding 60° C. (140° F.); dissolve this in the reserved portion, mix thoroughly, and finally add a sufficient quantity of Menstruum II to obtain one thousand mils [or 33 fluidounces, 6½ fluidrachms] or the volume determined by calculation from the assay.

'Type Process C—The process of fractional or divided percolation. This is especially recommended for drugs containing volatile ingredients or constituents injured by exposure to heat. This process may likewise be used as an alternative process in the formulas in which Type Process A is directed. Divide one thousand, grammes [or 35 ounces av., 120 grains] of the powdered drug directed into three portions of five hundred grammes [or 17 ounces av. 279 grains] three hundred grammes [or 10 ounces av. 255 grains] and two hundred grammes [or 7
ounces av. 24 grains] respectively. Moisten the first portion of the drug (500 Gm.) [or 17 ounces av., 279 grains] with a sufficient quantity of the prescribed menstruum to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours and then allow the percolation to proceed slowly, gradually adding more of the menstruum. Reserve the first two hundred mils [or 6 fluidounces, 366 minims] of percolate and continue the process until the additional percolate measures fifteen hundred mils [or 50 fluidounces, 345 minims], the latter being collected in successive portions of three hundred mils [or 10 fluidounces, 69 minims] each.

"Moisten the second portion of the powdered drug (300 Gm.) [or 10 ounces av. 255 grains] with a sufficient quantity of the percolate collected in the preceding operation immediately after the reserved portion, to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and macerate and percolate as directed for the first part of the drug, using as menstruum the several portions of percolate from the preceding operation in the order in which they have been collected, and, if this be insufficient, follow with some of the original menstruum. Reserve the first three hundred mils [or 10 fluidounces, 69 minims] of percolate and continue the process until the additional percolate measures eight hundred mils [or 27 fluid-ounces, 24 minims] collecting the weaker percolate in successive portions of two hundred mils [or 6 fluidounces, 366 minims] each.

"Moisten the third portion of the powdered drug (200 Gm. [or 7 ounces av. 24 grains]) with a sufficient quantity of the percolate collected in the preceding operation immediately after the reserved portion, to render it evenly and distinctly damp and to maintain it so after macerating for six hours in a tightly-covered container. Then pack it in a cylindrical percolator and macerate and percolate as before, using as menstruum the several portions of percolate from the preceding operation in the order in which they have been collected, and, if this be insufficient, follow with more of the original menstruum. Collect five hundred mils [or 16 fluidounces, 435 minims] of percolate and mix this with the two portions previously reserved so as to make one thousand mils [or 33
fluid-ounce's, 6½ fluidrachms] of finished fluidextract.

"When Type Process C is directed for fluidextracts which are adjusted by assay to a definite alkaloidal standard, collect only four hundred and twenty mils [or 14 fluidounces, 97 minims] of percolate from the third portion of drug instead of the five hundred mils [or 16 fluid-ounces, 435 minims] directed above. Mix this percolate with the two portions previously reserved, assay a portion of the mixture and then adjust its volume, by the addition of the menstruum directed, so that each one hundred mils [or 3 fluidounces, 183 minims] of finished fluid-extract will contain the prescribed amount of alkaloid.

'Type Process D—In this class are included those fluidextracts in which extraction is effected by infusion and percolation with boiling water, alcohol being added to the concentrated liquid as a preservative.

To one thousand grammes [or 35 ounces av., 120 grains] of the ground drug add five thousand mils [or 169 fluidounces, 33 minims] of boiling water, mix thoroughly and allow it to macerate in a covered container for two hours in a warm place. Then transfer the moist drug to a tinned or enameled metallic percolator and allow percolation to proceed, gradually adding boiling water until the drug is exhausted. Evaporate the percolate on a water bath or steam bath to the volume specified and when cold add the alcohol directed and mix thoroughly." U. S.

"In the preparation of fluidextracts by either Process A, B, or C, the rate of percolation must be carefully controlled and, for the quantities directed in the formulas of the Pharmacopoeia, the flow should not exceed ten drops per minute until the reserved percolate is collected, and twenty drops per minute thereafter. As a rule one thousand grammes [or 35 ounces av., 120 grains] of powdered drug may be exhausted by percolation with sufficient menstruum to yield three thousand mils [or 101 fluidounces, 212 minims] of percolate.

"Fluidextracts should be kept in tightly-stoppered containers for one month and then, if perfectly clear, they should be stored in amber-colored bottles protected from sunlight and extremes of temperature. If sedimentation has occurred the clear portion should be decanted, the remainder filtered and the liquids thoroughly mixed before storing.

" The percentage of alcohol in fluidextracts made by type processes A, B,
or C is variable and always less than that in the menstruum employed, due, among other causes, to loss of alcohol by evaporation during manufacture, to the presence of a variable proportion of water in the air-dried drug, and to the extraction from the drug of its soluble constituents, which also often vary greatly in different lots of the same drug. The percentage of alcohol in the finished product can therefore only be ascertained by an actual determination.

**FLUIDEXTRACTUM AROMATICUM. U. S.**

**AROMATIC FLUIDEXTRACT Fldext. Aromat**

Extrait liquids aromatique, Fr.; Flussiges Aromatisches Extrakt, G.

"Aromatic Powder (see PULVIS AROMATICUS), one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process C, using alcohol as the menstruum." U. S.

This is a valuable fluidextract; it is an excellent aromatic in concentrated form, and will be found very useful not only as an addition to liquids when an aromatic is desired, but its concentrated form permits its use in small quantities with dry powders, like pepsin, bismuth subnitrate, etc., when desired for administration. It is rarely used alone.

Dose, from ten to twenty minims (0.6-1.3 mils), diluted with water, or dropped on sugar.

**FLUIDEXTRACTUM ASPIDOSPERMATIS. U. S.**

**FLUIDEXTRACT OF ASPIDOOSPERMA Fldext. Aspidosp. [Fluidextract of Quebracho]**

"Aspidosperma, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains], Prepare a Fluidextract by Type Process B, using a mixture of one hundred and ten mils [or 3 fluidounces, 345 minims] of glycerin, six hundred and seventy mils [or 22 fluidounces, 315 minims] of alcohol and two hundred and twenty mils [or 7 fluidounces, 211 minims] of water as Menstruum I, and a mixture of two volumes of alcohol and one volume of water as Menstruum II." U. S. (See Aspidosperma)
Dose, one fluidrachm (3.75 mils).

FLUIDEXTRACTUM AURANTII AMARI. U. S.

Extrait liquide d'Ecorce d'Orange amere, Fr.; Flussiges Pomeranzenschalenextrakt, G.

"Bitter Orange Peel, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process C, using a mixture of three volumes of alcohol and one volume of water as the menstruum." U. S.

This fluidextract is useful as a tonic; when dry, the bitter orange peel having very little oil present, there is necessarily little agreeable orange flavor to the fluidextract. Monroe Bond recommends a Fluidextract of Sweet Orange Peel, made with a menstruum of seven parts of alcohol and one of glycerin. (A. J. P., 1873, p. 482.)

Dose, fifteen to thirty minims (0.9-1.8 mils).

Off. Prep.—Vinum Rhei Compositum, IV. F.

EXTRACTUM BELAE LIQUIDUM. Br.

LIQUID EXTRACT OF BAELE

"Bael Fruit, bruised, 1000 grammes; Chloroform Water, 15000 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Macerate the bruised Bael Fruit for twelve hours in five thousand millilitres of the Chloroform Water; pour off and reserve the clear liquid; repeat the maceration a second and a third time for one hour in each case, using for each maceration five thousand millilitres of the Chloroform Water; press the marc; strain the mixed liquids through flannel. Evaporate to seven hundred and fifty millilitres; cool; add sufficient of the Alcohol to produce the required volume; filter." Br.

This represents whatever therapeutic virtues may reside in Bael Fruit. (See Belae Fructus)
Dose, one to two fluidrachms (3.75-7.5 mils).

**FLUIDEXTRACTUM BELLADONNAE RADICIS. U. S. (Br.)**

**FLUIDEXTRACT OF BELLADONNA ROOT** Fldext. Bellad. Rad.

"One hundred mils of Fluidextract of Belladonna Root yields not less than 0.405 Gm. nor more than 0.495 Gm. of the alkaloids of belladonna root." U. S.

"Liquid Extract of Belladonna contains in 100 millilitres, 0.75 gramme of the alkaloids of Belladonna Root." Br.

**Extractum Belladonnae Liquidum**, Br., Liquid Extract of Belladonna; Extrait liquide de Racine de Belladone, Fr.; Flussiges Tollkirschenwurzelextrakt, G.

"Belladonna Root, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]." U. S.

"Prepare a Fluidextract by Type Process A, using a mixture of five volumes of alcohol and one volume of water as the menstruum, and reserving the first eight hundred mils [or 27 fluidounces, 24 minims] of the percolate.

"After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make one hundred mils of the finished Fluidextract contain 0.45 Gm. of the alkaloids of belladonna root." U. S.

"Belladonna Root, in No. 20 powder, 1000 grammes; Alcohol (90 per cent.), Distilled Water, of each a sufficient quantity. Exhaust the Belladonna Root with a mixture of seven volumes of the Alcohol and one volume of Distilled Water by the repercolation process until from every three grammes of the Root one millilitre of strong percolate has been obtained." Br.

"Assay.—Introduce 10 mils of Fluidextract of Belladonna Root into a separator and add 10 mils of distilled water and 2 mils of ammonia water. Completely extract the alkaloids by shaking out repeatedly with
chloroform and then extract the alkaloids from the chloroform solution by shaking out repeatedly with weak sulphuric acid until the alkaloids are completely removed. Collect the acid washings in a separator, add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Evaporate the combined chloroform washings to dryness, dissolve the alkaloids from the residue in exactly 5 mils of tenth-normal sulphuric acid V.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal 1.8. as indicator.

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the alkaloids of belladonna root (see Proximate Assays, Part III)." U. S.

"Determine the proportion of alkaloids in this strong percolate by the following process: Introduce into a separator 10 millilitres of the strong percolate, 50 millilitres of water, 2 millilitres of diluted sulphuric acid, and 10 millilitres of chloroform. Shake vigorously, set aside until complete separation has taken place, draw off the lower layer, and wash it with two successive portions, each of 10 millilitres, of water acidified with diluted sulphuric acid. Add the washings to the upper layer left in the separator. Make the mixture distinctly alkaline with solution of ammonia, and extract the alkaloids by shaking with three successive portions, each of 10 millilitres of chloroform. Mix the chloroformic solutions, shake with 10 millilitres of water, allow separation to take place, draw off the lower layer into a beaker, and set aside for the chloroform to evaporate. Heat the residue on a water-bath for thirty minutes, add 10 millilitres of N/20 solution of sulphuric acid, warm gently until dissolved, and titrate back with N/20 solution of sodium hydroxide, tincture of cochineal being used as indicator. Deduct the number of millilitres of alkaline solution required from 10; the remainder, multiplied by 0.01446, gives the number of grammes of the alkaloids contained in 10 millilitres of the strong percolate. To the remainder of the strong percolate add sufficient of the alcoholic menstruum to produce a Liquid Extract of Belladonna containing 0.75 gramm of the alkaloids of Belladonna Root in 100 millilitres. Examined by the foregoing process, Liquid Extract of Belladonna is found to contain in 100 millilitres 0.75 gramm of the alkaloids of Belladonna Root. Limit of error 0.05 gramm in excess or defect. This Liquid Extract contains 0.75 gramm of the alkaloids of Belladonna Root in 100 millilitres; 110 minims contains 3⁄4 grain." Br.
The British liquid extract, 1914, represented several radical improvements in British pharmacy,—i.e., the use of repercolation with absence of heat in the process, and standardization, thus making the end product bear a definite relation towards the quantity of active constituents found in the root (0.75 per cent.). It is based upon the formula proposed by R. A. Cripps. (P. J., 1895, 795.) It will be observed that the alkaloidal standards of the U. S. and Br. Pharmacopoeias are not identical; the U. S. fluid-extract is made from the standardized drug (belladonna root) (0.45 per cent.); the British liquid extract is made from the unstandardized drug and hence the standard for the liquid extract can be made stronger (0.75 per cent.). The fluidextract of the root is a good preparation, of reddish-brown color, very different in appearance from the deep-green fluidextract of the leaves which is often seen in the market.

Dose, from one to two minims (0.06-0.12 mil) of the British liquid extract, not more than one minim (0.06 mil).

**FLUIDEXTRACTUM BUCHU. U. S.**

**FLUIDEXTRACT OF BUCHU** Fidext. Buchu.

Extrait liquide de Bucco, Fr.; Fliissiges Buccoextrakt, G.

"Buchu, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum." U. S.

The menstruum selected for this fluidextract has been alcohol, although experience has shown that with the weaker alcohol used in the U. S. P. VIII formula it was possible to percolate buchu leaves satisfactorily. We prefer as a menstruum that of the U. S. P. VIII, i.e., alcohol 3, water 1.

This fluidextract is of a dark green color, and shows in a high degree the sensible properties of the leaves. It acquires the odor of mint when long kept, showing that some change takes place in its volatile oil. This
fluidextract affords the best means at our command for the exhibition of buchu.

Dose, thirty minims to a fluidrachm (1.8-3.75 mils), three to five times a day.

**Off. Prep.**—Elixir Buchu, N. F.

**FLUIDEXTRACTUM CANNABIS. U. S.**

**FLUIDEXTRACT OF CANNABIS Flidext. Cannab. [Fluidextractum Cannabis Indicae, U. S. P. VII]**

"When assayed biologically Fluidextract of cannabis produces incoordination when administered to dogs in a dose of not more than 0.03 mil per kilogramme of body weight." U. S.

Extrait liquide de Chanvre Indien, Fr.; Flussiges Indisch-Hanfextrakt. G.

"Cannabis, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below and from the result thus obtained adjust the volume of the finished Fluidextract to conform to the above biological standard.

"**Assay.**—Proceed as directed under Cannabis and also under Biological Assays," U. S.

**Uses.**—The fluidextract of cannabis represents the therapeutic virtues of that drug in a convenient form. The smallness of the dose is an advantage over the tincture and many believe that the extract is injured by the evaporation. Unfortunately the fluidextract, even when properly made, does not retain its powers and after a year is almost worthless. For this reason the commercial samples vary so greatly in power that it is impossible to assign the proper dose. The only satisfactory way to use it is to start in with doses of one or two minims, increasing each day until some effect is obtained.

Dose, one to four minims (0.06-0.25 mil).
Off. Prep.—Collodium Salicylici Compositum, N.F.

**FLUIDEXTRACTUM CASCARAE SAGRADAE. U. S. (Br.)**

**FLUIDEXTRACT OF CASCARA SAGRADA Fldext. Case. Sagr.**
*[Fluidextractum Rhamni Purshianae, U. S. VIII]*

**Extractum Cascarae Sagradae Liquidum**, Br.; Liquid Extract of Cascara Sagrada; Extrait liquide de Cascara Sagrada, Fr.; Flussiges Cascara-Sagradae-extrakt, G.

"Cascara Sagrada, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains];

Alcohol, two hundred and fifty mils [or 8 fluid-ounces, 218 minims]. Prepare a Fluidextract by Type Process D. Evaporate the aqueous percolate to seven hundred and fifty mils [or 25 fluidounces, 173 minims] and when cold gradually add the alcohol and, if necessary, sufficient water to make the product measure one thousand mils [or 33 fluid-ounces, 61/2 fluidrachms]." U. S. "Cascara Sagrada, in No. 20 powder, 1000 grammes; Alcohol (90 per cent.), 250 millilitres; Distilled Water, sufficient to produce 1000 millilitres. Exhaust the Cascara Sagrada with the Distilled Water by the percolation process; evaporate the percolate to six hundred millilitres; add the Alcohol previously mixed with one hundred and fifty millilitres of the Distilled Water, or with sufficient to produce the required volume." Br.

This fluidextract is a good preparation, but the aromatic fluidextract is more largely used.

The emodin strength of this and similar preparations of cascara, which has been arbitrarily set by most manufacturers at 1.50 grammes in each 100 mils of the fluidextract, may be estimated by the method of Vanderkleed. and Ewe (*Proc. Pa. Pharm. Assoc.*, 1913, p. 325.)

Dose, fifteen minims to one fluidrachm (0.9—3.75 mils).

**FLUIDEXTRACTUM CASCARSE SAGRADAE AROMATICUM.**
AROMATIC FLUIDEXTRACT OF CASCARA SAGRADA

Tasteless Fluidextract of Cascara Sagrada; Extrait liquid Aromatique de Cascara Sagrada, Fr.; Bitterloses flüssiges Cascara-Sagradaextrakt, G.

"Cascara Sagrada, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Magnesium Oxide, one hundred and twenty-five grammes [or 4 ounces av., 179 grains]; Pure Extract of Glycyrrhiza, forty grammes [or 1 ounce av., 180 grains]; Glycerin, two hundred mils [or 6 fluidounces, 366 minims]; Alcohol, two hundred and fifty mils [or 8 fluidounces, 218 minims]; Benzosulphinide, one gramme [or 15 grains]; Oil of Anise, two and five-tenths mils [or 40 minims]; Oil of Cinnamon, two-tenths of a mil [or 3 minims]; Oil of Coriander, one-tenth of a mil [or 1 1/2 minims]; Methyl Salicylate, two-tenths of a mil [or 3 minims]; Boiling Water, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 6 1/2 fluidrachms]. Thoroughly mix the cascara sagrada "with the magnesium oxide, moisten the mixture with two thousand mils [or 67 fluidounces, 301 minims] of boiling water, set it aside for two hours, stirring occasionally, and then pack it in a percolator. Now pour on boiling water and allow the percolation to proceed until the drug is exhausted. Evaporate the percolate to five hundred mils [or 16 fluid-ounces, 435 minims] and while yet warm dissolve in it the extract of glycyrrhiza. When cold, add the glycerin, then the alcohol in which the benzosulphinide and the oils have been dissolved, and finally sufficient water to make the Fluidextract measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]." U. S.

An aromatic fluidextract was introduced into the U. S. P. VIII for the first time. It is given as a laxative, the object of the addition of magnesium oxide is to destroy the bitter taste of the cascara sagrada. Lime is sometimes used instead of magnesia but it has been shown that lime acts injuriously upon the laxative principles of cascara sagrada.

Dose, fifteen minims to one fluidrachm (0.9-3.75 mils).

Off. Prep.—Elixir Cascharae Sagradse, N. F.; Elixir Cascharae Sagradae
Compositum, N. F.

**FLUIDEXTRACTUM CIMICIFUGAE. U. S.**

**FLUIDEXTRACT OF CIMICIFUGA**
Fldext. Cimicif. [Fluidextract of Black Cohosh, Fluidextract of Black Snakeroot]

Extractum Cimicifugae Liquidum, Br. 1898, Liquid Extract of Cimicifuga; Liquid Extract of Actaea Racemosa; Extrait liquide d'Acteea Grappes, Fr.; Flussiges Cimicifugaextrakt. G.

"Cimicifug'a, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum." U. S.

There probably cannot be two opinions about the menstruum, although it has been asserted that a good fluidextract can be made with a menstruum of three parts alcohol and one part water. The probabilities are, however, that a portion of the resinous principle would precipitate on standing. This fluidextract is of a deep reddish-brown color, and thoroughly represents the drug.

Dose, from ten to thirty minims (0.6-1.9 mils).

**Off. Prep.**—Elixir Sodii Salicylatis Compositum, N. F.; Syrupus Cimicifugas Compositus, N. F.

**FLUIDEXTRACTUM CINCHONA. U. S. (Br.)**

**FLUIDEXTRACT OP CINCHONA**
Fldext. Cinchon. [Fluidextract of Calisaya Bark]

"One hundred mils. of Fluidextract of Cinchona yields not less than 4 Gm. nor more than 5 Gm. of the alkaloids of cinchona." U. S. “Liquid Extract of Cinchona contains in 100 millilitres 5 grammes of the alkaloids of -Red Cinchona Bark." Br.

**Extractum Cinchona; Liquidum**, Br., Liquid Extract of Cinchona; Extractum Chinae Calisayae Fluidum; Extrait liquide da Quinquina jaune, Fr.; Flussigea Kalisayarinden extrakt, Flussiges Chinaextrakt, G.
"Cinchona, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, one hundred mils [or 3 fluidounces, 183 minims] of diluted hydrochloric acid and eight hundred mils [or 27 fluidounces, 24 minims] of alcohol as Menstruum I and a mixture of four volumes of alcohol and one volume of water as Menstruum II. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough of Menstruum II to make each one hundred mils of the finished Fluidextract contain 4.5 Gm. of the total alkaloids of cinchona." U.S.

"Red Cinchona Bark, in No. 60 powder, 1000 grammes; Hydrochloric Acid, 31 millilitres; Glycerin, 125 millilitres; Alcohol (90 per cent.), Distilled Water, of each a sufficient quantity. Mix the Red Cinchona Bark with five thousand millilitres of the Distilled Water, to which the Hydrochloric Acid and Glycerin have been added; set aside in a covered vessel for forty-eight hours, stirring frequently; transfer to a-percolator; when the liquid ceases to pass continue the percolation with Distilled Water until the percolate ceases to give a precipitate with excess of solution of sodium hydroxide. Evaporate the percolate in a porcelain or enameled iron vessel at a temperature not exceeding 85° C. (185° F.), until it is reduced to one thousand millilitres." Br.

**Assay of Fluidextract of Cinchona.**—"From a pipette drop 5 mils of Fluidextract of Cinchona evenly over the surface of 10 Gm. of purified sawdust (see Part III) and evaporate it to dryness at a temperature not exceeding 80° C. (176° F.). Transfer the mixture to a 500 mil flask, and proceed as directed under Cinchona, third line of the Assay, beginning with the words 'and add' modifying the process there given by increasing the amount of ammonia water to 10 mils, using this in divided portions to rinse the dish in which the mixture was evaporated, and adding the rinsings to the flask.

"The weight of the residue is the amount of total alkaloids from 4 mils of Fluidextract of Cinchona." U. S.

**British Assay.**—"Determine the proportion of alkaloids in the liquid product by the following process: Transfer 5 millilitres to a stoppered glass separator; add 15 millilitres of benzolated amylic alcohol and 10
millilitres of N/1 alcoholic solution of potassium hydroxide; shake well, set aside in a warm place for a few minutes, shaking occasionally, and then allow the liquids to separate; pour off the clear -upper layer into a second separator and repeat the shaking with two further portions of 15 and 10 millilitres of benzolated amylic alcohol. Shake the mixed alcoholic liquids with two portions, each of 5 millilitres, of water, and reject the aqueous liquid; then shake vigorously with a warm mixture of 12 millilitres of diluted hydrochloric acid and 60 millilitres of water, using three successive portions of 30, 30, and 12 millilitres, and drawing off the acid liquids into a separator. To this acid liquid add 15 millilitres of chloroform and distinct excess of solution of ammonia, shake vigorously, allow the liquids to separate and draw off the chloroformic layer into a tared dish; repeat the shaking and separating with further portions, each of 10 ‘millilitres, of chloroform until the aqueous liquid, after acidification with diluted sulphuric acid, gives no further precipitate with solution of potassio-mercuric iodide. Add the chloroformic solutions to that in the dish, allow the chloroform to evaporate slowly; dry the residue in the dish at a temperature of about 110° C. (230° F.) and weigh. The weight of the residue is that of the total alkaloids in 5 millilitres of the liquid product. Having thus ascertained the alkaloidal strength of the liquid product, bring every volume of it containing 5 grammes of total alkaloids to eighty-five millilitres, either by evaporation or by dilution with Distilled Water as may be necessary, add twelve and a half millilitres of the Alcohol, and finally sufficient Distilled Water to produce one hundred millilitres of the Liquid Extract. Examined by the foregoing process, Liquid Extract of Cinchona is found to contain in 100 millilitres 5 grammes of the alkaloids of Red Cinchona Bark. Limit of error 0.2 gramme in excess or defect. This

Liquid Extract contains 5 grammes of the alkaloids of Red Cinchona Bark in 100 millilitres; 110 minims contain 5 grains." Br.

The process for this fluidextract was changed in the U. S. P. IX by the addition of diluted hydrochloric acid to the menstruum of alcohol, glycerin and water.

The U. S. fluidextract of cinchona is a moderately thin, dark reddish-brown, translucent fluid, of a bitter, astringent taste.

Dose, five to twenty minims (0.3-1.3 mils).
FLUIDEXTRACTUM COLCHICI SEMINIS. U. S.

"One hundred mils of Fluidextract of Colchicum Seed yields not less than 0.36 Gm. nor more than 0.44 Gm. of colchicine." U. S.

Extrait liquide do Semences de Colchique, Fr.; Flussiges Zeitlosensamenextrakt, G.

"Colchicum Seed, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]; Purified Petroleum Benzin, a sufficient quantity. Pack the colchicum seed in a cylindrical percolator and slowly percolate with purified petroleum benzin until a few drops of the percolate leave no greasy stain when evaporated on a piece of filter paper. Reject the benzin solution, remove the powder from the percolator and dry it by exposure to the air. Then proceed to make the Fluidextract by Type Process A, using a mixture of two volumes of alcohol and one volume of water as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid, and dilute this with enough menstruum to make each one hundred mils of the finished Fluidextract contain 0.4 Gm. of colchicine." U. S.

"Assay of Fluidextract of Colchicum Seed. —Introduce 15 mils of Fluidextract of Colchicum Seed into a 500 mil flask, add 10 mils of solution of lead subacetate, previously diluted with 35 mils of distilled water, shake the mixture thoroughly, then add 240 mils of distilled water, again agitate the mixture and proceed as directed under Colchici Semen." U. S.

The use of glycerin in the former U. S. fluidex-traet was objectionable, as the fixed oil contained in the seeds was always thrown out of solution, and was usually found floating on the fluidextract, rendering the preparation unsightly. The present formula, U. S. P. IX, is an improvement, as the fixed oil is removed by the benzin treatment. L. I. Morris (A. J. P., 1881, 7) believes that it is unnecessary to grind the colchicum seeds, and that if the whole seeds are digested with diluted alcohol at 80° C. (176° F.) the colchicine is easily extracted.
Dose, two to eight minims (0.12-0.5 mil).

Off. Prep.—Vinum Colchici Seminis. N. F.

**FLUIDEXTRACTUM ERIODICTYI. U. S.**

**FLUIDEXTRACT OF ERIODICTYON**
Fldext. Eriodict. [Fluidextract of Yerba Santa]

Extrait liquide d'Eriodictyon, Fr.; Flussiges Eriodictyonextrakt, G".

"Eriodictyon, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of four volumes of alcohol and one volume of water as the menstruum, and reserving the first eight hundred mils [or 27 fluidounces, 24 minims] of percolate." U. S.

For a process for Aromatic Fluidextract of Yerba Santa, see U. S. D., 19th ed., p. 539.

This fluidextract has a dark brownish-green color, and has proven a valuable addition.

Dose, from fifteen minims to a fluidrachm (0.9-3.75 mils).

Off. Prep.—Elixir Eriodictyi Aromaticum, N. F.; Syrupus Eriodictyi Aromaticus, N. F.

**FLUIDEXTRACTUM EUCALYPTI. U. S.**

**FLUIDEXTRACT OF EUCALYPTUS**
Fldext. Eucalypt.

Extrait liquide d'Eucalyptus, Fr.; Flussiges Eucalyptusextrakt, G.

"Eucalyptus, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains], Prepare a Fluidextract by Type Process A, using a mixture of three volumes of alcohol and one volume of water as the menstruum, and reserving the first eight hundred mils [or 27 fluidounces, 24 minims] of percolate." U. S.

This fluidextract well represents the drug, and is of a dark greenish-
brown color, having the peculiar odor and taste of eucalyptus very strongly developed, but in effectiveness it is much inferior to the volatile oil.

Dose, from ten to thirty minims (0.6-1.8 mils).

**FLUIDEXTRACTUM FRANGULAE. U. S.**

**FLUIDEXTRACT OF FRANGULA FlIdext. Frangul. [Fluidextract of Buckthorn Bark]**

Extrait liquide d'Ecorce de Bourdaine, Fr.; Extractum Frangulae fluidum, P. G.; Faulbaum-Fluidextrakt, Flussigea Faulbaumriadenextrakt, G.

"Frangula, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, two hundred and fifty mils [or 8 fluidounces, 218 minims]. Prepare a Fluidextract by Type Process D. Evaporate the aqueous percolate to seven hundred and fifty mils [or 25 fluidounces, 173 minims] and, when cold, add the alcohol and, if necessary, sufficient water to make the product measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]." U. S.

This is a fluidextract which has been quite largely used in this country. It is intended to be a laxative, but it is frequently disappointing, as the drug is rarely to be obtained of uniformly good quality. The fluidextract is of a dark reddish-brown color. For a process for Sweet Fluidextract of Buckthorn, see U. S. D., 19th ed., p. 540.

Dose, ten to -twenty minims (0.6-1.3 mils).

**Off. Prep.—Elixir Catharticum Compositum, N. F.; Syrupus Sennae Compositus, N. F.**

**FLUIDEXTRACTUM GELSEMII. U. S.**

**FLUIDEXTRACT OF QELSEMIUM FlIdext. Gelsem.**

Extrait liquide de J asmin jaune ou Gelsemium, Fr.; Flussiges Gelber J asminextrakt, Flussiges Gelsemiumextrakt, G.

"Gelsemium, in No. 40 powder, one thousand grammes [or 35 ounces
av., 120 grains], Prepare a Fluidextract by Type Process, using a mixture of four volumes of alcohol and one volume of water as the menstruum." U. S.

In this fluidextract the former menstruum of alcohol has been replaced in the U. S. P. IX with alcohol, 4 volumes, and water, 1 volume. It is of a dark reddish-brown color.

Dose, from one to three minims (0.06-0.2 mil).

Off. Prep.—Elixir Sodii Salicylatis Compositum, N. F.

FLUIDEXTRACTUM GENTIANAE. U. S.

FLUIDEXTRACT OF GENTIAN Fldext. Gentian.

Extrait liquide de Gentiane, Fr.; Flussiges Enzianextrakt. G.

"Gentian, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using diluted alcohol as the menstruum." U. S.

This is a translucent, reddish-brown fluid, with the odor and taste of the root. It may be questionable whether it is needed, though it has the advantage that we may obtain from it the tonic effects of the drug with less alcohol than in an equivalent quantity of the tincture, and pharmaceutically it affords a convenient method of giving to mixtures the tonic properties of gentian when required.

Dose, from ten to thirty minims (0.6-1.8 mils).

Off. Prep.—Elixir Gentianae, N. F.; Elixir Gentianae et Ferri, N. F.; Elixir Gentianae et Ferri Phosphatis, N. F.; Elixir Gentianae Glycerinatum, N. F.

FLUIDEXTRACTUM GLYCYRRHIZAE. U. S. (Br.)

FLUIDEXTRACT OF GLYCYRRHIZAE Fldext. Glycyrrh.

Extractum Glycyrrhizae Liquidum, Br.; Liquid Extract of Liquorice; Fluidextract of Licorice or Liquorice; Extrait liquide de Reglisse, Fr.; Flussiges Sussholzwurzelextrakt, G.
“Glycyrrhiza, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, two hundred and fifty mils [or 8 fluid-ounces, 218 minims]; Ammonia Water, Chloroform Water, Water, each, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6½ fluidrachms]. Mix three hundred mils [or 10 fluidounces, 69 minims] of ammonia water with twenty-seven hundred mils [or 91 fluid-ounces, 142 minims] of chloroform water and moisten the glycyrrhiza with a sufficient quantity of the mixture; pack it in a cylindrical percolator and add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more of the same menstruum until the glycyrrhiza is exhausted. Reserve the first five hundred mils [or 16 fluidounces, 435 minims] of the percolate and evaporate the remainder on a water bath to a soft extract; dissolve this in the reserve portion and add enough water to make the product measure seven hundred and fifty mils [or 25 fluidounces, 173 minims]. A few drops of ammonia water may be added if necessary to facilitate solution. Now gradually add the alcohol, allow the product to stand for seven days in a stoppered container, then decant the clear liquid, filter the remainder and wash the residue on the filter with enough of a mixture of one volume of alcohol and three volumes of water to make the Fluidextract measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]." U.S.

“Liquorice Root, in No. 20 powder, 1000 grammes; Chloroform Water, 5000 millilitres; Alcohol (90 per cent.), a sufficient quantity. Mix the Liquorice Root with one-half of the Chloroform Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Chloroform Water, and set aside for six hours; strain; press; mix the strained liquids; heat to 100° C. (212° F.); strain through flannel; evaporate until the liquid has acquired, when cold, a specific gravity of 1.200; add to this one-fourth of its volume of the Alcohol; let the mixture stand for twelve hours; filter." Br.

The process for this fluidextract was materially changed in the U. S. P. VIII. The former processes, while making stable fluidextracts of good appearance, were deficient in not providing for the removal of the acrid, oily constituent found in licorice root; the U. S. P. VIII process overcame
this difficulty by exhausting the coarsely powdered root with boiling water, concentrating the infusions, adding alcohol to precipitate inert constituents, and filtering; the filtrate was distilled to recover the excess of alcohol, and glycerin, ammonia water and alcohol added to bring the measure to the required standard. This process was essentially that recommended by A. R. L. Dohme. The U. S. P. IX process differs materially. Chloroform water is used to exhaust the licorice root with ammonia water to dissolve the glycyrrhizin, alcohol is added finally to preserve the fluidextract. The object of using chloroform water in the U. S. and British processes is to prevent decomposition in the aqueous liquids. The British formula for the liquid extract has several inconvenient manipulative features, such as the repeated macerations and expressions, evaporating to a certain specific gravity, etc. (See Mont. Pharm. Journ., 1893, 147; P. J., 1898, 188.) This preparation is now very largely used as an adjuvant, and for disguising the bitter taste of quinine, which should be added to the preparation of licorice just before the dose is taken. It is a very convenient form for using licorice, as the ammonia renders the glycyrrhizin soluble, thus materially adding to the power and sweetness of the fluid-extract, and it also greatly lessens the acridity. It is a very dark reddish-brown liquid, having the well known sweet taste of licorice, and froths when shaken with water. A syrup of licorice may be made by adding two parts of fluidextract to fourteen parts of simple syrup. (See also N. F., Part III.) An elixir containing licorice (Elixir Adjuvans) was made official in the U. S. P. VIII and introduced into the U. S. P. IX under the name of Elixir of Glycyrrhiza.

Used as a vehicle only.

**EXTRACTUM GOSSYPII RADICIS CORTICIS LIQUIDUM. Br.**

**LIQUID EXTRACT OF COTTON ROOT BARK**

"Cotton Root Bark, in No. 30 powder, 1000 grammes; Glycerin, 250 millilitres; Alcohol (90 per cent.) sufficient to produce 1000 millilitres. Mix the Glycerin with seven hundred and fifty millilitres of the Alcohol;
moisten the Cotton Root Bark with this mixture and continue the percolation process, using as menstruum first the remainder of the mixture of Glycerin and Alcohol, and afterwards sufficient of the Alcohol to produce the required volume." Br.

The fluidextract of cotton root bark (U. S. P. 1890) was not retained in the U. S. P. VIII or IX, but the National Formulary IV introduced a fluidextract made from the recently-gathered air-dried bark of the root, using alcohol for the menstruum. (See Part III.) The British process requires the use of glycerin which may have a tendency to prevent gelatinization.

Uses.—There is reason to believe that cotton-root bark loses some of its activity in drying. For this reason the preparation of the N. F. IV is to be preferred to the Br. For therapeutic properties of cotton root, see Gossypii Radicis Cortex.

Dose, one-half to one fluidrachm (1.8-3.75 mils).

**FLUIDEXTRACTUM GRANATI. U. S.**

**FLUIDEXTRACT OF POMEGRANATE** Fluidext. Granat.

Fluidextract of Pomegranate Root Bark; Extrait liquide d'Ecorce de Balaustier, Extrait liquide d'Ecorce de Grenadier, Fr.; Flussiges Granatwurzelrindenextrakt, G.

"Pomegranate, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains], Prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluid-ounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." U. S.

This fluidextract was admitted to the U. S. Pharmacopoeia (8th Revision) for the first time; it well represents the virtues of pomegranate.

Dose, from one-half to one fluidrachm (1.8-3.75 mils).
FLUIDEXTRACTUM GRINDELIA. U. S. (Br.)

FLUIDEXTRACT OF GRINDELIA Fl/dext. Grindel.

Extractum Grindeliae Liquidum, Br., Liquid Extract of Grindelia; Extrait liquide de Grindelia, Fr.; Flussiges Grindelienextrakt, G.

“Grindelia, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of three volumes of alcohol and one volume of water as the menstruum." U. S. "Grindelia, in No. 40 powder, 1000 grammes; Sodium Bicarbonate, 100 grammes; Distilled Water, 500 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Exhaust the Grindelia by percolation with the Alcohol. Recover the alcohol from the percolate by distillation, and dissolve the residue in the Distilled Water, to which the Sodium Bicarbonate has previously been added; after effervescence has ceased, add sufficient Distilled Water to produce seven hundred and fifty millilitres, and then sufficient of the Alcohol to produce the required volume." Br.

This is a fluidextract which well represents the drug; owing to the large quantity of resinous matter present, it does not mix well with aqueous liquids. The so-called "alkaline fluid extract of grindelia" may be made by evaporating one pint of official fluidextract until reduced to twelve fluidounces, making a solution of 180 grains of sodium bicarbonate in four fluidounces of water, adding it slowly to the evaporated fluidextract, and filtering; the British liquid extract is made upon this principle. The fluidextract is a dark brown liquid having the peculiar odor of grindelia.

For medical properties and uses, see Grindelia.

Dose, from one-half to one fluidrachm (1.8-3.75 mils).

FLUIDEXTRACTUM GUARANAE. U. S.

FLUIDEXTRACT OF GUARANA Fl/dext. Guaran.

"One hundred mils of Fluidextract of Guarana yields not less than 3.6 Gm. nor more than 4.4 Gm. of caffeine." U. S.

Extrait liquide de Guarana, Fr.; Flussiges Guaranaextrakt, G.
"Guarana, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of three volumes of alcohol and one volume of water as the menstruum, and reserving the first eight hundred mils [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloid in the remainder of the liquid and dilute this with enough menstruum to make each one hundred mils of the finished Fluidextract contain 4 Gm. of caffeine." U. S.

"Assay.—Introduce 5 mils of Fluidextract of Guarana into a separator, add 1 mil of ammonia water, and shake out the alkaloid with chloroform until completely extracted, as shown by testing with iodine T.S. Evaporate the combined chloroform solutions to dryness and dissolve the residue in 20 mils of distilled water with the aid of heat. Allow this to cool, filter it into a separator and wash the container and filter with several small portions of distilled water, adding the rinsings to the liquid in the separator. Then shake out the alkaloid with chloroform until completely extracted, as shown by testing with iodine T.S., evaporate the combined chloroform solutions and dry the residue to constant weight at 80° C. (176° F.). The weight represents the alkaloid in 5 mils of Fluidextract of Guarana." U. S.

The menstruum for this fluidextract, U. S. P. IX (alcohol 3, water 1), is stronger than that of the U. S. P. VIII (diluted alcohol).

This fluidextract is of doubtful utility. The powdered drug itself is portable, not unpleasant to the taste, and is efficient when given suspended in water; nothing is gained by making it into a fluidextract. The fluidextract is of a deep reddish-brown color. (See Proc. A. Ph. A., 1897, 423.)

Dose, one to two fluidrachms (3.75-7.5 mils).

Off. Prep.—Elixir Guarana1, N. F.
EXTRACTUM HAMAMELIDIS LIQUIDUM. Br.

LIQUID EXTRACT OF HAMAMELIS

Fluidextractum Hamamelis Foliorum, Fluidextract of Hamamelia Leaves; Fluidextract of Witch-hazel Leaves; Extrait liquide de Hamamelis, Fr.; Flussiges Hamamelisextrakt, G.; Extracto fluido de hamamelis, Sp.

"Hamamelis Leaves, dried, in No. 40 powder, 1000 grammes; Alcohol (45 per cent.), sufficient to produce 1000 millilitres. Exhaust the Hamamelis Leaves by percolation with the Alcohol. Reserve the first eight hundred and fifty millilitres of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." Br.

This liquid extract well represents the virtues of witchhazel. The fluidextract of hamamelis leaves of the U. S. P. VIII was not retained in the U. S. P. IX, but will be found in the N. F. (See Part III.) It has a dark reddish-brown color.

Dose, ten to thirty minims (0.6-1.8 mils).

Off. Prep.—Unguentum Hamamelidis, Br.

FLUID EXTRACT OF HYDRASTIS. U. S. (Br.)

FLUID EXTRACT OF HYDRASTIS

Flidext. Hydrast. [Fluidextract of Golden Seal]

"One hundred mils of Fluidextract of Hydrastis yields not less than 1.8 Gm. nor more than 2.2 Gm. of the ether-soluble alkaloids of Hydrastis." U. S. " Liquid Extract of Hydrastis contains in 100 millilitres 2 grammes of hydrastine." Br.

Extractum Hydrastis Liquidum, Br.; Liquid Extract of Hydrastis; Extrait liquide de Hydrastis, Fr.; Extractum Hydrastis fluidum, P. G.; Hydrastis-Fluidextrakt; Flussiges Hydrastisextrakt, G; Estratto di idraste liquido, It.; Extracto fluido de hidrastine, Sp.

"Hydrastis, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B, using a mixture
of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, six
hundred mils [or 20 fluidounces, 138 minims] of alcohol and two
hundred mils [or 6 fluidounces, 366 minims] of water as Menstruum I,
and a mixture of two volumes of alcohol and one volume of water as
Menstruum II. Reserve the first seven hundred and fifty mils [or 25
fluidounces, 173 minims] of percolate. After dissolving the soft extract in
the reserve liquid, assay a portion as directed below, and, from the
result thus obtained, ascertain by calculation the amount of alkaloids in
the remainder of the liquid and dilute this with enough of Menstruum
II to make each one hundred mils of the finished Fluidextract contain 2
Gm. of the ether-soluble alkaloids of hydrastis.

"Hydrastis Rhizome, in No. 60 powder, 1000 grammes; Alcohol (60 per
cent.), a sufficient quantity. Exhaust the Hydrastis Rhizome with the
Alcohol by the percolation process; reserve the first eight hundred and
fifty millilitres of the percolate; recover the alcohol from the remainder
by distillation; evaporate to a soft extract and dissolve in the reserved
portion.

"Assay.—Proceed as directed under Fluidextractum Belladonna Radicis,
modifying the process there given by using 5 mils of Fluidextract of
Hydrastis instead of 10 mils of the fluidextract of belladonna root and
using only ether as the immiscible, solvent throughout the assay. Dry
the residue to constant weight at 100° C. (212° F.), instead of titrating it.
The weight represents the amount of ether-soluble alkaloids in 5 mils of
the Fluid-extract of Hydrastis." U. S.

"Determine the proportion of hydrastine in the liquid extract thus
obtained by the following process: Transfer 10 millilitres of the liquid
extract to a 100 millilitre graduated flask, add 20 millilitres of solution of
potassium iodide diluted with 60 millilitres of water, and then sufficient
water to produce 100 millilitres. Shake the mixture for several minutes
and filter. Transfer 50 millilitres of the filtrate to a separator, render
alkaline with solution of ammonia, add 30 millilitres of ether, and shake
at intervals during several minutes. Allow the liquids to separate, draw
off the aqueous solution into a beaker and the ethereal solution into a
tared beaker. Return the aqueous solution to the separator and repeat
the operation with two successive portions, each of 20 millilitres, of ether
for one minute. Draw off and reject the aqueous layer; transfer the
ethereal solutions to the tared beaker and evaporate at a gentle heat;
dry the residue on a water-bath and weigh. The weight is that of the
hydrastine in 5 millilitres of the liquid extract examined. To the remainder of the liquid extract add sufficient of the menstruum to produce a Liquid Extract of Hydrastis containing 2 grammes of hydrastine in 100 millilitres. Examined by the foregoing process Liquid Extract of Hydrastis is found to contain in 100 millilitres 2 grammes of hydrastine. Limit of error 0.1 gramme in excess or defect. This Liquid Extract contains 2 grammes of hydrastine in 100 millilitres; 110 minims contain 2 grains.” Br.

The fluidextract thoroughly represents the drug. It is of a deep brownish-yellow color.

Dose, from fifteen minims to one fluidrachm (0.9-3.75 mils).

Off. Prep.—Tinctura Hydrastis, Br.; Mistura Rhei Alkalina, N. F.

**FLUIDEXTRACTUM HYOSCYAMI. U. S.**

**FLUIDEXTRACT OF HYOSCYAMUS**

"One hundred mils of Fluidextract of Hyoscyamus yields not less than 0.055 Gm. nor more than 0.075 Gm. of the alkaloids of hyoscyamus.” U. S.

Extrait liquide de J usquiame, Fr.; Flussiges Bilsenkrautextrakt, G.

"Hyoscyamus, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A (see page 483), using a mixture of three volumes of alcohol and one volume of water as the menstruum. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make each one hundred mils of the finished Fluidextract contain 0.065 Gm. of the alkaloids of hyoscyamus.” U. S.

"Assay.—Proceed as directed under Fluid-extractum Belladonna Radicis, modifying the process there given by using 25 mils of the Fluidextract of Hyoscyamus in place of 10 mils of fluidextract of belladonna root, and before titrating treating the residue twice with 5
mils of ether and evaporating to dryness each time.

"Each .mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the total alkaloids of hyoscyamus." U. S.

The menstruum for this fluidextract was improved in the revision of the U. S. Pharmacopoeia IX by increasing the alcoholic strength to alcohol 3, water 1. It is of a very dark greenish-brown color. For the medicinal properties, see Hyoscyamus.

Dose, from three to ten minims (0.2-0.6 mil).

**FLUIDEXTRACTUM IPECACUANHA. U. S. (Br.)**

**FLUIDEXTRACT OF IPECAC**

"One hundred mils of Fluidextract of Ipecac yields not less than 1.8 Gm. nor more than 2.2 Gm. of the ether-soluble alkaloids of ipecac." U. S. "Liquid Extract of Ipecacuanha contains in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root." "

**Extractum Ipecacuanhae Liquidum**, Br.; Liquid Extract of Ipecacuanha; Extrait liquide d'Ipecacuanha, Fr.; Flussiges Ipecacuanhaextrakt, G.

"Ipecac, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of diluted hydrochloric acid, two hundred mils [or 6 fluid-ounces, 366 minims] of alcohol and two hundred mils [or 6 fluidounces, 366 minims] of water as Menstruum I, and a mixture of two volumes of alcohol and three volumes of water as Menstruum II. Reserve the first eight hundred mils [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and, from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough of Menstruum II to make each one hundred mils of the finished Fluidextract contain 2 Gm. of the ether-soluble alkaloids of ipecac." U. S.

"Ipecacuanha Root, in No. 120 powder, 1000 grammes; Alcohol (90 per cent.), a sufficient quantity. Pack the Ipecacuanha Root uniformly in a conical percolator, add two hundred millilitres of the Alcohol, and set
aside for twelve hours; then percolate with successive portions, each of two hundred millilitres, of the Alcohol, added at intervals of twelve hours, until the liquid begins to drop from the orifice of the percolator. Continue the percolation with more of the Alcohol until seven hundred and fifty millilitres of percolate have been collected. Reserve this portion. Then percolate until exhaustion is complete; recover the alcohol from this percolate by distillation, and dissolve the residual extract in the reserved portion." Br.

**Assay of Fluidextract of Ipecac.**—" From a pipette drop 10 mils of Fluidextract of Ipecac evenly over the surface of 10 Gm. of purified sawdust (see Part III), and evaporate it to dryness at a temperature not exceeding 80° C. (176° F.). Transfer the impregnated sawdust to a 250 mil flask and add 100 mils of ether. Rinse the dish in which the mixture was evaporated with 6 mils of ammonia water, previously diluted with an equal volume of water, used in several portions, and add the rinsings to the flask. Stopper the flask and shake in vigorously every few minutes, during two hours. Now add 15 mils of distilled water, again shake the flask well, and when the sawdust has subsided decant 50 mils of the ether solution, representing 5 mils of the Fluidextract. Completely extract the alkaloids from this solution by shaking out with weak sulphuric acid. Collect the acid washings in a separator; add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with ether. Evaporate the combined ether washings to dryness, dissolve the alkaloid from the residue in exactly 10 mils of tenth-normal sulphuric acid V.S. and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., cochineal T.S. being used as indicator (see Proximate Assays, Part III).

"Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 24 milligrammes of the ether-soluble alkaloids of ipecac." U. S.

"Determine the proportion of alkaloids in the liquid extract thus obtained by the following process: Introduce 5 millilitres of the liquid extract into a separator and add 4 millilitres of water, 1 millilitre of diluted sulphuric acid, and 10 millilitres of ether. Shake, and separate the ethereal solution. Repeat the shaking with 5 millilitres of ether and again separate. Wash the mixed ethereal solutions in a second separator with two successive portions, each of 5 millilitres, of water, and add the washings to the contents of the first separator. Shake this aqueous
liquid with 10 millilitres of chloroform and excess of solution of ammonia. Separate the chloroformic solution and filter it through a small filter-paper into a tared dish. Repeat the shaking with chloroform, separation, and filtration, twice, finally washing the filter-paper with a little chloroform. Evaporate the mixed chloroformic solutions to about 2 millilitres, add 5 millilitres of ether, evaporate, dry at a temperature not exceeding $80\degree$ C. ($176\degree$ F.) and weigh the residual alkaloids. To the remainder of the liquid extract add sufficient of the Alcohol to produce a Liquid Extract of Ipecacuanha containing in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root. Examined by the foregoing process Liquid Extract of Ipecacuanha is found to contain in 100 millilitres 2 grammes of the alkaloids of Ipecacuanha Root. Limit of error 0.1 gramme in excess or defect. This Liquid Extract contains 2 grammes of the alkaloids of Ipecacuanha Root in 100 millilitres; 110 minims contains 2 grains." Br.

The menstruum for the U. S. fluidextract was altered in the U. S. P. IX by the addition of hydrochloric acid, which combines with the alkaloids and more thoroughly exhausts the ipecac. It was proved by J. U. Lloyd that when alcohol alone is used a portion of emetine escapes solution. On the other hand, it is known that when the menstruum is more aqueous large amounts of the pectinous principles are taken up, and it is very desirable to separate these in order to prevent their appearance as a flocculent precipitate in syrup of ipecac; but efficiency is to be sought for as the first desideratum, and hence a menstruum which will extract the activity and make a fluidextract that will not let fall a bulky precipitate of inert matter has been secured; usually this will not mix with syrup without slight precipitation, but the improved official process for syrup of ipecac should effectually separate any precipitate resulting from the presence of apotheme in the fluidextract. The British liquid extract (1914) is standardized; the excellent researches of Paul and Cownley on ipecac, and the assay work of Kremel, Keller, and others, undoubtedly prompted the introduction of the process for the liquid extract. (See Ipecacuanha.) It will probably be found, however, that the V. S. menstruum is preferable. An acetic extract of ipecac (dry) is used in Great Britain; it has been shown that the heating necessary to dry it is injurious to its emetic properties. (P. J., 1895, 158.)

This fluidextract is a thin, dark reddish-brown, transparent liquid, of a bitterish, slightly acrid taste, but without the nauseous flavor of the root. It is a convenient preparation for adding to expectorant and
diaphoretic mixtures, and is used officially in preparing the syrup of ipecac, and other preparations named below.

Dose, as emetic, fifteen to thirty minims (0.9-1.8 mils); as an expectorant, one to two minims (0.06-0.12 mil).

**Off. Prep.**—Syrupus Ipecacuanhae, U. S.; Tinctura Ipecacuanhae et Opii, N. F.; Vinum Ipecacuanhae, Br., N. F.; Mistura Rhei Composita, N. F.; Syrupus Asari Compositus, N. F.; Syrupus Cimicifugae Compositus, N. F.

**EXTRACTUM KAVAE LIQUIDUM. Br.**

**LIQUID EXTRACT OF KAVA**

“Kava Rhizome, in No. 20 powder, 1000 grammes; Alcohol (90 per cent.), a sufficient quantity; Alcohol (45 per cent.), a sufficient quantity. Mix the powdered Kava Rhizome with two thousand millilitres of the Alcohol (90 per cent.); set aside in a closed vessel for forty-eight hours; transfer to a percolator and percolate slowly, reserving the first seven hundred and fifty millilitres of the percolate. Continue the percolation, adding the Alcohol (45 per cent.) until the powder is exhausted; recover most of the alcohol from this percolate by distillation; evaporate the residue at a temperature below 80° C. (176° F.) to a soft extract, and dissolve this in the reserved percolate; add sufficient of the Alcohol (90 per cent.) to produce one thousand millilitres of the Liquid Extract.” Br.

This fluidextract was introduced into the British Pharm. (1914), and is also official in the N. F. IV. (See Part III.) It represents kava and may be given in the dose of thirty minims to one fluidrachm (1.8-3.75 mils).

**FLUIDEXTRACTUM LOBELIAE. U. S.**

**FLUIDEXTRACT OF LOBELIA Flvdx. Lobel.**

Extrait liquide de Lobelie enflee, Fr.; Flussiges Lobelienkrautextrakt, Flussiges Lobelienextrakt, G.

"Lobelia, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B, using a mixture of fifty mils [or 1 fluidounce, 331 minims] of acetic acid, five hundred
mils [or 16 fluidounces, 435 minims] of alcohol and four hundred and fifty mils [or 15 fluidounces, 104 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." U. S.

This fluidextract differs from that of the U. S. P. VIII in that the menstruum is acetic acid 1, alcohol 10, water 9 parts. The acetic menstruum is well adapted for exhausting the drug.

This is a valuable fluidextract. It is of a dark olive color, having the acrid taste of lobelia in a very marked degree.

Dose, as an expectorant, from one to five minims (0.06-0.3 mil); as an emetic, from ten to twenty minims (0.6-1.3 mils).

**FLUIDEXTRACTUM PILOCARPI. U. S.**

**FLUIDEXTRACT OF PILOCARPUS**

Fldext. Pilocarp. [Fluidextract of J aborandi]

“One hundred mils of Fluidextract of Pilo-carpus yields not less than 0.55 Gm. nor more than 0.65 Gm. of the alkaloids of pilocarpus." U.S.

Extractum Jaborandi Liquidum, Br., 1898: Liquid Extract of Jaborandi; Extrait liqueide deJ aborandi, Fr.; Flussiges Jaborandiextract, G.

"Pilocarpus, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of two volumes of alcohol and one volume of water as the menstruum, and reserving the first eight hundred mils [or 27 fluidounces, 24 minims] of percolate. After dissolving the soft extract in the reserve liquid, assay a portion as directed below, and from the result thus obtained, ascertain by calculation the amount of alkaloids in the remainder of the liquid and dilute this with enough menstruum to make each one hundred mils of the finished Fluidextract contain 0.6 Gm. of the alkaloids of pilocarpus."

"Assay.—From a pipette drop 15 mils of Fluidextract of Pilocarpus evenly over the surface of 15 Gm. of purified sawdust (see Part III), and evaporate it to dryness on a water bath. Transfer the mixture to a 250 mil flask, add 150 mils of chloroform, and proceed as directed under Belladonnae Radix, fifth line of the Assay, beginning with the word
‘Stopper’ modifying the process there given by increasing the amount of ammonia water to 6 mils, mixed with 5 mils of distilled water, which is to be used, in divided portions, to rinse the dish in which the mixture was evaporated, the rinsings being added to the mixture in the flask; the 100 mils of chloroform solution must be drawn off from the bottom of the flask.

"Each mil of tenth-normal sulphuric acid V.S. corresponds to 20.815 milligrammes of the alkaloids of pilocarpus." U. S.

This fluidextract represents Jaborandi leaves thoroughly. Of the liquid preparations of the drug, the infusion and tincture are both open to objection, the former on account of the bulkiness of the dose, and the latter because of the amount of alcohol it contains. Liquid abstract of jaborandi was deleted from the Br. Pharm. (1914).

Dose, from fifteen minims to half a fluidrachm (0.9-1.8 mils).

**FLUIDEXTRACTUM PODOPHYLLI. U. S.**

**FLUIDEXTRACT OF PODOPHYLLUM** Fluid. Podophyll.

Fluidextract of May Apple or Mandrake; Extrait liquide de Podophylyle, Fr.; Flussiges Fussblattwurzelextrakt, Flussiges Podophyllumextrakt, G.

"Podophyllum, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum." U. S.

The menstruum of the U. S. P. VIII fluid-extract which was alcohol 4, water 1, was changed to alcohol in the U. S. P. IX. This is a fluidextract which well represents the root, but is of very little use, since Podophyllum is much better administered in other forms.

Dose, from five to fifteen minims (0.3-0.9 mil).

**FLUIDEXTRACTUM RHEI. U. S.**

**FLUIDEXTRACT OF RHUBARB** Fluid. Rhei

Extrait liquide de Rhubarbe, Fr.; Flussiges Rhabarberextrakt, G.
"Rhubarb, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of four volumes of alcohol and one volume of water as the menstruum." U. S.

The present process affords a fluidextract which thoroughly represents the root, but when mixed with syrups and water, it loses its transparency. An alkali or an alkaline carbonate dissolves this precipitate, but the use of the fluidextract is limited. The British Pharm. (1898) "Liquor Rhei Concentratus " is made with alcohol (20 per cent.) as a menstruum and is one-half the strength of the U. S. fluidextract of rhubarb.

Dose, for an adult, as a purgative, twenty to thirty minims (1.3-1.8 mils); as a laxative, from five to ten minims (0.3-0.6 mil).

Off. Prep.—Syrupus Rhei, U. S.; Mistura Rhei Alkalina, N. F.; Mistura Rhei Composita, N. F.; Syrupus Sennae Compositus, N. F.; Vinum Rhei Compositum, N. F.

FLUIDEXTRACTUM ROSAE. U. S.

FLUIDEXTRACT OF ROSE Flidext. Rossae

Fluidextract of Red Rose; Extrait liquide de Rose rouge, Fr.; Flussiges Essigrosenblumenblatterextrakt, G.

"Red Rose, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluid-ounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." U. S.

This fluidextract is a useful adjuvant and an excellent astringent. It is of a deep red color, with the agreeable flavor of rose. Wm. C. Alpers prefers repercolation for this fluid-extract, stating that even a moderate heat imparts an unpleasant odor to the finished product. (Proc. A. Ph. A., 1897, 425.)

Dose, from one to two fluidrachms (3.75-7.5 mils).
Off. Prep.—Mel Rosse, U. S.; Syrupus Rosse, N. F.

FLUIDEXTRACTUM SABAL. U. S.

FLUIDEXTRACT OF SABAL
Fldext. Sabal [Fluidextract of Saw Palmetto]

"Sabal, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of four volumes of alcohol and one volume of water as the menstruum." U. S.

This fluidextract was introduced into the U. S. P. IX. It represents the virtues of saw palmetto berries.

Dose, fifteen minims (0.9 mil).

FLUIDEXTRACTUM SARSAPARILLA. U. S.

FLUIDEXTRACT OF SARSAPARILLA Fldext. Sarsap.

Extractum Sarsae Liquidum., Br. 1898; Liquid Extract of Sarsaparilla; Liquor Sarsae; Extrait liquide de Salsepareille, Fr.; Flussiges Sarsparillaextrakt, G.

"Sarsaparilla, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using diluted alcohol as the menstruum." U. S.

The British Pharm. (1914) deleted Extractum Sarsae Liquidum. The process will be found in the 19th ed., U. S. Dispensatory, page 559.

The introduction of a simple fluidextract of Sarsaparilla into our Pharmacopoeias was judicious, as it enables the physician to associate this medicine with others at his pleasure, and in such proportions as he may deem expedient. He may rely upon the efficiency of the preparation, if made with sufficient care and skill and from good parcels of the root. The U. S. fluid-extract is a somewhat dense, scarcely translucent liquid, of a very dark reddish-brown color, and of a sweetish and a slightly acrid taste.
Dose, thirty to sixty minims (1.8-3.75 mils).

**Off. Prep.**—Syrupus Sarsaparillae Compositus, U. S.

**FLUIDEXTRACTUM SARSAPARILLAE COMPOSITUM. U. S.**

**COMPOUND FLUIDEXTRACT OF SARSAPARILLA**

Extrait liquide de Salsepareille compose, Fr.; Zusammen gesetztes flussiges Sarsaparillaextrakt, G.

"Sarsaparilla, in No. 20 powder, seven hundred and fifty grammes [or 26 ounces av., 199 grains]; Glycyrrhiza, in No. 20 powder, one hundred and twenty grammes [or 4 ounces av., 102 grains]; Sassafras, in No. 30 powder, one hundred grammes [or 3 ounces av., 231 grains]; Mezereum, in No. 30 powder, thirty grammes [or 1 ounce av., 25 grains]. Mix the powders and prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluidounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." U. S.

The compound fluidextract is intended to represent, in a concentrated state, the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. It was originally proposed by Wm. Hodgson, Jr. (A. J. P., ii, 285), and the official process differs from his mainly in the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. The British Pharm. (1898) "Liquor Sarsae Compositus Concentratus" is of the same strength as the fluidextract of the U. S. Pharmacopoeia, and is made with a menstruum of distilled water with 225 mils of alcohol as a preservative in 1000 mils of finished solution.

Dose, from thirty minims to one fluidrachm (1.8-5.75 mils).
"If assayed biologically the minimum lethal dose should not be greater than 0.0006 mil of Fluidextract, or the equivalent in Fluidextract of 0.0000005 Gm. of ouabain, for each gramme of body weight of frog." U. S.

Extrait liquide de Scille, Fr.; Flussiges Meerzwiebelextrakt, G.

"Squill, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, Alcohol, Water, each, a sufficient quantity, to make one. thousand mils [or 33 fluid-ounces, 6\(\frac{1}{2}\) fluidrachms]. Mix two thousand mils [or 67 fluidounces, 301 minims] of alcohol with one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms] of water, moisten the squill thoroughly with sufficient of the mixture and allow it to macerate for two hours in a tightly-covered container. Then transfer it to a percolator, shake it down evenly without packing, and pour on enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding more menstruum composed of two volumes of alcohol and one volume of water. When the percolate measures one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms] close the lower orifice and macerate the drug twelve hours before continuing the percolation. Then collect a second one thousand mils [or 33 fluidounces, 6\(\frac{1}{2}\) fluidrachms of percolate, again interrupt the percolation, macerate for twelve hours and then continue the percolation until the total percolate measures five thousand mils [or 169 fluid-ounces, 33 minims]. Recover the alcohol from the percolate at as low a temperature as possible and then concentrate the residue to a volume measuring eight hundred mils [or 27 fluidounces, 24 minims]. When the residue is cold, add slowly, with continuous agitation, two thousand mils [or 67 fluidounces, 301 minims] of alcohol and set the mixture aside in a tightly-stoppered container for twelve hours. Decant the supernatant liquid from the syrupy layer, filter the decanted liquid and wash the syrupy residue with two portions
of three hundred mils [or 10 fluidounces, 69 minims] each of a mixture of four volumes of alcohol and one volume of water, passing the washings through the filter into the previously collected alcoholic liquid. Reduce the combined alcoholic liquids to eight hundred mils [or 27 fluidounces, 24 minims] by distillation and finally add enough diluted alcohol to make the finished Fluidextract measure one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]." U. S.

The U. S. P. has very properly returned to an alcoholic instead of an acetic acid menstruum for this preparation, as Houghton has shown that the fluidextract of the U. S. P. VIII did not represent the activity of squills, but it is doubtful whether the complicated process of the U. S. P. IX will be employed for such a rarely used fluidextract.

Dose, from one to three minims (0.06-0.2 mil).

**FLUIDEXTRACTUM SENEGA. U. S.**

**FLUIDEXTRACT OF SENEGA Fldext. Seneg.**

Extrait liquide de Polygale de Virginie, Extrait liquide de Seneca, Fr.; Flussiges Senegaextrakt, G.

"Senega, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Ammonia Water, Alcohol, Water, each, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Mix two thousand mils [or 67 fluidounces, 301 minims] of alcohol with one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms] of water, and, having moistened the powder with sufficient of this mixture, pack it in a cylindrical percolator and add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding menstruum, composed of a mixture of two volumes of alcohol and one volume of water, until the drug is exhausted. Reserve the first eight hundred mils [or 27 fluidounces, 24 minims] of the percolate and evaporate the
remainder to a soft extract; dissolve this in the reserved liquid and then gradually add ammonia water until the product is faintly alkaline and possesses a slight odor of ammonia. Finally add enough of the menstruum to make the Fluid-extract measure one thousand mils [or 33 fluid-ounces, 6½ fluidrachms]." U. S.

Formerly, Fluidextract of Senega was very frequently the cause of annoyance to the pharmacist through gelatinization. This was due to the presence of pectinous bodies in the root. The addition of an alkali to the menstruum effectually prevents this, and in this respect the present preparation is a great improvement over the 1890 fluidextract. We prefer, however, solution of sodium hydroxide, as the alkaline liquid, to ammonia water, as the latter is rarely uniform in quality as found in commerce. This fluidextract is a blackish-brown, moderately thin liquid. For other processes, see N. R., 1883, pp. 195, 196. The British Pharm. (1898) "Liquor Senegae Concentratus" was made half the strength of the U. S. fluidextract with a menstruum composed of 2 parts of 20 per cent. alcohol and 1 part of 45 per cent. alcohol.

Dose, five to twenty minims (0.3--1.3 mils).

Off. Prep.—Syrupus Scillae Compositus, U. S.; Syrupus Senega;,, U. S.; Mistura Pectoralis, Stokes, N. F.; Syrupus Cimicifuga; Compositus, N. F.

**FLUIDEXTRACTUM SENNAE. U. S.**

**FLUIDEXTRACT OF SENNA Flidext. Senn.**

Extrait liquide de Sene, Fr.; Flussiges Sennaextrakt, G.

"Alexandria Senna, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains], Prepare a Fluidextract by Type Process A, using a mixture of one volume of alcohol and two volumes of water as the menstruum, and reserving the first eight hundred mils [or 27 fluidounces, 24 minims] of percolate." U. S.

The U. S. P. VIII process provided for the elimination of the griping principles by the previous percolation of the powdered senna with alcohol; diluted alcohol was then used to exhaust the drug of the purgative principles. This previous treatment of the senna was deleted from the U. S. P. IX process and the menstruum was made less alcoholic.
The fluid-extract is a dark, blackish, thick, and somewhat turbid liquid, with a strong flavor of senna. It is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluidextract should be given at once.

The British Pharm. (1898) "Liquor Senna Concentratus" was more like a concentrated infusion than a fluidextract, but had the same strength of the latter, the menstruum is distilled water; tincture of ginger and alcohol being added.

Dose, from one-half to two fluidrachms (1.8-7.5 mils), for an adult.

Off. Prep.—Syrupus Sarsaparillae Compositus, U. S.; Syrupus Sennae, U. S.; Elixir Cascara; Compositum, N. F.; Elixir Catharticum Compositum, N. F.; Syrupus Ficorum Compositus, N. F.; Syrupus Sennae Aromaticus, N. F.; Syrupus Sennae Compositus, N. F.

FLUIDEXTRACTUM SPIGELIA. U. S.

FLUIDEXTRACT OF SPIGELIA
Flldext. Spigel. [Fluidextract of Pink Root]

Extrait liquide de Spigelie, Fr.; Flussiges Spigelienextrakt, G.

"Spigelia, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using diluted alcohol as the menstruum." U. S.

This preparation differs from that official prior to 1890 in having no glycerin in the menstruum; the U. S. P., 1870, fluidextract contained 50 per cent. of glycerin. Diluted alcohol is an excellent menstruum.

The fluidextract of spigelia is a dark-brown translucent liquid, with the flavor of the root. The dose may be repeated morning and evening for three or four days, and then followed by a brisk cathartic. It is, however, most used in connection with the fluidextract of senna, the fluidextract of spigelia and senna formerly official being an excellent combination, which should not have been dropped from the Pharmacopoeia. The formula is as follows:
Extractum Spigeliae et Sennae Fluidum, U. S. 1870. Fluid Extract of Spigelia and Senna.— "Take of Fluid Extract of Spigelia ten fluid-ounces; Fluid Extract of Senna, six fluidounces; Oil of Anise, Oil of Caraway, each, twenty minims. Mix the Fluid Extracts, and dissolve the Oils in the mixture." U. S. 1870.

Dose, for an adult, from one to two fluidrachms (3.75-7.5 mils); for a child of two or three years, from ten to twenty minims (0.6-1.3 mils).

**FLUIDEXTRACTUM STAPHISAGRIAE. U. S.**

**FLUIDEXTRACT OF STAPHISAGRIA**  
Fldext. Staphisag. [Fluidextract of Stavesacre]

Fluidextract of Stavesacre Seed; Extrait liquide des Semences de Staphisaigre, Fr.; Flussiges Stephanskornerextrakt, G,

"Staphisagria, in No. 20 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum. The oil which separates in the freshly prepared Fluidextract may be removed by chilling and filtering the cold Fluidextract through a filter moistened with alcohol." U. S.

This fluidextract was first made official in the U. S. P. VIII. Mixed with two or three parts of alcohol and ether, it is used as an external application to destroy lice.

**FLUIDEXTRACTUM STILLINGIAE. U. S.**

**FLUIDEXTRACT OF STILLINGIA**  
Fldext. Stilling. [Fluidextract of Stillingia]

Extrait liquide de Stillingie, Fr.; Flussiges, Stillingiaextrakt, G.

"Stillingia, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using diluted alcohol as the menstruum." U. S.

The glycerin in the menstruum has been abandoned in this fluidextract, which is of a dark reddish-brown color.

Dose, from fifteen to forty-five minims (0.9— 2.8 mils).
Off. Prep.—Elixir Corydalis Compositum, N. F.

**FLUIDEXTRACTUM SUMBUL. U. S.**

**FLUIDEXTRACT OF SUMBUL**
Fldext. Sumbul [Fluid-extract of Musk Root]

Extrait liquide de Sumbul, Fr.; Flüssiges Sumbulwurzelextrakt oder Moschuswurzelextrakt, G.

"Sumbul, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of four volumes of alcohol and one volume of water as the menstruum." U. S.

This fluidextract was made official for the first time in the U. S. P. VIII, superseding the tincture of sumbul, to which it is superior.

Dose, half a fluidrachm to one fluidrachm (1.8-3.75 mils).

**FLUIDEXTRACTUM TARAXACI. U. S.**

**FLUIDEXTRACT OF TARAXACUM**
Fldext. Tarax. [Fluidextract of Dandelion]

Extractum Taraxaci Liquidum, Br. 1898; Liquid Extract of Taraxacum; Fluidextract of Dandelion; Extrait liquide de Pissenlit, Fr.; Flüssiges Löwenzahnwurzelextrakt, G.

"Taraxacum, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains], Prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, five hundred mils [or 16 fluidounces, 435 minims] of alcohol and four hundred mils [or 13 fluidounces, 252 minims] of water as Menstruum I, and diluted alcohol as Menstruum II." U. S.

The activity depends more upon the proper selection of the root than upon anything else.

The addition of solution of sodium hydroxide to the menstruum in the U.
S. P. VIII revision was dropped in the U. S. P. IX. The process of exhausting the drug is not difficult, and one of the best tests of this fluidextract is its bitter taste. It is a blackish, moderately thick liquid.

Dose, from one to three fluidrachms (3.75-11.25 mils).

Off. Prep.—Elixir Gentianae Glycerinatum, N. F.; Elixir Taraxaci Compositum, N. F.

**FLUIDEXTRACTUM TRITICI. U. S. (Br.)**

**FLUIDEXTRACT OF TRITICUM**

Fldext. Tritic. [Fluidextract of Couch Grass]

Extractum Agropyri Liquidum, Br.; Liquid Extract of Couch Grass; Liquid Extract of Triticum; Fluidextract of Couch-grass Root; Extrait liquide de petit Chiendent, Fr.; Flüssiges Queckenwurzelextrakt, G.

"Triticum, finely cut, one thousand grammes [or 35 ounces av., 120 grains]; Alcohol, two hundred mils [or 6 fluidounces, 366 minims]. Prepare a Fluidextract by Type Process D, evaporate the aqueous percolate to eight hundred mils [or 27 fluidounces, 24 minims] and when cold add the alcohol and, if necessary, sufficient water to make the product measure one thousand mils [or 33 fluidounces, 6½ fluidrachms]." U. S.

"Couch Grass, cut small, 1000 grammes; Distilled Water, boiling, 10,000 millilitres; Alcohol (90 per cent.), sufficient to produce 1000 millilitres. Boil the Couch Grass with the Distilled Water for thirty minutes; strain; evaporate to seven hundred and fifty millilitres; cool, and add sufficient of the Alcohol to produce the required volume; filter." Br.

For therapeutic uses, see Triticum and Agropyrum.

In making this fluidextract in warm weather, it is advisable to commence evaporating the percolate before the drug is exhausted, or fermentation may set in; triticum contains fermentable sugars, and diluted aqueous solutions do not keep well.

This fluidextract represents whatever virtues triticum possesses. The German Pharmacopoeia formerly directed an Extractum Graminis, by
digesting 1 part of Triticum with 6 parts of hot water, for six hours, straining, evaporating to a syrup, mixing 1 part of this extract with 4 parts of cold distilled water, filtering, and evaporating to an extract. The fluidextract is preferable, as the excessive use of heat is avoided.

Dose, from three to six fluidrachms (11.25-22.5 mils).

**FLUIDEXTRACTUM UVAE URSI. U. S.**

**FLUIDEXTRACT OF UVA URSI Fldext. Uvae Ursi**

Extrait liquide de Busserole, Fr.; Flussiges Barentraubenblatterextrakt, G.

"Uva Ursi, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process B, using a mixture of one hundred mils [or 3 fluidounces, 183 minims] of glycerin, three hundred mils [or 10 fluidounces, 69 minims] of alcohol and five hundred mils [or 16 fluid-ounces, 435 minims] of water as Menstruum I, and a mixture of one volume of alcohol and two volumes of water as Menstruum II. Reserve the first eight hundred mils [or 27 fluid-ounces, 24 minims] of percolate." U. S.

This preparation is a dense, black liquid, of a sweet, bitterish, astringent, but not very disagreeable taste.

Dose, from thirty minims to a fluidrachm (1.8-3.75 mils).

**FLUIDEXTRACTUM VERATRI VIRIDIS. U. S.**

**FLUIDEXTRACT OF VERATRUM VIRIDE**

Fldext. Verat. Vir. [Fluidextract of Green Hellebore]

Fluidextract of American Hellebore; Extrait liquide de Veratre americain, Fr.; Flussiges Grungermerextrakt, G.

"Veratrum Viride, in No. 40 powder, one thozisand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum." U.S.

This is the best preparation of veratrum and thoroughly represents the drug.
Dose, one to four minims (0.06-0.24 mil).

**FLUIDEXTRACTUM VIBURNI PRUNIFOLII. U. S. (Br.)**

**FLUIDEXTRACT OF VIBURNUM PRUNIFOLIUM**  
Fldext. Viburn. Prun. [Fluidextract of Black Haw]

Extractum Viburni Liquidum, Br.; Liquid Extract of Black Haw; Extrait liquide de Viburne, Fr.; Flussiges Viburnumextrakt, G.

"Viburnum Prunifolium, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of two volumes of alcohol and one volume of water as the menstruum." U. S.

"Black Haw, in No. 60 powder, 1000 grammes; Alcohol (70 per cent.), sufficient to produce 1000 millilitres. Exhaust the Black Haw with the Alcohol by the percolation process. Reserve the first eight hundred and fifty millilitres of the percolate; recover the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient of the Alcohol to produce the required volume." Br.

This is a fluidextract which well represents the drug. It is of a dark reddish-brown color.

Dose, from one-half to one fluidrachm (1.8— 3.75 mils).

**Off. Prep.**—Elixir Vibumi Prunifolii, N. F.

**FLUIDEXTRACTUM XANTHOXYLI. U. S.**

**FLUIDEXTRACT OF XANTHOXYLUM**  
Fldext. Xanthox. [Fluidextract of Prickly Ash]

Extrait liquide d'Ecorce de Clavalier, Fr.; Flussiges Zahnwehrindenextrakt, G.

"Xanthoxylum, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using a mixture of three volumes of alcohol and one volume of water as the menstruum." U. S.
This fluidextract thoroughly represents the virtues of the drug. (See Xanthoxylum.)

Dose, from one-half to one fluidrachm (1.8-3.75 mils).

**Off. Prep.**—Elixir Corydalis Compositum, N.F.

**FLUIDEXTRACTUM ZINGIBERIS. U. S.**

**FLUIDEXTRACT OF GINGER** Fldext. Zingib.

Extrait liquide de Gingembre, Fr.; Flussiges Ingwerextrakt, G.

"Jamaica Ginger, in No. 40 powder, one thousand grammes [or 35 ounces av., 120 grains]. Prepare a Fluidextract by Type Process A, using alcohol as the menstruum." U. S.

This fluidextract is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish color.

Dose, from five to twenty minims (0.3-1.3 mils).

**Off Prep.**—Syrupus Zingiberis, U. S.

**FOENICULUM. U. S. (Br.)**

**FENNEL** Foenic. [Fennel Seed]

"The dried, ripe fruit of cultivated varieties of Foeniculum vulgare Miller (Fam. Umbelliferae), without the presence or admixture of more than 4 per cent. of foreign matter." U. S." Fennel Fruit is the ripe fruit of Foeniculum vulgare, Mill., collected from cultivated plants, and dried." Br.

Foeniculi Fructus, Br.; Semen Foeniculi, Fennel Fruit (Seed), Sweet Fennel Fruit; Fenoil doux(Fruit), Fr. Cod.; Fruits (Semences) de Fenoil, Fr.; Fructus Foenicuii, P. G.; Fenchel, Fenchelsamen, G.; Finocchio, It.; Hinojo, Sp.

The plant producing fennel seed was attached by Linnaeus to the genus Anethum, but was separated from it by De Candolle, and placed, with three or four others, in a new genus styled Foeniculum, which has been
generally adopted by botanists. The Anethum Foeniculum of Linnaeus embraced two varieties, the common or wild fennel, and the sweet fennel, the latter being the plant usually cultivated in the gardens of Europe. These are considered by De Candolle as distinct species, and named respectively Foeniculum vulgare and Foeniculum dulce, but the correctness of the opinion of the great Swedish botanist is now generally admitted.

Foeniculum vulgare is a stout, glabrous biennial or perennial, aromatic herb, with leaves dissected into numerous filiform segments. The flowers are in large, flat, terminal umbels, with from thirteen to twenty rays, and destitute both of general and partial involucres. The corolla consists of five petals, which, as well as the stamens, are golden yellow. The fruit is ovate, and of a dark color, especially in the grooves. The plant is a native of Europe, growing wild upon sandy and chalky ground throughout the continent, and is also abundant in Asia, possibly extending as far as China. It is extensively cultivated in Europe as well as in this country. It has escaped from gardens and is somewhat naturalized in Maryland and Virginia. In India fennel is said to be obtained from F. panmorium DC., which is probably, however, only a variety of the official plant. Sicilian fennel is affirmed to be the fruit of F. piperitum.

F. dulce De Cand., Sweet Fennel bears a general resemblance to F. vulgare, but differs in having its stem somewhat compressed at the base, its radical leaves somewhat distichous, and the number of rays in the umbel only from 6 to 8. It is also a much smaller plant, being only about a foot high; its flowers appear earlier, and its young sweet shoots or turiones are eaten in Italy boiled or as a salad. According to Index Kewensis it is identical with F. vulgare.

**Properties.**—The roots of fennel were formerly employed in medicine, but are generally inferior in virtues to the fruit, which is now the only portion recognized by any of the pharmacopoeias. It is stated that manufacturers of the oil usually distil the whole plant.

The official description is as follows: "Mericarps usually separate, each being broadly elliptical, more or less curved, from 4 to 10 mm. in length and from 1 to 3.5 mm. in breadth, some having a slender stalk from 2 to 10 mm. in length; dorsal surface convex, yellowish-green to grayish-brown, with three prominent, longitudinal primary ribs and at the
summit a short, conical stylopodium; commissural surface with three narrow, light brown, longitudinal areas separated by two dark brown or brownish-black areas containing the vittae or oil-tubes; odor and taste aromatic and characteristic. Under the microscope, transverse sections of Fennel show a pentagonal mericarp, four of the edges being nearly equal and slightly concave, the other or commissural surface being much longer and more or less undulate; cells of the seed-coat closely united with those of the pericarp, giving the section two very distinct areas, the inner and larger portion (endosperm) more or less rounded-pentagonal and somewhat reniform, composed of polygonal cells, filled with aleurone grains containing rosette aggregates of calcium oxalate and a thin protoplasmic layer enclosing a fixed oil; the outer or pericarp layer distinguished by large elliptical vittae with thick, brown walls, occurring singly and alternating with the primary ribs, and two vittae on the dorsal surface, making usually six vittae in all, there sometimes being, however, one or two vittae additional; in the central portion of each of the ribs occurs a nearly circular, fibro-vascular bundle with a few tracheae and numerous thin-walled, strongly lignified sclerenchymatous fibers. The powder is yellowish-brown consisting of irregular angular fragments; tissues of endosperm, colorless, the cells filled with aleurone grains, each containing a rosette aggregate of calcium oxalate, about 0.002 mm. in diameter; fragments containing yellowish-brown vittae, from 0.1 to 0.2 mm. in width; sclerenchymatous fibers few, strongly lignified and with numerous, oblique, simple pores; parenchyma cells with more or less thick walls and simple pores and occasionally reticulately thickened; tracheae few and either spiral or annular; in mounts made with hydrated chloral T.S., numerous globules of a fixed oil separate. Fennel yields not more than 9 per cent. of ash." U. S.

Fennel seeds (half fruits) are officially described in the Br. Pharm. as follows:

"Small, oblong, straight or slightly curved, from three to ten millimetres long, and from two to four millimetres in diameter. Greenish or greenish-brown. Each of the two mericarps with five prominent principal ridges and six large vittae. Aromatic odor; taste strong, sweet and camphoraceous. Ash not more than 11 per cent." Br.

There are ten chief varieties of fennel known in commerce, the fruits differing very much in size and considerably in taste. They are as
follows: French (sweet); French (bitter); German; Puglis; Indian; Russian; Macedonian; Galician; Persian and Japanese. For histological differences of the different commercial varieties see monograph by Hartwich and J ama in B. P. G., 1909, p. 306. Rosenthaler (B. P. G., 1913, p. 570) has made a pharmacognostical study of a Chinese fennel.

Commercial fennel varies greatly in quality, this being either due to lack of care in harvesting or deliberate adulteration. It may contain sufficient sand, dirt, stem tissues, weed seeds, or other material beyond the 4 per cent. limit prescribed by the Pharmacopoeia that it amounts to adulteration. The fruits, especially the powder, may be deficient in volatile oil, inferring that they have been partly exhausted. Exhausted or otherwise inferior fennel is occasionally improved in appearance by the use of a factitious coloring. (See Spaeth, in Ph. Zentralh., 1908, p. 545; and 1913, p. 736.)

Schimmel & Co.'s Semi-Annual Report for April, 1897, gives as additional varieties of fennel—Aleppo, oil amounting to 0.75 per cent.; Macedonian, 3.4 to 3.8 per cent.; Moravian, 3 per cent.; Milanese, 4.2 per cent.; Roumanian, 4.6 per cent.; Spanish, amount not stated; and Syrian (Damascus), 1.6 per cent. Of these, the Syrian may be the same as that called Persian by Umney, and the Roumanian the same as that called Russian. Several additional varieties are also mentioned by Umney (P. J., 1897, lviii, p. 226), who states that the European varieties were almost entirely displaced by the East Indian seed and that the latter would probably be supplanted by the Japanese variety.

The odor of fennel seed is fragrant, its taste warm, sweet, and agreeably aromatic. It yields its virtues to hot water, but more freely to alcohol. The essential oil may be separated by distillation with water. (See Oleum Foeniculi.) From 960 parts of the seed Neumann obtained 20 parts of volatile and 120 of fixed oil.

Uses.—Fennel seed was used by the ancients. It is one of our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicine, particularly senna and rhubarb. It is recommended for these purposes by the absence of any highly excitant property. An infusion may be prepared by introducing two or three drachms of the seeds into a pint of boiling water. In infants the infusion is frequently employed as an enema for the expulsion of flatus.
Dose, of the bruised or powdered seeds, twenty grains to half a drachm (1.3-2.0 Gm.).

FRANGULA. U. S.

FRANGULA Frang. [Buckthorn Bark]

"The dried bark of Rhamnus Frangula Linne (Fam. Rhamnaceae)." U. S.

Rhamni Frangulae Cortex, Br. (1885); Frangula Bark; Alder Buckthorn; Ecorce de Bourdaine, Bourgene, Fr.; Cortex Frangulae, P. G.; Faulbaumrinde, G.; Corteccia di frangola. It.

R. Frangula or Alder Buckthorn is an erect glabrous shrub from ten to fifteen feet high, without thorns, with broadly ovate obtuse leaves, the margins being entire or slightly sinuate, the under side sometimes slightly downy, and the rather numerous lateral veins diverging equally almost from the whole length of the midrib. Flowers all hermaphrodite, two or three together in each axil, with the calyx teeth, petals, and stamens in fives. Fruit dark purple, the size of a pea. This plant grows in hedges and bushy places throughout Europe and Russian Asia, except in the far north. It has become established on Long Island, northern New Jersey and in Ontario.

It is probable that most of the species of the genus Rhamnus have cathartic properties. An article upon R. Purshiana will be found elsewhere, as it is official in both of the Pharmacopoeias. (See Cascara Sagrada.) The R. catharticus Linn., or common buckthorn, grows in Europe along with the official species, and has become locally naturalized in the Eastern portions of the United States. Its bark is probably often sold for the official article. It is distinguished by its more spreading, thorny habit, and its dioecious flowers, which are thickly clustered in the axils and have their parts in fours. The leaves also are more acute, have their margins finely serrate and their lateral veins mostly proceeding from the proximal half of the midrib. The fruit is
Properties.—This bark is officially described as "in quills varying in length, frequently flattened or crushed; from 0.5 to 1 mm. in thickness; outer surface grayish-brown or purplish-black, with numerous, prominent, lighter-colored, transverse lenticels and occasional patches of foliaceous lichens bearing small, blackish apothecia; inner surface smooth, dark brown with occasional purplish blotches, longitudinally striate, becoming red when moistened with solutions of the alkalies; fracture short, slightly fibrous in the inner layer; odor distinctive; taste slightly bitter. Under the microscope, transverse sections of Frangula show a distinctly undulate corky layer, composed of about 12 rows of reddish-brown cells; parenchyma cells of the primary cortex with numerous rosette aggregates of calcium oxalate, from 0.01 to 0.025 mm. in diameter; inner bark with bast-fibers in narrow, interrupted rows, the groups of fibers being separated radially by the medullary rays; bast-fibers with thick, strongly lignified, yellowish walls and narrow lumina and each group surrounded by a layer of crystal fibers, the prismatic crystals of calcium oxalate varying from 0.007 to 0.015 mm. in diameter; medullary rays one to two cells in width, occasionally three; cells of the parenchyma and medullary rays with numerous starch grains, 0.003 mm. in diameter. The powder is yellowish-brown; stone cells absent (distinguishing it from the powder of Cascara Sagrada). Add 0.1 Gm. of powdered Frangula to 10 mils of hot distilled water, shake the mixture occasionally until cold and filter; on the addition of a few drops of ammonia water, the filtrate is colored a deep red. Macerate 0.1 Gm. of powdered Frangula with 10 drops of alcohol, boil with 10 mils of distilled water and filter when cold. Shake this filtrate with 10 mils of ether; a yellow, ethereal solution separates, and 3 mils of this ethereal solution, when shaken with 3 mils of ammonia water, yields an alkaline solution, which, on being diluted with 20 mils of distilled water, still possesses a distinct cherry-red color. Frangula yields not more than 6 per cent. of ash." U. S.

As first pointed out by Schrenk (Am. Drug., April, 1887), the bark of Rhamnus Frangula can be distinguished from that of R. Purshiana (Cascara Sagrada) by the absence of the irregular angular selerenchymatous cells, which in R. Purshiana are wedged together in large compact groups, increasing in size and number towards the surface, and causing the short fracture of the outer bark.
Tschirch and Pool (S. W. P., 1908, p. 665) have made a comparative pharmacognostical and chemical study of the barks of R. Frangula and R. Purshiana. Wurffel (Zeit. Oest. Apoth. Ver., 1907, p. 211) and Mitlacher (Bull. sc. pharmacol., 1911, p. 10) report the substitution of Frangula by the bark of an alder (Alnus glutinosa Medic). The latter may be detected by not being reddened with solutions of the alkalies. Mitlacher (Ph. Post, 1905, p. 751) and Moser (A. J. P., 1909, p. 580) have found that the official Frangula is either admixed with or entirely substituted by the bark of R. carniolica A. Kerw. E'we (Proc. A. Ph. A., 1914, p. 131) obtained a sample of Frangula which proved to be wild-cherry bark.

It is not certainly known which of the several bodies isolated from frangula bark is the purgative principle. The most important body, frangulin, the rhamnoxanthin (C$_{20}$H$_{20}$O$_{10}$) of Bucner and Binswanger, may be obtained by Phipson's process by macerating the bark for three or four days in carbon disulphide, then permitting the liquid to evaporate, exhausting the residue with alcohol, which leaves the fatty matter behind, evaporating the alcoholic liquid to dryness, and recrystallizing from ether. As thus obtained it is in fine yellow crystals, melting at about 226° C. (438.8° F.), and subliming in golden-yellow needles. It is insoluble in water, soluble in 160 parts of warm 80 per cent. alcohol, nearly insoluble in cold alcohol, soluble in hot fixed oils, petroleum benzin, and oil of turpentine. It communicates its color to cotton, silk, and wool. Faust (A. Pharm., clxxxvii, 8) first proved the glucosidal character of frangulin by boiling it in alcoholic solution with hydrochloric acid, obtaining glucose and frangulinic acid, C$_{14}$H$_{8}$O$_{4}$. This forms fine microscopic needles of reddish color, fusing at 248° to 250° C. (478.4°-482° F.). Liebermann and Waldheim (Ber. d. Chem. Ges., 9, p. 1775) obtained in this decomposition instead of frangulinic acid, emodin, C$_{15}$H$_{10}$O$_{5}$, trioxymethylanthraquinone. Frangulinic acid, on the other hand, would be a dioxyanthraquinone and an isomer of alizarin. Schwabe, in 1888, also found that emodin and rhamnodulcute were the decomposition products of frangulin, to which latter he gave the formula C$_{21}$H$_{20}$O$_{9}$, instead of that given above by Buchner. (Planchon et Collin, Drogues Simples (1896), vol. ii, 590.) E. Amweg has devised a method of separating the glucosides from frangula, cas-cara and rhubarb by extraction with solvents; he uses, 1, benzene; 2, a mixture of two parts of benzene, and one part of absolute alcohol, and 3, alcohol (60 per cent.) (Ap. Ztg., 1897, 747.) Kubly isolated a crude acid
which, when purified, he termed frangulic acid; Amweg regards this acid as a decomposition product and calls it pseudo-frangulic acid. The emetic action of the green bark is attributed to a hydrolytic ferment, which is destroyed by heating. (P. J., 1898, 24.)

Tschirch and Bromberger state that the bark of Rhamnus cathartica was found to contain rhamnosterin, rhamnofluorin, emodin, chrysophanol and d-glucose. (S. W. P., 1912, v. 50, pp. 193-197.)

**Uses.**—In its fresh state this drug is very irritant to the gastrointestinal mucous membrane, producing, when taken in sufficient quantity, violent catharsis, accompanied by vomiting and much pain. During drying it is said to lose much of its irritant power, and the dried bark is affirmed to resemble rhubarb in its action. The U. S. P. VIII required that the bark should be at least one year old, but this requirement does not appear in the U. S. P. IX. A decoction (an ounce to the pint) may be used in tablespoonful doses, or a dessertspoonful of an elixir, made by mixing four fluidounces of the fluidextract with twelve of elixir of orange, may be employed.

Dose, of frangula, fifteen to thirty grains (1-2 Gm.).

**Off. Prep.**—Fluidextractum Frangulae, U. S.; Elixir Catharticum Compositum (from Fluidextract), N. F.; Syrupus Sennaa Compositus (from Fluidextract), N. F.

**Frankenia.** Frankenia grandifolia Cham. and Schlecht. Yerba Rezima. (Fam. Frankeniaceae.)—This herb, which grows in California, Nevada, Arizona and Northern Mexico, contains about 6 per cent. of tannin and is employed as a topical remedy in catarrhal affections, especially of the nose and genito-urinary tract; also internally in doses of from ten to twenty minims (0.6 to 1.3 mils) of the fluidextract. For local application the fluidextract may be diluted with from two to five times its volume of water.

**Frasera.** Radix Fraserae. Radix Colombo Americana; Racine de Colombo de Mariette (d' Amerique), Fr. Frazerawumel, Amerikanische Colombowurzel, G.—American Columbo is yielded by Frasera carolinensis Walt. (Fam. Gentianaceae), a perennial herb which nourishes in rich dry soil from New York and Wisconsin southward. The period of flowering is from May to July; but the stems and flowers are produced only in the third year, the radical leaves being the only part of the plant which previously appears above ground. From this manner of growth, it is inferred that the roots, which were formerly included in the Secondary List U. S. P., should be...
collected in the autumn of the second or the spring of the third year. Before being
dried, they should be cut into transverse slices.

As formerly in the market, frasera was in disc-like pieces resembling calumba, but
are easily distinguishable by the greater uniformity of their internal structure, the
absence of concentric and radiating lines, and their purer yellow color, without a
greenish tinge. The root sliced longitudinally, so as to imitate gentian, has been offered
in the market as American gentian. The taste of frasera is bitterish and sweetish.
Water and diluted alcohol extract its virtues, and the tincture precipitates upon the
addition of water, but is not affected by tincture of galls. The hot infusion is not
precipitated by solution of gelatin, and gives with iodine no signs of starch. These
reactions afford additional means of distinguishing the root from calumba. It contains
gum, pectin, glucose, wax, resin, fatty matter, yellow coloring matter, bitter
extractive, and an acid which is probably peculiar. (A. J. P., Jan., 1862, 23.)

Frasera is a feeble, simple bitter. Dose, of powder, one drachm (3.9 Gm.); of infusion
(1 fl. oz. to 1 pint boiling water), two fluidounces (60 mils) a day. The fresh root is said
to be emetic and cathartic.

Marina. Fucus (Varech) vesiculeux, Fr. Blasentang, Sætang, Meeriche, G. (Fam.
Fucaceae)— Fucus was retained in the National Formulary IV as "the dried thallus
of Fucus vesiculosus Linne (Fam. Fucaceae)." This is a common seaweed growing on the
rocks in the North Atlantic Ocean. " Sometimes a meter in length, but usually in
shorter pieces, from 1 to 4 cm. in width, dichotomously branched, brownish black,
usually with a slight, whitish incrustation; flat, smooth, entire-margined, having a
stout midrib throughout, along which are irregularly disposed pairs of air-vesicles
which vary in diameter from 5 to 15 mm.; receptacles terminal, compressed, mostly
ovate or elliptical and about 1 cm. in length, but varying from spherical and 5 mm. in
diameter to linear-lanceolate and 5 cm. in length, forked, solitary, or in pairs. Odor
strongly seaweed-like; taste saline and nauseous. Fucus yields not more than 20 per
cent. of ash." N. F. The plant grows upon the shores of Europe and of this continent,
attaching itself to the rocks by its expanded woody root. On the coasts of Scotland
and France it is much used in the preparations of kelp. It is also employed as a
manure, and is mixed with the fodder of cattle. It contains from 22 to 62 per cent.
of mucilage and a peculiar cellulose, and about 0.1 per cent. of a volatile oil; the ash
containing both iodine and bromine. Tollens and Kovoir state that 0.8 per cent. of a
sugar named fucose, C$_6$H$_{12}$O$_6$, exists in dried seaweed. Votocek and Potmesil obtained
from fucose an alcohol which they named fucitol. (B. P. G., 1913, 3653.) Convoy has
found in it 0.21 per cent. of iodine. (P. J., x, 434.) These ingredients remain in its
ashes, and in the charcoal resulting from its exposure to heat in close vessels. On the
coast of France about a dozen species of seaweed have been used in making kelp.
According to Eugene Marchand, Fucus vesiculosus is one of those poorest in iodine, the
different species of Laminaria containing far larger amounts of iodine than this
Fucaceae. (See P. J., 1884, 1011.) Laminaria digitata (L.) Lam. and L. stenophylla
contain ten times as much iodine as the Fuci, and are practically now the only kelps
used in making iodine. (See P. J., 1884, 1026.)

The charcoal derived from kelp was at one time used, under the name of Aethiops vegetabilis or vegetable ethiops, in the treatment of goitre and scrofulous swellings. The mucus contained in the vesicles was applied externally, with advantage, by Russell, as a resolvent in scrofulous tumors. Duehesne Duparc has obtained from it very good results in the treatment of morbid obesity. (J. P. C., 1862, 65.) A. T. Carson affirms, however, that the Fucus vesiculosus is largely used in Ireland for fattening pigs, and it is doubtful whether its preparations are capable of reducing human obesity unless given in such doses as to interfere with digestion and injure the health. A possible explanation of the action of bladderwrack in obesity, if it exercise any, is found in the experiments of Hunt and Seidell (J. P. Ex. T., 1910, ii, p. 15), who present evidence to show that the extract of this plant is a powerful stimulant to the thyroid gland. Dannecy prepares the extract from the plant, collected at the period of fructification and rapidly dried in the sun. The coarse powder he treats for three days, with four times its weight of alcohol of 86°, expresses at the end of this time, and subjects the residue twice successively to a similar treatment with alcohol of 54°. The tinctures are then mixed, the alcohol distilled off, and the remainder evaporated to the consistence of an extract. Of this extract, which is one-fifteenth of the plant, three pills, each containing 0.25 Gm. (3.75 grains), may be taken daily in the beginning, and increased gradually to twenty-four pills. (J. P. C., 1862, 434.) From the tincture a syrup may be prepared. Fluidextractum Fuci, N. F. IV is made with a menstrum of three volumes of alcohol and one volume of water from fucus in No. 30 powder.

Other species of Fucus are in all probability possessed of similar properties. Many of them contain a gelatinous matter and a sweet principle analogous to mannite, and some are used as food in times of scarcity. The varieties are classified by Fristedt as follows:

The Ceylon moss is a delicate fucus (Fucus amylaceus) growing on the coast of Ceylon. It abounds in starch and vegetable jelly, and is used like carrageen or Irish moss. (P. J., xiii, 355.) Sphaerococcus Helminthochorton (L.) Ag. (Fucus Helminthochorton L., Gigartina Helminthochorton Grev.) has some reputation in Europe as an anthelmintic and febrifuge. It is an ingredient in the mixture of marine plants sold in Europe under the name of Corsican moss or helminthochorton. This is used in decoction, from four to six drachms to the pint; dose, a wine-glassful three times a day. Large quantities of a seaweed, agar-agar, are gathered on the rocky coasts of the East India islands, and sent to China, where it is valued for making jellies and as a size for stiffening silks. (See Agar.)

Attention has been called by Sloan of Ayr, Scotland, to Laminaria digitata (L.) Lamx., (L. Cloustoni Edmonst.), commonly called sea-girdles or tangles, of Scotland, as supplying an admirable material for bougies. The stem is from two to twelve feet long and an inch or more in breadth, is of great strength and tenacity, with the property of drying readily, and, in doing so, of shrinking much, and acquiring an elastic firmness, with a consistence, if the desiccation be arrested at the proper point, somewhat softer than horn. In this state the plant may be kept for years, and is capable of absorbing moisture at any time and swelling to the original size, so that it
has been used for the making of dilating bougies and tents.

**Fumaria.** Fumaria officinalis L.  Fumitory. Beggary. Fumeterre, Fr. Erdrauch, Feldraute, G. (Fam. Fumariaceae)—A small annual European plant, naturalized in this country, growing in waste places, and flowering from May to August. It was formerly considerably employed as a medicine, and is still used in Europe. The leaves are the official part. They are inodorous, have a bitter, saline taste, and are very succulent, yielding by expression a juice which has the sensible and medicinal properties of the plant. An extract, prepared by evaporating the expressed juice or a decoction of the leaves, throws out upon its surface a copious saline efflorescence. Fumaric acid, \( C_4H_4O_4 \), was early identified as present, and its isomerism with maleic acid, the acid obtained from malic acid by heat, was established later. The alkaloid fumarine, which was observed by Peschier, has been believed by some chemists to be identical with corydaline, but according to Reichwald (P. J., xix, 990) its formula, \( C_{21}H_{19}C_4N \), is different from that of corydaline, from which it further differs in producing immediately an intense violet with concentrated sulphuric acid and an intense golden color with strong nitric acid. It occurs in colorless, tasteless crystals, freely soluble in chloroform, less so in benzene, still less so in alcohol and ether, sparingly soluble in water. He obtained it by treating the pulp of the leaves with concentrated acetic acid, with the aid of heat, filtering, evaporating the liquid, treating the extract with boiling alcohol, filtering the alcoholic solution, and, finally, decolorizing, and evaporating so that crystals might form. The acetate thus procured was decomposed by the alkalies and yielded the fumarine. (See Adermann, A. J. P., 1890, 396.) Fumitory has been considered gently tonic, alterative, and, in large doses, laxative and diuretic. Hannon has found fumarine, in the dose of about one-third or one-fourth of a grain (0.021-0.016 Gm.) to be moderately excitant; in that of three grains (0.2 Gm.) to be at first irritant and afterwards sedative. (Ann. Ther., 1854, 78.) Both in ancient and modern times fumitory has been esteemed a valuable remedy in visceral obstructions, particularly those of the liver, in scorbatic affections, and in various troublesome eruptive diseases. Cullen gave two fluidounces (60 mils) of the expressed juice twice a day. Others have prescribed it in much larger quantities. The leaves, either fresh or dried, may be used in decoction or extract, in almost indefinite dose. The inspissated juice has also been employed.

**Fustic.**—A yellow dye-wood, obtained from Chlorophora tinctoria (L.) Gaud. (Madder tinctoria D. Don.,) a tree of the Fam. Moraceae, growing in the West Indies and South America. It is not used in medicine or pharmacy. According to Bancroft, two different woods bear in England the name of fustic, one the product of the tree just mentioned, distinguished as old fustic, probably from the greater magnitude of the billeta in which it is imported; the other derived from the Rhus cotinus L., or Venicemachum, and called young fustic, or sometimes Hungarian fustic. The wood of *C. tinctoria* owes its coloring properties to two principles, which have been isolated by R. Wagner; one denominated morin, or morindon, \( C_{15}H_{10}O_6 \), and the other moritannic acid, \( C_{13}H_8O_6 \), from its resemblance to tannin. The former, when distilled with zinc dust, yields methylanthracene, whence the conclusion has been drawn that it is a trioxymethylanthraquinone, \( C_{15}H_7O_2(OH)_3 \). (See Chem. Gaz., ix, 1, 21, and 241.)
From the fustic of Rhus cotinus L. (fam. Anacardiaceae), or Hungarian fustic, Chevreul extracted a yellow coloring matter, in small crystalline needles when pure, which he called fisetin. J. Schmidt (Ber. d. Chem. Ges., 19, 1734-1749) has made a thorough study of fisetin, and prepared a number of derivatives of it. He states that it occurs in the wood as a tannic acid compound of the glucoaide of fisetin, which he calls fustin. This latter body crystallizes from hot water in fine silvery needles, easily soluble in alcohol and dilute alkalies, sparingly in ether. It melts at from 218°-219° C. (424.4°-426.2° F.) with decomposition. By warming with dilute H₂SO₄ it is split up into fisetin and a glucose (probably isodulcite). The fisetin has the formula C₁₅H₁₀O₆, and as it contains four hydroxyl groups, it is probably a tetroxymethylanthraquinone, C₁₅H₆O₂(OH)₄. It is obtained by recrystallization from dilute alcohol or acetic acid; it forms fine yellow needles or yellow prisms. It is very slightly soluble in hot water, easily soluble in alcohol and acetic ether, sparingly in ether and benzene.

The recent importations have been: 1914, 7121 tons, valued at $100,501; and for 1915, 12,354 tons, valued at $179,959.

It has long been known in the Southwest that the wood of the Osage orange tree, Maclura pomifera (Raf.) Schneider, contains a dyestuff that would give a more or less fast yellow color. An examination of the wood from Texas by Kressmann showed that it not only contains moric acid and morintannic acid, the same as fustic wood, but also that the dyeing principles are present in amount to be commercially valuable. A comparative series of dyeing experiments made with fustic and Osage orange wood and extracts showed the latter to be of equal value with fustic in regard to depth of colors produced, the amount of extract, the character of the dyeing, and fastness to light, weather, washing, etc. (Science, 1914, 37.)
The Dispensatory of the United States of America  
Twentieth Edition (1918)  
Edited by Joseph P. Remington, Horatio C. Woods and others.

[This was the last era in pharmacy when plant drugs were widely prepared, both for Regular School, Eclectic and Irregular physicians, and the Dispensatories were the major reference works used by pharmacists to prepare these products. Official plant drugs and preparations are in larger case, unofficial plant drugs and preparations are in smaller case. I have extracted all plant drugs and preparations, excluded non botanicals and those most reasonably used only by physicians...Opium, Digitalis, etc. Michael Moore]

**Galangal.** N. F. IV. Galanga. China Root. India Root. Galanga, Fr. East India Catarrh Root. Rhizoma Galangae, P. G. Galgant, G. —This is described in the National Formulary IV as "the dried rhizome of Alpinia officinarum Hance. (Fam. Zingiberaceae.)" Two varieties are described by authors, the Galanga major and Galanga minor, or large and small galangal. They are probably the roots of different plants. The large galangal is derived from Alpinia Galanga Willd. (MarantaGalanga L., Galanga officinalis Salisb.). According to H. F. Hance of Canton, the smaller galangal is the product of a distinct but closely allied plant, Alpinia officinarum Hance. (A. J. P., xliii, 408.) Both forms are brought from the East Indies. Galangal of the N. F. is described as "irregularly branched, from 2 to 10 cm. in length and from 1 to 2 cm. in thickness, the branches thinner toward the base; marked with the fine annuli of the leaf bases, which are from 3 to 10 mm. apart and of lighter color than the general surface; externally reddish- or rusty-brown; internally of a lighter orange-brown; cut ends of the branches circular, with recurved margin; fracture fibrous. Odor aromatic and agreeable; taste hot, spicy, resembling ginger. The powder is reddish-brown and, when examined under the microscope, exhibits numerous simple starch grains up to 0.06 mm. in diameter, the small grains few in number, the large grains narrow-clipsoidal, broadened at one end, sometimes truncate, frequently curved, occasionally with a lateral development, lamellae mostly indistinct, point of origin of growth circular or a deft in the larger end of the grain, sometimes absent; numerous yellowish oil cells and reddish resin cells; fragments of tracheae with reticulate thickenings or simple pores; thiek-walled sclerenchymatous fibers with oblique pores. Galangal yields not more than 10 per cent. of ash."  
N. F. According to Morin, galangal contains a volatile oil, an acrid resin, kaempferid, C_{16}H_{12}O_{6}, galangin, C_{15}H_{10}O_{5}, alpinin, C_{17}H_{12}O_{6}, and galangol, with an unknown gummy substance and lignin. A. Vogel, J r., found also starch and fixed oil. (Ph. Cb., 1844, 158.) The active principles are the volatile oil and acrid resin. Galangal is a stimulant aromatic. It was known to the ancient Greeks and Arabsians, and formerly entered into numerous compounds. (A. J. P., xliii.) Dose, from fifteen to thirty grains (1.0-2.0 Gm.) in substance, and twice as much in infusion.

1898. This gum resin was not admitted to the British Pharmacopoeia, 1914. It was also formerly official in the U. S. Pharmacopoeia, but was dropped in the 1890 revision. There has been some confusion as to the plant yielding galbanum. It is fairly well established now through the studies of the German traveller, F. A. Buhse, that it is a species of Ferula. He stated that in 1848 he met with the galbanum plant on the declivities of the Demavend, near the southern coast of the Caspian. He saw the gum-resin exuding spontaneously from the plant, and was informed by the natives that the drug was collected from it. The plant is the F. galbaniflua Bossier and Buhse. Buhse also stated that the Persian galbanum is yielded by a second plant, which is doubtfully distant from F. galbaniflua, the F. rubricaulis Boissier. Schumann considers this identical with F. galbaniflua. Holmes is of the opinion (P. J., 1891, 194) that "Levant" galbanum is yielded by Ferula galbaniflua, and its variety ß-Ancheri; that solid "Persian" comes possibly from F. Schair Borscz, while the liquid "Persian," judging from the fruits found in it, derived from an undescribed species allied to F. galbaniflua. It would appear that all the varieties of galbanum of commerce come through Persia. Galbanum is said to be obtained by making incisions into the stem, or cutting it off a short distance above the root. A cream-colored juice exudes, which concretes upon exposure to the air. A portion of juice also exudes spontaneously from the joints, and hardens in the shape of tears.

Galbanum usually appears in the form of masses composed of whitish, reddish, or yellowish tears, from the size of a pin's head to that of a pea and larger, irregularly agglutinated by a darker colored yellowish-brown or greenish substance, more or less translucent, and generally mixed with pieces of stems, seeds, or other foreign matters. It is also found, though rarely, in our markets, in the state of distinct roundish tears, about as large as a pea, of a yellowish-white or pale brownish-yellow color, shining externally as if varnished, translucent, and often adhering together. Galbanum has in cool weather the consistence of firm wax, but softens in summer, and by the heat of the hand is rendered ductile and adhesive. At 180° C. (212° F.) it is sufficiently liquid to admit of straining, and it generally requires to be strained before it can be used. It is of a dark-brown or blackish color, and of a soft consistence. The absence of whitish grains, a deficiency in the characteristic odor and taste, and the intermixture of earthly impurities are signs of inferiority. According to Hirschsohm (Ph. Z. R., 1893, 353), galbanum of commerce differs from that formerly found in the market; its consistence is now like that of white turpentine, although the odor is still that of Levant galbanum; the greatest difference is shown in the action of strong acids and solvents on it. (See A. J. P., 1893, 384.)

The odor of galbanum is peculiar and disagreeable; its taste bitterish, warm, and acrid; its sp. gr. 1.212. Triturated with water, it forms an imperfect milky solution, which on standing deposits the greater portion of what was taken up. Wine and vinegar act upon it in a similar manner. Alcohol dissolves a considerable proportion, forming a yellow tincture, which has the odor and taste of galbanum, and becomes milky with water, but affords no precipitate. In diluted alcohol it is wholly soluble, with the exception of impurities, Ether dissolves the greater portion. "When moistened with alcohol, galbanum acquires a purple color on the addition of a little hydrochloric acid." U. S., 1880. According to Conrady, the composition of galbanum is as follows: ethereal oil, 9.5 per cent.; resin, soluble in alcohol, 63.5 per cent.; gum and impurities,
27 per cent. The purified resin was found by Conrady to contain about 20 per cent. of combined umbelliferone, about 0.23 per cent. of free umbelliferone, and about 50 per cent. of galbaresino-tannol. This latter representative of the class of resino-tannols, first established by Tschirch, was proved to have the alcohol character by forming the acetyl and benzoyl derivatives. Conrady also considers that the umbelliferone is combined with this galbaresino-tannol in the form of an ester. The volatile oil which is obtained from galbanum to the extent of about 10 per cent. he found to consist essentially of a hydrocarbon of the formula $C_{10}H_{16}$ with small amounts of a sesquiterpene, $C_{15}H_{24}$. The terpene has been identified as d-pinene by the terpin hydrate formation, while the sesquiterpene, according to Wallach, is cadinene, identified by the formation of its chlorhydrate fusing at 117° to 118° C. (242.6° to 244.4° F.). (Gildemeister and Hoffman, Aetherische Öle, p. 753.) When the oil is extracted by solvents it is free from acid reaction, but when distilled with steam it acquires an acid reaction, and notable quantities of iso-valeric acid are developed. These fatty acids are probably bound up as esters in the cold extracted oil. (A. Pharm., ccxxxii (1894), 98.) The crude oil is dextrogyrate. The resin, constituting about 60 per cent., is very soft, and dissolves in ether or in alkaline liquids, even in milk of lime, but only partially in carbon disulphide. When heated with hydrochloric acid for some time, it yields umbelliferone, $C_9H_6O_3$, which may be dissolved from the acid liquid by means of ether or chloroform, and obtained on evaporation in colorless acicular crystals. The aqueous solution of umbelliferone exhibits, especially on addition of an alkali, a brilliant blue fluorescence, which is destroyed by an acid. If a small fragment of galbanum be immersed in water, a fluorescence will be produced by a drop of ammonia. Asafetida shows the same reaction, but ammoniac does not.

Galbanum submitted to dry distillation yields a thick oil of brilliant blue color. This oil on rectification yields a greenish portion, and then a superb blue oil. Kachler (Ber. d. Chem. Ges., 1871, p. 36) found a colorless oil, $C_{10}H_{16}$, and a blue oil, $C_{10}H_{16}O$, boiling at 289° C. (552.2° F.). The blue oil, according to Kachler, after purification, agrees with the blue oil of the flowers of Matricaria Chamomilla. By fusing galbanum resin with potassium hydroxide, Hiasiwetz and Barth (Ann. Ch. Ph., 130, p. 354) obtained resorcinol, together with acetic and volatile fatty acids.

According to Ludewig, a gum-resin, designated as Persian galbanum, is received in Russia by the way of Astrakhan or Orenburg, and is the kind used in that country. It comes enclosed in skins, and is in masses of a reddish-brown color with whitish streaks, of a disagreeable odor, somewhat like that of asafetida, and of an unpleasant bitter, resinous taste. It is so soft as to melt with a slight elevation of temperature. It differs from common galbanum in its odor, in its color, which is never greenish, and in the absence of tears, and is probably derived from a different plant. It abounds in impurities. This variety of galbanum is probably the same as that obtained by Aitchison in Afghanistan, which on chemical examination yielded—volatile oil, 3.108 per cent.; resin (ether extractive, 61.2, alcohol extractive, 7.576), 68.776; water extractive (gum), 17.028; insoluble matter, 1056. (P. J., Dec. 11, 1886.)

Galbanum was known to the ancients. It is stimulant, expectorant, and antispasmodic, and is considered as intermediate in power between ammoniac and...
asafetida. It has chiefly been used in chronic affections of the bronchial mucous membrane, amenorrhea, and chronic rheumatism. It is occasionally applied externally as a plaster to indolent swellings, with the view of promoting resolution or suppuration.

Compound pills of galbanum were official in the British Pharmacopoeia, 1898, under the name of Pilula Galbani Composita, the former name was Pilula Asafoetida Composita and the pills consisted of equal parts of galbanum, asafetida and myrrh, syrup of glucose being used as excipient.

Dose from ten to twenty grains (0.65 to 1.3 Gm.), given in pill, or triturated with gum araoic, sugar and water, so as to form an emulsion.

Under the name of Zolou root there appears in the Bayrout markets the root of the Ferula Hermonii Boiss. This contains, according to Guiges (P. J., 1906, p. 65) a resin which differs from Galbanum in that it gives with hydrochloric acid a green color, which disappears on heating. It is used by the people of that section as an aphrodisiac.

**Galega.** N. F. IV. European Goat's Rue. Goat's Rue. Herba Rutas Caprarice. Rue de Chevre, Fr. Geisraute, Pestilenskraut, G.—Galega was made official in National Formulary IV and thus defined: "The dried flowering tops of Galega officinalis Linne (Fam. Leguminosae)." This is a perennial leguminous herb, growing in the south of Europe, and sometimes cultivated in gardens. It is without odor unless bruised, when it emits a disagreeable odor. The N. F. describes it as follows: "Stem smooth, erect, branched, when entire from 15 to 45 cm. in length, commonly cut and broken; leaves oddly-pinnate with from six to eight pairs of leaflets; stipules lanceolate, sagitate on one side; leaflets bright green, smooth or slightly hairy, short petioled, lanceolate or ovate-lanceolate, obtuse, slightly mucronate, from 2 to 5 cm. in length and from 2 to 6 mm. in breadth; flowers small, white to violet, in axillary racemes. Odor indistinct, taste mucilaginous, slightly bitter and astringent; it colors the saliva yellowish-green. Galega yields not more than 12 per cent. of ash." N. F. It contains a bitter principle and tannin. In former times it was much employed in malignant fevers, the plague, the bites of serpents, worms, etc. In 1873 Gillet-Damitte, in a communication to the French Academy, stated that this plant when fed to cows would increase the secretion of milk from 35 to 50 per cent.; since which time Cerisoli, Goubeaux, Mas son d'Aury, Millbank, and Carron de la Carriere have affirmed that goat's rue is a powerful galactagogue. The best preparation appears to be an aqueous extract prepared from the fresh plant. This almost black extract has a pronounced odor, and may be given in doses of from eight to fifteen grains (0.5-1.0 Gm.), from three to five times a day.

Fluidextract of Galega is official in the National Formulary IV. It is made with a menstruum of diluted alcohol. Dose, sixty minims (3.75 mils). The root of the indigenous Tephrosia virginiana, (L.) Pers. (Galega virginiana L.) is said to be diaphoretic and powerfully anthelmintic. It is given in decoction.
Galium. Galium Aparine L. Cleavers. Goose-grass. Grateron, Rieble, Fr. Klébkraut, G.—This is an annual, succulent, rubiaceous plant, common to Europe and the United States, growing along the seashore and much in shaded ground inland. It is inodorous, and has a bitterish, herbaceous, somewhat acrid taste. Analyzed by Schwartz, it was found, besides chlorophyll, starch, and other principles common to all plants, to contain three distinct acids—viz., a variety of tannic acid, which he names galitannic acid, citric acid, and a peculiar acid, previously discovered by Schwartz and Eochleder, and named ribichloric acid, \( C_{14}H_8O_9 \). (P. J., xii, 190.) The expressed juice is said to be aperient, diuretic, and antiscorbutic, and has been used in dropsy, congestion of the spleen, scrofula, scorbutic eruptions, and lepra. Orwin (T. G., vol. i, 767) commends it highly in psoriasis. Three ounces (90 mils) may be given twice a day.

Galium verum L. Yellow Ladies' Bedstraw. Cheese Rennet. Caille-lait jaune, Fr. Meger-kraut, Liebfrauenstroh, G.—This European Galium (fam. Rubiaceae) is inodorous, but has an astringent, acidulous, bitterish taste. The bruised plant is sometimes used to color cheese yellow, being introduced into milk before coagulation. It is also used for dyeing yellow. The roots of this and of most other species dye red, and the plant, eaten by animals, colors the bones like madder. Schwartz found the same principles in it as in G. Aparine. It was formerly highly esteemed as a remedy in epilepsy and hysteria, and was applied externally in cutaneous eruptions, in the form either of the recently expressed juice or of a decoction from the fresh plant. Of the American species, G. tinctorium L. is closely allied in properties to G. verum. It is said to be useful in cutaneous diseases, and the root is employed by the Indians for staining their feathers and other ornaments red. G. triflorum Michx. contains coumarin, as pointed out by L. von Cotzhausen. (A. J. P., 1876, 405.)

GALLA. U. S., Br.

NUTGALL Gall. [Aleppo Galls, Smyrna Galls]

"Excrescences on the young twigs of Quercus infectoria Olivier and other allied species of Quercus (Fam. Fagaceæ), induced by the punctures on the leaf-buds and by the deposited ova of Cynips tinctoria Hartig (Order Hymenopterae). Not more than 5 per cent. of Galls float in water." U. S. "Galls are excrescences on Quercus infectoria, Olivier, resulting from the deposition of the eggs of Cynips gallae tinctoriae, Olivier." Br.

Galls, Syrian Galls; Galla Halepensis, s. Turcica, s. Le-antica, s. Tintoria, s. Quercina; Galle de Chene, d'Alep, Fr. Cod.; Noix de Galle, Fr.; Gallae, P. G.; Gallapfel, Gallen, G.; Noce di galla, It.; Agalla, Sp.

Many plants, when pierced by certain insects, particularly those of the genus Cynips, are affected at the points of puncture with a morbid
action, resulting in excrescences, which, as they are derived from the
juices of the plant, partake more or less of its chemical character. Most of
the oaks are occasionally thus affected, and the resulting excrescences,
having in a high degree the astringency of the plant, have been
employed for various practical purposes. They are known by the name
of galls, a term which, as well as their use in medicine, has been handed
down from the ancients. Quercus infectoria, Q. aegilops, Q. excelsa, Q.
Ilex, Q. Cerris, and Q. Robur have been particularized as affording this
product; but it is now generally admitted, on the authority of Olivier,
that the official galls are derived chiefly, if not exclusively, from Q.
infectoria. Under the name of Chinese galls, a product has been
brought from China, supposed to be caused by an insect allied to the
aphis, as such an insect has been found in the interior of them. They
are irregularly spindle-shaped, often more or less bent, with obtusely
pointed protuberances, about two inches long by an inch in diameter at
the central thickest part, of an ash color and a soft velvety feel, very
light, hollow, with translucent walls about a line in thickness, of a slight
odor recalling that of ipecac, and a bitter astringent taste. From an
examination of fragments of leaves and petioles found among these
galls, Schenck concluded that the tree on which they are found is a
species of Rhus; but according to Decaisne, their true source is probably
the Distylium racemosum of Zuccarini, a large tree of Japan, the leaves
of which produce a velvety gall, resembling the one in question.
(Guibourt, Hist. Nat. des Drogues, 1850, iii, 703.) Daniel Hanbury
asserts that this opinion of Decaisne is erroneous (P. J., Feb., 1862, p.
421), as in his examination of the packages imported from China and
Japan he has found remains of different parts of a species of Rhus, but
never any of a Distylium. Besides, the form of the galls of the
Distylium, as figured by Siebold and Zuecarini, is entirely different. The
species of Rhus which yields the commercial Chinese galls is the R.
semialata Murray. The Chinese make great use of this product both in
dyeing and as a medicine. L. A. Buchner, Jr., has found it to contain 65
per cent. of tannic acid identical with that of the official galls. (Ph. Cb.,
July, 1851, p. 526.) It is recommended by Stenhouse for the
manufacture of gallic acid, being preferable for this purpose to the
official galls, in consequence of its less amount of coloring matter. (P. J.,
Dec., 1862.) An inferior kind of galls is produced in great quantities in
England, by the attack of the Cynips kollari of Hartig, upon the
common English oak; but they have been ascertained to contain little
tannic acid, and are of little value.
Quercus infectoria, or the so-called dyer's oak, is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are petiolate, obtusely toothed, smooth and of a bright-green color on both sides. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy, and scaly. This species of Quercus grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. M. Kinnier found it also in Armenia and Kurdistan; Hardwicke observed it growing in the neighborhood of Adwanie, and it probably pervades the middle latitudes of Asia.

The gall originates from the puncture of the Cynips tinctoria Hartig, a hymenopterous insect or fly, with a fawn-colored body, dark antennae, and the upper part of its abdomen shining brown. The insect pierces the shoots and young boughs, and deposits its egg in the wound. This irritates the part, and a small tumor quickly rises, which is the result of a morbid growth, exhibiting various cells under the microscope, but no proper vegetable fiber. The egg grows with the gall, and is soon converted into a larva, which feeds upon the vegetable matter around it, and thus form a cavity in the center of the excrescence. The insect at length becomes a fly, and escapes by eating its way out. The galls are in perfection when fully developed, before the egg has been hatched or the fly has escaped. Collected at this period, they are called, from their dark color, blue, green, or black galls, and are most highly esteemed. Those which are gathered later and have been injured by the insect are white galls. They are usually larger, less heavy and compact, and of a lighter color than the former.

The galls collected in Syria and Asia Minor are brought to this country chiefly from the ports of Smyrna and Trieste, or from London. As they are produced abundantly near Aleppo, it has been customary to designate them by the name of that town, though the designation, however correct it may formerly have been, is now wholly inapplicable, as they are obtained from many other places, and the product of different parts of Asiatic Turkey is not capable of being discriminated, at least in our markets. Great quantities of galls, very closely resembling those from the Mediterranean, have been brought to the United States from Calcutta. Royle states that they are taken to Bombay from Bussorah through the Persian Gulf. "We are, nevertheless, informed that galls are among the products of Moultau. Those of France and other southern countries of Europe have a smooth, shining reddish
surface, are little esteemed, on account of their small yield of tannin, and are seldom brought to the United States.

Properties.—Galls are "nearly globular, from 0.8 to 2.2 cm. in diameter; externally blackish-olive-green or blackish-gray, more or less tuberculated on the upper portion, the basal portion being nearly smooth and contracted into a short stalk; heavy, sinking in water, excepting the smaller galls; fracture short-horny; internally grayish or dark brown, consisting of a central portion slightly radiating and resinous, occasionally hollow and traversed by a narrow radial canal extending to the exterior as shown by the perforation in the whole gall; odor slight; taste strongly astringent. The powder consists of numerous fragments of thick-walled starch-bearing parenchyma; starch grains numerous; more or less free in the powder and varying in shape from spherical or ellipsoidal to polygonal, and from 0.005 to 0.03 mm. in diameter; stone-cells few, resembling those found in fruits and seeds, varying considerably in shape and size, and from 0.025 to 0.3 mm. in length; occasional fragments with spiral or reticulate tracheae; fragments mounted in dilute ferric chloride T.S. assume a deep blue or greenish-blue color. Macerate 0.5 Gm. of the powdered Nutgall with 2 mils of alcohol for a few minutes, add 500 mils of water, stir the mixture well for five minutes and filter. Take 1 mil of the light yellowish-brown solution, and dilute it with 10 mils of water; it shows a distinct blue or violet-blue color upon the addition of a drop of ferric chloride T.S." U. S.

"Hard, heavy, subglobular, from twelve to eighteen millimetres or more in diameter, tuberculated on the surface, the tubercles and intervening spaces being smooth; dark bluish-green or dark olive-green externally, yellowish or brownish-white within, with a small central cavity. Galls sink in water and exhibit no perforation. No odor; taste intensely astringent." Br.

The best are externally of a dark bluish or lead color, sometimes with a greenish tinge, internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the centre, indicating the presence of the undeveloped or decayed insect. Their powder is of a light yellowish-gray. Those of inferior quality are of a lighter color, sometimes reddish or nearly white, of a loose texture, with a large cavity in the centre, communicating externally by a small hole through which the fly has escaped.
Kraemer (Bot. Gaz., 1900, p. 275) made a microchemical study of American galls. These closely resemble the Aleppo variety and are formed on Quercus coccinea Muench and Q. imbricaria, Michx. by Cynips aciculata. Kraemer found the chemical constituents to vary with the development of the insects. At the chrysalis stage gallic acid is more abundant than when the winged insect is developed. Texas galls are formed on the live oak (Q. virens), California oak balls are formed on Q. lobata.

Galls are formed on a number of trees and shrubs, including oaks, rhus, rhododendron, juniper, eucalyptus and sage. Hartwich (Arch. d. Pharm., 1905, p. 584) illustrates these several varieties and discusses their composition. Richter gives minute descriptions of the origin, structural characteristics and microscopical appearance of galls in Ph. Zentralh., 1912, p. 533. Feist and Haun have published (A. Pharm., 1913, v. 251, p. 468) an article on the constitution of the tannin in Turkish and Chinese galls.

Galls have a bitter, very astringent taste, and when whole are inodorous or nearly so, but bruised or in powder they have a decided and peculiar though not very strong odor. The tannin of galls, usually known as gallo-tannic acid, appears to exist in the galls, in part at least, as a glucoside, but one very easily broken up by ferments like pectase into glucose and di-gallic acid, C_{14}H_{10}O_{9}, which is the material, therefore, extracted from the galls. This di-gallic acid may be considered as the anhydride of gallic acid, C_{7}H_{6}O_{5}, formed from two molecules of this latter by the elimination of one molecule of water. Commercial tannin yields from 0 to 22 per cent. of glucose, showing the presence of varying amounts of the unaltered glucoside. Galls yield, on an average, from 65 to 77 per cent. of tannin. All the soluble matter of galls is taken up by forty times their weight of boiling water, and the residue is tasteless. Alcohol dissolves seven parts in ten, ether five parts. A saturated decoction deposits upon cooling a copious pale-yellow precipitate. The infusion or tincture affords precipitates with sulphuric and hydrochloric acids, lime water, and ammonium and potassium carbonates, with solutions of lead acetate and subacetate, copper and iron sulphates, silver and mercuric nitrates, and potassio-anti-monyl tartrate; with solution of gelatin; and with the infusions of Peruvian bark, calumba, opium, and many other vegetables, especially those containing alkaloids, with most of which
Tannic acid forms insoluble compounds. The infusion of galls reddens litmus paper, is rendered orange by nitric acid, milky by mercuric chloride, and has its color deepened by ammonia, but yields no precipitate with either of these reagents. Zinc sulphate was said by A. T. Thomson to slowly occasion a precipitate, but this result was not obtained by Dun-can. Infusion of galls is rendered more permanent by the addition of 10 per cent. of glycerin.

A variety of galls was imported into Germany, which was said to be derived from Central Asia, especially from the provinces of Khokan, Khiva, and Bokhara, where they are used in dyeing. They are of various forms, some being long, others round, cylindrical, or angular, and sometimes they are grouped upon a single stalk, and covered with little elevations. They differ from all other galls by their color, being on one side yellow, and on the other of a fine red. Most of them present a little opening, and in the interior are eggs and larvae of a peculiar species of aphids. They have yielded, on analysis, 43.10 per cent. of tannin, 3.03 of a green wax, 16 of cellulose, and an undetermined quantity of fecula and volatile oil. (R. Palne, J. P. C., April, 1873.)

From the so-called gall-wax of certain kinds of galls, M. Nierenstein obtained a nitrogenous constituent, C_{13}H_{17}O_{6}N, which is probably a laevorotatory galloleucin. (Z. Phys. Ch., 92, 53.)

**Uses.**—Galls have a powerfully astringent action, but are no longer prescribed internally. Aromatic Syrup of Galls is sometimes prescribed. For a process, see U. S. Dispensatory, 19th ed., p. 574. Nutgalls may be used externally for the same purposes as tannic acid.

Dose, five to fifteen grains (0.3-0.9 Gm.).

**GAMBIR. U. S.**

**GAMBIR [Pale Catechu] [To replace Catechu, U. S. 1890]**

"A dried extract prepared from decoctions of the leaves and twigs of Ourouparia Gambir (Hunter) Baillon (Fam. Rubiaceae)." U. S. (See Catechu and Catechu Nigrum.)
Ourouparia Gambir (Hunter) Baillon (Uncaria Gambier Roxb.) This is a climbing shrub with slender stems somewhat thickened at the nodes; leaves ovate or oblong, entire, rounded at the base but abruptly attenuated at the summit, opposite and stipulated, smooth on both sides. The flowers are small, crowded into a dense globular head on a hairy receptacle; the flower heads are borne on long axillary peduncles which bear in the middle a whorl of bracts. At the point where these bracts occur the peduncle breaks after the falling of the inflorescence and the remainder of the peduncle becomes elongated and curved into hooks by means of which the plant climbs. Corolla gamopetalous, trumpet-shaped, tube slender; fruit one inch long, pericarp dry, dehiscing vertically into two valves; seeds very numerous.

It is a native of Malacca, Sumatra, Cochin-China, and other parts of Eastern Asia, and is largely cultivated in the islands of Bintang, Singapore, and Prince of Wales. The gambir is prepared by lopping off the leaves, shoots, and twigs of the plant, chopping them into pieces, and throwing them into an iron pot filled with boiling water. When the leaves are exhausted and the liquid sufficiently thick, it is poured into small wooden tubs, and so soon as sufficiently cool, a half-closed hand is plunged into the semi-fluid mass and a piece of light wood shaped like an elongated dice box rapidly worked up and down in the hollow formed by the hand. The extract begins to thicken by a process which is compared to crystallization. The mass is finally turned out, and cut into cubes, which are put upon trays and smoke-dried. (See also P. J., 1892, 1003.) This extract, which is known by the native Malays as pinang or siren was first brought to the attention of the profession by Campbell.

The amount of gambir exported from the Straits Settlements in 1910 amounted to 40,000,-000 pounds, of which about 15,000,000 pounds was shipped to the United States.

Most of the commercial article is shipped from Singapore to London and Hamburg. The natives of Malay distinguish four different kinds: 1. Gambir bulat or round Gambir, which occurs in biscuit-like pieces and is mostly used for chewing. 2. Gambir papan or table Gambir which occurs in yellowish-brown thin tablets and is also used in chewing. 3.
Gambir paku (nail or finger Gambir) which occurs in long black sticks resembling licorice extract. 4. Gambir dutoor or cube Gambir. The latter is the form in which it is usually found in commerce. Gambir is also imported in large blocks, being used in this form for dyeing and tanning.

Properties.—Gambir is "usually in cubical or rectangular pieces from 20 to 30 mm. in diameter; externally pale grayish-brown to reddish-brown, more or less dull and porous; friable; internally of a light brown or dull earthy color; inodorous; taste bitterish and very astringent. Upon scraping a piece of Gambir and mounting the separated fragments in hydrated chloral T.S. and examining them under the microscope, numerous acicular crystals, from 0.01 to 0.03 mm. in length, separate at the edges of the fragments and gradually dissolve, leaving a few, thick-walled, non-glandular hairs which, when entire, may be 0.35 mm. in length; a few fragments of leaves may also be present showing either epidermal cells or small narrow trachea? with spiral or annular markings; a few starch grains either single or compound, of variable shapes and from 0.005 to 0.015 mm. in diameter; a number of bacteria may also be present. Macerate 1 Gm. of Gambir with 50 mils of water, and filter; the pale yellowish-brown solution obtained gives an intense, green color with dilute ferric chloride T.S.; but yields no precipitate with copper sulphate T.S. Not less than 65 per cent. of Gambir is soluble in water and not less than 60 per cent. is soluble in alcohol. Gambir yields not more than 9 per cent. of ash." U. S.

The microscopical appearance of gambir is very characteristic and Brumwell (J. S. C. Ind., 1911, p. 475) illustrates the appearance of commercial specimens. Gambir is light and porous, so that it floats when thrown in water. It is partially soluble in cold water, and almost wholly so in boiling water, which deposits a portion upon cooling. Duhamel, Ecky, and Procter dissolved 87.5 per cent. of it in cold water by means of percolation. (A. J. P., xvi, 166.) Nees von Esenbeck found it to consist of from 36 to 40 per cent. of catechutannic acid, a peculiar principle called catechuh, catechin, or catechuic acid, gum or gummy extractive, a deposit like cinchonic red, and 2.5 per cent. of lignin. Catechin, when perfectly pure, is snow-white, of a silky appearance, crystallizable in fine needles, melting at 217° C. (422.6° F.), unalterable in the air if dry, fusible by heat, very slightly soluble in cold water, with which it softens and swells up, soluble in boiling water, which deposits it on cooling, and soluble also in alcohol and ether. It very slightly reddens litmus paper,
and, though coloring solution of chloride of iron green, and producing with it a grayish-green precipitate, differs from tannic acid in not affecting a solution of gelatin. The very great discordance of different authors as to its formula seems to be explained by some experiments of Etti (Ann. Ch. Ph., 186, p. 327), who showed that catechin, \( C_{19}H_{18}O_{8} \), readily gives at 100° C. (212° F.), or even when kept for some time over sulphuric acid, an anhydride, \( C_{38}H_{34}O_{15} \), and at 160° C. (320° F.) a second anhydride, \( C_{38}H_{32}O_{14} \), which, mixed in varying proportions, explain the varying results. Gautier (Bull. Soc. Chim., 30, 567) finds three different catechins separable by their different solubility in water, all of them crystallizable. These are: a-catechin, \( C_{40}H_{38}O_{18} + 2H_2O \), melting at from 204° to 205° C. (399.2°-401° F.), and present in gambir to the amount of 12 per cent.; b-catechin, \( C_{47}H_{38}O_{16} + H_2O \), melting at from 176° to 177° C. (348.8°-350.6° F.), and 2 per cent. present in gambir; and c-catechin, \( C_{40}H_{38}O_{16} + H_2O \), melting at 163° C. (325.4° F.), and present in gambir to the amount of 6.5 per cent.

Perkin and Yoshitako (P. J., 1902, p. 530) have made an elaborate investigation of gambir and acacia catechus. They find three catechins, designated respectively as (a), (b), and (c). Catechin (b), \( C_{15}H_{14}O_{6} + 4H_2O \), occurs in air dried, colorless needles, melting at 175° to 177° C. (347°-350.6° F.), and gives on fusion with alkali, phloroglucinol, protocatechuic acid, and an acid resembling acetic acid. Catechin (c), \( C_{16}H_{14}O_{6} \), air dried, contains no water of crystallization and forms colorless prisms, melting at 235° to 237° C. (455°-458.6° F.). Catechin (a), \( C_{14}H_{14}O_{6} + 3H_2O \) (or less probably \( C_{14}H_{14}O_{6} + 3H_2O \)), air dried, forms colorless needles, melting at 204° to 205° C. (399.2°-401° F.).

Good gambir should occur in a hard compact mass, breaking up, "when the adhering mat is removed, into distinct cubes of a brownish-black color externally, and a deep mahogany-red with an occasional streak of yellow internally. It should not steam when the mat is opened. From this quality it grades down to a stuff which has been prepared by mixing the material obtained by reboiling the exhausted leaves with various mixtures. This lowest grade is not in cubes, steams when opened, frequently shows large patches of black or dirty blue color, and often has a sour fetid odor; its color varies from black to light-brown.

The varieties between the two extremes are very great; sometimes...
gambir occurs in solid mass of fair quality; sometimes the cubes are of extraordinary size, and of a color varying from a dirty white to a very pale yellow. At the Edinburgh Forestry Exhibition in 1885 the Maharajah of Johore exhibited specimens labelled "gambir produced in Johore." The first quality, which was "makan" (for eating), was in regular cubes, externally cassia-brown color, internally pale cinnamon brown, and yielded 32 per cent. of tannic acid; the second quality was in badly formed cubes, externally brown and black, internally cinnamon, and yielded 30 per cent. of tannic acid; the third quality was in dull-brown, well-shaped cubes, internally pale brown, and yielded 19 per cent. of tannic acid. The oblong or parallelepiped gambir was of a uniform dull brown, very hard and strong, and yielded only 2 per cent. of tannic acid. MacEwan believes that the low percentage of tannin was due to the decoction not having been subjected to prolonged boiling, which favors the decomposition of catechin, with the formation of catechu-tannic acid. None of the finest varieties of gambir, such as are used by the natives for chewing, occur to any extent in American commerce. Prebble records his examination of a cube gambir of fine appearance which contained a large percentage of starch. (P. J., 1893, 21.)

Enormous quantities of gambir are used both in Europe and America in tanning, calico printing, dyeing, as an ingredient in boiler compounds for preventing the hard scaly incrustation caused by certain kinds of water, and other art processes requiring tannic acid.

Vanderkleed and E'we call attention to the fact that the apparent alcohol soluble content of gambir may be unduly raised by the high moisture content of some of the commercial varieties, which they report as containing over 21 per cent. of moisture, all of which would be calculated in the alcohol soluble extractive by the ordinary methods in which no allowance is made for water. (J. A. Ph. A., 1914, 1685.)

**Uses.**—Gambir is a serviceable remedy in those cases where astringents are indicated.

The complaints to which it is best adapted are diarrhea dependent on debility or relaxation of the intestinal mucous membrane, and passive hemorrhages, particularly from the uterus. A small piece held in the mouth and allowed slowly to dissolve is an excellent remedy in relaxation of the uvula and the irritation of the fauces and troublesome
cough which depend upon it. Applied to spongy gums, in the state of powder, it sometimes proves useful; and it has been recommended as a dentifrice in combination with powdered charcoal, Peruvian bark, myrrh, etc.

Dose, from ten grains to half a drachm (0.65—2.0 Gm.), which should be frequently repeated, and is best given with sugar, gum arable, and water.

**Off. Prep.**—Tinctura Gambir Composita, U. S. (Br.); Trochisci Gambir, N. F.; Pulvis Gambir Compositus, N. F.; Tinctura Pectoralis (from Compound Tincture), N. F.

**Gardenia.** Gardenia grandiflora Lour. (Fam. Rubiaceae) —A Chinese tree, the fruit of which is employed in dyeing the yellow robes of the mandarins, and, according to Lorenz Mayor, contains crocin, which in powder is of a bright red color, and soluble in water and alcohol. According to the researches of Kayser (Ber. d. Chem. Ges., 1884, 2228), its formula is C₄₄H₇₀O₂₈. When heated with diluted hydrochloric or sulphuric acid, it is decomposed into crocetin, C₃₄H₄₆O₉, and a dextrorotatory sugar called crocose. Alkalies bring about the same decomposition almost instantly. Concentrated sulphuric acid dissolves both the crocin and crocetin with deep blue color. The fruit of another species, G. campanulata, Roxb., growing in the forests of Chittagong, in India, is said to be used by the natives as a cathartic and anthelmintic. (Lindley, Flor. Med; 434.)

**Garlic.** N. F. IV. Allium. English Garlic.—The genus Allium includes a large number of species, of which nearly seventy are indigenous in this country. Many, and perhaps all, of these species contain volatile oil upon which their activity depends. The cultivated garlic, of which the bulbs are official in the N. P., is Allium sativum L., for which, according to Griffith, A. canadense L., has been substituted and found efficient.

Allium sativum, L., is a perennial plant with numerous bulbs which have a common membranous covering, from the base of which the fibers that constitute the proper root descend. The stem is simple, and rises about two feet. The leaves are long, flat, and grass-like, and sheathe the lower half of the stem. At the termination of the stem is a cluster of flowers and bulbs mingled together, and enclosed in a pointed spathe, which opens on one side and withers. The flowers are small and white, and make their appearance in July. This species of garlic grows wild in Sicily, Italy, and the south of France. The bulbs, or so-called cloves, are usually six or eight in number, oblong or wedge-shaped, and covered with dry membranous scales, with a pungent odor and a disagreeable and acrid taste.

The N. F. description is as follows: "The fresh bulb of Allium sativum Linne (Fam. Liliaceae). Bulb subglobular, from 4 to 6 cm. in diameter, compound, consisting of from eight to fifteen bulbels and surrounded by one or two dry, whitish,
membranaceous scales and attached to a flattened circular base from the lower portion of which arise numerous yellowish-white roots; bulbels more or less ovoid, in transverse section on three to four sided, the outer surface being convex, summit acute and narrowed into a thread-like fibrous portion, base truncate, each bulbel covered by one or two layers of whitish, membranaceous, scale-like leaves beneath which is the light brown or pinkish, thin and coriaceous layer of epidermis, cohering but easily separable from the solid portion of the bulbel. Odor of broken or bruised bulbels powerfully alliaceous, taste intensely pungent and persistent. Under the microscope, transverse sections of the bulbels show, three distinct portions: (a) the large fleshy scale consisting chiefly of parenchyma enclosing scattered vascular bundles, epidermis in both ventral and dorsal surfaces consisting of small tabular cells; (b) the middle layer nearly circular in outline, about 0.75 mm. in diameter, the tissues resembling those of the outer fleshy scale, but the cells containing numerous yellowish-brown plastids; (c) an innermost bright green layer consisting of a single leaf folded lengthwise along the midrib so that the ventral surfaces lie close together.

The oil of garlic is of a dark brownish-yellow color, heavier than water, and decomposed at its boiling temperature. It may be purified by repeated distillation in a salt water bath, and is then lighter than water, of a pale yellow color, and not decomposed by boiling. Semmler obtained from garlic bulbs 0.09 per cent. of the volatile oil, sp. gr. at 14.5° C. (58° F.) 1.0525; it was yellow, having an intense odor and optically inactive. By fractional distillation he obtained four products, C₆H₁₂S₂, C₆H₁₀S₂, C₆H₁₀S₃, and C₆H₁₀S₄, which decomposed during distillation, and hence could only be obtained by distillation in vacuo. The oil, according to Semmler, is free from allyl sulphide, the latter having the sp. gr. 0.8991. (A. Pharm., 1892, p. 434.) The impure oil has an exceedingly pungent odor and a strong acrid taste, and, when applied to the skin, produces much irritation and sometimes even blisters. The pure oil combines with silver nitrate, forming a precipitate soluble in heated alcohol and afterwards separating in crystals. Besides this oil, fresh garlic, according to Cadet de Gassicourt, contains, in 1406 parts, 520 of mucilage, 37 of albumen, 48 of fibrous matter, and 801 of water. Bouillon-Legrange mentions among its constituents sulphur, a saccharine matter, and a small quantity of starch. The fresh bulbs yield upon pressure nearly a fourth part of juice, which is highly viscid, and so tenacious as to require dilution with water before it can be easily filtered. When dried, it serves as a lute for porcelain. It has the medicinal properties of the bulbs. Water, alcohol, and vinegar extract the virtues 'of garlic. Protracted boiling renders it inert. According to Semmler (A. Pharm., 1887, p. 927), Allium ursinum contains a volatile oil which consists mainly of vinyl-sulphide, C₄H₆S or (C₂H₃)₂S.

Medicinal Properties and Uses.—The use of garlic as a medicine and as a condiment can be traced to earliest antiquity. When taken internally, and even when applied externally, the oil is absorbed and imparts its odor to the breath, urine, perspiration, etc. The oil of garlic has some influence upon the human system as a general mild stimulant. Its chief value in medicine is for its local action upon the stomach and as a stimulant expectorant. The garlic itself is sometimes employed as a rubefacient which, by yielding its volatile oil to absorption, stimulates the nervous system, especially in the case of young children. The oil may often be given with advantage in
chronic bronchitis and in the advanced stages of obstinate acute bronchitis. It is especially valuable in the treatment of children when there is a distinct nervous element. In catarrhal pneumonia of young children the bruised garlic cloves are often applied as a poultice to the lungs, and similar applications were formerly used upon the feet for the nervous restlessness or even the convulsions of young children. Garlic clove may be swallowed either whole or cut into pieces of a convenient size, but the syrup has replaced most other methods of administration. The dose in substance is from half a drachm to two drachms (2-7.7 Gm.) of the fresh bulb. That of the juice is half a fluidrachm (1.8 mils). A syrup is official in the N. F. (see Part III).

**Garrya Fremontii** Torr. California Fever Bush. Skunk Bush.—The leaves of this bush (fam. Cornaceae), indigenous to California and Oregon, have an intensely bitter taste, and are said to be largely used by Californians as a tonic and anti-periodic. D. W. Ross (A. J. P., 1877) states that he found in them a new alkaloid, garryine. The dose of the fluidextract of the leaves is from ten to thirty minims (0.6-1.8 mils).

**Gaultheria.** Wintergreen. Boxberry. Teaberry. Feuilles de Gaultherie couchee (de Palownier), The du Canada, The de Terreneuve, Fr. Canadischer Thee, Bergthee, G.—Gaultheria procumbens L. (Fam. Ericaceae) is a small indigenous, shrubby, evergreen plant. The leaves, which were formerly official in the U. S. Pharmacopoeia, are short-petiolate, obovate or oval, about 4 cm. in length and 2 cm. in breadth, acute, revolute, obscurely serrate at the edges, coriaceous, shining, bright green above, paler beneath, of unequal size, and supported irregularly on short red petioles.

The plant extends from Newfoundland to Georgia, growing in large beds in mountainous tracts, or in dry barrens and sandy plains, beneath the shade of shrubs and trees, particularly of other evergreens, as the Kalmiae and Rhododendra. In different parts of the country it is variously called checker-berry, tea-berry, aromatic wintergreen, and mountain-tea. The flowers appear from July to August, and the fruit ripens at corresponding periods. To the very peculiar aromatic odor and taste which belong to the whole plant the leaves add a marked astringency. The aromatic and medicinal properties of wintergreen reside exclusively in an official volatile oil.

**GELSEMIUM. U. S. (Br.)**

**GELSEMIUM Gelsem.**

[Yellow Jasmine Root, Yellow Jessamine]

"The dried rhizome and roots of Gelsemium sempervirens (Linne) Aiton filius (Fam. Loganiaceae)." U. S. "Gelsemium Root is the dried rhizome and root of Gelsemium nitidum, Michaux." Br.

**Gelsemii Radix,** Br.; Gelsemium Root, Yellow Jasmine, Yellow Jessamine, Carolina or American Yellow Jessamine, Yellow or Evening Trumpet Flower; Gelsemium, Fr. Cod.; Jasmin sauvage, Fr.; Gelsemie, Giftjasmin, G.; Gelsemio, Sp.
The yellow or Carolina Jessamine (Gelsemium sempervirens) is one of the most beautiful climbing plants of our Southern States, ascending lofty trees, and forming festoons from one tree to another, and during its flowering season, in the early spring, scenting the atmosphere with its delicious odor. The stem is twining, smooth, and shining; the leaves perennial, opposite, nearly persistent, short, petiolate, lanceolate, entire, dark green above, and paler beneath;

the flowers in axillary clusters, large, of a deep-yellow color, and fragrant, with a very small, five-leaved calyx, and a funnel-shaped corolla, having a spreading, five-lobed, nearly equal border. The fruit is a flat, compressed capsule, divisible into two parts, two-locular, and furnished with flat seeds, which adhere to the margins of the valves. The plant grows in rich, moist soils along the sea-coast from Virginia to the south of Florida and Texas. The flowers are said to be poisonous. Gelsemium elegans Benth., of upper Burma, is an extremely poisonous creeper which contains gelsemine or an allied alkaloid.

This official plant must not be confounded with the true yellow jasmine of Madeira, often planted in the Southern States, which is the Jasminum odoratissimum L., which also has very fragrant yellow flowers.

Properties.—It is officially described as; "Rhizome cylindrical, usually in pieces from 3 to 20 cm. in length and from 3 to 30 mm. in diameter; externally light yellowish-brown, longitudinally wrinkled, with purplish-brown longitudinal lines and transverse fissures; the upper surface with a few stem-scars, the under and side portions with numerous roots and root-scars; fracture tough, splintery; internally light brown or pale yellow, bark thin, wood distinctly radiate, excentral, pith disintegrated; odor slight; taste bitter. Roots light brown; fracture one-half transverse, the other oblique or splintery. Under the microscope, sections of the rhizome of Gelsemium show a strong development of cork, the walls being grayish or yellowish-brown and more or less lignified; a cortex made up chiefly of parenchyma containing starch and having in the outer portion small scattered groups of stone cells or sclerenchymatous fibers, and in the inner portion in the region of the medullary ray prisms of calcium oxalate; woody portion made up of broad wedges consisting of large trachea? and fiber-tracheids separated by starch-bearing medullary rays, the innermost cells, or those nearer
the pith, being strongly lignified, while the outermost layers, or those nearer the cortex, are non-lignified and may contain prisms of calcium oxalate; an internal phloem or sieve, the cells forming distinct, more or less rounded groups, the latter being partly surrounded by a thin-walled starch-bearing pith. The powder is dark yellow, tracheae with bordered pores numerous, and conspicuous; spiral tracheae few; bast-fibers and fiber-tracheids long and narrow, strongly lignified; starch grains spherical, from 0.004 to 0.008 mm. in diameter; calcium oxalate in mono-clinic prisms from 0.015 to 0.03 mm. in length; occasional groups of stone cells or sclerenchymatous fibers, the walls being very thick, porous, and strongly lignified." U. S.

"In nearly cylindrical pieces about fifteen centimetres or more long, and usually from six to eighteen millimetres thick; occasionally with fibrous rootlets attached. Fracture splintery. In transverse section, a thin cortex, and a porous, yellowish, distinctly radiate wood with numerous, conspicuous, straight medullary rays. Rhizome usually with a brown or dark brownish-violet cork, often much fissured; nearly straight, and exhibiting silky fibres in the bast. Root yellowish-brown, finely wrinkled, and somewhat tortuous. Slightly aromatic odor; taste bitter." Br.

A microscopic character, said by Rothrock to be diagnostic, is the more or less complete division of the pith into four parts by plates of large thin-walled cells. (A. J. P., 1884.) For elaborate study of structure of gelsemium, see A. J. P., 1898, 398; A. J. P., 1899, 422; D. C., 1901, 244. Holm has contributed an article on the morphology of the overground portion of Gelsemium sempervirens. (Merck's Rep., 1908, p. 86.) Tunmann (Ph. Zentralh., 1907, p. 679) has made a pharmacognostic study of gelsemium and has proposed its identification through the microsublimation of aesculin. (See Ap. Ztg., xxvi, p. 812.) Tutin (P. J., Feb. 10, 1912) has shown that the sublimate obtained by Tunmann from gelsemium root must have consisted of scopoletin. Tutin further states that "The detection of scopoletin in gelsemium may prove to be a valuable means of distinguishing this drug from others of a similar appearance, such as that derived from Gelsemium elegans Benth., but it is doubtful whether the sublimation method is the most convenient one. If 0.5 gramme of ground gelsemium be heated in a test tube with chloroform, the mixture filtered, and the filtrate shaken with water to which a few drops of dilute ammonia have been added, the aqueous layer, on separation, will be found to show a distinct, blue fluorescence,
thus indicating the presence of scopoletin."

Sayre (A. J. P., 1897, 8) found specimens of the root mixed with considerable proportions of the stem. Ingham (A. J. P., 1897, 234) found that there was not much difference between the root and rhizome in alkaloidal value, but the stem does not appear to contain either gelsemine or gelsemic acid. (See also A. J. P., 1897, 140.) Gelsemium yields its virtues to water, and readily to diluted alcohol. Analyzed by Henry Kollock, it was found to contain gum, starch, pectic acid, albumen, gallic acid, fixed oil, a fatty resin, a dry acrid resin, yellow coloring matter, volatile oil, extractive, lignin, a peculiar alkaloid called gelsemine, potassium, calcium, and magnesium salts, iron, and silica. The alkaloid, however, was not obtained sufficiently pure to admit of a full investigation of its properties. (A. J. P., xxvii.) After Kollock’s experiments, the alkaloid was obtained in a crystalline form, but still impure, by Maisch, from a tincture of the root, by a process of which a very brief abstract is given in A. J. P., 1869, by C. L. Eberle, who in the same paper publishes the results of his own investigation. Eberle not only extracted gelsemine, but also satisfactorily established its alkaline properties, and proved that it was not contained in the wood of the root. Soon afterwards, the chemistry of yellow jasmine was more thoroughly investigated by Theo. G. Wormley. (A. J. P., 1870.) He obtained pure gelsemine from the root and a peculiar acid, which he called gelseminic (gelsemic) acid.

Wormley obtained the acid by acidulating a concentrated aqueous solution of the drug and extracting with ether. (For details of his method, see U. S. D., 19th ed., p. 578.) The acid, when pure, is colorless, inodorous, almost tasteless, and readily crystallizable, usually in groups or tufts of fine needles. The action of concentrated nitric acid upon gelsemic acid or any of its salts, produces a yellow, reddish, or red solution, which, if treated with ammonia in excess, becomes of a deep blood-red color, lasting for hours. The one-thousandth of a grain will exhibit these changes. Potassium, sodium, or ammonium hydroxide, added to the acid, cause it to become intensely yellow, and form with it highly fluorescent solutions. The acid is fusible, and, at a high heat, volatilizable without change. Robbins (Deut. Chem. Ges. 1876, 1182), stated that it was identical with aesculin (the glucoside of the horse-chestnut), and gave it the formula $C_{15}H_{16}O_9 + 1 \frac{1}{2}H_2O$.

But Coblentz (Proc. A. Ph. A., 1897, 225) showed that it differs from
aesculin in several particulars, and gave for its formula $C_{13}H_{11}O_5$, which melts at 206° C. (402.8° F.). E. Schmidt believes that Wormley's gelsemic acid is identical with scopoletin derived from scopola root, and gives the name as β-methylaesculetin, $C_9H_5(CH_3)O_4$.

Gelsemine was obtained by Wormley, from the concentrated extract from which gelsemic acid has been separated by ether, by rendering it slightly alkaline, then shaking out repeatedly with chloroform. It is a brittle, transparent solid, crystallizing with difficulty from alcohol. Boiling water sparingly dissolves it. It softens at 38° C. (100.4° F.), and fuses at 45° C. (113° F.). The pure base gives no color reaction with strong nitric acid, and the mixture is scarcely changed in color by heating. Strong sulphuric acid has no apparent action upon it, but if to the mixture a little manganic oxide be added and then rubbed with a glass rod, a deep crimson-red is obtained, passing to green. This reaction is so delicate, that it can be demonstrated with a solution of 1 in 100,000. If this reaction be performed upon the pure alkaloid, the color may be sufficiently intense to cause it to be mistaken for strychnine, but if a parallel experiment be carried on with strychnine, the two alkaloids cannot be mistaken, for the strychnine gives an intense purple, passing to red. Gerrard analyzed the alkaloid with care, and gives the formula $C_{12}H_{14}NO_2$ as its correct composition. F. A. Thompson (Ph. Era, 1887, p. 3) announced the presence of a second alkaloid, which he called gelseminine. After obtaining a solution of the alkaloids as sulphates he agitates it with an alkali and ether; the ethereal solution is shaken with water acidulated with hydrochloric acid, and the alkaloids are converted into hydrochlorides; gelseminine hydrochloride being easily soluble, and gelsemine hydrochloride less soluble, the latter is deposited on standing, and may be obtained pure by repeated crystallizations. He asserts that gelseminine differs greatly in physical and chemical properties from gelsemine, but, as he did not succeed in obtaining it absolutely pure, did not give the differences.

Sayre (J. A. Ph. A., 1912, p. 458; 1913, p. 436; 1914, p. 314, and 1915, p. 60) has made a series of investigations of the principles of gelsemium based partly upon the work of C. W. Moore (J. Ch. Soc., 1910, p. 2223), who reported gelseminine to consist of two amorphous alkaloids. Sayre found two alkaloids differing in physiological activity and color reactions, the one of which he called gelseminine (the former name for the combination of the two), and the other gelsemoidine, which was
later changed to sempervirine. This latter alkaloid is similar in some of its properties to cinchonamine, particularly in the matter of the insolubility of its salts in water. Sayre also calls attention to the fact that the alkaloid commercially supplied under the name gelseminine is usually the crystalline alkaloid gelsemine. He states that the principles obtained by him show the following color reactions with sulphuric acid and manganic oxide: Gelsemine, at first crimson, then green, and finally yellow; gelseminine, at first brown, then pink, and finally yellow; gelsemoidine, at first purple and finally blue.

**Uses.**—According to the researches of Cushny (A. E. P. P., 1892, xxxi, 49), gelseminine is so much more powerful than gelsemine that it is improbable that the latter alkaloid plays any part in the effect of the whole drug in mammals. Gelsemine is a depressant to the centers in the spinal cord and, in large doses, also paralyzes the peripheral motor nerves. Gelsemine acts, in the frog, much like strychnine, causing convulsions, by stimulating the spinal cord, which are followed by paralysis due to an effect on the motor nerves. In toxic quantities gelsemium lowers the blood pressure, probably by a direct action on the heart, but death is usually brought about through respiratory failure. When locally applied, or if given internally in poisonous dose, it causes dilatation of the pupil with loss of accommodation.

Formerly gelsemium was used as an arterial sedative and febrifuge in various sthenic fevers, but is probably useless for this purpose. Bartholow (Pract., 1870, v, 200) has recommended it in spasmodic disorders, as asthma and whooping cough. It is, at present, rarely used except in the treatment of neuralgias, especially those involving the facial nerves. The mode of its action in these cases is obscure, but there is considerable clinical evidence of its utility.

The symptoms of gelsemium poisoning are: dizziness, dimness of vision, dilated pupil, general muscular debility, and universal prostration, reducing the frequency and force of the pulse, and the frequency of respiration. After very pronounced poisonous doses the symptoms which have just been enumerated are intensified: double or impaired vision, ptosis, dilated insensitive pupils, falling of the lower jaw, loss of power of enunciation, and excessive muscular relaxation are associated with slow, labored breathing, which in some cases is interrupted by violent spells of dyspnea; consciousness is long unimpaired, but is apt to be lost before death, and in rare cases unconsciousness has been present, even
although recovery followed. Of the various symptoms of gelsemium poisoning the most characteristic are the dropping of the jaw and the ocular manifestations, combined with general muscular relaxation. The effects usually begin in half an hour, but sometimes almost immediately. According to Wormley, death has occurred at periods which vary from one to seven and a half hours. Twelve minims of the fluidextract are said to have proved fatal to a boy three years old, and thirty-five drops of a tincture of the bark have caused death in one hour and a half. In several instances a drachm of the fluidextract has, under treatment, been recovered from.

The treatment of poisoning by gelsemium should consist in evacuating the stomach, maintaining absolute rest in the horizontal position, keeping up the bodily temperature, if required, by external warmth, and administering spinal and arterial stimulants. We have very little experimental data as to the physiological antidotes to gelsemium. Our general knowledge indicates that ammonia, strychnine, and digitalis given hypodermically should be of service in the treatment of the poisoning.

Gelsemium should be administered in the form either of the tincture or of the fluidextract, the dose of the tincture being ten minims (0.6 mil), that of the fluidextract two minims (0.12 mil); to be repeated, if necessary, every 2, 4, or 6 hours, and gradually increased until the object is obtained, or some obvious effect is produced on the system.

Dose, of gelsemium, one to two grains (0.065-0.13 Gm.).

**Genista.** Genista tinctoria L. Dyers' Broom. Dyers' Weed. Green Weed. Wood-Waxen. Genet des Teinturiers, Fr. Farberginster, G. (Fam. Leguminosae)—A low shrub, growing wild in Europe, and established on sterile hills and roadsides from Maine to New York, cultivated in greenhouses in this country on account of its profusion of yellow leguminous flowers. The flowering tops of the plant are employed to dye yellow, whence its name was derived. Both these and the seeds have been used in medicine. They are said to be purgative and even emetic, especially the seeds, which were formerly given as cathartic in the dose
of a drachm and a half (5.8 Gm.). By some authors they are said to be diuretic and to be useful in dropsy.

**GENTIANA. U. S. (Br.)**

**GENTIAN Gentian. [Yellow Gentian Root]**

"The dried rhizome and roots of Gentiana lutea Linne (Fam. Gentianaceae)." U. S. "Gentian Root is the dried rhizome and root of Gentiana lutea, Linn" Br.

**GentianaeRadix**, Br.; Gentian Root, Bitter Root, Fel Root; Radix Gentianae Rubrae (vel Luteae vel Majoris); Gentiane (Racine), Fr. Cod.; Racine de Gentiane (de Gentiane jaune), Gentiane jaune, Fr.; Radix Gentianae, P. G.; Enzian, Enzianwurzel, Bitterwurzel, Rother Enzian, G.; Genziana, It.; Genciana (Raiz de), Sp.

Gentiana lutea or Yellow Gentian is among the most remarkable of the species which compose this genus, both for its beauty and great comparative size. From its thick, long, branching, perennial rhizome, an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, ovate, acute, five-nerved leaves of a bright-green color, and somewhat glaucous. The lower leaves, which spring from the root, are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow color, peduncled, and placed in whorls at the axils of the upper leaves. The calyx is monophyllous, membranous, yellowish, and semi-transparent, splitting when the flower opens, and reflected when it is fully expanded; the corolla is rotate, and deeply divided into five or six lanceolate, acute segments; the stamens are five or six, and shorter than the corolla. The plant grows among the Apennines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe. It is stated by Bourquelot and Herissey that in order to develop the deep colored fracture preferred by many druggists the root is frequently submitted to fermentation by heaping it up into a mass which becomes heated. Gentian root which has thus been treated is said to yield 27 per cent. less extractive than does that which has been properly dried. Further, even in the best commercial dried root the sucrose, gentianose and gentiopicrin of the fresh root are present only in extremely small amounts. (J. P. C., 6,16, 513.)

Several other species possess analogous virtues, and are used for similar purposes. The roots of G. purpurea L. and G. punctata L., inhabiting the
same regions as G. lutea, and of G. pannonica Scopoli, growing in Austria, are said to be often mingled with the official, from which they are scarcely distinguishable. In fact the German Pharmacopoeia permits the use of the rhizome and roots of these three species. The G. macrophylla of Pallas is used in Siberia.

G. quinquefolia L. (G. quinqueflora Lam.), growing throughout the Northern and Northwestern States, is said to be much used in domestic practice. In Europe the rhizome of the G. asclepiaadæa L. is often admixed with the official rhizome. According to Vogi, they can be detected by the abundance of lignified pros-enchymatous elements and stone cells, the genuine powder containing scarcely any lignified elements other than large reticulated vessels. (O. Z., 1903, 141.)

One indigenous species G. Catesboei (now G. Elliottii Chapm.), growing in the Southern States, formerly had a place in the secondary catalogue of the U. S. Pharmacopoeia, and is reputed to be but little inferior to the official species.

This plant, popularly called blue gentian, has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite leaves, which are ovate-lanceolate, acute, and rough on their margin. The flowers are of a palish-blue color, crowded, nearly sessile, and axillary or terminal. The divisions of the calyx are linear-lanceolate, and longer than the tube. The corolla is large, ventricose, plaited, and divided at its border into ten segments, of which the five outer are more or less acute, the five inner bifid and fringed. The number of stamens is five, and the stigmas are bifid. The capsule is oblong, acuminate, with two valves, and a single cell. G. Elliottii Chapm. grows in the grassy swamps from Virginia to Florida, where it flowers from September to December. It may be given in powder in the dose of from fifteen to thirty grains, or in the form of extract, infusion, wine or tincture.

Powdered gentian is not infrequently adulterated with ground olive stones, ground peanut shells, and even quassia root. These are all readily detected by means of their lignified tissues, which may be seen through the use of the microscope. Gadd and Gadd assert (P. J., 1905, xxii, p. 439) that adulterations of Gentian are most readily detected by means of the microscope, but that good evidence of quality is also furnished by the yield of extract, which should be about 40 per cent.
**Properties.**—As found in commerce, gentian is in pieces of various dimensions and shapes, usually of considerable length, consisting sometimes of longitudinal slices, sometimes of the rhizome and root cut transversely. They are twisted, wrinkled externally, sometimes marked with close transverse rings of a grayish-brown color on the outside, yellowish or reddish within, and of a soft, spongy texture. It is officially described as occurring " in nearly cylindrical, sometimes branching pieces, of variable length, from 5 to 35 mm. in thickness; externally yellowish-brown, the rhizome portion annulate, the roots longitudinally wrinkled; fracture short and uneven when dry, but tough and flexible when damp; internally yellowish-brown, the bark from 0.5 to 2 mm. in thickness, separated from the somewhat spongy, woody portion by a dark brown cambium zone; odor strong, characteristic; taste slightly sweetish, then strongly and persistently bitter. The powder is light brown or yellowish-brown, consisting chiefly of parenchymatous cells with fragments of scalariform or reticulate tracheae; starch grains few or none. Stone cells and sclerenchymatous fibers are absent. Gentian yields not more than 6 per cent. of ash." U. S.

"Parenchymatous tissue of rhizome and root abundant, containing small oil globules and minute crystals of calcium oxalate but not more than an occasional starch grain; vessels reticulated; no sclerenchymatous cells or fibres. Characteristic odor; taste at first slightly sweet but afterwards bitter. When 5 grammes of the powdered root are macerated with 100 millilitres of water for twenty-four hours, shaken occasionally and filtered, 10 millilitres of the filtrate yield on evaporation in a flat-bottomed dish not less than 0.165 gramme of residue dried at 100° C. (212° F.). Ash not more than 6 per cent." Br.

Kromayer, in 1862, first obtained the bitter principle of gentian in a state of purity, and gave it the name of gentiopicrin, and the formula $C_{20}H_{31}O_{12}$. This principle has been found in many other species of the genus Gentiana and seems to be a characteristic principle of the genus. It is a glucoside, crystallizing in colorless needles, which readily dissolve in water. It is soluble in 95 per cent. alcohol, but: in absolute alcohol only when aided by heat; it does not dissolve in ether. A solution of sodium hydroxide forms with it a yellow solution. Under the influence of diluted acids, gentiopicrin is resolved into glucose and an amorphous yellowish-brown neutral substance named gentiogenin. Fresh gentian roots yield about one-tenth per cent. of gentiopicrin. Another constituent
is gentianin or gentisin, C₁₄H₁₀O₅. It forms tasteless, yellowish prisms, subliming with partial decomposition at a temperature over 300° C. (572° F.) sparingly soluble in alcohol, and with alkalies yields intensely yellow, crystallizable compounds, easily decomposed by carbon dioxide. Von Kostanecki (A. J. P., 1891, p. 192), by boiling gentisin with hydnodic acid, succeeded in demethylating it, and so obtained gentisein, C₁₃H₈O₃, which crystallizes with 2H₂O in fine straw-colored needles; these become anhydrous at 100° C. (212° F.). A triacetyl derivative was then formed from this gentisein. Gentisin is therefore the methyl ether of gentisein, and can be

\[
\text{written } C_{13}H_{6}O_2 \left\{ \begin{array}{c} \text{OCH₃} \\ \text{OH} \\ \text{OH} \end{array} \right\} \text{. Hlasiwetz and Habermann showed, in 1875, that when gentianin was melted with potassium hydroxide it yielded phloroglucin, } C₆H₃(OH)₃, \text{ and dioxybenzoic acid, } C₆H₃(OH)₂COOH. \text{ The latter was at first called gentianic or gentisinic acid. Maisch believed that tannin is absent from gentian root, and states that the dark olive-green coloration observed when ferric chloride is added to its preparations is due to gentisic acid. (A. J. P., 1876.) Ville (A. J. P., 1877) and Davies (P. J., 1879) maintain that there is a small quantity of tannin in gentian root. Patch (A. J. P., 1876) found that an alcoholic solution of an ethereal extract of gentian yielded a dark-green coloration with ferric salts, but if the alcoholic solution were diluted with water it yielded no precipitate with gelatin. Subsequently (Proc. A. Ph. A., 1881) he showed that there was a principle associated with the resinous matter in gentian (but which was not isolated in a state of purity) that produced the reactions of a tannin, viz., a greenish-black color with ferric chloride, and precipitates with tartar emetic, cin-chonidine sulphate, and gelatin. Louis Magnes found in the root, when perfectly dried at 100° C. (212° F.), 15 per cent. of glucose. When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence of the presence of this saccharine principle. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter, and having an unpleasant odor, is said to be relished by the Swiss and Tyrolean. A. Meyer (Ph. Cb., May, 1882) obtained a sweet principle, which he called gentianose, C₁₆H₆₆O₃₁, by precipitation of the filtered juice with alcohol, treatment with ether, and crystallization from alcohol. It does not reduce Fehling’s solution. Infusion of gentian is precipitated by tannic acid and the
soluble salts of lead, but is compatible with the salts of iron. Pectin, so frequently found in fleshy roots, exists in gentian. (Bourquelot and Herissey, Repert de Pharm., 1898.) The yellow coloring matter of the root was investigated by E. V. Howell, who concludes that it is quereitrin. Tanret (P. J., lxxvi, p. 87) found two glucosides, gentiamarin and gentiin. He also states (B. G. T., 1905, p. 730) that in fresh roots the amount of gentiopicrin is about 1.5 per cent., but that it is destroyed in the process of drying so that dried roots contain only 0.1 per cent.

**Uses.**—Gentian has been known from the highest antiquity and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients. The ordinary preparations of gentian are, however, almost without physiological properties except their local effects on the mucous membrane of the alimentary tract. Moorhead (J. P. Ex. T., 1915, vii) has given a scientific rationale for the ancient empirical belief in the bitters, by showing that gentian markedly increased the gastric secretions in cachectic dogs. As a stimulant to gastric digestion gentian is perhaps the most popular of all bitters in the treatment of atonic dyspepsia, anorexia, and similar complaints. In overdose it acts as a local irritant and may occasion nausea or vomiting. The porous property of the root causes it to expand with moisture and it has been employed as a substitute for the sponge tent to enlarge stricture passages. According to Tanret (B. G. T., 1905, p. 730) gentiopicrin is highly poisonous to the plasmodium and in doses of twenty to thirty grains (1.3-2.0 Gm.) is a useful remedy in malarial fevers; it might be pointed out in this connection that it would require between four and five pounds of dried gentian root to produce one dose of gentiopicrin.

Dose, fifteen to thirty grains (1-2 Gm.).

**Geranium.** N. F. IV (U. S. VIII). Cranesbill. Cranesbill Root. Spotted or Wild
Cranesbill, or Storksbill. Alum Root. Racine de Bec-de-Oruetachet, Racine de Pied-de-
Comelle, Fr. Fleck-storchschnabelwurzel, G.—" The dried rhizome of *Geranium*
maculatum Linne (Fam. Geraniaceae)." N. F. Geranium was deleted from the U. S.
Pharmacopoieia but is now official in the National Formulary IV. The stem is erect,
round, dichotomously branched, from one to two feet high, of a grayish-green color,
and thickly covered, in common with the petioles and peduncles, with reflexed hairs.
The leaves are deeply divided into three, five, or seven lobes, which are variously
incised at their extremities, hairy, and of a pale green color, mottled with still paler
spots. Those which rise from the root are supported on foot-stalks eight or ten inches
long; those of the stem are opposite, the lower petiolate, the upper nearly sessile, with
lanceolate or linear stipules. The flowers are large, and usually of a rose-purple color.
The peduncles spring from the forks of the stem, and severally support two flowers
upon short pedicles. The calyx is composed of five oblong, ribbed, cuspidate leaves; the
petals are five, obovate, and entire; the stamens ten, with oblong, deciduous anthers,
the five alternate filaments being longer than the others, and having glands at their
base; the ovary is ovate, supporting a straight style as long as the stamens, and
surmounted by five stigmas. The fruit consists of five aggregate, one-seeded capsules,
attached by a beak to the persistent style, curling up and scattering the seeds when
ripe. The plant is indigenous, growing throughout the United States in moist woods,
thickets, and hedges, and generally in low grounds. It flowers from May to July. The
root should be collected in autumn.

Geranium is described as: "Rhizome cylindraceous, somewhat branched, bent,
flattened and strongly tuberculated, from 2.5 to 10 cm. in length and from 3 to 15
mm. in diameter; surface marked with root scars and remnants of slender roots,
longitudinally wrinkled; externally dark purple-brown; internally light purple-brown;
fracture short, non-fibrous, the section shows a thin bark, a distinct cambium,
irregular in outline, large central pith, wood indistinct, the fibro-vascular bundles few
and at unequal distances. Odorless; taste strongly astringent. The powder is purplish-
brown and, when examined under the microscope, exhibits tangentially elongated cork
cells; parenchyma containing starch, scattered cells of pith and bark parenchyma
containing tannin both in the content and walls of the cells' and colored bluish-black
by ammonio-ferric alum T.S.; tracheae small, with scalariform markings;
characteristic starch more or less abundant, grains smooth, mostly single, ovate, up
to 0.035 mm. in length, hilum near the larger end, inner lamellae concentric with
hilum, the outer excentric. Geranium yields not more than 8 per cent. of ash." N. F.
Water and alcohol extract the virtues of geranium. According to Edward Staples, it
contains tannic and gallic acids, mucilage, red coloring matter, resin, and a
crystallizable vegetable principle. (A. J. P., 1829, p. 171.) Tilden found, besides tannic
and gallic acids, gum, pectin, sugar, starch, albumen, resin soluble in alcohol, oleoresin
soluble in ether only, coloring matter, chlorophyll, lignin, and various salts. (P. J.,

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - G - Page 29
The Southwest School of Botanical Medicine http://www.swsbm.com
Tannic and gallic acids are probably the sole active ingredients. Henry Trimble and J. C. Peacock (A. J. P., 1891, p. 265) collected the plant at periods of the year ranging from January to October, and determined the percentage of tannin as calculated for the perfectly dry drug to vary from 9.72 to 27.85 per cent. They also determined that it belonged to the class of tannins analogous to gallo-tannic acid, yielding pyrogallol on heating. They decomposed the tannin by the action of hydrochloric acid, obtaining gallic acid, glucose, and geranium red as products.

Geranium is one of our best indigenous astringents, and may be employed for all the purposes to which these medicines are applicable. The absence of unpleasant taste and of other offensive qualities renders it peculiarly serviceable in the case of infants and of persons of very delicate stomach. Diarrhea, chronic dysentery, cholera infantum in the later stages, and the various hemorrhages, are the forms of disease in which it is most commonly used and with greatest advantage. As an application to indolent ulcers, an injection in gleet and leucorrhea, and a gargle in relaxation of the uvula and aphthous ulcerations of the throat, it answers the same purpose as kino, catechu, and other medicines of the same class. It is a popular domestic remedy in various parts of the United States, and is said to be employed by the Indians. It may be given in substance, decoction, tincture, or extract. (See Fluidextractum Geranii, N. F. IV, Part III.) Dose fifteen to thirty grains (1-2 Gm.).

**Geum.** Water Avens. Radix Caryophyllatae Aquaticae. Radix Benedictae Sylvestris. Racine de Benoite aquatique (de Benoite des Ruisseaux), Fr. Sumpfnelkenwurzel, Wasser-Benedikten-Wurzel, G.—Several species belonging to this genus have been medicinally employed, but three or four are deserving of particular notice—Geum rivale L., which once had a place in the U. S. Secondary List, G. urbanum L., formerly recognized by the Dublin College, G. virginianum, L., an indigenous species, the root of which has been recommended in dysentery by W. A. Gibson (Med. Rec., 1868), and G. canadense Jacq. (G. album Gmel.), recommended by W. A. Spurgeon in gastric irritation and headache. (A. J. P., 1883.)

The rhizome and roots of Geum urbanum L., of Europe and Asia, are used in medicine. The rhizome is from 3 to 7 cm. in length and about 8 mm. in thickness. It is more or less branching, having on the upper surface the remains of the short stems and petiole-bases and on the lower surface numerous fibrous roots. Externally it varies from a brownish to a brownish-yellow. The fracture is short and internally it is dark brown. When quite dry it is nearly inodorous, but in the recent state has an odor like that of cloves, whence it is sometimes called radix caryophyllatce. The taste is bitterish and astringent. It imparts its virtues to water and alcohol, which it tinges red. Buchner obtained a yellow, amorphous, neutral, bitter-tasting mass, which he calls geum-bitter. Distilled with water it yields 0.04 per cent. of a thick, greenish-yellow volatile oil, consisting chiefly of eugenol, a tasteless resin, gum, bassorin, and starch. It has been much used in Europe as a tonic and astringent, in chronic and passive hemorrhages, chronic dysentery and diarrhea, leucorrhea, intermittent fever, etc. The dose is from thirty grains to a drachm (2.0-3.9 Gm.) of the powder three or four times a day, or an equivalent quantity in decoction.
**Geum rivale** L.—Water or purple avens, a plant growing in bogs and wet places in the northern United States, has a perennial, horizontal, jointed, scaly, tapering root, about 15 cm. long, of a reddish-brown color externally, white internally, and furnished with numerous descending yellowish fibers. The dried root is hard, brittle, easily pulverized, reddish or purplish, without odor, and of an astringent, bitterish taste. Boiling water extracts its virtues.

Water avens possesses similar therapeutic properties to avens, for which it is sometimes substituted, but is less esteemed. The dose of the powdered root is from twenty grains to a drachm (1.3-3.9 Gm.), to be repeated three times a day. Dose of the decoction (ounce to the pint), one or two fluidounces (30-60 mils). A weak decoction is sometimes used by invalids in New England as a substitute for tea and coffee.

**Gillenia.**  Bowman's Root.  Indian Physic. American Ipecac. Racine de Gillenie, Fr. Gillieniewurzel, G.—Under this name the U. S. P. formerly included in its Secondary List the roots of two species of Gillenia. (Fam. Rosaceae.)

Gillenia trifoliata (L.) Moench. is an herbaceous plant with a perennial rhizome, having many long, slender, roots. It grows throughout the United States, east of the Allegheny ridge, and, in Pennsylvania, may also be found abundantly west of these mountains. The root should be gathered in September. (See A. J. P., 1898, 501.)

G. stipulata (Muhl.) Trel. is herbaceous and perennial, though much taller and more bushy than the preceding. It grows as far north as the State of New York, and extends as far west as Kansas. Its root is precisely similar to that of the Eastern species, and is reputed to possess the same properties.

The roots of G. stipulata resemble those of Ipecac, the bark being thinner and endorsing in the inner layers numerous reddish resin cells. The roots of G. trifoliata are smaller and indistinctly annulate, exhibiting few or no distinct fissures. For microscopic characters, see G. L. Curry. (Am. Pract. and News, May, 1892.) The bark, which is easily separable, has a bitter, not disagreeable taste; the wood is nearly insipid and comparatively inert, and should be rejected. The powder is of a light brownish color, and possesses a feeble odor, which is scarcely perceptible in the root. The bitterness is extracted by boiling water, which acquires a red color. The root yields its bitterness also to alcohol. By various experimenters it has been shown to contain gum, starch, gallotannic acid, fatty matter, wax, resin, coloring matter, albumen, and lignin, besides salts. (A. J. P., xxvi, 490.) Gillenin of W. B. Stanhope was a whitish substance, very bitter, slightly odorous, permanent in the air, soluble in water, alcohol, ether, and the dilute acids, and neutral to test paper. Nitric acid rendered it blood-red, chromic acid green. Tanriic acid produced no effect. It gave white precipitates with potassium hydroxide, lead-aub-acetate, and tartar emetic. Half a grain (0.032 Gm.) of it produced nausea and retching. (A. J. P., xxviii, 202.) G. L. Curry (A. J. P., 1892, 513) has found two glucosides: the first, gillein, obtained from the ethereal extract, formed white feathery crystals, was colored red by sulphuric acid, yellow by nitric acid, and deepened the color of chromic acid; the second,
gilleenin, obtained from the aqueous infusion, was amorphous, of yellowish color, of faint taste at first but becoming very bitter, and giving no color reactions with the acids.

Gillenia is a mild and efficient emetic, and, like most substances belonging to the same class, occasionally acts upon the bowels. In very small doses it has been thought to be tonic, and has been used as a substitute for ipecacuanha, which it is said to resemble in its mode of operation. It was employed by the Indians, and became known as an emetic to the colonists at an early period. Linnaeus was aware of its reputed virtues. Dose of the powdered root, as an emetic, from twenty to thirty grains (1.3-2.0 Gm.).

**Ginseng.** Panax quinquefolius L., Panax. U. S. 1870. Ginseng, Fr., G., Sp. Ginsén, It.—American ginseng grows in rich, cool woods, especially along the mountains from Quebec and Ontario, south to Georgia. The root is the part employed. This is collected to the extent of about 100,000 pounds annually in the United States and shipped largely to Shanghai. It is also cultivated. (A. J. P., 1891; Ph. Era, 1895, 359.) It is not used in America, but is exported to China. While supplied with ginseng exclusively from their own country, which furnished the root only in small quantities, the Chinese entertained the most extravagant notions of its virtues, considering it a remedy for all diseases, and as possessing almost miraculous powers in preserving health, invigorating the system, and prolonging life. It is said to have been worth its weight in gold at Pekin, and the first shipment from North America to Canton yielded enormous profits. John Henry Wilson (P. J., July, 1888) states that there are in the Chinese market five ginsengs, four of them of Asiatic origin, derived from Panax Ginseng C. A. Meyer, the fifth, the American ginseng, from Panax quinquefolium. According to E. M. Holmes, T'ang-shen, which is used by the poor of China as a substitute for the costly ginseng, is a root of a new campanulaceous plant, Codonopsis Tangshen, and is exported from Hankow and Oo-chang to the extent of five hundred tons annually. (P. J., xxii.) For an account of the Chinese methods of using ginseng, see P. J., vi, 86.

On account of the growing scarcity of the American ginseng plant, experiments have been made by the State of Pennsylvania to determine whether it can be grown profitably, resulting in the conclusion that in five years an acre of ground would yield a profit of fifteen hundred dollars, without allowance for rental, but, according to Jackson (P. J., lxx, p. 785), many precautions are necessary for success. The cultivated roots were larger than those of the wild plant. For an account of the ginseng cultivation in Corea, see P. J., 1885, 732; and of its collection in the United States, see D. C., 1884, 33. (For details of culture and preparation, see Bulletin 62, Pennsylvania State Agricultural Experiment Station; Bulletin No. 16, Division of Botany, U. S. Department of Agriculture; J. U. Lloyd's paper, Proc. A. Ph. A., 1901, p. 90; Ph. Era, 1900, p. 581; 1903, p. 497; P. J., 1904, p. 652.)

The root is fleshy, somewhat spindle-shaped, from 5 to 12 cm. long, and 1 to 2.5 cm. thick, and terminated by one or more stem scars. Frequently there are two portions, sometimes three or more, connected at their upper extremity, and bearing a supposed, though very remote, resemblance to the human figure, from which
circumstance it is said that the Chinese name ginseng originated. When dried, the root is yellowish-white and wrinkled externally, and within consists usually of a hard central portion, surrounded by a soft whitish bark. It has a feeble odor, and a sweet, slightly aromatic taste, somewhat analogous to that of licorice root. It contains a glucosidal principle, panaquilon, besides saponin, a bitter principle, a volatile oil, resin, sugar, mucilage and starch. S. S. Garrigues prepared panaquilon, to which he gave the formula \( \text{C}_{12}\text{H}_{25}\text{O}_{9} \), by heating a cold infusion so as to separate the albumen, filter, concentrate to a syrupy consistence, precipitate by a concentrated solution of sodium sulphate, wash the precipitate thoroughly with the saline solution, then treat it with alcohol, which dissolves the principle in question, and yields it on evaporation. To purify it, he dissolved it in water, treated the solution with animal charcoal, again evaporated, and dissolved the residue in absolute alcohol, which is finally distilled off. Panaquilon is an amorphous, yellow powder, soluble in water and alcohol, but not in ether, of a sweet bitterish taste, and has the characteristic property that, when treated with strong acids, it is converted into a white substance, insoluble in water, with the escape of carbon dioxide and water. Garriguea proposed for this white substance the name of panacon, \( \text{C}_{11}\text{H}_{19}\text{O}_{4} \). (A. J. P., xxvi, 511.) Davydow (A. J. P., 1890, 338) investigated these principles discovered by Garrigues, but adds nothing new to our information concerning them. The root is sometimes submitted, before being dried, to a process of clarification, which renders it translucent and horny, and enhances its value as an article of export. The extraordinary medicinal virtues formerly ascribed to ginseng had no other existence than in the imagination of the Chinese. It is little more than a demulcent, and in this country is rarely employed as a medicine. Some persons, however, are in the habit of chewing it, having acquired a relish for its taste, and it is sold chiefly to supply the wants of these.

**Glechoma.** Nepeta hederacea (L.) Trevisan (N. Glechona Benth.). Herba Hederae Terrestris. Lierre-terrestré, Fr. Guntermann, Gundrène, G. Ground-ivy. Gill-over-the-ground.—A small perennial, labiate herb, indigenous in Europe and widely naturalized in the United States, and growing in damp, shady, grassy places, as in orchards and along fences and hedges. The herb was formerly official, and still enjoys some credit as a domestic remedy. It has a peculiar, disagreeable odor, and a bitterish, somewhat aromatic taste, and imparts its properties to boiling water. It is very prone to have galls developed on it, and to be infested with certain fungi. (J. P. 0., 1875, 127.) It is said to be gently stimulant and tonic, diuretic, and aperient; used in chronic pulmonary and urinary catarrhs. From a half drachm to a drachm (2-3.9 Gm.) was usually given in infusion as a dose.

**Gleditschione.**—Gleditschia triacanthos L., or Honey Locust, and G. Macracantha
Desf. (Fam. Leguminosae), and are small, thorny trees having pinnate leaves and forming elongated pods filled with a sweetish pulp. The trees grow in rich woods in the Eastern and Central United States and are common in cultivation. G. Macracantha is indigenous to China. These trees were chemically studied by B. F. Lautenbach (P. M. T; 1878), who abstracted from them an alkaloid, which he found to produce in the frog stupor and loss of reflex activity, due to an action upon the spinal cord. To this alkaloid Lautenbach gave the name of gleditschine. In 1887 (Med. Rec., 1887) Goodman, Seward, and Claiborne brought before the profession, as a local anesthetic, an alkaloid under the name of stenocarpine which was asserted to be obtained from the Gleditschia triacanthos. In November, 1888, however, F. W. Thompson, of Detroit (Med. Age), and T. G. Novy (Ph. Rund.) and John Marshall of the University of Pennsylvania (Phila. Med. News), published analyses of this solution, showing that it contained 6 per cent. of cocaine, besides some atropine or other mydriatic alkaloid. (See also A. J. P., 1887, 589.)

**Globularia.** Globularia Alypum Delile, Wild Senna of Europe. (Fam, Globulariaceae)—This is a small shrub, growing on the European shores of the Mediterranean, the leaves of which have been occasionally used as a cathartic since the Middle Ages. Heckel and Schlagdenhauffen obtained from the leaves globularin, C_{15}H_{20}O_{8}, an amorphous glucoside which splits by treatment with mineral acids into glucose and globularetin, C_{9}H_{6}O. Globularia vulgaris L. was found to contain the same substances. (J. P. C., 1883, 361.) It is asserted that globularin is a vasomotor constrictor which acts especially upon the renal arteries. Jaksch [R. T., 1910, p. 596] has observed diminution of the quantity of urine in diabetes insipidus, also of diabetes mellitus after the administration of the glucoside. The dose of globularin is one-half to one grain (0.03-0.065 Gm.) daily. It does not diminish the excretion of sugar. Globularetin, a brownish-yellow powder, has also been used in medicine as a diuretic and purgative, although no definite information can be found regarding either its efficiency or its manner of use. Dose, of globularia, according to Planchon, one ounce (31 Gm.), in decoction.

**Gloriosa.** Gloriosa superba L.—The roots, stalk, and leaves of this climbing liliaceous plant growing in the forests of tropical Africa and extending as far East as the East Indies, are said to be an acrid narcotic poison, and not infrequently used for suicidal purposes in India. C. J. H. Warden found in them two resins, and a very poisonous bitter principle, superbine. (P. J., xi, 496.)

**GLYCERINUM TRAGACANTHAE. Br.**

**GLYCERIN OF TRAGACANTH**

Glycere de Gomme Adragante, Fr.; Traganth-Glycerit, G.

"Tragacanth, in powder, 10 grammes; Glycerin, 30 millilitres; Distilled Water, 10 millilitres. Mix the Glycerin with the Tragacanth; add the Distilled Water; triturate until a homogeneous paste is produced." Br.
This preparation has been introduced into the British Pharmacopoeia mainly to serve as an excipient for pills.

GLYCERITA

GLYCERITES

Glycerinum, Br.; Glycerins; Glycerata, Glycerolata, Glycerole; Glyceres, Fr. Cod.; Glycerats, Glyceroles, Fr.; Glycerit, Glycerolat, G.

These are solutions of medicinal substances in glycerin. In the thirteenth edition of the Dispensatory various reasons were adduced for preferring the name glycerates for these preparations, but, as the revisers of the U. S. Pharmacopoeia have adopted that of glycerites, these reasons are omitted. The U. S. name is certainly much better than the British name glycerin (Glycerinum) for this does not distinguish a class of preparations from the solvent used in making them.

Glycerin has valuable properties as a solvent and vehicle for medicinal substances. Such are its not unpleasant taste and bland character, its wide range of solvent power, which adapts it sometimes as a menstruum where neither water nor alcohol could be advantageously used, and enables it to retain in solution otherwise insoluble substances so frequently found in infusions and decoctions, and its preservative influence, which often protects against oxidation, and, by a destructive agency upon all of the lowest forms of vegetable and animal life, prevents the various fermentative processes so destructive to organic bodies. Another important property, as a vehicle for external remedies, is the permanence of its liquid character, so that it does not, like water and alcohol, dry up when applied to the skin, resembling in this respect, as well as in its demulcent quality, the fixed oils, without their tendency to rancidity. Hence it has of late come into extensive use in the preparation of medicinal solutions, which, under the name of Glyceres found admission into the French Codex of 1866, and are now recognized by both the United States and British Pharmacopoeias.

GLYCERITUM HYDRASTIS. U. S.

GLYCERITE OF HYDRASTIS Glycer. Hydragt. [Glycerite of Golden Seal]
"One hundred mils of Glycerite of Hydrastis yields not less than 1.12 Gm. nor more than 1.37 Gm. of the ether-soluble alkaloids of hydrastis."

U.S.

Glycere d'Hydrastis du Canada, Fr.; Gelbwurzel-Glycerit, G.

"Hydrastis, in No. 60 powder, one thousand grammes [or 35 ounces av., 120 grains]; Glycerin, Alcohol, Water, each, a sufficient quantity, to make about one thousand mils [or 33 fluidounces, 6 1/2 fluidrachms]. Moisten the Hydrastis with three hundred and fifty mils [or 11 fluidounces, 401 minims] of Alcohol, pack it firmly in a cylindrical percolator; and add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed slowly, gradually adding Alcohol, until the drug is exhausted. Remove nearly all of the Alcohol, by distillation or evaporation, pour the thick concentrated liquid into four hundred and fifty mils [or 15 fluid-ounces, 104 minims] of ice-cold Water, and set it aside, in a cold place, for twenty-four hours. Then filter and assay a portion of this filtrate by the process given below, and, from the result thus obtained, ascertain by calculation the amount of ether-soluble alkaloids in the remainder of the liquid. Add to this enough cold water to make each one hundred mils of the product contain 2.5 Gm. of the ether-soluble alkaloids of hydrastis. Finally add an equal volume of glycerin, and mix." U. S.

"Assay.—Proceed as directed under Fluid-extractum Belladonna Radicis, first line of the Assay, modifying the process there given by using 5 mils of Glycerite of Hydrastis instead of 10 mils of fluidextract of belladonna root and using only ether as the immiscible solvent throughout the assay. Wash the final ether extractions with 10 mils of distilled water, draw off the water and discard it. Then filter the ether solution through a pledget of purified cotton, wash the cotton with ether, evaporate the filtrate and washings, and dry the residue at 100° C. (212° F.) to constant weight instead of titrating it. The weight represents the amount of ether-soluble alkaloids in 5 mils of the Glycerite of Hydrastis." U. S.

The process for this glycerite has been improved by adopting J. U. Lloyd's suggestion to concentrate the alcoholic tincture by distillation or
evaporation and pouring the thick liquid into ice-cold water, for the purpose of separating the oily and resinous matter which is useless. F. A. Sieker found that glycerite of hydrastis as made by the former U. S. process varies greatly in strength. (See Proc. A. Ph. A., 1893, 691; also Ph. Rund., 1895, 236, and Proc. A. Ph. A., 1894, 668.) Its medicinal properties are those of hydastis.

Dose, from one-half to one fluidrachm (1.8-3.75 mils).

**GLYCYRRHIZA. U. S. (Br.)**

**GLYCYRRHIZA. Glycyrrh.**
*(Licorice Root Liquorice Root)*

“The dried rhizome and roots of Glycyrrhiza glabra typica Regel et Herder, known in commerce as Spanish Licorice, or of Glycyrrhiza glabra glandulifera Regel et Herder, known in commerce as Russian Licorice (Fam. Leguminosae). Preserve powdered and whole Glycyrrhiza in tightly-closed containers to which a few drops of chloroform or carbon tetrachloride are added from time to time to prevent attack by insects." U S. "Liquorice Root is the peeled root and peeled subterranean stem of Glycyrrhiza glabra, Linn., and other species of Glycyrrhiza." Br.

Glycyrrhiza glabra has a perennial root, which is round, succulent, tough, and pliable, furnished with sparse fibers, rapid in its growth, and in a sandy soil penetrates deeply into the ground. The stems are herbaceous, erect, slightly branching, and usually four or five feet in height. The leaves are alternate, pinnate, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale-green color, and clammy on their under surface. The flowers are violet or purple, formed like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to six small kidney-shaped seeds. There are two very distinct varieties of the plant yielding the root: in the typical form, or var. typica, the underground portion is spreading, producing slender rhizomes. This plant grows best on sandy soil near streams, usually not being found...
more than fifty meters from a body of water. It is indigenous to southern Europe and southwestern Asia, and is cultivated in England, Germany and Austria and has been grown on an experimental scale in the United States. The second variety, var. glandulifera, has been sometimes designated as a distinct species, because the entire plant is pubescent or roughly glandular. The underground portions are not spreading and it produces a large fusiform root. This variety is indigenous to southeastern Europe and in western Asia. It is also cultivated to some extent in Russia. Asiatic licorice, known as "Chuntschir," is obtained from G. uralensis Fisch. The plant is found in Siberia, Turkestan and Mongolia, and it is claimed that the root is of better quality and is but little inferior to the best Russian licorice. (Pharm. Journ. Russ., 1908, p. 1063; also P. J., 1908, lxxxi, 164.)

It is probable that a portion of the root from Italy and Sicily is the product of G. echinata, which grows wild in Apulia. This species is also abundant in the south of Russia, where, according to Hayne, sufficient extract is prepared from it to supply the whole Russian empire. Large quantities of licorice root are now imported for the purpose of making the extract. The annual imports of licorice root in the United States is enormous. Between 75,000,000 and 100,000,000 pounds are annually imported from Turkey and about half of this quantity from Russia. The U. S. Department of Agriculture has had Spanish licorice under cultivation in South Carolina and the plant thrives in various localities in this country. It is said that the soil and climatic conditions in the Coachella Valley of California are ideal for the growing of the licorice plant. Ozmun describes the plantation of licorice in Turkey and the Levant and the manner of harvesting and handling this article. The licorice plant has been cultivated according to precedence of date in Spain, Italy, Greece, The Ottoman Empire, Russia, China, Turkestan and Persia. (See Proc. A. Ph. A., 1905, p. 273, A. J. P., 1907, p. 39; Oil, Paint and Drug Sep., 1906, p. 37, and 1908, p. 22.)

A species of Glycyrrhiza, G. lepidota Pursh., grows abundantly about St. Louis, in the State of Missouri, and flourishes from Colorado to New Mexico, westward into Nevada and Northern California and northward to Washington. It is probably the same as the licorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Nuttall states that its root possesses in no inconsiderable degree the taste of licorice, and M. L. McCullough found it to contain 6.39 per cent. of crude glycyrrhizin, in contrast with 7.18 per cent. in the official
species. (A. J. P., 1890.) Schneider reports that G. lepidota glutinosa Pursh., a native of California, is much like G. glabra and can no doubt be substituted for the true licorice. (Pacific Pharm., II, p. 144.)

Properties.—The two varieties are described in the U. S. Pharmacopoeia as follows:

"Spanish Licorice (also known as Italian, Levant, Persia, Turkish, or Arabian Licorice)—Nearly cylindrical, upper portion more or less knotty; usually in pieces from 14 to 20 cm. or more in length and from 5 to 20 mm. in thickness, externally yellowish-brown or dark brown, longitudinally wrinkled, the thinner rhizomes often having prominent alternate buds, the thicker rhizomes having distinct corky patches; fracture coarsely fibrous; internally lemon-yellow, radiate; bark from 1 to 3 mm. in thickness; wood porous, in narrow wedges, rhizome with small pith; odor distinctive; taste sweetish and slightly acrid. Under the microscope, transverse sections of pieces of the older rhizome of Spanish Licorice show a periderm of numerous layers of yellowish-brown cork cells, a phellogen and one or more rows of cells of the phelloderm, the cells showing a tendency to collenchymatous thickenings and with occasional monoclinic prisms of calcium oxalate; a middle bark of starch-bearing parenchyma and whitish groups of bast-fibers surrounded with crystal-fibers; inner bark with a very characteristic radial arrangement of phloem and medullary rays, the phloem consisting of wedges of small groups of bast-fibers and parenchyma, separated by an almost continuous, obliterated sieve tissue, the cells of the latter being very irregular in outline and with thick, highly refracting walls; medullary rays from 1 to 8 cells wide; wood characterized by broad wedges consisting of large tracheae with yellowish walls, small compact groups of wood-fibers and starch-bearing parenchyma alternating with the broad medullary rays; pith composed of parenchyma, the cells being large, more or less polygonal in outline and containing numerous starch grains, or prisms of calcium oxalate. In sections of roots the pith is absent.

"Russian Licorice.—Nearly cylindrical, somewhat tapering, sometimes split longitudinally, from 15 to 30 cm. in length and from 1 to 5 cm. in diameter; when deprived of the outer corky layer, it is externally pale-yellow; fracture coarsely fibrous; internally lemon-yellow, wood radially cleft; odor distinct; taste sweetish. Under the microscope, transverse sections of the rhizome and roots of Russian Licorice somewhat resemble
those of Spanish Licorice, but the cork cells are absent.

Powdered Glycyrrhiza is pale brownish-yellow (Spanish Licorice) or pale yellow (Russian Licorice); starch grains numerous, mostly single and elliptical or oval, and from 0.002 to 0.02 mm. in diameter; tracheae mostly with bordered pores; wood- and bast-fibers numerous, strongly lignified, very long, much attenuated at the ends and about 0.01 mm. in width; crystal-fibers with monoclinic prisms of calcium oxalate, the latter from 0.01 to 0.02 mm. in diameter, occasional fragments of reddish-brown cork cells occur in Spanish Licorice, but are practically absent in the Russian Licorice. Add 10 Gm. of powdered Glycyrrhiza to 100 mils of distilled water, allow the mixture to macerate for fifteen minutes with occasional stirring; and then heat it for one-half hour on a water bath. Filter the mixture and add through the filter enough water to make the filtrate measure 100 mils; not less than 0.2 Gm. of residue remains on evaporating 10 mils of this filtrate and drying it at 100° C. (212° F.). Glycyrrhiza yields not more than 7 per cent. of ash. U. S.

"When 5 grammes are macerated with 50 millilitres of chloroform water for twenty-four hours, shaken occasionally and filtered, 10 millilitres of the filtrate evaporated in a flat-bottomed dish yield not less than 0.200 grammme of residue dried at 100° C. (212° P.). Ash not more than 6 per cent." Br.

Formerly commerce was chiefly supplied with licorice root by Italy and Spain, but the amount coming from these sources is at present probably not more than 10 per cent. of the whole, the greater portion coming from Southern Russia, a large amount from Anatolia and Syria, and a little from Turkey and Persia. The Spanish variety has been most esteemed, but, according to H. N. Rittenhouse, the peeled Russian licorice is richer in glycyrrhizin and extractives than is any other variety, and is in fact the most valuable. Russian licorice is usually very large, quite sweet, but at the same time rather more bitter and acrid than is the Spanish variety. Licorice root is often worm eaten and more or less decayed; such root should be rejected, as should also the small fibrous roots often shipped from Spain. The best pieces are large, bright yellow internally, and have the layers and the bark distinct. Rusby has stated that he has seen ground licorice imported which apparently consisted of the peelings of Russian licorice. (Ph. Era, 1909, p. 634.)

A character said by Rothrock (A. J. P., 1884) to be diagnostic is the
occurrence of crystal fibers adjoining the wood and bast fibers. These are recognized in the official description of the powdered drug. In the Russian root the parenchymatous wood-cells are larger than in the Spanish. The powder is of a grayish-yellow color, when the root is pulverized without being deprived of its epidermis; of a pale sulphur-yellow, when the epidermis has been removed. Bobiquet found the following ingredients in licorice root: (1) a peculiar transparent yellow substance, called glycyrrhizin, of a sweet taste, scarcely soluble in cold water, very soluble in boiling water, with which it gelatinizes on cooling, thrown down from its aqueous solution by acids, readily soluble in cold alcohol, insusceptible of the vinous fermentation, yielding no oxalic acid by the action of nitric acid, and therefore wholly distinct from sugar; (2) a crystallizable principle named agedo'ite by Robiquet, but subsequently proved to be identical with asparagin; (3) starch; (4) albumen; (5) a brown acid resin; (6) a brown nitrogenous extractive matter; (7) lignin; (8) salts of calcium and magnesium, with phosphoric, sulphuric, and malic acids. Fluckiger states that a small amount of tannin is also always contained in the root, or rather its bark. The chief constituent, glycyrrhizin, \( \text{C}_{44}\text{H}_{63}\text{NO}_{18} \), Gorup-Besanez (Ann. Ch. Ph., 118) considered to be a glucoside, as on boiling with diluted acids it breaks up into glycyrrhizin and an uncrystallizable sugar capable of fermentation. Roussin (J. P. C., July, 1875) found that the sweet taste of the root was not owing to the free glucoside, but to its compound with ammonia. Habermann (Ann. Ch. Ph., 197) found that glycyrrhizin-ammonia was the acid ammonium salt of glycyrrhizic acid, a nitrogenous acid, and gave the formula \( \text{C}_{44}\text{H}_{62}\text{NO}_{18}\cdot\text{NH}_4 \) for it. He succeeded in extracting from the commercial "ammoniacal glycyrrhizin," glycyrrhizic acid, which may be considered to be the active constituent of licorice. It was obtained by dissolving the crude glycyrrhizin in glacial acetic acid at a boiling temperature, rapidly filtering, again treating the crystalline parts of the filtrate in the same manner, and finally purifying by repeated crystallizations from 90 per cent. alcohol. Its properties are peculiar, and account to a great extent for the singular behavior of liquid licorice preparations. With water, in which the substance is but little soluble at ordinary temperature, it forms a transparent, faintly yellow jelly. On mixing 1 Gm. of the body with 100 mils of water, the mixture after a few hours becomes so jelly-like that the open vessel may be inverted without losing any substance. It is insoluble in ether, but slightly soluble in absolute alcohol (even boiling), more so in alcohol of 90 per cent., and especially so when hot. Its solubility increases with the
decrease of the percentage of alcohol. The apparent glucosidal character of glycyrrhizic acid Habermann explains by the fact that it breaks up on boiling with diluted sulphuric acid into glycyrrhetin and parasaccharic acid, according to the reaction:

\[
\text{C}_{4}H_{6}N_{0} \text{O}_{18} + 2\text{H}_{2}\text{O} = \text{C}_{22}H_{47}N_{0} + 2\text{C}_{6}H_{10}O_{2}.
\]

For methods of quantitatively determining glycyrrhizin, see Ext. Glycyrrh., p. 452.

**Uses.**—Powdered licorice root is used for various pharmaceutical purposes as in the preparation of pills, either to give due consistence or to cover their surface and prevent them from cohering, and as a diluent of powdered extracts, etc. As a remedial agent it has been almost entirely replaced by the extract.

**Gnaphalium.** Gnaphalium margaritaceum L. (More correctly Anaphalis margaritacea (L.) Benth. and Hook.) Cudweed. Life-everlasting. Pied de Chat, Immortelle, Fr. Katisenpfotchen, Immerschon, G. (Fam. Compositea.)—An indigenous herbaceous perennial, which with *G. obtusifolium* L. (*G. polyccephalum* Michx.), or sweet-scented life-everlasting, is sometimes used in the form of tea in intestinal and pulmonary catarrhs, and, externally, in the way of fomentation, in bruises, but it probably possesses little medicinal virtue. In Europe different species of Gnaphalium are occasionally employed for similar purposes.

**Gomabrea.**—This is an exudation from a Chilian tree, which has been offered in large quantities in France as a substitute for gum arabic, and is said to be of practical value.
GOSSYPII RADICIS CORTEX. Br.

COTTON ROOT BARK

"Cotton Boot Bark is the dried root-bark of Gossypium herbaceum, Linn., and of other cultivated species of Gossypium." Br.

"The recently-gathered air-dried bark of the root of one or more of the cultivated varieties of Gossypium herbaceum Linne, Gossypium Barbadense Linne, or Gossypium arboreum Linne (Fam. Malvaceae), without the presence of more than 5 per cent. of wood or other foreign matter." N. F.

Gossypii Cortex, N.F.; Ecorce de la Racine de Cottonnier Fr.; Baumwoll-Wurzelrinde, G.; Corteza de la raiz d'algodon, Sp.

In consequence of changes produced in the plants of this genus by cultivation, botanists have found great difficulty in determining which are distinct species and which are merely varieties. By some taxonomists more than fifty species of Gossypium are recognized. There are only 5 or 6 species which yield useful products and the bulk of the cotton is the product of two species: G. herbaceum L., which furnishes the Upland or short staple cotton, and G. barbadense L., the source of the Sea Island or long staple cotton. All of the species are of tropical origin. The Upland cotton has been cultivated in East India and Arabia since ancient times. The Sea Island cotton is indigenous to America and is of the type observed by Columbus.

Gossypium herbaceum is a biennial or triennial plant, with a branching stem from two to six feet high, and palmate hoary leaves, the lobes of which are somewhat lanceolate and acute. The flowers possess yellow petals, having a purple spot near the claw. The leaves of the involucre or outer calyx are serrate. The capsule opens when ripe, and displays a loose white tuft of long slender filaments, which surround the seeds and adhere firmly to the outer coating. The plant is a native of Asia, but is cultivated in most tropical countries. It requires a certain duration of warm weather to perfect its seeds, and, in the United States, does not mature north of Virginia.

The herbaceous part of the plant contains much mucilage, and has been used as a demulcent. The seeds yield by expression a fixed oil of the...
semi-drying kind, which is employed for making soap and for other purposes. (See Oleum Gossypii.) The bark of the root has been supposed to possess medicinal virtues, and is recognized by the National Formulary IV. Another portion, for which the plant is cultivated, is the filamentous substance surrounding the seeds. This, when separated, constitutes the cotton of commerce, and when purified, is official as Purified Cotton. Cotton seeds have been employed in our Southern States with great asserted success in the treatment of intermittents, but are at present seldom, if ever used. (For details, see U. S. D., 16th ed.) For an account of a microscopical and microchemical examination of cotton root bark by F. W. Morgan, see A. J. P., 1898, p. 427. Farwell has made a histological study of the root and stem barks. (See Merck's Rep., 1914, p. 133.) The drug of commerce frequently contains a considerable woody material. It is said it deteriorates with age and therefore only recently gathered bark should be used.

**Properties.**—Cotton Root Bark is described as: "In strips or quilled pieces; thin, tough and fibrous. Cork thin, pale brown, longitudinally striated; removed in places and then disclosing the orange-brown cortex. Inner surface whitish, silky and finely striated. Secondary bast readily separable into thin fibrous laminae. No odor, taste slightly acrid and astringent." Br.

The N. F. describes the bark as follows: "In flexible bands or quilled pieces, attaining a length of 30 cm. and a thickness of about 1 mm.; outer surface orange-brown, smooth, slightly wrinkled, with small circular lenticels, the outer corky layer frequently exfoliated and showing the more or less fissured and fibrous middle bark; inner surface light brown, longitudinally striate; fracture tough, fibrous, the inner bark readily separable into fibrous layers. Odor slight; taste very slightly acrid. Under the microscope, sections of Cotton Root Bark show an outer layer of cork composed of four to six layers of tabular, thin-walled, yellowish-brown, non-lignified cells; a thin primary cortex, consisting of starch-bearing parenchyma and an occasional large secretion reservoir with yellowish-brown contents; inner bark with large groups of bast fibers arranged in interrupted, concentric circles, separated radially by medullary rays and tangentially by the leptome or sieve tissue; bast fibers from 0.3 to 1 mm. in length and about 0.015 mm. in width, the walls being about 0.005 mm. in thickness, strongly lignified and with very few pores, the ends being acute and markedly attenuate; medullary rays one to six cells wide, the cells usually filled..."
with starch grains; the latter from 0.003 to 0.02 mm. in diameter; occasional cells containing rosette aggregates of calcium oxalate from 0.009 to 0.025 mm. in diameter. Cotton Root Bark yields not more than 7 per cent. of ash." N. F.

E. S. Wayne, of Cincinnati, found in it a peculiar acid resin, colorless and soluble in water, when pure, but absorbing oxygen on exposure, and then becoming red and insoluble in water. It is deposited from the fluidextract on standing. He suggests that this may be the active principle of the root; but the fact has not been determined. (A. J. P., 1872.) William C. Staehle (A. J. P., 1875) made an examination of this resin, and obtained results somewhat different from those of Wayne. Staehle's percolate was of a dark reddish-brown color, while Wayne's was pale amber. This is accounted for, however, by the presence of a principle which is colorless in the fresh bark, but of a dark red in bark which has been exposed to air and light. W. A. Taylor noticed that the change in color from pale amber to dark red took place in an alcoholic tincture. (A. J. P., 1876.) Staehle found the resin soluble in 14 parts of alcohol, 15 parts of chloroform, 23 parts of ether, and 122 parts of benzene.

Power and Browning (P. J., 1914, xciii, 420) found in an investigation of cotton root bark the following constituents: acetovanillone (in the steam distillate), a phenolic acid (probably two-thirds dihydroxybenzoic acid), salicylic acid, a new colorless phenolic substance, C$_9$H$_{10}$O$_3$, a new yellow phenolic substance, C$_{13}$H$_{18}$O$_6$, betaine, a fatty alcohol, C$_{20}$H$_{42}$O, a phytosterol, C$_{27}$H$_{46}$O, triacontane, ceryl alcohol, oleic and palmitic acids, and a sugar. Almost all of these constituents were separated from the resinous extractive which constituted between 10 and 11 per cent. of the air dried bark. No tannin was present and no alkaloids were detected.

**Uses.**—Cotton root bark was introduced into medicine by Bouchelle (A. J. M. S., August, 1840), who stated that it was habitually resorted to by the slaves of the south as an abortifacient. His favorable opinion has been confirmed by various southern practitioners, and Scott (T. G., 1911) has shown experimentally that cotton root bark increases the contractions and tonus of the uterus in the lower animals, although it is somewhat less powerful than ergot. It is used not only to strengthen the contractions in uterine inertia during labor, but also in the treatment of
metrorrhagias, especially when dependent on fibroids. Bellany, of Georgia, asserts that the root should be gathered as late as possible in the fall before frost. Bouchelle used a decoction made by boiling four ounces of the inner bark of the root in a quart of water down to a pint, of which he gave a wine glass full (60 mils) every twenty or thirty minutes. The U. S. P., 1890, recognized a fluidextract (see U. S. Dispensatory, 19th edition, p. 525); for the N. F. IV fluidextract, see Part III.

Dose, thirty to sixty grains (2.0-3.9 Gm.).

**GRANATUM. U. S.**

**POMEGRANATE** Granat. [Pomegranate Bark]

"The dried bark of the stems and roots of Punica Granatum Linne (Fam. Punicaceae), without the presence or admixture of more than 2 per cent. of wood or other foreign matter. Preserve it in tightly-closed containers."
U. S.

Granati Cortex, Br., 1898; Pomegranate Bark; Grenadier, Fr. Cod.; Ecorce de la Racine de Grenadier (de Balaustier), Ecorce de Granade, Fr.; Cortex Granati, P. G.; Granatrinde, Granatwurzelrinde, G.; Melogranato. Malicorio, Scorza del Melogranati, It.; Granada (Corteza de), Sp.

The pomegranate is a small tree, attaining in favorable situations the height of twenty feet, with a very unequal trunk, and numerous branches which sometimes bear thorns. The leaves are opposite, petiolate, entire, oblong or lance-shaped, pointed at each end, smooth, shining, and of a bright-green color. The flowers are large, of a rich scarlet color, and stand at the end of the young branches. The petals are roundish and wrinkled, and are inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular berry, about the size of an orange, crowned with the calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many loculi, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia,
Persia, Bengal, China, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher latitudes, where it does not bear fruit, it is raised in gardens and hot houses for the beauty of its flowers, which become double and acquire increased splendor of coloring by cultivation. Doubts have been entertained as to its original country. The name of Punicum Malum, applied by the ancients to its fruit, implies that it was abundant at an early age in the vicinity of Carthage. The fruit, for which the plant is cultivated, varies much in size and flavor. It is said to attain greater perfection in the West Indies than in its native country. The edible pulp is red, succulent, pleasantly acid, and sweetish. The flowers were recognized by the Dublin College, and the seeds are official in France. See a paper by J. U. Lloyd in West. Drug., 1897,202.

The pomegranate may be grown in the United States as far north as Virginia. It is cultivated to some extent in California, and the Gulf States as a garden and hedge plant. The seeds are utilized in the south in making cooling drinks. There are several varieties of the pomegranate. The typical having an acid pulp, and others having a sweet and sub-acid character. There is an East Indian variety which is seedless and is highly prized in India. There are several double-flowered varieties which do not bear fruit and are largely cultivated in the south and in greenhouses for ornamental purposes.

The rind of the fruit is seen in commerce in the form of irregular fragments, hard, dry, brittle, of a yellowish or reddish-brown color externally, paler within, without odor, and of an astringent, slightly bitter taste. It contains a large proportion of tannin, and in countries where the tree abounds, has been employed for tanning leather.

The flowers, sometimes called balaustines, are inodorous, have a bitterish, astringent taste, and impart a violet-red color to the saliva. They contain tannic and gallic acids, and were used by the ancients in dyeing.

Properties.—"The stem bark is mostly in somewhat flattened or transversely curved pieces, to some extent in quills, from 2 to 8 cm. in length; bark from 0.5 to 3.5 mm. in thickness; outer surface yellowish to grayish-brown, with grayish patches of foliaceous lichens with their brownish-black apothecia, longitudinally wrinkled, also marked with
small, broadly elliptical lenticels and with more or less abraded patches of cork; inner surface light yellow or yellowish-brown, finely striate; fracture short, smooth, inner bark yellowish-green; odor slight; taste astringent, somewhat bitter and nauseous. The root bark is in transversely curved pieces; externally brownish-yellow to dark brown with irregular patches of cork; internally dark yellow, the medullary rays extending nearly to the outer surface. The powder is yellowish-brown to dark brown; calcium oxalate crystals in rosette aggregates, monoclinic prisms or crystal fibers, the individual crystals from 0.01 to 0.018 mm. in diameter; starch grains numerous, spherical, ellipsoidal biconvex, polygonal or irregular, and single or compound, from 0.002 to 0.01 mm. in diameter; fragments of whitish cork with strongly lignified walls; stone cells mostly single, occasionally in small groups, the individual cells from 0.05 to 0.18 mm. in length, the walls being very thick and strongly lamellated; occasional fragments of wood with long wood-fibers from 0.015 to 0.02 mm. in width, the walls being slightly lignified and from 0.003 to 0.008 mm. in thickness and associated with tracheae possessing simple and bordered pores. Mix 1 Gm. of powdered Pomegranate with 100 mils of distilled water, macerate it with occasional agitation for about an hour and filter; a light yellow filtrate is obtained. Upon the addition of a drop of ferric chloride T.S. to 10 mils of this filtrate a bluish-black precipitate is produced. Upon the addition of from 40 to 50 mils of lime water to another portion of 10 mils of the filtrate, an orange-brown, flocculent precipitate is produced. Pomegranate yields not more than 16 per cent. of ash." U.S.

The roots of the pomegranate are hard, heavy, knotty, ligneous, and covered with a bark which is yellowish-gray or ash-gray on the outer surface, and yellow on the inner. The root bark occurs in quills or fragments similar to but differing from those of the stem as shown in the official characterization. "The transverse section exhibits numerous fine radial and tangential lines." Br. (1898). It has little or no odor, colors the saliva yellow when chewed, and leaves in the mouth an astringent taste without disagreeable bitterness. There is considerable question as to the relative value of the root and stem barks of granatum. The drug of commerce usually consists of a mixture of stem and root bark, the former commonly predominating. Granatum is sometimes substituted by the barks of other plants. The principal of these being Berberis vulgaris, which is bitter and not astringent; Buxus sempervirens, which is also bitter and free from tannin; and Strychnos Nux Vomica or false Angostura bark which has a dark inner surface
and a very bitter taste. None of these barks have the characteristic checkered appearance of the transverse surface of genuine Granatum.

The bark of the stem of the pomegranate is sold as root bark: for microscopic diagnosis, see P. J., 1873. As the activity of the barks of different portions of the plant is important, represented by the alkaloids the analyses of Stoeder are of interest. His results are: stem and branch bark, in thin quills, 0.612 per cent.; average quills, 0.350 per cent.; thick quills, 0.498 per cent.; root bark from south of Europe, in thick quills, 1.010 per cent.; shaved root bark from Java, 1.326 per cent.; exfoliated bark from dry thick roots of unknown age, 1.240 per cent.; finely rasped wood from these roots, 0.218 per cent. According to the same authority (Nederl. Tijd. Pharm., 1890), of the bark of three varieties of the wild pomegranate recognized and used by the natives of Java, the red-flowered "merah," yielded 2.43 per cent.; the white-flowered, "poetih," yielded 3.75 per cent.; the black-flowered, "hitam," yielded 1.71 per cent.

The infusion of granatum yields a deep-blue precipitate with salts of iron, and a yellowish-white precipitate with solution of gelatin. The inner surface of the bark, steeped in water and then rubbed on paper, produces a yellow stain, which by the contact of ferrous sulphate is rendered blue, and by that of nitric acid acquires a slight rose tint, which soon vanishes. These properties serve to distinguish this bark from those of the box root and barberry. When used, it should be separated from the ligneous portion of the root, as the latter is inert. The bark contains more than 22 per cent. of tannic acid, which Rembold (Ann. Ch. Ph., 143, 285) found to consist for the most part of a peculiar variety, punico-tannic acid, C_{20}H_{16}O_{13}; when boiled with diluted sulphuric acid it is resolved into ellagic acid, C_{14}H_{8}O_{9}, and sugar. Punico-tannic acid is accompanied by common tannic acid, yielding by means of sulphuric acid, gallic acid, which appears sometimes to pre-exist in the bark. Henry Trimble, however (A. J. P., 1897, 636), as the result of an ultimate analysis of the purified tannin and a study of its reactions, pronounced it to be identical with gallotannic acid. Pomegranate bark also yields a considerable quantity of mannite, which was formerly described under the names of punicin or granatin. The medicinal value of the root, however, is due, according to Tanret (C. R. A. S., lxxxvi, 1270, and lxxxvii, 358), to an alkaloid pelletierine, C_{8}H_{15}NO, a dextrogyrate liquid boiling at 195° C. (383° F.), easily soluble in water, alcohol, and ether, and specially so in chloroform. It
has strong basic properties and precipitates many metallic salts: 1000 parts of dry bark yielded 4 parts of it.

Tanret (C. R. A. S., lxxxviii, p. 716) announced that he had found three additional volatile bases in the bark, a liquid left-rotating one, a liquid optically inactive one, and a crystallizable inactive one, to which the names of methylpelletierine, C$_9$H$_{17}$NO, and pseudopelletierine (granatonine), C$_9$H$_{15}$NO, and isopelletierine, have been given. Carl J. Bender (Ph. Centralh., 1885, p. 6) found three bases in pomegranate bark, one crystallizable and two amorphous. He objects to the name pelletierine, and substitutes punicine. Wm. F. Junkunz analyzed pomegranate bark, and believed that the alkaloid exists in the bark as a tannate. (A. J. P., 1884.) The old idea that the bark loses activity when kept seems to be negatived by the analysis of De Vrij. (P. J., xxi.) Piccinni isolated a tertiary alkaloid, C$_{10}$H$_{18}$NO, from pomegranate root bark. (P. J., 1900, 24-9.) Fluckiger stated that methyl pelletierine predominates in the bark of the root and pelletierine in the bark of the overground portions of the plant. For Leger's method of determining total alkaloids, see P. J., 1904, 581. Assay processes for granatum are given in most of the foreign pharmacopoeias and these were critically reviewed by Dichgans (Ph. Ztg., 1914, 852), who finds the one in the Swiss Pharmacopoeia to be the best.

**Uses.**—The rind of the pomegranate fruit was formerly recognized by the U. S. Pharmacopoeia. It is astringent, and in the form of decoction is sometimes employed in diarrhea and colliquative sweats, and, more frequently, as an injection in leucorrhea, and as a gargle in sore throat in the earlier stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in intermittent fever. The flowers have the same medicinal properties and are used for the same purposes. The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna, but was unknown in modern practice until brought into notice by F. Buchanan, who learned its powers in India. The Mahometan physicians of Hindostan consider it a specific against taenia. One of these practitioners, having relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. The French writers prefer the product of the wild pomegranate, growing on the borders of the Mediterranean, to that of the plant cultivated in gardens for ornamental purposes. The bark may
be administered in powder or decoction, but the latter form is usually preferred. The decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling to a pint. Of this a wineglassful may be given every half hour, hour, or two hours, until the whole is taken. It often nauseates and vomits, and usually purges. Portions of the worm often come away soon after the last dose. It is recommended to give a dose of castor oil and to diet the patient strictly on the day preceding the administration of the remedy, and, if it should not operate on the bowels, to follow it by castor oil, or an enema. If not successful on the first trial, it should be repeated daily for three or four days, until the worm is discharged. It appears to have been used by the negroes of San Domingo before its introduction into Europe.

Pomegranate owes its anthelmintic powers to the alkaloids, pelletierine and isopelletierine, the mixture of which is official. The efficacy of these taenicides has been abundantly confirmed, and it appears to be established that the tannate is the most effective and the least dangerous form of the remedy,—probably because its insolubility prevents its rapid absorption and enables it to come in prolonged contact with the worm. The experiments of Dujardin-Beaumetz have shown that the alkaloids from pomegranate act upon the higher animals like curare, causing paralysis of the motor nerves without affecting sensation. The same authority asserts that hypodermic injections of six grains produce in man severe vertigo, muscular weakness, and great retinal congestion. Double vision has also been noted, and Galezowski has been led by it to prescribe pelletierine in paralysis of the third and sixth pairs of nerves; he affirms that he has succeeded in affording relief after the failure of potassium iodide and blisters. The proper dose of pelletierine tannate is variously given by authorities. It has been stated to be from one-half to three-quarters of a grain (0.032-0.048 Gm.) (B. G. T., xcvi, xcvi), but others place it as high as eight grains (0.5 Gm.). Commercially, it occurs almost exclusively as a syrupy solution, put up, we believe, under the supervision of its discoverer, each bottle containing a single dose, it is stated, of about five grains (0.32 Gm.). We have seen pronounced temporary general palsy produced in a female adult by this dose. The dose of pomegranate rind and flowers in powder is from twenty to thirty grains (1.3-2.0 Gm.). Decoctum Granati Corticis was formerly official in the British Pharm. (1898). The decoction may be prepared in the proportion of four ounces of the bark to twenty fluidounces of water, and given, in the dose of half a fluidounce (15
mils). The remedy should always be given after a twelve hours fast, and be followed in two hours by a brisk cathartic. The seeds are demulcent.

Dose, twenty to thirty grains (1.3-2.0 Gm.).

**Off. Prep.**—Fluidextractum Granati, U. S.

**Gratiola.** Gratiola officinalis L. Hedge-hyssop, Gratiate, Fr. Gnadenkraut, Gottesguadenkraut, Gr. (Fam. Scrophulariaceae)—This is a perennial herb, indigenous in the south of Europe, in meadows and other moist grounds. The whole herb is used. It is nearly inodorous, but has a bitter nauseous taste. The indigenous G. virginiana L. closely resembles the European plant and indeed was regarded by Michaux as identical with it. Both water and alcohol extract its active properties. F. G. Walz found in it the following constituents: 1, gratiolin; 2, gratiosolin; 3, gratioloic acid; 4, gratiola fat; and 5, a brown resin. For chemistry, see P. J., Ixix, 295, and lx, 385. The gratiolin is decomposed on prolonged boiling with diluted H2SO4 into gratioletin, gratiolaretin, and sugar; the gratiosolin is similarly decomposed by dilute acids or alkalis into gratiosolatin and sugar; the gratioloic acid is obtained in the form of pearly white scales of a fatty odor. Hedge-hyssop is a drastic cathartic and emetic, possessing also diuretic properties, and has been used in Europe for the relief of dropsy, jaundice, worms, chronic hepatic affections, and scrofula. The dose of the powdered herb is from fifteen to thirty grains (1.0-2.0 Gm.); of the infusion (half an ounce to the pint of boiling water), half a fluidounce (15 mils).

**Ground Nuts.** Peanuts. Earth nuts. Goober-nuts.—The fruit of Arachis hypogaea L., a leguminous, annual plant, indigenous probably in Africa and South America and abundantly cultivated in our Southern States, China, etc. Recent government statistics show that about 16,000,000 bushels are produced annually in the United States, and about 29,000,000 bushels imported. There has, however, been a great increase in the domestic production in the last year or two, and the American crop will probably be much larger in the near future.

A remarkable property of the plant is that its fruit ripens under the surface of the ground, into which the pods penetrate after flowering, until the young fruit is completely buried under the soil in the progress of their growth. The kernels or seeds contain about 45 per cent. of a fixed oil. (See Oleum Arachis, Part I.)

**GRINDELIA. U. S., Br.**

**GRINDELIA** Grindel.

"The dried leaves and flowering tops of Grindelia camporum Greene, or Grindelia cuneifolia Nuttall, or Grindelia squarrosa (Pursh.) Dunal (Fam. Compositae), without the presence or admixture of more than 10 per cent. of stems or other foreign matter." U. S. "Grindelia consists of
the dried leaves and flowering tops of Grindelia camporum, Greene." Br.

California Gum-plant; Grindelia, Fr.; Grindelie, G.

The genus Grindelia includes some twenty-five species, six or eight of which are found in South America and the remainder occurring in the United States west of the Mississippi. They are coarse perennial or biennial herbs, being occasionally shrub-like. Most, if not all, of the species produce a resinous exudation on the stem and leaves and especially on the flower-heads. The leaves are alternate, sessile or clasping and spinulose-dentate. The flowers occur in large terminal heads composed of both discoid and radiate yellow flowers. The ray flowers are pistillate and the involucre is more or less hemispherical, the bracts being imbricated, in several series, being usually subulate-tipped. The drug of the market appears to be derived in large part from G. camporum Greene, which is the common "gum plant" of California. It occurs abundantly in the inner coast ranges, where it has been collected in quantity in Lake and Napa Counties. It is also common in the foothills of the Sierra Nevada and is almost the only plant found on the plains in certain regions of the Sacramento Valley. The leaves are oblong or spatulate, sessile or clasping, coarsely serrate and of a pale-green color. The flower-heads are yellow and the involucre consists of several rows of lanceolate acuminate recurved bracts. The achenes are distinctive in this species and are usually biauriculate or more rarely unidentate at the summit.

G. cuneifolia closely resembles G. camporum. The leaves are cuneate oblong or linear oblong and either sessile or amplexicaul. It is a marsh plant and is not as glutinous as G. camporum. The leaves of this species, in addition to their being cuneiform in shape, are darker green and not so thick as in G. camporum. The achenes are compressed and closely resemble those of G. camporum.

G. squarrosa is a common plant on the prairies and dry banks of the West. It has been reported as occurring from the Saskatchewan to Minnesota, Texas and California. It is a glabrous, erect, branching herb having linear-oblong or spatulate leaves, which are more or less clasping at the base and sharply spinulose-dentate. It is especially characterized by the bracts of the involucre being linear-lanceolate, subulate tipped and spreading or squarrose at the summit, giving the species its name. The achenes are truncate, those of the outer flowers
being usually thicker. The pappus consists of two or three awns.

It was formerly supposed that the drug of commerce was derived from G. robusta. The studies of Perredes (Proc. A. Ph. A., 1906, 370) showed this not to be the case. G. robusta is apparently not a very common plant and is distinguished by having cordate-oblong, amplexicaul, coarsely serrate leaves. The involucre is squarrose and leafy at the base. The pappus consists of two awns. At one time both G. cuneifolia and G. camporum were considered merely as varieties of G. robusta.

According to Joseph Beauvais (A. J. P., Feb., 1889), the resin of the leaf of G. robusta is contained in epidermal glands, and also in rather large resin-ducts situated in an interior collen-chymatous layer.

Properties.—The official description of grin-delta is as follows: "Stems with attached branches terminated with resinous flower-buds; stems cylindrical, not exceeding 2 mm. in diameter; light yellow or rose-colored, with alternate leaf-scars, occasionally with basal portions of leaves, sometimes more or less irregularly flexuous and coated with resin, especially at the nodes; leaves usually separate and more or less broken and varying in shape when entire from oblong and lanceolate, to oblanceolate-spatulate and cuneate-spatulate, from 1 to 7 cm. in length, mostly sessile or amplexicaul and more or less sharply serrate or evenly spinosely-toothed, pale yellow to yellowish-green, very resinous, somewhat coriaceous and brittle; bracts of flowering branches almost entire and usually more or less spreading; heads more or less resinous, viscid, many-flowered, either conical-urceolate or depressed-urceolate, involucres from 5 to 20 mm. in breadth, composed of numerous imbricated bracts with more or less recurved tips; ray flowers yellow, ligulate and pistillate; disk florets yellow, tubular and perfect; pappus of two or three mostly unequal linear awns about the length of the disk florets; disk achenes more or less ovoid or oblong; more or less compressed or triquetrous, and either biauriculate or broadly unidentate or with a broad truncate corky, thickened summit; odor balsamic; taste aromatic and bitter, resinous. The powder is yellowish-brown; consisting of numerous fibrous fragments made up of tissues of the stem, the most prominent being the tracheae with annular and spiral thickenings or marked with simple or bordered pores, associated with numerous, narrow, strongly lignified wood-fibers; pith cells more or less tabular and containing a layer of protoplasm in which are embedded numerous spheroidal granules; fragments of epidermis of leaves very characteristic
and showing more or less polygonal areas containing large chloroplastids, and the large, colorless, basal cells of the multicellular glandular hairs; pollen grains spherical, about 0.035 mm. in diameter, spinose, and in section showing three pores." U. S.

"Stems slender, yellow, smooth. Leaves three to five centimetres long, oblong or spatulate, sessile or amplexicaul, pale green, rigid, brittle, smooth, glabrous; surface minutely dotted; margin coarsely serrate. Flower-heads yellow, hard, resinous, with several rows of lanceolate-acuminate, recurved bracts. Fruits biauriculate or unidentate at the summit, with a pappus consisting of two thick, stiff bristles. All parts more or less resinous. Slightly aromatic odor, taste aromatic and bitter." Br.

As it occurs in commerce, grindelia is in the form of the whole dried herb; the stems are about eighteen inches in length, light brownish, very frequently stripped of their leaves, but with some of the floral heads adherent. The brittle leaves are much broken, and, with separate floral heads, are mixed with the stem. The taste is warm, peculiar, and very persistent. Tunmann (Ph. Zentralh., 1908, p. 457) has made an excellent pharmacognostical study of G. robusta. Wohn (Merck's Rep., 1910, p. 310) presents the results of a morphological study of G. squarrosa. Farwell (D. C., 1907, p. 460) reports having received one of the California "tar weeds," Hemizouella minima Gray, for grindelia. The plant is very diminutive in size, but the inflorescence is very glutinous. Perredes (P. J., 1909, xxix, pp. 596 and 604) gives the results of some experiments in the cultivation of G. camporum. The activity of the drug probably resides in the resinous exudation. C. J. Rademaker obtained from it an oil, the odor of which closely resembled that of oil of turpentine, resin, and a crystalline body having an alkaline reaction. (N. R., 1S76, p. 205.) W. H. dark and John L. Fischer (A. J. P., 1888, p. 433) failed to verify all of Rademaker's results, but obtained an alkaline principle to which the name of grindelina was given. A. Schneegans (A. J. P., 1892, 369) found in Grindelia robusta, saponin, which, he states, is composed of two glucosides; he also found indications of an alkaloid, but believes that its presence is not yet certainly proved. See also M. R., 1898, 394. Grindelia robusta is said to contain 0.28 per cent. of a dark-brown essential oil, having a specific gravity of 0.9582 at 15° C. (59° F.), and the optical rotation in alcoholic solution of -8° 08'. It is soluble in ether, amyI alcohol, and chloroform. (Ph. Ztg., 48, 574.)
**Uses.**—Grindelia is possessed of only feeble physiologic powers, but according to Buffington, when given to the lower animals in very large doses produces narcosis, with dilated pupils, slowing of the action of the heart from stimulation of the inhibitory nerves, and elevation of the blood pressure from stimulation of the vasomotor center. Dobroklowsky has found that it had a primary stimulating and later depressant effect on the isolated frog's heart. He further states that it acts chiefly upon the motor nerves and muscles, but Buffington asserts that it paralyzes first the sensory nerve-trunks, than the sensory side of the spinal cord, and afterwards involves the motor nerve-trunks and cord. Grindelia is used almost solely in the treatment of bronchial catarrhs, especially when there is a tendency to asthma. Its action is probably simply that of a stimulating expectorant, but some believe it exerts also an antispasmodic influence. It is frequently used in conjunction with stramonium leaves in the preparation of "Asthma powders" or cigarettes. It has been employed with asserted success in whooping cough. Its active principles appear to be excreted from the kidneys; hence, after large doses, there are sometimes evidences of renal irritation, and in chronic catarrh of the bladder good has been effected by its stimulant influence upon the mucous membrane of the viscus. As a local application, grindelia has been employed with asserted advantage in burns, vaginitis, genito-urinary catarrh, etc., applied either in the form of a poultice or in solution. It has considerable use also as a local application in the treatment of rhus poisoning. The fluidextract, diluted with water, is employed.

Dose, thirty to forty grains (2.0-2.6 Gm.).

**Off. Prep.**—Fluidextractum Grindeliae, U. S. (Br.).

**Guaco.**—This name is given in Central and South America and the West Indies to various plants belonging to the genera Willughboae (better known under the newer name, Mikania) and Aristolochia; but it is in its application to the different species of the former genus that the drug is known in medicine. The species most used is W. amara (Willd.) O. Kze. (Mikania amara Willd.), and M. Quaco, genus Eupatorium, Humb. and Bonpl. Plants closely allied to the M. Houstonis (Willd.) O. Kze.—as M. gonocrotada (DC.) O. Kze. (of the Fam. Composites); Aristolochia fragrantissima Ruiz., A. grandiflora Sw., A. pentalanara J acq. (of the Fam. Aristolochiaceae) ; Comocladia integrifolia J acq. (Fam. Anacardiaceae)—are also known locally as guaco. M. amara is described as having twining stems, with round, sulcate, and hairy branches; ovate subacute-minate, remotely dentate leaves, somewhat narrowed at the base, rough above and hairy beneath, and flowers in opposite axillary corymbs. The plant is a native of tropical America, and has been introduced into the West Indian Islands from
the continent. The leaves are the part used. The result of a long and close investigation into the natural history of guaco by Guibourt is, that the guaco from this source, instead of possessing, as has been asserted, a strong, penetrating, and nauseous odor, is in fact inodorous, and destitute of all active properties, and that the strongly aromatic plants which have been employed under the name of guaco all belong to the genus Aristolochia, especially A. cymbifera Mart. and Zucc., growing in Brazil, after this A. maxima (DC.), and in less degree A. maxima Jacq. (A. geminiflora H.B.K.). (J. P. C., 1867, 99.)

Although the guacos of South America seem to be entirely distinct drugs they appear to be indiscriminately used by the natives for the cure of the bites of poisonous serpents. The medicine is also used in South America as a febrifuge and anthelmintic, and has been considered antisyphilitic. A few years ago it attracted on the continent of Europe considerable attention on account of its alleged power in epidemic cholera and chronic diarrhea. The Aristolochia cymbifera Mart. and Zucc. has been the subject of a careful study by L. Butte. (Annales de la Polidin, deParis, Sept., 1890.) The root of this plant as it occurs in commerce is cylindrical, from three to four centimeters in diameter, much broken up into long rootlets, yellowish, with a strong odor, especially in the bark. The plant itself is a vine, growing in great abundance in the province of Tabasco in Mexico. Butte was not able to find in it either an alkaloid or a glucoside, but he found a blackish resin which may be the active principle of the plant, though this does not seem probable, since Butte found the alcohol extract much less active than the aqueous extract, which would hardly be the case if the resin were really the active principle. In the physiological experiments made with the aqueous extract it was found that massive doses produced cries and excitement, followed after a time by sleep, with muscular relaxation and symptoms of gastro-intestinal irritation. There was also depression of the nerve center, both sensory and motor. If the dose were sufficient death was produced by an arrest of the respiration. The heart continued to beat after the cessation of respiration; nevertheless there was depression of the arterial pressure, apparently due to the action of the drug upon the heart. After death marked signs of irritation of the gastro-intestinal tract and kidneys were found. Butte believes that guaco has valuable therapeutic properties in the treatment of skin affections, especially eczema and pruriginous maladies, in which he used it both locally and internally. He gives the dose of the aqueous extract of guaco as three grains (0.2 Gm.) three times a day. In the external application the following formula was used. Guaco (bruised), 30 parts; sodium bicarbonate, 5 parts; water, 1000 parts; boil for a quarter of an hour, allow to macerate one hour, decant, and use the liquid as a lotion. Guaco is said to be largely used in South America as an antirheumatic and E. W. Pritchard (P. J., 1861) affirms that in the gouty paroxysms it is especially effective given in the dose of a fluidrachm (3.75 mils) of the tincture every four hours, and applied locally.

**GUAIACI LIGNUM. Br.**

**GUAIACUM WOOD**

"Guaiacum Wood is the heart-wood of Guaiacum officinale, Linn., or of

---

The Southwest School of Botanical Medicine http://www.swsbm.com
Guaiacum sanctum, Linn." Br. "The heart-wood of Guaiacum officinale Linne or of Guaiacum sanctum Linne (Fam. Zygophyllaceae)" N. F.

Lignum Sanctum (vel Benedictum); Lignum Vita; Gayac, Fr. Cod.; Bois de Gayac, Fr.; Lignum Guajaci, P. G.; Gua-jakholz, Franzosenholz, Pockholz, G.; Guajaco, Legno guaijaco, It.; Guayaco (Leño de), Sp.

Guaiacum officinale is a large tree, of a very slow growth. When of full size it is from forty to sixty feet high, with a trunk four or five feet in circumference. The branches are knotted, and covered with an ash-colored striated bark. That of the stem is of a dark-gray color, variegated with greenish or purplish spots. The leaves are opposite, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are obovate, veined, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue color, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

G. sanctum L. is distinguished from G. officinale by its five-celled fruit and its oblong or obliquely obovate or sometimes rhomboid-ovate leaflets, six to eight to each leaf. It grows in Cuba, the Bahama Islands and Florida. Its wood is smaller than that of G. officinale, and is said by Fee to be paler and less dense.

The commercial supplies are shipped from the Bahama Islands and Florida to London, Hamburg and Havre.

G. officinale grows throughout tropical America, particularly in the Lesser and Greater Antilles, also in Brazil, Venezuela and Colombia. The commercial drug is exported from Port au Prince, Puerto Plata and St. Domingo, also Savanilla (Colombia) and Puerto Cabello (Venezuela). G. arboreum of De Candolle has been said to furnish some of the guaiacum wood of commerce.

As imported, guaiac wood is in the shape of logs or billets, covered with thick gray bark, which presents on its inner surface, and upon its edges, when broken, numerous shining crystalline particles. These were supposed by Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant; but Otto Berg has determined that they are crystals of calcium sulphate. The billets are used by turners for the fabrication of various instruments and utensils, for which the wood is
well adapted by its extreme hardness and density. It is sometimes kept
by pharmacists in the state of shavings or raspings, which they obtain
from the turners. It is commonly called lignum vitae, a name which
obviously originated from its durable properties.

Properties.—Guaiacum wood is hard and heavy. The color of the sap-
wood is yellow, that of the older and central layers greenish-brown, that
of the shavings a mixture of the two. It is said that when the wood is
brought into a state of minute division its color is rendered green by
exposure to the air, and bluish-green by the action of nitric acid fumes,
and the latter change may be considered as a test of its genuineness.
(Duncan.) An easier test is a solution of corrosive sublimate, which,
added to the shavings and slightly heated, causes a bluish-green color
in the genuine wood. Guaiacum wood is almost without odor unless
rubbed or heated, when it becomes odorous. When burned, it emits an
agreeable odor. It is bitterish and slightly pungent, but requires to be
chewed for some time before the taste is developed.

"Dark greenish-brown, dense, hard; heavier than water. In transverse
section, abundant sclerenchymatous fibres, scattered, isolated vessels,
and medullary rays one cell wide. Odor, on warming, somewhat
aromatic; taste slightly acrid. An alcoholic tincture prepared from the
Wood assumes a blue color on the addition of diluted T. Sol. of ferric
chloride." Br.

The N. F. IV describes it as follows: "Usually in the form of shavings,
chips or raspings of a greenish-brown color, heavier than water, entirely
free from adhering bark and containing only a few chips or shavings of
a whitish color (sap wood). Almost odorless except when heated; taste
bitter and acrid when chewed for some time. The powder, when
examined under the microscope, exhibits numerous fragments of more
or less lignified, thick-walled wood fibers, up to 0.028 mm. in width,
some with simple, oblique pores; tracheae from 0.09 to 0.16 mm. in
width, some filled with resin; numerous small masses of resin; wood
parenchyma and medullary ray cells up to 0.02 mm. in width, with
lignified, porous walls and usually containing resin; occasionally
tangential views of the medullary rays show an elliptical group of from
three to six cells; the resin masses and resinous tissue become bluish-
green on the addition of iodine T.S. Place powdered Guaiac Wood in a
solution of sodium chloride (1 in 3); the blackish-brown part only will
sink and this does not exceed in amount the portion which floats. Shake
10 mils of alcohol with 0.5 Gm. of ground Guaiac Wood for a few seconds and filter the mixture; the filtrate yields a deep blue color with one drop of a solution of ferric chloride (1 in 10). Guaiac Wood yields to alcohol not less than 15 per cent. of extractive. Guaiac Wood yields not more than 3 per cent. of ash." N. F.

Guaiac wood contains, according to Trommsdorf, 26 per cent. of resin, and 0.8 of bitter pungent extractive, upon both of which, probably, though chiefly on the former, its medicinal virtues depend. (See Guaiacum.) Paetzold (Schim Rep., 1902, 43) states that the bark of the guaiac tree yields 1 per cent. of a volatile oil, having an exquisite odor. The wood yields its virtues but slightly to water. One pound of the wood afforded to Geiger two ounces of extract.

**Uses.**—Guaiacum wood possesses no therapeutic powers which are not contained in its resin and the latter is always to be preferred.

Dose, thirty to sixty grains (2.0-3.9 Gm.).

**Off. Prep.**—Decoctum Sarsaparillae Compositum, N. F.

**GUAIACUM. U. S. (Br.)**

**GUAIAC Quaiac. [Guaiaci Resina, Pharm. 1890, Guaiac Resin]**

"The resin of the wood of Guaiacum officinale Linne, or of Guaiacum sanctum Linne (Fam. Zygophyllaceae)." U. S. "Guaiacum Resin is the resin obtained from the stem of Guaiacum officinale, Linn., or of Guaiacum sanctum, Linn." Br.

For a description of Guaiacum officinale, see Guaiaci Lignum.

Guaiac resin was introduced into the London Pharmacopoeia in 1677. It exists in the tree as a physiological product filling up the tissues of the wood. It is obtained in several different modes. The most simple is by spontaneous exudation, or by incisions made into the trunk. Another method is by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet on
the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. But the plan probably most frequently pursued is to boil the wood, in the state of chips or sawdust, in a solution of common salt, and skim off the substance which arises to the surface. Guaiace is chiefly produced in the eastern portion of the Island of Haiti, being exported from Port au Prince and Gonaives. (Ap.-Ztg., xxv, p. 556.) It is estimated that in 1912 about 6000 pounds of guaiac resin were exported to the United States. It is usually in large irregular pieces of various sizes, in which small fragments of bark, sand, and other impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes it is found in small roundish homogeneous portions, separate or agglutinated; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac obtained from the billets in the manner above described is of uniform consistence.

Properties.—The masses are irregular or somewhat globular, of a glassy luster and resinous fracture. They are of a deep greenish-brown or dark-olive color on their external surface, and internally wherever the air can penetrate. The predominant hue of those parts not exposed to the air is reddish-brown or hyacinthine, diversified, however, with shades of various colors. The odor is feeble but fragrant, and is rendered stronger by heat. The taste, which is at first scarcely perceptible, becomes acrid after a short period, and a permanent sense of warmth and pungency is left in the mouth and fauces. Guaiac is brittle, and when broken presents a shining glass-like surface, conchoidal or splintery, with smaller fragments more or less translucent. It is readily pulverized, and the powder, at first of a light-gray color, becomes green on exposure to the light. Its sp. gr. varies from 1.2 to 1.23. It softens in the mouth, and melts with a moderate heat. Water dissolves a small proportion of guaiac, not exceeding nine parts in 100, forming an infusion of a greenish-brown color and sweetish taste, which upon evaporation yields a brown substance soluble in hot water and alcohol, but scarcely so in ether. Alcohol takes up the whole, with the exception of impurities. The official requirements are as follows: "In irregular fragments or in large, nearly homogeneous masses, occasionally in more or less rounded or ovoid tears, enclosing fragments of vegetable tissues; externally brown, becoming greenish-gray-brown on exposure, the fractured surface having a glassy luster, the thin pieces being
translucent and varying in color from reddish to yellowish-brown; odor balsamic; taste slightly acrid. Guaiac melts between 85° and 90° C. (185° and 194° F.). It is readily soluble in alcohol, ether, chloroform, creosote, and in solutions of the alkalies or in hydrated chloral T.S. It is sparingly soluble in carbon disulphide or benzene and not more than 15 per cent. is insoluble in alcohol; the alcoholic solution, on the addition of an excess of chlorine water or tincture of ferric chloride, becomes blue, changing quickly to green, the color being best seen when the solutions are diluted with an equal volume of water. Macerate the crushed or powdered Guaiac with 4 or 5 times its weight of purified petroleum benzin for three hours and then filter; the filtrate is colorless, and does not give a green color on the addition of an equal volume of cupric acetate T.S. (rosin). The powder is grayish, becoming green on exposure to the air. Guaiac yields not more than 4 per cent. of ash." U. S.

"In masses, or sometimes in large more or less rounded tears. Brittle; fracture vitreous; thin splinters transparent, from yellowish-green to reddish-brown. Powdered Resin greyish, but becoming green on exposure to light and air. Odor, on warming, somewhat aromatic; taste slightly acrid. A solution in alcohol (90 per cent.) is colored blue by diluted T. Sol. of ferric chloride. 1 gramme of the powdered Resin, shaken for five minutes with 5 millilitres of petroleum spirit, yields a colorless filtrate which does not become green when shaken with an equal volume of diluted solution of copper acetate (absence of colophony). Not more than 10 per cent. insoluble in alcohol (90 per cent.). Ash not more than 4 per cent." Br.

The tincture is of a deep-brown color, is decomposed by water, and affords blue, green, and brown precipitates with the mineral acids. It is colored blue by nitric acid, by chlorine, and by tincture of ferric chloride, and usually by spirit of nitrous ether, and is similarly changed when treated successively by diluted hydrocyanic acid and solution of copper sulphate. Either in substance or tincture, guaiac gives a blue color to gluten and substances containing it, to mucilage of gum arabic, to milk, and to various freshly cut roots, as to the potato, carrot, and horseradish. This is on account of the fact that oxidizing enzymes or oxidases are present in all of these substances and guaiac resin is one of the most delicate reagents for detecting this class of enzymes. It is soluble also in ether, alkaline solutions, and sulphuric acid. The solution in sulphuric acid is of a rich claret color, deposits, when diluted with water, a lilac precipitate, and, when heated, yields charcoal. Exposed to
air and light, guaiac absorbs oxygen and becomes green, and the change takes place rapidly in the sunshine. Schaer states that a good natural guaiac resin is preferable to a resin purified by alcoholic treatment as a reagent, but a solution of resin extracted by chloroform from the wood is the most sensitive of all. Tincture of guaiac has been used for the detection of blood stains, which it does by the blue color produced by it, when in contact with the red coloring matter of blood, in connection with some ozonized substance, especially hydrogen dioxide. R. M. Bertolet (Am. J. M. S., Jan., 1874) has used it to distinguish between the blood of man and other mammals, in which the corpuscles are non-nucleated, from that of other classes, as birds, fishes, and reptiles, which have nucleated corpuscles.

Lucker (Proc. A. Ph. A., 1894, 953), finds in guaiac three acids,—viz., guaiacic, C_{20}H_{24}O_{4}, occurring in crystals melting at 86 C. (186.8° F.); guaiaconic, Q_{20}H_{24}O_{5}, an amorphous body melting at from 81° to 83° C. (177.8°-181.40 F.); and guaiacinic, C_{21}H_{22}O_{7}. He considers all three of them to be probably condensation products from tiglic aldehyde with creosol and guaiacol. Dobner has also determined that these three acids form a series of hydroxyl-containing acids which may be represented by the formulas: C_{20}H_{23}O_{3}(OH), C_{20}H_{22}O_{3}(OH)_{2} and C_{21}H_{19}O_{4}(OH)_{3}. (Tschirch, Harze und Hambehalter, 1900, p. 300.) Guaiac yellow, the coloring matter of guaiac resin, was first observed by Pellier. It crystallizes in pale yellow quadratic octahedra having a bitter taste, but is not a gluco-side. Guaiac resin also yields interesting products on dry distillation. First, according to Hiasiwetz, is obtained guaiacene, C_{5}H_{8}O,

\[ \text{at 118° C. (244.4° F.)} \]

next guaiacol, \( C_{6}H_{4} \left\{ \begin{array}{c} \text{OCH}_{3} \\ \text{OH} \end{array} \right\} \)

being the methyl ether of pyrocatechin, at 205° to 210° C. (401°-410° F.), and with it kresol, C_{6}H_{3}(CH_{3})_{2}OH, and finally pyroguaiaicin, C_{38}H_{44}O_{6} (according to Wiesner, C_{18}H_{18}O_{3}), in pearly scales, melting at 180° C. (356° F.). According to Lieben and Zeisel (Ber. d. Chem. Ges., xiv, p. 932), guaiacene is the aldehyde of tiglic acid, C_{5}Hs02, and can be made synthetically from a mixture of acetaldehyde and propionaldehyde. When distilled with zinc dust there is obtained kresol (50 per cent. in the case of resin purified by alcohol) and 30 per cent. of a mixture of toluene, meta- and paraxylene, with a little pseudocumene and guaiion, C_{12}H_{12}.
Saponin has been found by E. Paetzold in the bark, the wood, and the
natural resin of guaiacum. (Bull. des Sciences Pharm., iii, 407.)
According to the experiments of W. Frieboes (In. Dis., Rostock, 1903),
this saponin (1 to 1000) forms a frothing solution which is persistent, is
an excellent emulsifier, has the power to maintain in solution large
proportions of sparingly soluble substances and is innocuous and non-
irritant.

The mineral acids are incompatible with the solutions of guaiac.

Adulterations.—This drug is sometimes adulterated with the rosin of
the pine. The fraud may be detected by the terebinthinate odor exhaled
when the sophisticated guaiac is thrown upon burning coals, as well as
by its partial solubility in hot oil of turpentine. This liquid dissolves
rosin, but leaves pure guaiac untouched. Amber was said to be another
adulterant at one time. Nitric acid affords an excellent test of guaiac. If
paper moistened with the tincture be exposed to the fumes of this acid, it
speedily becomes blue. Purgotti proposed guaiac resin as a test for
copper. (See A. J. P., June, 1880.)

Uses.—Guaiac, like many other resinous substances, is stimulant and
alterative. If given to a patient when covered warm in bed, and
accompanied with hot drinks, may assist in exciting perspiration, and
hence it has been ranked among the diaphoretics. In large doses it
purges, and it has been especially commended as a laxative in chronic
rheumatism, and it is thought by some practitioners to be possessed of
emmenagogue powers. It has been given in chronic rheumatism, gouty
affections, secondary syphilis, scrofulous diseases, and cutaneous
eruptions, but is of doubtful service. The medicine is given in substance
or tincture. The dose of the powder is from ten to thirty grains (0.65-2.0
Gm.), which may be exhibited in pill or bolus, in the shape of an
emulsion formed with gum arable, sugar, and water, or as a syrup. An
objection to the form of powder is that it quickly aggregates. Guaiac is
sometimes administered in combination with alkalies, with which it
readily unites. The ammoniated tincture of guaiac is a preparation of
this kind. Several European Pharmacopoeias direct a soap of guaiac,
under the name of sapo guaiacinus, to be prepared by diluting solution
of potassium hydroxide with twice its weight of water, boiling lightly,
then adding guaiac gradually, with continued agitation, so long as it
continues to be dissolved, and finally filtering, which was followed by
evaporating to the pilular consistence.

T. C. Craig (A. J. P., July, 1880) recommends a Syrup of Guaiac made as follows: Powd. Guaiac Resin, 640 grains; Caustic Potassa, 58 grains; White Sugar, 1 lb. (av.); Water, q. s. Dissolve the Potassa in 8 fluidounces of water; moisten the Guaiac with this solution; pack it in a percolator, and gradually pour on the remainder of the solution; when this ceases dropping, add sufficient water to make the percolate measure 8 fluidounces; add the sugar, and dissolve.

Dose, from ten to thirty grains (0.65-2.0 Gm.).

GUARANA. U. S.

GUARANA

"A dried paste consisting chiefly of the crushed seeds of Paullinia Cupana Kunth (Fam. Sapindaceae), yielding not less than 4 per cent. of caffeine." U. S.

Paullinia, Brazilian Cocoa, Guarana Bread; Guarana, Fr. Cod.; Pasta Guarante; Guarana, G., lt.; Paulinia, Guarana, Sp.

There are described of the genus Paullinia 121 species, all of them confined in their geographical range to tropical and subtropical South America, except one, which has strayed to Eastern and Western Africa, and two others which are found in Mexico and in the gardens of the Sandwich Islands. The name of the genus was given in honor of Christ. Fred. Paullini, a German medico-botanical writer, who died in 1712.

The Paullinia Cupana Kunth is a climbing shrub with alternate compound impari-pinnate leaves, which is native to the Northwestern provinces of Brazil. The flowers are of yellowish color, growing in spicate panicles. The leaves are long petioled, the leaflets being 5 to 6 inches
long by 2 or 3 inches wide, and sinuate dentate on the margins. The fruit is ovoid or pyriform and about the size of a grape, and contains 1 to 3 seeds which resemble small horse chestnuts.

It is probable that in the preparation of guarana the seeds of the allied species P. sorbilis Martins, are used interchangeably with those of the official species.

The seeds, which look like small horse-chestnuts, are lenticular and almost thorny, and invested with a flesh-colored arillus, which is easily separable when dry. Guarana is made exclusively by the Guaranis, a tribe of South America Indians, and probably varies in the details of its preparation, as it certainly does in appearance and quality. The drug appears to be produced almost exclusively from plants cultivated in the region of the lower Madeira and southward. After the seeds are shelled and thoroughly washed they are roasted for about six hours, and their external papery shells are then removed by placing them in sacks and beating them with clubs; or, after the seeds have been broken in a mortar, the coarse powder is mixed with a little water, and then kneaded into a paste, which is shaped into cylindrical or globular masses. The latter are dried, sometimes in the sun, or more usually by the heat of a slow fire so arranged as to avoid smoke. When finished, the masses are of a reddish-brown color, rugose on the surface, very hard, with an irregular fracture, and of a marbled appearance when broken, due to the fragments of the seeds and their black testa embedded in the mass.

Guarana occurs in a number of molded forms, and an excellent collection of these can be found in the Philadelphia Commercial Museum. Stockman (P. J., liii; P. J., lxxxix, p. 685) describes and illustrates some of these interesting forms.

Properties.—It is officially described as follows: "Usually in cylindrical sticks, about 3 to 5 cm. in diameter, externally dark reddish-brown; hard and heavy; fracture uneven, often fissured in the center; internally pale reddish-brown, showing more or less coarse fragments of seeds and occasionally their blackish-brown integuments; odor slight; taste slightly astringent and bitter. The powder is light pinkish-brown; consisting mostly of irregular masses of parenchyma containing more or less altered starch grains; unaltered starch grains occasional, varying from spherical and polygonal to ellipsoidal and broadly ovoid, 0.01 to 0.025
mm. in diameter; occasional fragments with narrow, elongated sclerenchymatous cells; the walls being thick, yellowish and non-lignified. Place on a slide a drop of hydrochloric acid, add about 0.001 Gm. of powdered Guarana, then add a drop of gold chloride T.S. and allow the mixture to stand for a few minutes; beginning at the edge of the mount, crystals of caffeine and gold chloride separate in the form of orthorhombic plates and needles, the latter usually occurring in spheroidal aggregates and finally forming branching groups.

"Assay.—Introduce 6 Gm. of Guarana, in No. 60 powder, into a flask and add 120 mils of chloroform and 6 mils of ammonia water. Stopper the flask, shake it frequently for half an hour, then let it stand four hours. Again shake the flask vigorously and when the drug has settled, filter the liquid rapidly through a pledge of purified cotton and collect 100 mils of the filtrate, representing 5 Gm. of Guarana. Evaporate the clear filtrate to dryness and dissolve the residue in weak sulphuric acid with the aid of a gentle heat. When the liquid has cooled, filter it into a separator and wash the container and filter with several small portions of distilled water. Now add ammonia water until the liquid is distinctly alkaline to litmus and shake out the caffeine with chloroform until completely extracted, as shown by testing with iodine T.S. in place of the usual mercuric potassium iodide T.S. Evaporate the united chloroform solutions and dry the residue to constant weight at 80° C. (17610 P.). The weight is the amount of caffeine from 5 Gm. of Guarana (see Proximate Assays, Part III)."

U. S.

Guarana is of a somewhat astringent and bitterish taste, and in this, as well as in its odor, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. It is also partly soluble in alcohol. Martius found in it a crys-tallizable principle, which he named guaranine, but which was later proved by Berthemot and Dechastelus to be identical with caffeine. Alexander Bennett, in an elaborate series of physiological experiments, confirmed this identity. Caffeine may be obtained by microsublimation and Rosenthaler (B. P. G., xxi, p. 532) describes the crystals obtained from guarana by means of pyroanalysis. According to Berthemot and Dechastelus, the caffeine exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients the seeds contain free tannic acid, gum, albumen, starch, and a greenish fixed oil. (J. P. C., xxvi, 514.)
M. I. Wilbert (J. A. Ph. A., 1914, 1286) reported a compilation of analyses of guarana comprising 41 samples in which the caffeine content varied from 3.72 to 5.16 per cent.

Rochefontaine and Gusset prepared caffeine by mixing one part of calcined magnesia with five parts of powdered gnarana, moistening with water, and, after standing twenty-four hours, exhausting the mass with boiling chloroform, evaporating the chloroform, treating the residue with boiling water, filtering, and evaporating over sulphuric acid. (A. J., P., 1886, p. 248.) F. V. Greene (United States Navy) prefers a process for obtaining caffeine from gnarana similar to one proposed by Wayne for its extraction from tea and coffee. See U. S. D., 19th ed., p. 606.

F. V. Greene has shown that the tannic acid from gnarana has different properties from that found in other plants, and proposes to call it paullinitannic acid. (A. J., P., 1877, 390.) Foumier has found in guarana, besides caffeine tannate, the following principles: gum, starch, an acrid green fixed oil, a concrete volatile oil, an aromatic liquid volatile oil soluble in water with a little alcohol, another liquid volatile oil scarcely soluble in water, a peculiar principle not precisely determined, and tannic acid. (J. P. C., April, 1861, 291.) E. R. Squibb examined commercial guarana, and obtained 4.38 per cent. of alkaloid from good specimens. On account of the uncertainty of the composition of guarana, he recommended physicians to prescribe fluidextract of green coffee in its place. (See Ephem., 1884, 612.)

Uses.—The effects of guarana upon the system are chiefly those of its alkaloid, although it contains enough tannin to have an appreciable influence. It is habitually employed by the Indian's, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water, precisely as other nations use teas, coffees, etc. It is also considered by the Indians useful in the prevention, and cure of bowel complaints. Gavrelle, who was at one time physician to Dom Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. It is now used in medicine almost exclusively to give relief during the
paroxysm of migraine, and in atonic chronic diarrhea, taken three or four times a day.

Dose, of the powder, twenty to sixty grains (1.3-3.9 Gm.); of the fluidextract, twenty to sixty minims (1.3-3.75 mils).

Off. Prep.—Fluidextractum Guaranae, U. S.; Elixir Guaranae (from Fluidextract), N. F.

Gum Cebil.—This gum is a product of the Brazilian leguminous tree Piptadenia Cebil Griseb. It occurs in reddish-yellow tears, or in dark-colored angular masses, and forms a reddish-yellow, odorless, viscous mucilage of acid reaction. It is said to contain 80.78 per cent. of arabin.

Gum, Cedar.—This, the product from Cedrela Toona Roxb. (C. australis F. Muell.), or Red Cedar of Queensland (Fam. Meliaceae), is a very pale yellow or brownish gum, occurring in tears about 2.5 cm. long, having an astringent taste, swelling and, finally, almost dissolving in water. It contains about 68 per cent. of arabin, and 6 per cent. of metarabin, but no resin. (P. J., vol. xx, 1890.)

Gum, Grass-tree. Yellow Resin. Botany Bay Gum. Resina Acaroides. Yellow Acaroid Resin. Earth Shellac.—An Australian product, occurring as an exudation upon the stems of Xanthorrhoea hastilis R. Br. (Fam. Liliaceae.) It is of a resinous character, usually is found in the markets in the state of small fragments or coarse powder, resulting from the breaking up of the larger brittle masses in which it first occurs. It is of a deep reddish-yellow color in mass, but greenish-yellow in powder. It does not dissolve in the mouth when chewed, nor adhere to the teeth, but has a slightly astringent and aromatic flavor. It melts with heat, and at a higher temperature takes fire in the air, burning with a smoky flame, and emitting a fragrant odor not unlike that of balsam of Tolu. It yields picric acid largely under the action of nitric acid. The natives and early settlers employed it as a medicine in diarrhea. It is said to be used extensively, instead of shellac, as a resinous glaze for confectionery and also in cabinet work, but to be distinctly inferior. For much interesting information concerning it and other resinous products of the genus Xanthorrhoea, see paper by J. H. Maiden, P. J., 1891, xxi. It is obtainable in inexhaustible quantities as the plants producing it are abundant throughout almost the whole of Australia. (A. J. P., 1866, 465.) Three hundred tons of the resin of X. hastilis have been exported in one year, and at one time the price rose to £65 per ton for the best quality, but for ordinary quality it is from £7 to £10. (A. J. P., 1885, 405.) (See article on Xanthorrhoea Resins.)

Gum Hogg. Hog-Gum. Kuteera Gum.—Under the name of gum-hogg a peculiar gum is much used in marbling paper. A full discussion of it may be found in the 14th edition of the U. S. D., but, as it appears to be only a variety of Bassora gum, and rarely found in commerce, we omit any further account of it.

Gum, Indian. Ghatti Gum.—Under the name of Gummi Indicum the Br. recognizes
the gummy exudation from the wood of Anogeissus latifolia. The forests of India produce large quantities of other gums, a number of which have found their way into commerce and are used to a considerable extent as substitutes for gum arable and gum. tragacanth. Indian gum occurs in yellowish-white tears having a vitreous fracture. It is entirely soluble in water, forming a thick mucilage.

Of the other "so-called" Indian gums, that yielded by Prosopis spicigera L. (Fam. Leguminosae) occurs in small, angular, yellowish fragments, or sometimes in large ovoid tears 5 cm. long, of an amber color, frosted externally with fissures. It forms with water a dark-colored tasteless mucilage and resembles in its behavior to reagents the Mezquitegum. The gum of Feronia elephantum Corr. (Fam. Rutaceae) is in small, irregular tears varying from reddish-brown to pale yellow and forms a thick, tasteless, colorless mucilage which resembles gum arable, but is precipitated by neutralized lead acetate and gelatinized by ferric chloride, although unaffected by borax. The most important of the Indian gums is that which is recognized in the Br. Pharmacopoeia, and which in its solubility and relation to reagents closely resembles gum arabic. This is the product of Anogeissus Latifolia above referred to. It has double the viscosity of gum arable and forms with water a colorless mucilage having a faint characteristic odor. It is well suited for pharmaceutical use, and is said to be specially valuable in the making of emulsions. It is insoluble in 90 per cent. alcohol. For further description of the properties of this gum see Gummi Indicum.

The Br. Pharmacopoeia allows of the substitution of Indian gum in official preparations in place of gum acacia, with the statement that one part of it should be substituted for two of the acacia. The mucilage of Indian gum (Mucilago Gummi Indici, Br., 1914) is made with two avoirdupois ounces of gum to six fluidounces of distilled water. See also Gum Sterculia.

Gum Kauri.—This is an amber-like substance, varying from a soft cream-white to an amber color, dug in large quantities from the soil of Australia and New Zealand. It is a resinous exudation from the Kauri Spruce, Agathis australis Salisb. (Dammaries australis Lamb.), of the Fam. Coniferae. But, as it first exudes and is found on the surface of the ground, it is not esteemed. According to Tschirch and Niederstadt, it contains kaurin acid, C_{10}H_{16}O_{2}, 1.5 per cent.; α- and β-kaurolic acids, C_{12}H_{20}O_{2}, 48 to 50 per cent.; kaurinolic acid, C_{17}H_{34}O_{2}, and kauronolic acid, C_{12}H_{24}O_{2}, together, 20 to 22 per cent. All these resin acids are soluble in solution of sodium hydroxide. Baume Caledonien consists of a solution of kauri gum in an equal weight of 90 per cent. alcohol. It has been used with alleged great success in the treatment of wounds and ulcers, of eczema and other skin affections, and as a substitute for collodion and the soluble sodium silicate. When applied to a well cleansed and dried wound it leaves a slight deposit of resin as a varnish, which is not affected by friction or contact with water.

The commercial product known as Manila copal, according to Tschirch and Koch, is derived from Agathis Dammara Rich. (Dammara orientalis Lamb.), a conifer. It consists chiefly of free amorphous resin acids, namely, alpha- and beta-mancophalolic acid, C_{10}H_{18}O_{2} (about eighty per cent.), and contains besides about 12
per cent. of a resin, C\textsubscript{20}H\textsubscript{32}O\textsubscript{2}, and about five per cent. of essential oil. The latter, when fresh, forms a liquid as clear as water, very mobile, having a pleasant odor, and the sp. gr. 0.840; it boils at from 165° to 170° C. (329°-338° F.), and mixes in all proportions with alcohol, ether, chloroform and fatty oils. See also the article on Copal.

**Gum Mango.**—This gum, which is obtained from the mango tree, Mangifera indica L. (Fam. Anacardiaceae), occurs in the Indian bazars in amber-colored or reddish-yellow lumps, almost transparent, with a brilliant conchoidal fracture, 39.4 per cent. of which is soluble in water. (See J. P. C., xix, 584.)

**Gum Mesquite.** Mesquite Gum. Gum Mezquite.—This is the product of Prosopis juliflora C., and perhaps other species of the same genus. Mesquite is a small, thorny, acacia-like tree or shrub belonging to the Fam. Leguminosae, and growing in New Mexico, Texas, and other neighboring regions, where it covers vast extents of country. The fruit is a long, compressed pod, filled with a sweet pulp, which is said to contain 30 per cent. of grape sugar, and to be used by the Indians as a food. A gum exudes from the stem and branches. It occurs in irregular, roundish pieces, of various sizes and usually of a dark amber-brown color, though sometimes, especially when gathered from young trees, it is nearly colorless. Procter found it to resemble gum arable in its solubilities, but to differ essentially in not being precipitated by lead subacetate, and in its strong solution not being coagulated by borax. (A. J. P., xxvii, 224.) Campbell Morfit found in it a very little bassorin (0.206 per cent.), which did not exist in the specimens examined by Procter. (Am. J. Sci., March, 1855, 264.) See also A. J. P., 1855, 542, for a brief description of the gum and its character.

The saccharine pods of Prosopis odorata Torr. and Frem. (P. pubescens Benth.) are largely employed as food by the Indians, and those of all the species form valuable fodder for cattle.

**Gum Sassa.** Sassa Gum.—This name has been applied by Guibourt to a gum, occasionally brought into commerce from the East. It is produced by a tree growing in Abyssinia, Albizia Fastigiata Oliv. (Fam. Leguminosae). According to Guibourt's description, it is in mammillary masses, or in convoluted pieces resembling an ammonite, of a reddish color and somewhat shining surface, and more transparent than tragacanth. Its taste is like that of tragacanth, but slightly acrid. When introduced into water it becomes white, softens, and swells to four or five times its original bulk; but it preserves its shape, neither, like tragacanth, forming a mucilage, nor, like Bassora gum, separating into distinct flocculi. It is rendered blue by iodine.

**Gum Sonora.** Sonora Gum.—According to Krewson, the exudation from Covillea tridentata (DC.) Vaill. (Larrea mexicana Moric.) contains 17.27 per cent. of resin, and 11.71 per cent. of mucilage and allied substances. (For details, see P. J., xvi, 128; also A. J. P., May, 1898.) Covillea tridentata is also known in Southwestern United States and Mexico as "Creosote bush," because of the odor of the oleoresin which covers the herbage.
**Gum Sterculia.** Sterculia Gum. Indian Gum Tragacanth. Indian Gum.—A number of trees belonging to the genus Sterculia in India, particularly Sterculia avens and Cochlospermum gossypium, Africa, and Australia yield gums in considerable quantity, most of which resemble in their appearance tragacanth, some of which have remarkable adhesive properties and in some of which the adhesive power is lacking but the swelling power when moistened with water is enormous. These gums have been much used of recent years, frequently under the unqualified name of tragacanth. They are employed frequently as a filler in the manufacture of ice cream and even desserts where vegetable gums are found to be of service in preventing the product from losing its form as it melts. The difference between the sterculia gums and true tragacanth can be readily proved by a distillation test with water and the determination of the acidity which is due to acetic acid. (See P. J., Nov., 1889; A. J. P., Jan., 1900; 1912, pp. 155 and 393; Drug. Circ., 1909, p. 116.)

**GUMMI INDICUM. Br.**

**INDIAN GUM [Ghatti Gum]**

"Indian Gum is a gummy exudation from the stem of Anogeissus latifolia, Wall." Br.

The genus Anogeissus (Fam. Combretaceae) includes four or five different species of tropical trees. Of these A. latifolia is widely distributed in Farther India. The tree is large and handsome, and one of the most useful of tropical India. The leaves are broadly elliptical, obtuse at the base and summit. They contain large amounts of tannin and are used in Bombay for tanning. The flowers are axillary and the fruit is 2-wmged, being arranged horizontally into dense heads. The gum from this tree is collected in April and is used extensively in calico printing, especially in Lucknow. It is less adhesive than Acacia and is usually used in connection with turmeric with which there is some specific combination.

"In vermiform or rounded tears of varying size, colorless or pale yellow; surface dull, fracture vitreous. Slight odor; taste insipid and mucilaginous. Entirely soluble in water, forming a viscous, adhesive mucilage. Insoluble in alcohol (90 per cent.). The aqueous solution is gelatinised by the addition of alcohol (90 per cent.), or solution of lead subacetate; but it is unaffected by the addition of T. Sol. of ferric chloride or of solution of lead acetate (distinction from Amrad and certain other gums). It is not colored blue or brown by a small quantity of N/10 solution of iodine (absence of starch or commercial dextrin). Ash not more than 4 per cent. In India and the Eastern Divisions of the
Empire, Indian Gum may be employed in making the official preparations for which Gum Acacia is directed to be used, one part of the former being taken for every two parts ordered of the latter (see 'Mucilago Gummi Indici')." Br.

**Uses.**—Indian gum is used for the same purposes in pharmacy as acacia. It must not be confounded with the so-called India Gum which is only slightly soluble in water.

**Off. Prep.**—Mucilago Gummi Indici, Br.

**Gymnema.** Gymnema silvestre (Willd.) R. Br.—This is a woody climber, belonging to the Asclepiadaceae, which grows in Australia, India and also in Africa. The root has for a long time been employed by the natives as a remedy in snake bite, and it is affirmed by T. Dyer (Nature, 1887) that directly after the eating of one or two leaves it is impossible to taste sugar, though other tastes are not obscured. Thus, pungency alone is detected in gingerbread, and a sweet orange tastes like a lime. The active principle, gymnemic acid, C$_{32}$H$_{55}$O$_{12}$, was discovered by Hooper, and has been used with considerable success as a remedy for parageusia and hallucinations of taste. The 1 per cent. aqueous solution is to be applied with a brush to the inside of the mouth, or a hot infusion (15 per cent.) of the crude drug may be used. (See Th. M., vs..}

**Gymnocladus.** Gymnocladus dioica (L.) Koch. Kentucky Coffee-tree. Kentucky Mahogany. (Fam. Leguminosae)—A tall tree with pinnate leaves growing in the woods from New York southward and west as far as Oklahoma. The fruit is an oblong flattened pod containing several seeds in a fleshy pulp. The seeds are flattish and about 1 cm. in diameter. According to Bartholow, the aqueous extract of the seeds is toxic. (Am. Drug., April, 1886.) Samuel S. Mell (A. J. P., 1887, 230) obtained from them by petroleum benzin about 10 per cent. of fixed oil which is yellowish, saponifiable, and of sp. gr. 0.919. Ether extracted a little wax, fat, and resin. A little tannin and a small quantity of glucoside were also obtained. This latter had a peculiar odor and an acid burning taste. James H. Martin (A. J. P., 1892, 558) obtained a yellow, saponifiable oil from the bean and the bark and a glucoside from the pulp.
HAEMATOXYLI LIGNUM. Br.

LOGWOOD

"Logwood is the heart-wood of Haematoxylon campechianum, Linn." Br. "The heart-wood of Haematoxylon campechianum Linne (Fam. Leguminosae) that has not undergone fermentation." N. F.

Haematoxylon, N. F.; Lignum Campechianum, Lignum Coeruleum; Bois de Campeche ou Bois'Inde, Fr. Cod.; Bois de Sang, Fr.; Blauholz, Campecheholz, Blutbolz, Kampuschenholz, G.

Haematoxylon campechianum is a tree of middle size, usually not more than twenty-four feet high, though, under favorable circumstances, it sometimes rises forty or fifty feet. The trunk is often very crooked, and is covered with a dark rough bark. The branches are beset with sharp spines. The sap-wood is yellowish, but the interior layers are of a deep-red color. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obcordate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx and lemon-yellow petals. They exhale an agreeable odor, said to resemble that of the jonquil.

The tree is a native of Campeche, the shores of Honduras Bay, and other parts of tropical America, and has become naturalized in Jamaica. It is cultivated in tropical America and Asia. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs deprived of the sap-wood and having a blackish-brown color externally. It has been estimated that about 400,000,000 pounds of log-wood are annually consumed. In 1912 Haiti exported about 83,000,000 pounds of logwood to the United States.
States. (See A. J. P., 1912, p. 86.) According to Louis Siebold, the ground or chipped logwood of commerce is unfit for use as a medicinal agent, because it has been prepared as a dyestuff by being exposed in large moist heaps until its hematoxylin has been converted by oxidation into hematein. As a coloring agent, for commercial purposes, this fermented logwood, according to Siebold, is much superior to the natural wood. An inferior variety of logwood which contains little or no hematoxylin, but a pure yellowish-gray dye is that known as bastard logwood. According to the researches of E. S. Earl this bastard logwood is produced by a variety of the species, which, when growing, cannot be distinguished from the ordinary form. (B. D. A. J., i, 31.)

**Properties.**—Logwood is hard, compact, heavy, of a deep-red color, becoming purplish-black by exposure, internally brown-red, and marked with irregular, concentric circles, splitting irregularly, of a slight peculiar odor, and a sweet, somewhat astringent taste. Logwood is officially described as "Hard, heavy, dull orange to purplish-red externally and reddish-brown internally. In transverse section, alternating yellowish-brown and dark brown wavy tangential lines. In the form of chips or coarse powder, it is free from signs of fermentation, and from green metallic lustre. Slight, agreeable odor; taste sweetish, astringent. Readily imparts a reddish-violet color to water made slightly alkaline with solution of sodium hydroxide" Br.

The N. F. IV description is as follows: "Usually in small chips, reddish-brown, the freshly cut surface dark yellowish-red; a transverse section of the wood shows medullary rays which are up to four cells wide. Odor faint, agreeable; taste sweetish, astringent. Hematoxylon imparts a yellowish color to water containing a little acid, the color being changed to purple or violet-red by alkalies. The powder is reddish-brown and, when examined under the microscope, exhibits medullary ray cells in one to seven rows; wood fibers, long, with thickened walls; wood parenchyma with occasional crystals of calcium oxalate; tracheas from 0.09 to 0.17 mm. in width; walls of the cells colored brownish-red, the inner cells containing resin masses. Hematoxylon yields not more than 3.5 per cent. of ash." N. F.

Its solution affords precipitates with sulphuric, nitric, hydrochloric, and acetic acids, alum, copper sulphate, lead acetate, and ferrous sulphate, striking a bluish-black color with the last mentioned salt. Precipitates are also produced with it by lime water and gelatin. Chevreui found in
logwood a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin (tannin), another brown substance soluble in alcohol but insoluble in water or ether, a nitrogenous substance resembling gluten, free acetic acid, various salts, and a peculiar principle called haematoxylin or haematin (which must not be confused with the haematin of the blood), on which the coloring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture until it thickens, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hematoxylin is deposited in crystals, which may be purified by washing with alcohol and drying. Thus procured, the crystals are shining, of a yellowish-rose color, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. According to Erdmann, who obtained hematoxylin by the process of Chevreul, substituting ether for alcohol, its crystals, when quite pure, are colorless, without a tinge of redness; its taste is sweet, like that of licorice, without bitterness or astringency; and it is not of itself a coloring substance, but affords beautiful red, blue, and purple colors, by the joint action of an alkaline base and the oxygen of the air. He obtained from logwood 9 to 12 per cent. of crystallized hematoxylin, to which he gave the formula $C_{16}H_{14}O_6$. It crystallizes with 1 or with 3 molecules of water, and is readily soluble in hot water or alcohol, but sparingly in cold water or in ether. (J. Pr. Chem., xxxvi, p. 205.) By the combined action of ammonia and oxygen dark violet crystalline scales of hematein, $C_{16}H_{12}O_6 + 3H_2O$, are produced. They show a fine green hue, which is also very commonly observable on the surface of the logwood chips of commerce. Hematein may again be transformed into hematoxylin by means of nascent hydrogen or of sulphurous acid. Commercial extract of logwood extracted from the wood by boiling water contains both hematoxylin and hematein. Hematoxylin, in alcoholic solution, is used as an indicator in the U. S. P. IX. (See Hematoxylin Test-solution, Part III.)

**Uses.**—Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed cholera infantum. It is also occasionally used with advantage in ordinary chronic diarrhoea and chronic dysentery. Hematoxylin was found by Com-bemale (B. M. N., xxxiii, 1894) to be very feebly antiseptic, but capable in large doses of producing fatal
gastro-enteritis in the lower animals. It is used not only as a dye-stuff but also as a microscopical stain.

Dose, from ten to thirty grains (0.65-1.9 Gm.).

Off. Prep.—Decoctum Haematoxyli, Br.

HAMAMELIDIS CORTEX. Br.

HAMAMELIS BARK [Witchhazel Bark]

"Hamamelis Bark is the dried bark of Hamamelis virginiana, Linn." Br.

This bark was deleted from the U. S. P. IX, but retained by the British Pharm., 1914. The U. S. P. VIII definition was as follows: "The bark and twigs of Hamamelis virginiana Linne (Fam. Hamamelidaceae)."

Witchhazel is an indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and often on the banks of streams. It is the only species of the genus found in Eastern North America, occurring from New Brunswick to Minnesota and southward to Florida and Texas. Schneider asserts that it has been introduced into California and that it is extensively cultivated in this locality. It is specifically characterized by its leaves being obovate or oval, wavy-toothed, and somewhat downy when young. The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazelnut. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue until the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following summer, and is often mingled on the same plant with the new blossoms.

Properties.—The bark occurs "in curved or channelled pieces about one and a half millimetres thick, and from one-half to two decimetres long, sometimes covered with a silvery-grey or dark-grey scaly cork marked with transverse lenticels, but frequently freed from the cork, and then exhibiting a nearly smooth reddish-brown outer surface. Inner
surface pale reddish-pink, and finely striated longitudinally; fracture laminated and coarsely fibrous. In transverse section, a cortex containing prismatic crystals of calcium oxalate, a complete ring of sclerenchymatous cells, and numerous tangentially elongated groups of bast fibres. No marked odor; taste astringent." Br.

The twigs are "flexible and tough, of irregular length, not more than 6 Mm. in diameter, branching, or bearing nodes at intervals of 2 to 5 Cm.; externally varying from yellowish-brown to deep purplish-brown, lightly longitudinally wrinkled, and having scattered small circular whitish or pale lenticels; bark occupying about one-fifth of the radius; wood greenish-white, lightly radiate, and exhibiting one to three annual rings; pith centric, small." U. S. VIII.

Holm (Merck’s Rep., xxi, p. 5) has written an illustrated paper on the morphology of hamamelis.

Walter B. Cheney examined witchhazel bark, and found tannin, resin, extractive, but no indication of an alkaloid or other crystalline principle. (A. J. P., 1886, p. 418.) It contains a trace of volatile oil, however. John Marshall, of the University of Pennsylvania, also found that hamamelis root contains tannic acid and a trace of volatile oil, but no other active substance. (T. G; ii, 295.)

Uses.—The bark of the witchhazel is said to have first attracted attention on account of its use by the North American Indians as a sedative application to external inflammations. It was many years ago recommended by James Fountain and N. S. Davis (N. Y. M. J., x, 208; Trans. Amer. Med. Assoc., i, 350) in hemorrhage of the lungs and stomach. Professional attention was strongly directed to the remedy on account of the enormous sale of a much vaunted proprietary remedy said to be made by distilling the bark with very dilute alcohol (six per cent.), and used externally for sprains and bruises, and internally for most of the diseases to which flesh is heir. The pecuniary success of this remedy probably depended in very small part upon the virtues of the witchhazel, which seems to possess no active physiological properties. At least we have injected a very concentrated distillate in large quantities into frogs and into mammals without perceiving any more effects than would be produced by the injection of similar quantities of distilled water, and Guy, in Paris, has reached similar conclusions. This preparation has been so largely used that it has been widely replaced by
a similar preparation officially known as Aqua Hamamelidis, which see. The fluidextract of the drug is a mild astringent and has been especially recommended in varicose veins and hemorrhoids. The dose of the fluidextract given ordinarily is a teaspoonful (3.75 mls) four times a day. It may, however, be given in double the quantity with impunity and probably in such doses is an advantageous astringent.

Dose, of leaves or of bark, thirty grains (2 Gm.).

HAMAMELIDIS FOLIA. Br.

HAMAMELIS LEAVES
[Hamamelis, U. S. 1890 Witchhazel Leaves]

"Hamamelis Leaves are the fresh or dried leaves of Hamamelis virginiana, Linn." Br. "The dried leaves of Hamamelis virginiana Linne (Fam. Hamamelidaceae), collected in autumn before the flowering of the plants, and without the presence of more than 10 per cent. of stems or other foreign matter." N. F.

Hamamelidis Folia, N. F.; Feuilles de Hamamelis, Fr. Cod.; Witchhazel, Witch Hazel Leaves.

These leaves were deleted from the U. S. P. IX, but were retained in the British Pharm., 1914, and National Formulary IV.

The National Formulary IV added the following to the U. S. P. VIII definition: "Before the flowering of the plants and without the presence of more than 10 per cent. of stems or other foreign matter."

The British Pharm., 1914, describes the leaves as follows: "Broadly oval in outline, from seven to fifteen centimeters long. Upper surface dark green or brownish-green, under surface paler; apex obtuse, margin sinuate; narrowed towards the base, oblique, slightly cordate, and shortly petiolate. Veins pinnate and prominent on the under surface, where they are furnished with stellate hairs. No marked odor; taste astringent and slightly bitter." Br.

The N. F. IV description is as follows: "Petioles from 1 to 1.5 cm. in
length; laminae when entire broadly elliptical or rhomboid-ovate, usually inequilateral, mostly from 8 to 12 cm. in length; summits usually acute, sometimes rounded or acuminate; bases slightly heart-shaped and oblique; margins sinuate or sinuate-dentate; upper surfaces pale or brownish-green, occasionally dark brown with a few stiff, straight hairs; lower surfaces lighter in color, somewhat hairy, midrib and veins prominent. Odor slight; taste astringent, slightly aromatic and bitter. Transverse sections show in addition to the epidermal layers, a palisade layer consisting of a single row of cells and a dorsal pneumatic tissue made up of three to six rows of strongly branching cells; large collateral, fibro-vascular bundles occur in the midrib and petiole, the tracheae narrow, mostly spiral and associated with numerous narrow, strongly lignified and porous wood fibers; around the phloem occurs a nearly continuous circle of bast fibers, possessing strongly lignified walls; calcium oxalate in mono-clinic prisms, from 0.01 to 0.035 mm. in diameter, either in the cells of the mesophyll or in crystal fibers associated with the bast fibers. Under the microscope, surface sections of Hamamelis Leaves show upon the lower surface narrow elliptical stomata, about 0.015 mm. in length and with two to four neighboring cells; from both surfaces, but especially from the under surface, arise stellate hairs composed of from four to twelve cells united at the base, the individual cells being from 0.02 to 0.075 mm. in length, either straight or more or less bent and with very thick walls and narrow lumina, the latter sometimes only apparent in the lower portion of the cells. Hamamelis Leaves yield not more than 6 per cent. of ash. N. F.

The microscopical characteristics of the hamamelis leaves have been described by Hans Kramer in B. P. G., xvii, p. 323.

See Hamamelidis Cortex.

**Off. Prep.**—Fluidextractum Hamamelidis Foliorum, N. F. (Br.); Liquor Hamamelidis, Br.; Unguentum Hamamelidis (from Liquid Extract), Br.

This plant is entirely distinct from Mentha Pulegium, or European, pennyroyal. It is probable that various other species of the genus are used in the localities in which they grow. Thus, H. piperita Bentham is said to be used in Mexico as a substitute for
peppermint, and H. thymoides Gray, in Texas as an aromatic diaphoretic.

Hedeoma pulegioides (L.) Pers. (1807) [Cunila pulegioides L. (1762); Melissa pulegioides L. (1753)] is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent, quadrangular stem, which sends off numerous slender erect branches. The plant is common in the Eastern and Middle Western United States, preferring dry grounds. Hedeoma was officially described as "branchlets quadrangular, with numerous spreading hairs; leaves opposite, short-petioled, oblong, 15 to 35 Mm. long, thin, obtuse, obscurely serrate, glandular-hairy beneath; flowers in axillary fascicles, with a tubular-ovoid, bilabiate and 5-toothed calyx, and a pale blue, spotted, bilabiate corolla containing two sterile and two fertile, exserted stamens; odor strong, somewhat mint-like; taste aromatic and pungent." U. S. The activity of hedeoma depends upon a volatile oil. The oil of hedeoma (Oleum Hedeomae, U. S. VIII, Oil of Pennyroyal), is "A pale yellow, limpid liquid, having a characteristic, pungent, mint-like odor and taste. Specific gravity: 0.920 to 0.935 at 25°C (77°F.). It should form a clear solution with 2 volumes or more of 70 per cent. alcohol. It is dextrogyrate, the angle of rotation varying from about +18° to +22° in a 100 Mm. tube, at a temperature of 25°C (77°F.)." U. S. VIII. Its chemical composition was investigated by E. Kremers (A. J. P., 1887, p. 535) and F. W. Franz (A. J. P., 1888, p. 161). Each of them found a body of the composition C_{10}H_{18}O, boiling at 217° to 218° C. (422.6°-424.4° F.) (constituting, according to Franz, about 33 per cent. of the oil). For this the name hedeomol was proposed. Franz also found a body of the composition C_{10}H_{17}O, boiling at 220° to 225° C. (428°-437° F.), and constituting 12 per cent. of the oil; likewise a body of the composition C_{6}H_{12}O, boiling at 165° to 170° C. (329°-338° F.), and constituting about 0.7 per cent. of the oil. Both investigators found formic and acetic acids, and Kremers considers isoheptonic acid also to be present. Beckmann and Pleissner (Ann. Ch. Ph., cclxii, p. 1) found in American as well as in Spanish and Algerian pennyroyal oil a ketone, C_{10}H_{16}O, to which they gave the name of pulegone. This compound forms with hydroxylamine an oxime, C_{10}H_{16}NOH.H_2O, crystallizing in beautiful needles melting at 157° C. (314.6° F.), and with hydrogen bromide a crystalline compound melting at 40.5° G. (104.9° F.). The two compounds of the formula C_{10}H_{16}O, discovered by Kremers (Ph. Rund., ix, p. 130), are also ketones and yield corresponding oximes.

American pennyroyal is a gently stimulant aromatic, and may be given in flatulent colic and sick stomach, or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and of exciting the menstrual flow when the system is predisposed to the effort. A large draught of the warm tea is in popular practice often given at bedtime, in recent cases of suppression of the menses, the feet having been previously bathed in warm water. The drug may be given in doses of two drachms (7.7 Gm.). The oil in doses of two to ten minims (0.12-0.6 mil).
**Hedera.** Hedera Helix L. Ivy. (Fam. Araliaceae)—This well-known evergreen creeper is a native of Europe. The fresh leaves have a balsamic odor, especially when rubbed, and a bitterish, harsh, unpleasant taste. They are used for dressing issues, and, in the form of decoction, have been recommended in sanious ulcers and cutaneous eruptions, particularly tetter and the itch. The berries, which have an acidulous, resinous, somewhat pungent taste, are said to be purgative and even emetic. Vandamme and Chevallier discovered in ivy seeds a peculiar very bitter alkaline principle, hederine. It is obtained by treating the seeds with calcium hydroxide, dissolving the precipitated alkaloid in boiling alcohol, and evaporating the alcoholic solution. (A. J. P., xiii, 172.) Posselt has discovered two acids in the seeds, one of which has their taste in a high degree, and was named by him hederic acid, the other he did not obtain quite pure. (See Chem. Gaz., 1849, 93.) The seeds were also found to contain a variety of tannic acid, turning ferric salts dark green, to which Posselt gave the name of heda-tannic acid. (Ann. Ch. Ph., lxix, p. 62.) Moore (J. P. Ex. T., 1913, iv) has separated a saponoglucoside which he names hederin. This is not poisonous when taken by the mouth, but when injected intravenously causes death by respiratory paralysis. Davies and Hutchinson confirmed the existence of Posselt's hederic acid, and gave it the formula \( C_{16}H_{26}O_{4} \). Kingzett believes that it is not an acid, but a glucoside. J. Vernet (Ber. d. Chem. Ges., xiv, 685) obtained a glucoside, which separated from solution in boiling acetone, in silky needles, melting at 233° 0. (451.4° F.), insoluble in water, chloroform, and ligroine, slightly soluble in cold acetone, benzene, and ether, more soluble in hot alcohol and hot alkalies. Its formula he gives as \( C_{32}H_{54}O_{11} \), and states that it decomposes on heating with diluted sulphuric acid into a body, \( C_{26}H_{44}O_{6} \), which fuses at from 278°-280° C. (532.4°-536° F.), and a non-fermentable sugar which reduces Fehling's solution. (Y. B. P., 1877, 508.) Later, Van der Haar isolated two glucosides, hederin, \( C_{42}H_{66}O_{11} \), and hederagenin, \( C_{31}H_{50}O_{4} \). (A. Pharm., 1912, 424.) From the trunks of old ivy plants, growing in the south of Europe and the north of Africa, a resinous substance exudes through incisions in the bark, which has been employed in medicine under the name of ivy gum. It is in pieces of various sizes, of a dark yellowish-brown color internally, of a vitreous fracture, pulverizable, yielding a lively orange-yellow powder, of a peculiar not disagreeable odor when heated or inflamed, and of a bitterish resinous taste. Its chief constituent is resin, though some pieces contain a considerable proportion of bassorin, and other large quantities of ligneous matter. It was formerly used as a stimulant and emmenagogue, but is now scarcely employed. Placed in the cavities of carious teeth, it is said to relieve toothache. The light and porous wood of the ivy is sometimes used for making issue-peas.

**Hedychium.** Hedychium spicatum Sm. (Fam. Zingiberaceae)—The root of this plant, which is used in perfumery in India has been found by J. C. Thresh to contain ethylmethyl paracoumarate. (P. J., Nov. 8, 1884.)

**Helenium.** Helenium autumnale L. False Sunflower. Sneesewort. Sneezeweed.—An indigenous perennial, bitter, somewhat acrid composite herb. The leaves and flowers snuffed up in the state of powder produce violent sneezing, and have been used as an errhine. F. J. Koch (A. J. P., 1874, 221) found in the plant a bitter principle believed to be a glucoside, malic acid, traces of tannic acid, albumen, and volatile oil. Reeb found a crystalline bitter principle, helenin, with the formula \( C_{26}H_{25}O_{5} \). This has been
physiologically studied by Lamson (J. P. Ex. T., 1913, iv) who found that it is an intense irritant to the mucous membranes, capable of causing a fatal gastroenteritis, and that it acts as a paralysant to the heart and voluntary muscles. This principle must not be confounded with "helenin" from Inula. Helianthemum nudiflorum Nutt. has similar properties; H. tenuifolium Nutt., a common roadside weed of Mississippi and Louisiana, is stated by Galloway to produce in animals muscular twitchings, passing into violent convulsions, terminating in death. In four negroes helium caused spasms with delirium and loss of consciousness. (A. J. P., 1872, 309; DC., 1907, 459.)

**Helianthemum.** N. F. IV. Rock-rose. Frost-weed. Herbe de Helianthème de Canada, Fr. Canadisches Sonnenroschen, Gr. Helianthemum canadense (L.) Michx.—"The dried herb of Helianthemum canadense (Linne) Michaux (Fam. Cistaceae)." N. F. Frostwort grows in all parts of the Eastern United States, preferring dry sandy soils. It is official in the National Formulary IV. The dried herb is employed in medicine and is described as follows: "Stems mostly less than 5 cm. in length, branched above, terete, frequently reddish, canescent, the slender branches mostly erect; leaves very short-petioled, from 1 to 3 cm. in length, and from 4 to 8 mm. in width, oblong to oblanceolate, with entire, revolute margins, green and somewhat rough on the upper surface, canescent underneath; flowers of two kinds, rarely present at the same time, the early ones mostly solitary, pedicelled, with bright yellow corolla, from 2 to 3 cm. in breadth, hairy calyx, about thirty stamens and a single three-carpelled pistil, producing an ovoid capsule, about 7 mm. in length; later flowers apetalous, clustered in the leaf-axils, nearly sessile, having but four stamens and producing a capsule about 4 mm. in length. Odor slightly aromatic; taste astringent and bitter." N. F. William Crutcher (A. J. P., 1888, 390) found in it volatile oil, wax, fatty oil, tannin, and apparently a glucoside crystallizing in white needles. Fred J. Kruell found in H. corymbosum, Michx., tannin in large proportion, resin, glucose, gum, extractive, chlorophyll, and inorganic salts. (A. J. P., 1874, 358.) Frostwort has an astringent, slightly aromatic, and bitterish taste, and appears to possess tonic and astringent properties; it was formerly employed in scrofulous diseases. (See U. S. D., 14th ed.) According to D. A. Tyler (Pamphlet, New Haven, 1846), H. corymbosum Michx. possesses similar properties, and may be indiscriminately employed with H. canadense in scrofula, diarrhea, and secondary syphilis, and locally as a gargle in scarlatina, and a wash in prurigo. Tyler, however, has known the strong decoction and the extract to produce vomiting. He considers two grains (0.13 Gm.) of the latter a full dose for an adult. The Fluidextractum Helianthemi is recognized by the N F. IV. (see Part III). The menstruum is diluted alcohol.

**Helianthus.** Helianthus annuus L. Common Sunflower. Helianthe, Grand Soleil, Fr. Sonnenblume, G.—This very large composite is cultivated in this country, in Europe, and especially in China, chiefly for the sake of the fixed oil yielded by the seed. The oil has a sp. gr. of from 0.924 to 0.926, solidifies at -15° C. (5° F.), is colorless or yellowish, limpid, nearly tasteless and odorless, and dries slowly. It is said to make an excellent salad dressing, and to be one of the best burning oils known. The increase in cultivation is stated to be nearly a thousandfold, 275 pounds of oil being a fair yield per acre. For particulars as to cultivation, see A. J. P., 1875, 460; also N. R., 1876, 165. Ludwig and Kromayer (A. Pharm. (2), 99, 1 and 285) obtained a tannin which
they called helianthitannic acid, and gave it the formula $C_{14}H_9O_8$. On boiling with moderately diluted hydrochloric acid they obtained a fermentable sugar and a violet coloring matter. E. Diek (In. Dis., Gottingen, 1878) found only small quantities of inulin, large amounts of levulin, and a dextro-rotatory sugar. Chardon has obtained a peculiar oleoresin from sunflowers grown in Algeria. (P. J., 1873, 323.) Buschmann obtained from the flowers of Russian helianthus, betaine and choline, he believed that their presence accounts for the observed activity of the extract. Tincture of Helianthus has been used in Russia. (A. Pharm., 1911, 1; M. R., 1908.) The stalk, when treated as is flax, yields a long, fine fiber, which is said to be used in China for the adulteration of silk. The sunflower also enjoys the reputation of protecting against marsh miasmata. (See N. Y. M. R., 1868, 353.) Kazatchkoff states (B. G. T., Oct., 1889) that in the Caucasus the inhabitants employ the sunflower in malarial fevers. The leaves are spread upon a bed covered with a cloth, moistened with warm milk, and then the patient is wrapped up in the spread. Perspiration is produced, and the patient is kept in this condition for an hour or two. The same process is repeated every day until the access of the fever has ceased. A tincture of the flowers and the leaves of the sunflower has been recommended by Beldau in combination with balsamics in the treatment of bronchiectasis. The Pah Ute Indians are said to use very freely as food the seeds of two indigenous sunflowers, H. petiolaris Nutt. and H. lenticularis. (Proc. A. Ph. A., xxvii, 178.)

**Helleborus.** Helleborus niger L. Black Hellebore. Hellebore noir, Fr. Schwarze Niesswurzel, Weihnachtswurzel, Winterrose, Gr. Elleboro nero, It. Elleboro negro, Sp. (Fam. Ranunculaceae).—Hellebore is a native of the mountainous regions of Southern and temperate Europe, and is sometimes cultivated on account of the early opening and beauty of its flowers, whose expansion in midwinter has given to the plant the name of Christmas rose. Black hellebore is sometimes called melampodium, in honor of Melampus, an ancient shepherd or physician, who is said to have cured the daughters of King Perseus by giving them the milk of goats fed on hellebore. For a history of the use of hellebore by the ancients, see 15th edition, U. S. D.

The formerly official rhizome is knotted, blackish on the outside, white within, and sends off numerous long, simple, depending fibers which are brownish-yellow when fresh, but become dark brown upon drying. The roots of various other plants, not belonging to the same genus, are said to be frequently substituted for the black hellebore. They may usually be readily distinguished by comparing them with the genuine root. The rhizomes of various plants which are sometimes substituted for true hellebore have been examined by Tschirch and Neuber, who state their results as follows:

The rhizome of H. niger exhibits a small pith and comparatively large acutely wedge-shaped, radially-elongated wood-bundles. The odor of the rhizome and roots is slight but rather pleasant, especially in the fresh drug. The rhizome of H. viridis L. has a large pith and tangentially extended, bluntly wedge-shaped or almost square wood-bundles; older roots exhibit a wood with from five to seven-angular wedges. In both rhizome and root of H. foetidus L., the wood is more strongly developed and radiate in appearance; it contains abundance of wood-fibers and encloses little or no pith. The
rhizome of Actaea spicata L. is flattened and bears cushion-like protuberances, due to the remains of the aerial stems. The wood-bundles are thickened at either extremity and rounded by wood-fibers, so that in transverse section the wood-ring has a scalariform appearance. The root exhibits a regular three to five-rayed wood, the rays being broader toward the outside. (S. W. P., xl, 410.)

The roots are the portion usually recommended. They are from 0.5 to 6 cm. long and 2 to 3 mm. thick, smooth, brittle, externally black or deep brown, internally white or yellowish-white, with little odor, and a bitterish, nauseous, acrid taste. In their recent state they are extremely acrid. This acridity is diminished by drying, and still further impaired by age. William Bastick discovered a crystalline principle, helleborin, $C_{36}H_{42}O_{6}$, of a bitter taste with a tingling effect on the tongue, not volatilizable, slightly soluble in water, more so in ether and alcohol, and more readily in these liquids hot than cold. (P. J., xii, 274.) Marme and Husemann obtained from black and green hellebore a glucoside, helleborein, $C_{37}H_{56}O_{18}$, by precipitating a solution of an extract of the root with solution of lead subacetate, freeing from lead by hydrogen sulphide, and again precipitating with phosphi-molybdic acid; by boiling with acid it separated into glucose and helleboretin, $C_{14}H_{20}O_{3}$, a compound of a fine violet color. The helleborein exists both in the root and leaves. It has a taste at once sweet and bitter, is soluble in water and weak alcohol, much less so in ether and absolute alcohol, and is crystallizable in yellowish rhomboidal prisms. It is precipitable by tannic acid and mercurous acetate. (J. P. C., 4e ser., ii, 258.) Husemann and Marme (Ann. Chem., cxxxv, 61) examined more thoroughly the helleborin of Bastick. They found that when boiled with diluted sulphuric acid, or, better, zinc chloride, it is converted into sugar and helleboresin, $C_{30}H_{38}O_{4}$. They obtain this glucoside by treating with hot water the green fatty matter which is dissolved out of the root by boiling alcohol. Though both helleborin and helleborein are poisonous, the products of their decomposition are said to be harmless. Neither of them is volatile.

Helleborein is strongly irritant to the mucous membranes, causing, when applied to the conjunctiva, redness, swelling, and increased secretion, with indirect enlargement of the pupil, and when applied to the nasal membrane, sneezing, though less than veratrine. Small doses produce little effect on the stomach; but, repeated and accumulated, they cause anorexia, nausea even to vomiting, pain, increased secretion, and inflammation both of the stomach and bowels. The experiments of Van der Haide (A. E. P. P., 1885, xix), Trendelenburg (A. E. P. P., 1909, lxii, p. 262) and others demonstrate that physiologically helleborein belongs to the digitalis group of drugs. In small doses it diminishes the rate of the pulse, increases, the force and output of the heart, and causes a rise in the blood pressure. In toxic doses, the pulse becomes rapid, and small in volume, and the heart is finally arrested in systole. According to Cushny, the action of helleborein on cardiac inhibition is less than most of the other members of the digitalis group. The helleborin of Marme and Husemann is a more active poison, though less irritant to the mucous membrane. It acts on the tongue like aconite. Its influence appears to be directed especially to the nervous system. In the lower animals it causes quickened breathing, restlessness, tension and trembling of the muscles, uncertainty of movement; then retardation of the breathing and pulse, irritability of the peripheral nerves, dilatation of the pupil, loss of hearing,
and finally almost complete anesthesia, with cerebral and spinal congestion, even to apoplexy.

Hellebore was formerly used as a drastic purge in doses of from ten to twenty grains (0.65-1.3 Gm.). This employment has, however, justly passed out of vogue. It was highly esteemed by the ancients in mania, melancholy, amenorrhea, dropsy, and epilepsy. Bacher's pills, celebrated for the cure of dropsy, consisted chiefly of black hellebore. The glucoside helleborein has been used internally as a cardiac tonic in doses of from one-sixth to one-third of a grain (0.010-0.021 Gm.) several times a day, but its irritant action on the stomach militates against its practical usefulness. Ischistowitsch (Cb. M. W., 1887) has used an aqueous extract of hellebore with apparent benefit in heart diseases. Venturini and Gaspairini (B. G. T., June, 1888) state that helleborein is a local anesthetic, which, in affections of the eye, is preferable to cocaine, because of the great permanency of the anesthesia, and because neither the pupil nor the intra-ocular pressure is affected. They use from three to four drops of a solution, each drop of which represents one one-hundred and sixty-fourth of a grain (0.0004 Gm.). In overdoses hellebore produces inflammation of the gastric and intestinal mucous membrane, with violent vomiting, hypercatharsis, vertigo, cramp, and convulsions, which sometimes end in death. The fresh root applied to the skin produces inflammation and even vesication. The dose of the powdered root is from ten to twenty grains (0.65-1.3 Gm.) as a drastic purge, two or three grains (0.13-0.2 Gm.) as an alterative. Dose of the decoction (two drachms to a pint), a fluidounce (30 mils) every four hours till it operates.

Helonias. N. F. IV. False Unicorn. Chamaelirium luteum (L.) A. Gray (C. carolinianum Willd., Helonias dioica Pursh.). Starwort.—"The dried rhizome and roots of Chamaelirium luteum (Linne) A. Gray. (Fam. Liliaceae)." N. F. It is described by the N. F. as follows: "Rhizome upright, or oblique, nearly cylindrical, from 0.5 to 3 cm. in length and about 1 cm. in diameter; externally grayish-brown, annulate from scars of bud-scales; upper portion with leaf bases enclosing a small bud; oblique rhizomes with a few stem scars about 0.5 mm. in diameter; lower portion with numerous whitish or pale yellowish, nearly straight or slightly curved wiry roots, from 5 to 8 cm. in length; fracture hard and horny; internally grayish-yellow, cortex from 3 to 4 mm. in thickness, central cylinder with three or four circles of small, nearly circular fibro-vascular bundles. Odor distinctive; taste bitter, slightly astringent. Sections of the rhizome, when examined under the microscope, show parenchyma cells with numerous spherical or ellipsoidal starch grains, varying from 0.002 to 0.015 mm. in diameter; numerous raphides varying from 0.025 to 0.035 mm. in length; the fibro-vascular bundles vary from 0.2 to 0.3 mm. in diameter, the tracheae being at the periphery and the walls marked either with annular or reticulate thickenings or simple pores. In the root the cortex is always attached and there are usually six mestome strands. Helonias yields not more than 5 per cent. of ash." N. F. The rhizome and roots are used in medicine. They resemble those of Aletris but the rootlets of helonias are whitish or pale yellowish, nearly straight, grayish-yellow internally and of a bitter, slightly astringent taste. Fluidextractum Helonatis is official in the N. F. (see Part III).
Hemidesmus Root. Br. 1898. Hemidesmi Radix. Indian Sarsaparilla. Nunnari. Raoine de Hemidesmus, Fr. Hemidesmus-Wurzel, G.—"The dried root of Hemidesmus indicus R. Br." Br., 1898. Hemidesmus indicus (Fam. Asclepiadaceae) is a climbing plant, with twining, woody, slender stems, and opposite, petiolate leaves, which are entire, smooth, shining, and of a firm consistence. The leaves vary much in size and shape, some being linear and acute, others broad-lanceolate, and others again oval or ovate. The flowers are small, green on the outside, purple within, and disposed in axillary racemes. The fruit consists of two long, slender, spreading follicles. This plant is common over the whole peninsula of Hindostan. The official portion was the root, which has long been used in India as a substitute for sarsaparilla. It is 30 cm. or more long and from 3 to 6 mm. thick, rigid, tortuous, cylindrical, and little branched, consisting of a ligneous center, and a brownish, corky bark, marked with longitudinal furrows and transverse fissures. The odor is aromatic, recalling that of tonqua bean, the taste is aromatic and sweetish. On one side of the root the cork is frequently separated from and raised above the cortex, and is transversely fissured. The transverse section exhibits numerous laticiferous cells in the cortex. For details of microscopic structure, see P. J., 1872, 62. Garden obtained from hemidesmus a peculiar, volatilizable acid principle, which he named smilasperic acid, under the erroneous impression that the root was derived from Smilax aspera. Pereira proposed to call it hemidesmic acid. Scott also obtained a stearopten by distillation with water, presumably the same material. It has not been further investigated.

Hemidesmus root is said to be tonic, diuretic, and alterative. It was introduced into Great Britain from India, and was employed for some time under the name of Smilax aspera. It is used for the same purposes as sarsaparilla, and in some instances it is said to have proved successful in syphilis when that medicine had failed, but it cannot be relied upon. The native practitioners in India are said to employ it in nephritic complaints, and in the sore mouth of children. It is used in the form of infusion or decoction, made in the proportion of two ounces of the root to a pint of water. A pint (500 mils) may be given in wineglassful doses in the course of the day. A syrup was official in the Br., 1898.

Heracleum. Heracleum lanatum Michx. Masterwort. Cow-parsnip.—This is one of our largest indigenous umbelliferous plants. The root, which is the part used, bears some resemblance to that of common parsley. It has a strong disagreeable odor and a very acrid taste. Both the leaves and root excite redness and inflammation when applied to the skin. Bigelow considers the plant poisonous. It appears to be somewhat stimulant and carminative, and has been used in epilepsy. (See 16th cd., U.S. D.)

Heretine.—An ether-soluble alkaloid obtained from Heritiera javanica (Sterculiaceae), is said to be effective in the treatment of epilepsy, chorea and migraine.

Hermodactyls. Hermodactyli.—Under this name are sold in European commerce the roots or bulbs of an uncertain plant, growing in the countries about the eastern extremity of the Mediterranean. By some botanists the plant is thought to be a Colchicum, and C. variegatum L., a native of the south of Europe and the Levant, is
particularly indicated by Fee, Geiger, and others, while by authors, no less eminent, the roots are confidently referred to Iris tuberosa L. They certainly bear a considerable resemblance to the corm of Colchicum autumnale L., being heart-shaped, channelled on one side, convex on the other, and from 12 to 25 mm. in length by nearly as much in breadth. As found in commerce, they are destitute of the outer coat, are of a dirty yellowish or brownish color externally, white and amylopectineous within, inodorous and nearly tasteless, though sometimes slightly acrid. They are often worm-eaten. Their chief constituent is starch, and they contain no veratrine or colchicine. From this latter circumstance, and from their insipidity, it has been inferred that they are probably not derived from a species of Colchicum. They are in fact almost without action upon the system. It is doubted whether they are the hermodactyls of the ancients, which acted like colchicum and were useful in gout and rheumatism. Pereira describes a bitter variety of hermodactyls, which was brought from India by Royle. The bulbs are smaller and darker than the others, and have externally a striped or reticulated appearance.

**Herniaria.** Herniaria glabra L. (Fam. Caryophyllaceae)—This genus was formerly included in the family Illecebraceae, but this is now segregated with the Caryophyllaceae. Goblez has obtained from this plant a crystalline principle, herniarine (J. P. C., 4e ser., xx, 270), which proved to be methyl-umbelliferone, \( \text{C}_{10}\text{H}_{8}\text{O}_{3} \). Schneegans has also discovered an alkaloid, paronychine (A. J. P., 1890, 488.) This plant is recommended by Zeissi in catarrh of the bladder. Very active diuretic properties have been attributed to herniaria by Kuhn (Med.Kirn., 1908) and others, who have found that it was successful in the treatment of dropsy, whether of cardiac or nephritic origin.

**Heteromeles.** Heteromeles arbutifolia (Poir.) Roem. (Now ascribed to Photinia arbutifolia Lindl. (Fam. Rosaceae), D. D. Lustig has found in this Californian plant (toyoon of the Indians) tannic, gallic, and hydrocyanic acids. (A. J. P., April, 1882.)

**Heuchera.** Heuchera americana, L. Racine d'Heuchère d'Amerique, Fr. AmerikanischeSanikel wurzel, Gr.—The alum-root or American sanicle is a perennial, herbaceous plant, belonging to the Saxifragaceae, which grows in shady, rocky situations from New England to Carolina and westward to eastern Kansas. The rhizome, which was formerly official, is horizontal, somewhat compressed, knotty, irregular, yellowish, and of a strongly styptic taste. Alum-root is powerfully astringent, and may be employed in similar cases with other medicines belonging to the same class. J. Peacock (A. J. P., 1891, 174) found a percentage of tannin ranging from 9.33 to 19.66 reckoned on the dry drug, according to the season of the year when collected; also a percentage of starch, calculated the same way, ranging from 5.17 to 16.32. Frederick Steams (Proc. A. Ph. A., 1858, 263) speaks of two other indigenous species, H. villosa Michx. (H. caulescens Pursh.) and H. pubescens Pursh., as having similar properties; and F. W. Anderson reports (Botan. Gaz., 1887, 65) that the roots of H. hispida Pursh., H. cylindrical, Douglas, and H. parvifolia Nuttall are much used by hunters of Montana and others as astringents, particularly in diarrhea caused by the drinking of alkali water.
**Hibiscus.** Hibiscus Abelmoschus L. (Abelmoschus moschatus Mouch.) (Fam. Malvaceae) — An evergreen shrub, growing in Egypt, and in the East and West Indies, and yielding the seeds known under the names of Semen Abelmoschi, grana moschata. Musk seed, Abelmosch, Semence on Graine d'Ambrette, Ambrettekorner, Bisornkomer, and Ambrakomer. These are of about the same size as flaxseed, kidney-shaped, striated, of a grayish-brown color, of an odor like that of musk, and of a warm somewhat spicy taste. They were formerly considered stimulant and antispasmodic, but are now used only in perfumery. The Arabs flavor their coffee with them. They are said to be employed in the adulteration of musk. Another species. Hibiscus esculentus L., or Abelmoschus esculentus Moench., is cultivated under the name of okra, bendee, or gombo in various parts of the world, for the sake of its fruit, which abounds in mucilage (gombine), and is used for thickening soup. The leaves are sometimes employed for preparing emollient poultries. The roots, which are a foot or two long, are said also to abound in mucilage free from any unpleasant odor. Their powder is perfectly white, and superior to the marshmallow. The plant is largely cultivated near Constantinople, where it is much used as a demulcent. (A. J. P., 1860, 224; P. J., 1904, 892.) The bark is also used in making paper and cordage.

**Hieracium.** Hieracium venosum L. (Fam. Compositae.) Rattlesnake Weed. Poor Robin's Plantain. Eperviere, Fr. Habichtskraut, G.—The plant is common, growing in dry places and open woods from Maine to Georgia and westward. The leaves and roots are thought to possess medicinal virtues, and, being deemed astringent, have been used in hemorrhagic diseases. The juice is supposed by some to have the power of removing warts. Dose of infusion (two ounces to the pint), a wineglassful (60 mils).

**Hoang-Nan.**—This is the bark of Strychnos malaccensis Benth. (Fam. Loganiaceae), a climbing plant, which grows in Malacca and surrounding countries. Brucine and strychnine are stated to have been found in it, brucine being the more abundant of the two. It has been found to produce in animals general tetanic spasms similar to those caused by strychnine. It probably has the same range of medicinal application as has nux vomica, although special virtues have been claimed for it in the treatment of chronic skin diseases. Dose of powdered bark, three grains (0.2 Gm.).

**Holigarna.** Holigarna longifolia Roxb. Now Senecarpus longifolia Blume. (Fam. Anacardiaceae)—According to David Hooper (P. J., xxv, 1895), the black juice of this tree, which is used in India as the basis of a varnish, is actively vesicant, and contains a body closely allied to, if not identical with cardol.

**Hordeum.** Barley Orge, Fr. Gerste, G.—The grains of Hordeum sativum Jessen, and its cultivated varieties. The original country of the cultivated barley is unknown. The plant has been found growing wild in Sicily and in various parts of the interior of Asia.

Pillitz found (Zeit. An. Chem., 1872) in the dry barley 14.3 per cent. of insoluble albuminoids, 2.1 per cent. of soluble albuminoids, 62.6 per cent. of starch, 1.9 per cent. of dextrin, 2.7 per cent. of sugar, 1.7 per cent. of extractive material, 3.1 per cent. of fat, 1.4 per cent. of soluble ash, 1.2 per cent. of insoluble ash, and 8.9 per cent. of lignin. The presence of sugar seems to have been shown by Kuhnemann (Ber. d.
Chem. Ges., 1875 and 1876), who found a crystallized dextrogyrate sugar which did not reduce alkaline copper solution, and an amorphous lasvogyrate mucilaginous substance called sinistrin. According to Kuhnemann, barley does not contain dextrin.

Clifford Richardson (Bulletin No. 9, Department of Agriculture, 1886) gives the following as the average composition of American barley: water, 6.47 per cent.; ash, 2.87; oil, 2.67; sugar, etc., 7.02; dextrin and soluble starch, 3.4; starch, 62.09; albuminoids soluble in 80 per cent. alcohol, 3.66; albuminoids insoluble in 80 per cent. alcohol, 7.86; fiber, 3.81; total, 100.0. He finds, moreover, that on an average the grain makes up 84.78 per cent. and the hull 15.22 per cent. of the barley.

Barley contains hordein, a proteid substance somewhat related to gliadin which is derived from the kernels of wheat and rye. Hordein is soluble in alcohol. The name was formerly given to a pulverulent mixture obtained from barley which was believed to be a definite substance.

Hulled barley is merely the grain deprived of its husk, which, according to Einhoff, amounts to 18.75 parts in the hundred.

Barley meal is formed by grinding the seeds, previously deprived of their husk. It has a gray-ish-white color; the constituents are the same as described above for barley. It may be made into a coarse, heavy, hard bread, which in some countries is much used for food.

Pearl barley (Hordeum decorticatum, Br., 1885) is the seed deprived of all its investments and afterwards rounded and polished in a mill. It is in small round or oval grains, having the remains of the longitudinal furrow of the seeds, and of a pearly whiteness. It is wholly destitute of hordein, and abounds in starch, with some gluten, sugar, and gum. This is the proper form of barley for medicinal use.

Barley in the form of the decoction, popularly known as barley water, affords a mucilaginous drink much employed from the time of Hippocrates to the present. Pearl barley is the form usually preferred for the preparation of the decoction, made by pouring four pints of boiling water on two troyounces of pearl barley and boiling away to two pints, and straining. It is especially used in infant feeding, as it seems to prevent the formation of large milk curds.

**Houttuynia.** Houttuynia californica B. et H., now Anemopsis californica Hook. et Arn. Yerba Mansa.—The root of this piperaceous Californian plant is employed by the natives in chronic malaria, and also in diarrhea and dysentery, and has been used with asserted good results in gonorrhea and rheumatism. For elaborate histological study, see D. O., May, 1897. Dose of the fluidextract, from fifteen to sixty minims (0.9-3.75 mils). A decoction of this root was used by the Indians as a local application in cuts and ulcers as well as internally in diarrhea and dysentery. It has also been recommended as a local application in nasal and pharyngeal catarrhs. The investigations of Lloyd (A. J. P., 1879) showed a characteristic volatile oil and a tannin together with gum and a fixed oil.
Huamanripa.—This is a Chilian drug, the plant growing on the slope of the Cordilleras at considerable heights. Lapater found it to be stimulating, emetic, sialagogue, and diaphoretic. (West. Drug., 1886,410.)

HUMULUS. U. S.

HOPS Humul.

"The carefully dried strobiles of Humulus Lupulus Linne (Fam. Moraceae) bearing their glandular trichomes and without the presence or admixture of more than 2 per cent. of stems, leaves or other foreign-matter. Preserve it in tightly-closed containers, protected from light." U. S.

Lupulus, Br. Pharm. 1898; Hop; Strobili Humuli, s. Lupuli; Houblon, Fr. Cod.; Hopfen, G.: Luppolo, It.; Lupulo (Fruto de), Hombrecillo, Sp.

Hops, under the title "Lupulus" were deleted from the British Pharm. (1914).

The hop plant is a twining, rough perennial having angular, rough, flexible stems, which twine around neighboring objects in a spiral direction from left to right, and climb to a great height. The leaves are opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green color on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two to four smooth, ovate, reflexed stipules. The flowers are numerous, axillary, and furnished with bracts. The staminate flowers are a yellowish-white, and arranged in panicles; the pistillate, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears, near its base, on its inner surface, two flowers, consisting of a roundish compressed ovary, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain, each, at its base, two small achenes, surrounded by a yellow, granular powder or the so-called Lupulin. Only the pistillate plants are cultivated by the hop growers in Europe, and it is interesting to note that the unfertilized pistillate plants produce strobiles richer in aroma and more plenteous in lupulin. The
plants flower in August and the fruits are harvested during September. The hops grown in this country contain a great many achenes, showing that the staminate plants are also cultivated. The strobiles are collected when the scales change from a light golden to a somewhat deeper hue.

The hop plant is a native of North America and Europe. In parts of New England, New York, and Michigan it is extensively cultivated, and most of the hops consumed in the United States is supplied by those districts. England probably produces the largest quantity of hops, with Germany and Austria next in order. The part of the plant used is the fruit or strobiles. These, when fully ripe, are picked, dried by artificial heat, packed in bales, and sent into the market under the name of hops.

By separating the volatile oils and determining its acid and ester value, Rabak (C. D., lxxxv, 376) is able to distinguish American grown from imported hops. He finds that the European hops always show a lower ester value in the volatile oil than do the American.

Hops consists of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow color, and contain near the base two small, round, black achenes. They are officially described as follows: "Strobile ovoid-cylindrical, about 3 cm. in length, consisting of a narrow, hairy, flexuous rachis and numerous, imbricated, yellowish-green to pale brown, obliquely-ovate, membranous scales, the base of each with numerous, yellowish-brown, glandular hairs, and frequently infolded on one side, enclosing a subglobular, light brown, very glandular achene; odor strong and characteristic, becoming disagreeable and valerian-like on aging; taste aromatic and bitter. Hops yield not more than 8 per cent. of ash." U. S.

Though brittle when quite dry, they are pulverized with great difficulty. Their odor is strong, peculiar and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction, but the first mentioned property is dissipated by long boiling. The most active part of hops is a substance formed on the surface of the scales, and, in the dried fruit, existing in the state of very small granules. This substance was called lupulin by A. W. Ives of New York, by whom its properties were first investigated and made generally known, though it was previously noticed by Sir J. E. Smith of England, and Planche of France. The scales themselves, however, are not destitute of virtues, and contain, as shown
by Payen and Chevallier, the same active principles as does lupulin, though in less proportion.

Hops are often subjected in Germany to the fumes of burning sulphur, because of the supposition that they keep better when thus treated. Besides, by being partially bleached by the process, old hops, which have suffered from time, having become darker, generally spotted, and weaker, assume a brighter appearance, as if fresher, and generally command a better price in the market. To detect the consequent presence of sulphurous acid, the brewers put a silver spoon in a mixture of hops and water, under the impression that it will produce a black stain upon the silver. But this test will answer only when applied within a fortnight after the use of the sulphur. A more delicate method is that of Heidenreich, who puts twenty or thirty strobiles of the hops in a flask with zinc and hydrochloric acid, and passes the hydrogen evolved through solution of lead acetate. If sulphurous acid be present, hydrogen sulphide will be produced, which will occasion a dark precipitate with the solution. But even this plan often fails when the hops have been kept more than three or four weeks. A modification of this test has been proposed by R. Wagner. For the solution of lead acetate used in Heidenreich's method there is to be substituted a solution of sodium nitroprusside, so weak as to have a very light brown color, to which have been added a few drops of solution of potassium hydroxide. If the gas evolved contain the minutest proportion of sulphur, a violet color will be produced when the first bubble passes into the solution; and this will, by a continuance of the process become a magnificent purple. The least trace of sulphurous acid may thus be found, but a few months after the sulphuring of hops none at all can be detected.

Hops are said to be sometimes threshed in order to separate the lupulin, which is sold separately. Their efficiency is thus, no doubt, greatly impaired. Hops thus treated have the scales more or less broken; and any parcel presenting this appearance is to be suspected. Hops often contain a variable quantity of lupulin in consequence of the granules of this substance separating, especially on agitation, and seeking the lower portion of the mass, which thus becomes richer, while the upper is poorer. They should always be examined in reference to the lupulin they contain, and, if nearly or quite destitute of it, should be deemed of inferior value and not be used medicinally.
LUPULIN, N. F. IV.—Lupulin is obtained by rubbing or threshing and sifting the strobiles, of which it constitutes from one-sixth to one-tenth by weight. It is in the state of a yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavor of hops, and appeared to Lebaillif and Raspail, when examined by the microscope, to consist of glandular hairs filled with a yellow matter. They originate in a cell formed among those of the epidermis, and, when fully developed, secreting a resinous matter. (J. P. C; 3e ser., xxvi.) It is inflammable, and when moderately heated becomes somewhat adhesive. The odor of lupulinic grains resides in the essential oil. This is obtained to the extent of 0.9 per cent. by distilling hops with water. When distilled from the fresh strobiles the oil has a greenish color, but a reddish brown when old hops have been employed. It is devoid of rotatory power, neutral to litmus paper, and gives no remarkable coloration with concentrated sulphuric acid. According to Chapman (J. Chem. S., 1895, 54, 780) the essential oil consists of two terpenes, one $C_{10}H_{16}$, and the other $C_{10}H_{18}O$. The latter makes up almost two-thirds of the oil. There is also a small amount of an oxygenated constituent, probably $C_{10}H_{18}O$. The bitter principle formerly called lupulin or lupulite was first isolated by Lermer, who called it the bitter acid of hops (Hopfenbittersaure). It crystallizes in large brittle rhombic prisms, and possesses the peculiar bitter taste of beer. Its composition is $C_{32}H_{50}O_7$. Lupulin consists chiefly of wax (myricyl palmitate, according to Lermer) and resins, one of which is crystalline and unites with bases.

Besides the constituents of the glands, hops contain, according to Etti, lupulo-tannic acid and phlobaphene. The former is a whitish, amorphous mass, soluble in alcohol, hot water, or acetic ether, but not in ether. By heating the humulo-tannic acid to 130° C. (266° F.), or by boiling its aqueous or alcoholic solution, it gives off water and is transformed into phlobaphene, a dark-red amorphous substance,

$$2C_{25}H_{24}O_{13} - H_2O = C_{50}H_{46}O_{25}$$

The latter substance, on boiling it with diluted adneral acids, becomes hydrolized, and furnishes glucose and hop-red, according to the reaction:
From raw phlobaphene, ether removes the bitter principles of hops, a colorless crystallizable and a brown amorphous resin, besides chlorophyll and essential oil. (Pharmacographia, 2d ed.) The existence of a peculiar alkaloid in hops, suggested by Lermer in 1863, and confirmed by Griessmayer, has been denied. A. Chaston Chapman (P. J., 1912, xcii, 878), found cultivated hops to contain from 1.7 to 4 per cent. of nitrogen which is a constituent of the following principles recognized by him in an investigation of the subject: aspartic acid, 1-asparagine, choline, betaine, adenine, histidine, hypoxanthine, and arginine, besides an unidentified base, no trace of a morphine-like alkaloid could be detected, although this has been stated by some authorities to be present. Etti found arable (pectic) acid, phosphates, nitrates, malates, citrates, and also sulphates, chiefly of potassium, to occur in hops. The amount of ash afforded by hops dried at 100° C. (212° F.) would appear to be on an average about 6 to 7 per cent. (U. S. P. IX not more than 8 per cent.) H. Bungener has isolated from hops a bitter crystalline substance, C$_{25}$H$_{35}$O$_4$, which is insoluble in water, but soluble in alcohol and alkaline solutions. He believes it to be identical with Lenner's hop-bitter acid, to be feebly acid, and to possess the character of an aldehyde. (P. J., 1884.)

**Uses.**—Hops are an aromatic bitter and hence may be useful in atonic dyspepsia. By many they are believed to have a sedative effect on the nervous system and are used in hysteria, restlessness, insomnia, and the like. Whether this latter action is due to anything more than an effect through the imagination is open to question.

An infusion prepared with half an ounce of hops and a pint of boiling water may be given in the dose of four fluidounces (120 mils). The tincture was a British official preparation of hops, but the alcohol probably acts more decidedly upon the system than the hops. The fluidextract of hops of the N. F. IV is superior because of the relatively smaller amount of alcohol. A pillow of hops has proved useful in allaying restlessness and producing sleep in nervous disorders. They should be moistened with water containing a trace of glycerin previously to being placed under the head of the patient, in order to prevent rustling. Fomentations with hops, and cataplasms made by mixing them with some emollient substance, are often beneficial in local pains and
The effects of hops may be obtained conveniently by the use of lupulin, which, although at one time much employed as an anaphrodisiac, has fallen into deserved desuetude.

Dose, thirty to ninety grains (2.0-5.8 Gm.).

**Off. Prep.**—Elixir Humuli (from Fluidextract), N. F.; Fluidextractum Humuli, N. F.; Tinctura Humuli, N. F.

**Hura.** Hura crepitans L. Sandbox tree. Assacou. Sablier, Fr. Sandbuchsenbaum, G.—This tree belonging to the family of Euphorbiaceae is indigenous to tropical America and is extensively cultivated in the tropics. It is characterized by the tendency of its fruit when ripe to break with violence into several pieces, and thus scatter the seeds. It is an acrid emeto-cathartic; in large doses acting as a violent poison. The fresh juice, the seeds, and a decoction of the bark all have these properties; an oil expressed from the seeds is actively purgative. According to Richet, the toxicity is due to the presence of a toxalbumin to which he gave the name of crepitin. (P. J., 1910, lxxxiv, p. 571.) The juice of Hura crepitans, which, according to J. J. Surie (Nederl. Tijdsch. voor Pharm., 1900, 107), contains a volatile, colorless liquid, hurin, closely allied to cardol and is stated by Martins to be used to intoxicate fish, it has been employed to a considerable extent with alleged favorable results in the treatment of the elephantiasis, or leprosy, of Brazil. (For a method of using it, see J. P. C., xiv, 424.) The juice is extremely acrid, producing on the skin, when applied to it, an erysipelatous redness and a pustular eruption; the natives are said to employ it in the preparation of a poison.

**Hydrangea, N. F. IV. Seven Barks. Common Hydrangea. (Fam. Saxifragaceae).**—It is described by the N. F. as "the dried rhizome and roots of Hydrangea arborescens Linne. (Fam. Saxifragaceae.) Rhizome cylindrical, usually cut into pieces from 3 to 10 cm. in length and from 3 to 20 mm. in diameter; externally light brown to yellowish-brown with a pinkish tinge, longitudinally wrinkled, marked by few elliptical lenticels and occasional prominent buds, short branches or stem scars; from the lower surface arise a few coarse fibrous roots; fracture tough, splintery; internally yellowish-white or light brown, bark thin, easily separable from the distinctly radiant wood which surrounds a prominent whitish pith. Roots attaining a length of 25 cm. and a thickness of 2 mm., irregularly bent and branching, otherwise resembling the rhizome with the exception of the pith being absent. Inodorous; taste sweetish, becoming slightly acrid. Under the microscope, sections of the rhizome of Hydrangea show a gray cork of a few rows of tabular cells, a cortex made up chiefly of parenchyma containing starch, large cells containing raphides and small isolated groups of stone cells or sclerenchymatous fibers; a woody cylinder composed of slender wedges made up of prominent tracheae with reticulate thickenings and tracheids separated by medullary rays one to three cells wide, the cells of which are filled with small starch grains; pith of large polygonal cells with prominent simple pores. The powder is light.
yellowish-brown, containing irregular fragments consisting of strongly lignified tracheae, tracheids and medullary ray cells; stone cells and sclerenchymatous fibers from 0.05 to 0.2 mm. in length, strongly lignified, the walls marked by simple and branching pores; raphides numerous, from 0.07 to 0.13 mm. in length; starch grains mostly single, more or less ellipsoidal, occasionally with a prominent central cleft and varying from 0.002 to 0.01 mm. in diameter. Hydrangea yields not more than 3 per cent. of ash." N. F.

Bondurant (A. J. P., 1887, 122) isolated a characteristic glucoside, hydrangin, crystallizing in stellate clusters, melting at 235° C. (455° F.), and subliming without decomposition. It is decomposed by dilute acids into a resin-like body and glucose. Its aqueous solution fluoresces strongly on addition of an alkali, resembling sesculin, but distinctly different in several particulars. Bondurant also obtained a fixed oil and a volatile oil, the latter containing sulphur. Two resins seemed also to be present, together with saponin and sugar. He found no tannin, however. Y. Asahina has isolated two crystalline substances from the alcoholic extract of the flowers of H. Hortensia; hydagenol and hydrangeaic acid. The first occurs in white, odorless and tasteless crystals which are soluble in alkalis and dissolve in sulphuric acid without color; hydrangeaic acid forms yellowish, shining crystals, and its alcoholic solution when treated with ferric chloride yields a violet color. Its decoction is said to have been used with great advantage among the Cherokee Indians, and subsequently by settlers, in calculous diseases. (See N. J. Med. Rep., 1850, 1854, and 1885.) In overdoses it occasions vertigo, oppression of the chest. etc. Dose, thirty grains (1.9 Gm.).

HYDRASTIS. U. S. (Br.)

HYDRASTIS [Golden Seal]

"The dried rhizome and roots of Hydrastis canadensis Linne (Fam. Ranunculaceae), without the presence or admixture of more than 2 per cent. of the stems, leaves or other foreign matter and yielding not less than 2.5 per cent. of the ether-soluble alkaloids of Hydrastis." U. S. "Hydrastis Rhizome is the dried rhizome and roots of Hydrastis canadensis, Linn." Br.

Hydrastis Rhizoma. Br.; Hydrastis Rhizome; Rhizoma Hydrastis; Golden Seal, Yellow Root, Yellow Puceoon, Orange Root, Indian Dye, Indian Turmeric, Ohio Turmeric; Indian Paint, Ground Raspberry, Eye Root, Eye balm. Yellow Eye, Jaundice Root; Hydrastis, Fr. Cod.; Racine d'Hydrastis du Canada, Sceau d'or, Fr.; Canadische Gelbwurzel, Gelbes Blutkraut, G.; Idraste, It.; Hidrastis del Canada (Rhizoma de), Sp.

Hydrastis canadensis is a small, herbaceous, perennial plant, with a thick, fleshy, yellow (rhizome, from which numerous long roots arise,
and an erect, simple, pubescent stem, from six inches to a foot in height. There are usually but two leaves, which are unequal, one sessile at the top of the stem, the other attached to the stem, a short distance below by a thick roundish footstalk, causing the stem to appear as if bifurcate near the summit. The leaves are pubescent, roundish-cordate, with from three to seven, but generally five, lobes, which are pointed and unequally serrate. A solitary flower stands upon a peduncle rising from the basis of the upper leaf. It is without corolla, but with a greenish-white calyx, the sepals of which closely resemble petals, and are very caducous, falling very soon after the flower has expanded. The fruit is a globose, compound, red or crimson berry, half an inch or more in diameter, composed of many fleshy carpels, each tipped with a short curved beak, and containing one or rarely two seeds. The plant grows in moist, rich woodlands in most parts of the United States, and at one time abundantly in the North and West. The fruit bears a close resemblance to the raspberry, but is not edible. The root is the part used. The Indians employed it for staining and dyeing yellow under the name of yellow puccoon, and it is said to impart a rich and permanent yellow, and with indigo a fine green, to wool, silk, and cotton. There is but one other species of Hydrastis known—viz., H. jezoensis Sieb. et Zucc., which is found in Northern Japan.

Enormous quantities of hydrastis are consumed. It is estimated that between 200,000 and 300,000 pounds of the drug are annually used in medicine. As the natural supplies are becoming limited many experiments in the cultivation of hydrastis have been made. It can be grown from cuttings of the rhizome and from seed. It furthermore can be grown with the natural shade of the woodlands or by means of artificial shade. The important articles on the cultivation of hydrastis are the following: John Uri Lloyd, Proc. A. Ph. A., 1905, p. 307, and in A. Ph. A; vol. i, p. 5; Alice Henkel and G. Fred Klugh, Circ. No. 6, Bureau of Plant Industry, U. S. Department of Agriculture; J. C. Baldwin, A. J. P., 1913, p. 147. Most of the commercial supplies are obtained from the Ohio Valley. The States producing hydrastis are West Virginia, Ohio, Kentucky and Indiana. The chief market being Cincinnati.

**Properties.**—The fresh rhizome is juicy, and loses much of its weight in drying. The drug is officially described as “rhizome horizontal or oblique, sub-cylindrical and usually more or less flexuous, from 1 to 5 cm. in length and from 2 to 7 mm. in diameter, occasionally with stem-bases;
externally yellowish or grayish-brown, marked by numerous stem-scars and more or less annulate from scars of bud-scales, otherwise deeply longitudinally wrinkled; on the under and lateral portions arise numerous, long, filiform roots which are easily detached; fracture short, waxy; internally of, a deep yellow color and consisting mostly of parenchyma enclosing an interrupted circle of small fibro-vascular bundles; odor distinctive; taste, bitter. Macerate the drug for a short time in water until it is softened, then make sections and mount them directly in sulphuric acid and examine under the microscope; in a short time numerous acicular or rod-shaped crystals separate, some attaining a length of 0.2 mm. The powder is brownish-yellow; starch grains numerous, from 0.002 to 0.015 mm. in diameter, mostly single, nearly spherical, and either free or in the parenchyma cells; fragments with the tissues of the fibro-vascular bundles mostly associated with starch-bearing parenchyma; tracheae with simple and bordered pores and occasionally spiral thickenings, and associated with short sclerenchymatous fibers possessing thin walls with simple pores; occasional fragments of tabular cork cells with reddish-brown walls." U. S.

"Rhizome tortuous, simple or branched, from ten to forty millimetres long and from three to ten millimetres thick; yellowish-brown, becoming darker by age. On the upper surface, short ascending branches usually terminated by cup-shaped scars; on the lower surface and sides numerous thin, brittle roots. Fracture clean, resinous; fractured surface brownish-yellow or greenish-yellow. In transverse section, a ring of bright yellow, somewhat distant, wood-bundles. Slight but characteristic odor; taste bitter. Ash not more than 11 per cent." Br.

The color of the rhizome, though yellow in the recent root, becomes a dark yellowish-brown by age; that of the rootlets and the interior of the root is yellow, and that of the powder still more so.

Holm gives a valuable illustrated article on the morphology of the hydastis plant in Merck's Rep., xxii, p. 202. (See also Chem. Zeit., 1894, p. 134.) Roseuthaler has extended his studies of microsublimates to that of hydrastis and finds that the pyroanalytical sublimate of hydrastis gives general alkaloidal reaction and a characteristic reaction with sulphuric acid. (Apoth. Zeit., xxviii, p. 991.) Owing to the high price of hydrastis the quality of the commercial article has steadily deteriorated in recent years, and Lloyd asserts that every drug native to the soil
which resembles this rhizome, either in fiber or in color, has been known to be mixed with it. (Pharm. Rev., xxiii, p. 330.)

"Assay.—Introduce 10 Gm. of Hydrastis, in No. 60 powder, into a 250 mil flask and add 100 mils of ether and proceed as directed under Belladonnae Radix, fourth line of the Assay, beginning with the word "Stopper." Modify the process there given by using 50 mils of the ether solution, representing 5 Gm. of Hydrastis, to complete the assay. Use ether instead of chloroform for the final shaking out of the alkaloids, and dry the residue to constant weight at 100° C. (212° F.) instead of titrating. The weight is the amount of ether-soluble alkaloids from 5 Gm. of Hydrastis." U. S.

The medicine imparts its virtues and coloring matters to water and alcohol. Examined by Alfred B. Durand of Philadelphia, it was found to contain albumen, starch, fatty matter, resin, yellow coloring matter, sugar, lignin, and various salts. He also discovered a peculiar nitrogenous, crystallizable substance, for which he proposed the name of hydrastine. (A. J. P., 1851, p. 112.) It was also found that the root contained another alkaloid, to which it owes its yellow color. F. Mahla first ascertained that this alkaloid of hydrastis was berberine. (Am. J. S., Jan., 1862, p. 43.) It exists in large proportion in hydrastis, constituting, according to Perrins, nearly 4 per cent. For a valuable paper by J. U. Lloyd on the preparation of salts of berberine, see A. J. P., 1879, p. 11.

Lerre's process based on Lloyd's for preparing hydrastine and berberine will be found in the U. S. D., 19th ed., p. 643.

Wilhelm (P. J., 1888, 325) furnishes a process for obtaining the alkaloids from hydrastis as follows. The extract obtained by treating the coarsely powdered root with water acidified with acetic acid at 37.8° C. (100° F.) is evaporated to a syrup and excess of diluted sulphuric acid added, when berberine sulphate separates. The nitrate neutralized with ammonia water gives a precipitate containing much hy-drastine; this is separated, and on adding ammonia water in excess to the filtrate a further precipitate is produced, which contains canadine. Both precipitates, boiled with ethyl acetate, give solutions which, on cooling, deposit hydastine in large crystals, somewhat colored, but rendered pure by recrystallization. The crystals from the second ammonia precipitate are much purer than those from the first; by slow evaporation of the ethyl acetate solution they can be obtained as large as walnuts.
A substance obtained by the precipitation of an infusion of the root by hydrochloric acid has been for some time known and used by the "Eclectics," under the name of hydrastin; it consists of a small proportion of hydastine, with berberine and resin, and the reader must be cautious not to confound this substance with the alkaloid to which the name properly belongs. Perrins obtained 1.5 per cent. of the eclectic principle from the root, and, having given five grains of it to a rabbit without any other effect than a slight uneasiness which soon ceased concluded justly that it was not poisonous.

Canadine (C$_{20}$H$_{21}$NO$_{4}$) was extracted by E. Schmidt; it occurs in the form of brilliant, small, "white nodules, melting at 134° C. (273.2° F.). When canadine is dissolved in alcohol and treated with iodine, berberine hydriodide (which is yellow in color) is formed. Canadine was believed to be identical with dihydromethylberberine (Ph. Post, 1892, 230), and the formula C$_{21}$H$_{21}$NO$_{4}$ was given to it. E. Schmidt, however (A. Pharm., 1894, 136-154), has found that its true formula is C$_{21}$H$_{21}$NO$_{4}$, and, owing to the fact that iodine forms with it berberine hydriodide, he believes that canadine is a tetrahydroberberine. Schmidt also obtained, as an additional product of the iodine reaction, the hydriodide of another base, which he believes is intermediate between berberine and canadine. For a process for isolating canadine, see Proc. A. Ph. A., 1894, 1103. The alkaloid discovered by A. K. Hale, and obtained later by Burt and by Lerchen, and which was named xanthopuccine, is now considered to be identical with canadine. For processes for making hydrastine and berberine, see D. C., 1897, 34. It is probable, from the odor of hydrastis, that besides the two alkaloids here mentioned it contains also an active volatile principle, but this has not yet been isolated.

LaWall (Proc. Pa. Ph. A., 1912, p. 142) made separate assays of the rhizome and rootlets from a 98-pound lot of the drug. There was present 45.5 pounds of rhizome and 48 pounds of rootlets, the balance being dirt and waste. The rhizomes assayed 2.48 per cent. of hydrastine and the rootlets 1.38 per cent. The average of the entire lot was 1.92 per cent.

Uses.—Hydrastis owes its virtues almost entirely to hydrastine, the alkaloid berberine, aside from some effect as a bitter, being practically inert. It has enjoyed a widespread reputation as a local remedy in
various forms of catarrh, such as rhinitis, gastritis, vaginitis, and urethritis.

In chronic or subacute inflammations of the colon and rectum injections of hydrastis are often of great service, and it has been used in hemorrhoids with asserted excellent results.

The strength of the local application of hydrastis to be used in various diseases of the mucous membrane varies from five to twenty-five per cent. of the fluidextract. In gonorrhea from forty to eighty minims (2.5-5.0 mils) of the fluidextract, may be used to the fluidounce (30 mils). In hemorrhoids from two to four drachms to the fluidounce may be used. The glycerite is not so useful a local preparation as the fluidextract diluted with water, a deposit of the insoluble resinous substance upon the mucous membrane and its constant prolonged influence being important.

It is essential to recognize the differences, medicinally, between the preparations of hydrastis. The so-called hydrastin of commerce is really an impure body, containing berberine, canadine, hydrastine, and probably some resin. The dose of this hydrastin is from five to ten grains (0.32-0.65 Gm.).

There is some reason for believing that berberine has a special action upon the gastro-intestinal tract. Marfori has, however, found that even in large therapeutic dose it is without perceptible influence upon the circulation or the nervous system. When, therefore, a preparation of hydrastis is to be used for effects other than a local action on the gastro-intestinal or other mucous membrane, a salt of the pure alkaloid hydrastine should be used.

According to the studies of Faick and Guenste, berberine causes in dogs and rabbits restlessness, convulsive tremblings, hurried respiration, and diarrhea, followed, if the dose has been large enough, by decrease of the breathing rate, widespread paralysis, dyspnea, convulsions, and death. In man as yet no serious symptoms have been recorded as produced by it. Buchner is stated to have taken nearly twenty grains without causing anything more serious than a loose stool. Marek (W. M. W., 1911, 2146) has presented evidence that it possesses valuable oxytocic properties, and is useful in delayed labor. It has been employed in internal medicine as a simple bitter, in doses of from two to five grains.
Hydroberberine (Canadine), whose molecule contains four atoms of hydrogen more than the molecule of berberine, is said by Marfori to differ from berberine physiologically; it produces in moderate dose an increase in the blood pressure by stimulating the vasomotor center in the medulla. Opianic, hydrastinic, and berberinic acids are said by the same authority to be almost inert physiologically, except that they are feebly antiseptic (T. G., 1890.)

**Hydrocotyle.** Hydrocotyle asiatica L. Thick-leaved Pennywort. Indian Pennywort. Bevilacqua Fr. Wassernabel, G.—This is a small umbelliferous plant growing in Southern Africa and in India, where it has long been used as an alterative; it is apparently indigenous also in the Southern United States. Jules Lepine discovered in it a peculiar oleaginous substance, vellarin, having a strong odor recalling that of the plant, and a bitter, pungent, and persistent taste. (J. P. C; 1885, 49.) It is said to be diuretic, and has been given in fever and bowel complaints; also in syphilitic and scrofulous affections. (P.J.; 1860.)

C. Daruty de Grandpre (Nouv. Rem., April 8, 1888) finds that in small doses it is an energetic stimulant, and that in large doses it is narcotic, producing stupor, headache, and in some persona vertigo with a tendency to coma.

**Hygrophila.** Br. Add. 1900.—The dried herb including the root of Hygrophila spinosa T. And. (Asteracantha longifolia Nees). Br. Add. (Fam. Acanthaceae.) This species of hygrophila has long been used in India as a diuretic in the treatment of dropsies, especially where there is hepatic obstruction, and also as a popular aphrodisiac. In Southern India the root is an article of commerce, but in Bombay the seeds are commonly employed. By means of petroleum benzin C. H. Warden obtained from the roots a crystalline principle (Phg. Ind., vol. 3). The decoction, of hygrophila (Decoctum Hygrophilae, Br. Add., 1900), two ounces of the root with three pints of water boiled to a pint, is given in doses of one-half to two fluid-ounces (15-60 mils).

**Hylopeia Aethiopica (?).**—This plant is asserted to contain an alkaloid, anonaceine, which has been employed in combination with other reputed aphrodisiacs under the term of aphrodisin in the treatment of impotence.

**HYOSCYAMUS. U. S. (Br.)**

**HYOSCYAMUS Hyosc.**

[Henbane, Hyoscyami Folium P. I.]

“The dried leaves or fruiting tops of Hyoscyamus niger Linne (Fam. Solanaceae), yielding not less than 0.065 per cent. of the alkaloids of
Hyoscyamus." U. S. " Hyoscyamus Leaves are the leaves of Hyoscyamus niger, Linn., collected from the flowering plants, and dried." Br.

There are about eleven species of the genus Hyoscyamus known; these are distributed from the Canary Islands over Europe and Northern Africa to Asia.

Hyoscyamus niger, or henbane, is usually a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, not unlike that of parsley, for which it has been eaten by mistake, with poisonous effects. The stem, which rises in the second year, is erect, branching, from one to four feet high, and thickly furnished with leaves. These are large, oblong-ovate, deeply sinuated with pointed segments, undulated, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green color. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downward. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. The corolla is of an obscure yellow color, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx, and contains numerous small seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank, offensive odor.

H. niger is susceptible of considerable diversity of character, causing varieties which have by some been considered as distinct species. Thus, the plant is sometimes annual, the stem simple, smaller, and less downy than in the biennial plant, the leaves shorter and less hairy and viscid, and the flowers often yellow without the purple streaks.

The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the older settlements, particularly cemeteries, old gardens, and the foundations of ruined houses. It is, not, however, a native of this country, having been introduced from Europe. In Great Britain, and on the continent of Europe, it grows abundantly.
along the roads, around villages, amidst rubbish, and in uncultivated places. Both varieties were formerly cultivated in England, but at present the biennial is chiefly or solely grown. The annual plant flowers in July or August, the biennial in May or June. For an account of the cultivation of the biennial variety of Hitchin, England, see P. J., Feb., 1860.

Mitlacher, in connection with other plants, has carried on a series of experiments on the cultivation of Hyoscyamus and reports on the results of his work in Ph. Post, 1911, p. 390 and Zeit. Oest. Apoth. Ver., 1912, p. 401. Hyoscyamus has been successfully grown in the testing gardens of the Bureau of Plant Industry. There is usually some difficulty in growing hyoscyamus owing to its destruction by insects (A. J. P., 1912, p. 551), but Newcomb was very successful with his experiments in Minneapolis. (A. J. P., 1914, p. 531.) Schneider also has pointed out that henbane thrives well in California and says that it no doubt will do well in the Coast valleys. (Pac. Pharm., iii, p. 192.) Peckolt reports that Hyoscyamus niger grows wild in portions of Brazil. (B. P. G; xix, p. 33.) Chevalier has shown that by cultivation the alkaloidal content of hyoscyamus can be increased to 0.286 per cent. of total alkaloids. (C. R. A. S., 1910, p. 344.)

H. albus, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, with which it appears to be identical in medicinal properties. Hyoscyamus muticus L., of Egypt, is said to grow luxuriantly in the temperate zone and to produce a very much larger proportion of total alkaloids than does the official English plant, although the relative proportions of hyoscine and hyoscyamine are not the same. It appeared in the London market in the form of broken stalks with a few capsular fruits and traces of leaves and may become an important source of the alkaloids to the manufacturers.

Properties.—All parts of Hyoscyamus niger are active. The official description of the plant is as follows: "Usually much wrinkled, with numerous stems and with the flowering or fruiting tops intermixed; leaves when entire attaining a length of 25 cm., a breadth of 10 cm., ovate or ovate-oblong, very inequilateral, the lower with short petioles, the upper sessile, summits acute, margins coarsely and angularly 1-to 4-toothed or lobed; grayish-green, glandular-hairy, particularly on the lower surfaces; flowers nearly sessile with an urn-shaped, unequally 5-toothed calyx and a campanulate corolla which in the fresh state is of a..."
yellowish color; fruit a 2-locular pyxis, and enclosed in a large urn-shaped calyx with 5 acute teeth; odor heavy, distinctive; taste somewhat bitter and acrid. Stems from 3 to 10 cm. in length and from 2 to 5 mm. in thickness, nearly cylindrical or somewhat compressed, longitudinally wrinkled and hairy. The powder is grayish-green; under the microscope, it exhibits calcium oxalate crystals usually in the form of 4- to 6-sided, isolated prisms, sometimes in twins, from 0.015 to 0.025 mm. in length, also occurring in spherical aggregates either isolated or attached to the prismatic crystals, sometimes in rosette aggregates, 0.02 mm. in diameter, and occasionally in sphenoidal micro-crystals; hairs numerous, of two kinds; the non-glandular from 2 to 10 cells in length, the glandular with a 1- to many-celled head and a 1- to 4-celled stalk; fragments of epidermis with broadly elliptical stomata from 0.03 to 0.035 mm. in length and with 3 to 4 neighboring cells; fragments of trachea? with simple or bordered pores and spiral or reticulate thickenings, also associated with sclerenchymatous fibers having thin porous walls and showing little or no lignification; pollen grains, nearly smooth and from 0.035 to 0.05 mm. in diameter. The presence of the leaves of Hyoscyamus muticus Linne in either the crude or powdered Hyoscyamus may be determined by the characteristic, branching, non-glandular hairs occurring on both the stems and leaves of that species. Hyoscyamus yields not more than 30 per cent. of ash.\textemdash U. S.

"Pale green, varying in length but seldom exceeding twenty-five centimetres; mostly sessile; exstipulate, triangular-ovate or ovate-oblong, acute, undulated, irregularly toothed, sinu-ate or pinnatifid, with conspicuous midrib. On both surfaces, but particularly on the under surface and near the veins, long uniserial hairs terminating in plurieellulair glands. In the mesophyll prismatic and cluster-crystals of calcium oxalate.\textemdash Br.

Much of the efficacy of hyoscyamus depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are preferred to those of the first. The latter, according to Houlton, are less clammy and fetid, yield less extractive, and are medicinally much less efficient. It is said that the plant is sometimes destroyed by severe winters in England, and that no leaves of the second year's growth are then obtainable. This is, perhaps, one of the causes of the great uncertainty of the medicine as found in commerce. The root also is said to be much more poisonous in the second year than in the first.
"Assay.—Introduce 30 Gm. of Hyoscyamus, in No. 60 powder, into a 500 mil flask and add 300 mils of a mixture of 1 volume of chloroform and 2 volumes of ether. Stopper the flask, shake it well, and allow it to stand for ten minutes; then add 5 mils of ammonia water and shake the flask vigorously every ten minutes during two hours. Now add 40 mils of distilled water, again shake the flask and when the drug has settled decant 200 mils of the solution, representing 20 Gm. of Hyoscyamus, and proceed as directed under Belladonna Radix, beginning with the word 'Filter' on twelfth line of the Assay. Before titration treat the residue twice with 5 mils of ether and evaporate to dryness each time. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 28.92 milligrammes of the total alkaloids of Hyoscyamus." U. S. IX.

The recent leaves have, when bruised, a strong, disagreeable, narcotic odor, somewhat like that of tobacco. Their taste is mucilaginous and very slightly acrid. When dried, they have little odor or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odor.

Much of the henbane of commerce is taken from the plant in the first year of its growth. The drug of the market is very variable, frequently containing an excess of sand and the leaves of other species of hyoscyamus. A few years ago, it was admixed with H. muticus, a plant growing in Egypt. The latter is readily determined by the presence of characteristic branching non-glandular hairs which are found on both the stems and leaves. (See A. J. P., 1908, p. 361 and Kraemer's "Scientific and Applied Pharmacognosy.")

Hyoscyamus is completely extracted by diluted alcohol. The aqueous infusion is of a pale-yellow color, insipid, with the narcotic odor of the plant. The leaves were analyzed by Lind-bergsen, who obtained from them a narcotic principle. They contain a large proportion of potassium nitrate, F. Mahia having obtained, as nearly as he could estimate from his experiments, 2 per cent. of that salt. (A. J. P., 1859, p. 402.) The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray color, of the odor of the plant, and of an oleaginous, bitterish taste. Geiger and Hesse (1833) were the first to demonstrate the existence of an alkaloid in hyoscyamus. Ladenburg stated in 1880 that there are two alkaloids in the plant,—one crystallizable, hyoscyamine, and the other amorphous,
hyoscine (scopolamine). Hohn (Ann. Ch. Ph., 157, 98) obtained from the seeds a bitter principle which proved to be a glucoside. He calls it hyoscypicrin, and gives it the formula $C_{27}H_{52}O_{14}$.

From experiments made by Hirtz upon the relative medicinal power of extracts from the seeds and from the leaves, he inferred that the former had ten times the strength of the latter. Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

**Uses.**—Hyoscyamus combines the therapeutic actions of its two alkaloids, hyoscyamine and scopolamine. Because of the presence of the former it tends to check secretion and to relax spasm of the involuntary muscles, while through the narcotic effects of its scopolamine it lessens pain and exercises a slight somnifacient action. Its most important use is in relief of painful spasmodic affections of the unstriped muscle, as in lead colic and irritable bladder. It is also employed to allay nervous irritation, as in various forms of hysteria or irritable cough, but is inferior to scopolamine for these purposes. Externally cataplasms or fomentations of the fresh leaves have been employed to allay pain in cancerous ulcers and hemorrhoids, but its employment for this purpose is of doubtful advantage.

Hyoscyamus is preferably given in the form of the fluidextract or tincture. The inspissated juice of the fresh leaves (Extractum hyoscyami viride, Br.) is exceedingly variable in its operation and is not to be recommended.

Dose, of the leaves, two to five grains (0.13-0.32 Gm.).

**Hypericum.** Hypericum perforatum L. St. John's Wort. Millepertuis, Casse-diable, Fr. Johanniskraut, Harthen, G. (Fam. Hypericaceae)—A perennial herb, with a very acid juice, naturalized from Europe and a pernicious weed in this country. It has a peculiar balsamic odor, which is rendered more sensible by rubbing or bruising the plant. Its taste is bitter, resinous, and somewhat astringent. It imparts a yellow color to cold water, and reddens alcohol and the fixed oils. Its chief constituents are volatile oil, a resinous substance, tannin, and coloring matter. This latter, known as
Hypericum red, is a reddish resin, smelling like the flowers, soluble in alcohol, ether, ethereal and hot fatty oils, coloring the solution from wine red to blood red. It is soluble in alkalies with green color, and gives yellow precipitates with the alkaline earths and metallic salts. As a medicine it was in high repute among the ancients and the earlier modern physicians. Among the complaints for which it was used were hysteria, mania, intermittent fever, dysentery, gravel, hemorrhages, pectoral complaints, worms, and jaundice; but it was, perhaps, most highly esteemed as a remedy in wounds and bruises, for which it was employed both internally and externally. It probably has somewhat analogous power to the turpentines. It formerly enjoyed great reputation for the cure of demoniacs, and the superstition still lingers among the vulgar in some countries. At present the plant is scarcely used except as a domestic remedy. The summits were given in the dose of two drachms or more. A preparation, oleum hyperici or red oil, made by macerating four ounces of the tops in a pint of olive oil, is still used in many families for bruises.

**Hyssopus.** Hyssopus officinalis L. Hysope, Fr. Isop, Ysop, G.—This is a European labiate plant, found along roadsides in this country, whose flowering summits and leaves have been used in medicine. They have an agreeable aromatic odor, and a warm, pungent, bitterish taste, due to the presence of a volatile oil. This oil is colorless or greenish-yellow, of peculiar odor, sharp camphor-like taste, and neutral reaction. It has a sp. gr. from 0.88 to 0.98, distils between 142° and 162° 0. (287.6°-323.60 F.), and is soluble in its own bulk of alcohol of 0.85 sp. gr. The acid found in the oil has been identified as l-pinonic acid, and the ketone l-pinocamphene. Hyssop is a warm, gently stimulant aromatic, applicable to the same cases as the other labiate plants.
Iberis. Iberis amara L. Bitter Candytuft.—A small European herbaceous cruciferous plant. The leaves, stem, and root are said to possess medicinal properties, but the seeds are most efficacious. The plant appears to have been employed by the ancients in rheumatism, gout, and other diseases. In large doses it is said to produce giddiness, nausea, and diarrhea, and to be useful in cardiac hypertrophy, asthma, and bronchitis in doses of from one to three grains (0.065—0.2 Gm.) of the seed.

Ibogaine.—This alkaloid was separated by Dybouski and Landrim (Nouv. Rem., 1905) from the roots of the Tabernanthe Iboga, a plant found in the Congo. In overdose it causes hallucination and generally paralysis, with death due to failure of the respiratory muscles. In dose of one-third to one-half grain it is said to act as a stimulant to the nervous system somewhat similar to caffeine.

Ignatia, N. F. IV (U. S. P. 1880). Saint Ignatius Bean. Ignatia Amara. Semen Ignatice, Faba Ignatii, Faba Sancti Ignatii, Lat. Feveigasurique, Feve de Saint Ignace, Fr. Ignatius-bohne, Bittere Fiebermuss, Ignasbohnen, G. Fava di Santo Ignazio, It. Haba de Santo Ignazio, Sp.—"The dried ripe seeds of Strychnos Ignatii Bergius (Fam. Loganiaceae), yielding not less than 2 per cent. of the alkaloids of Ignatia." N. F. IV. Strychnos Ignatia Berg. (Ignatia amara L. f.) is a large climbing shrub, a native of the Philippine Islands, and introduced into Cochin-China where the seeds were highly esteemed as a medicine, and, having attracted the attention of the Jesuits, were honored with the name of their founder. Fluckiger and Arthur Meyer have found that the seed has a close structural analogy to nux vomica. (P. J., 1881, 1.)

It is described by the N. F. as "heavy, hard, angularly ovate with obtuse angles, from 20 to 30 mm. in length and about 15 mm. in breadth and thickness; externally grayish or reddish-black, nearly smooth with few or no hairs; fracture granular and translucent in small fragments; a small irregular cavity in the center. Nearly inodorous and intensely bitter. The powder is grayish-brown and, when examined under the microscope, exhibits thin cells of the epidermis and the subjacent layer of the seed coat, polygonal cells with thickened, pitted walls; hairs characteristic, spreading and thickened at the base and having linear markings; endosperm tissue, the outer cells small, contents granular, the inner large, with thickened walls; lumen irregular in size and shape. Ignatia yields not more than 4 per cent. of ash." N. F.
Assay.—"Introduce 15 Gm. of Ignatia, in No. 40 powder, into a 250 mil flask and add 150 mils of a mixture of chloroform, 1 volume, and ether, 2 volumes. Stopper the flask, shake it well and allow it to stand ten minutes, then add 10 mils of ammonia water, shake the flask vigorously every ten minutes during two hours and allow it to stand for ten hours. Now add 25 mils of distilled water, again shake the flask well, and, when the drug has settled, decant 100 mils of the solution, representing 10 Gm. of Ignatia. Filter the solution through a pledge of purified cotton into a separator, and rinse the graduate and cotton with a little ether. Completely extract the alkaloids from the solution by shaking out repeatedly with weak sulphuric acid. Collect the acid washings in a separator, add ammonia water until the solution is decidedly alkaline to litmus, and completely extract the alkaloids by shaking out repeatedly with chloroform. Evaporate the combined chloroform washings to dryness, dissolve the alkaloids from the residue in exactly 10 mils of tenth-normal sulphuric acid V.S., and titrate the excess of acid with fiftieth-normal potassium hydroxide V.S., using cochineal T.S. or methyl red T.S. as indicator. Each mil of tenth-normal sulphuric acid V.S. consumed corresponds to 36.4 milligrammes of the alkaloids of Ignatia." N. F.

To Pelletier and Caventou Ignatia beans yielded the same constituents as nux vomica, and, among them, 1.2 per cent. of strychnine and 0.5 per cent. of brucine. J. M. Caldwell found strychnine and brucine, combined with iaguaric acid, a volatile principle, extractive, gum, resin, coloring matter, fixed oil, and bassorin, but no starch or albumen. (A. J. P., 1857, 298.) Fluckiger, on the other hand, found 1.78 per cent. of nitrogen, corresponding to about 10 per cent. of albuminoid matter. (Pharmacographia, 443.)

They have been used instead of nux vomica, in the preparation of that alkaloid, when their cost would permit of the substitution, but the nux vomica bean has been imported in such large quantities, and is now so low in price, that the ignatia bean is rarely used. The medicinal uses are those of nux vomica.

For process of making the abstract (Abstractum Ignatiae, U. S., 1880), see U. S. D., 19th ed., p. 1524. The dose of the abstract is from one-half to one and a half grains (0.032-0.096 Gm.). A tincture is recognized by the N. F. (see Part III).

Ilex. Holly. Houx, Fr. StechpalmeChristdorn, G.—Several species of Ilex (Fam. Aquifoliaceae) are employed in different parts of the world. The I. Aquifolium- L., or European Holly, is usually a shrub, but in some places attains the magnitude of a middling-sized tree. It is the most beautiful of all evergreens, but is unsuited to our climate, being too tender to withstand the winters in the Northern States and equally affected by the hot, dry summers in the Southern States. A viscid substance called bird lime is prepared from the inner bark. The leaves, which are of a bitter, somewhat acrid taste, were formerly much esteemed as a diaphoretic, and in the form of infusion were employed in catarrh, pleurisy, smallpox, gout, etc. At one time they enjoyed a brief reputation in France as a cure for intermittents. They were used in powder, in the dose of a drachm two hours before the paroxysm, and this dose was sometimes repeated frequently during the apyrexia. Their febrifuge virtues are said to depend on a bitter principle, ilicin. Labourdais obtained this principle by boiling a filtered
decoction of holly leaves with animal charcoal, allowing the charcoal to subside, washing it, then treating it with alcohol, filtering off the alcoholic solution, and evaporating it to a syrupy consistence. The liquid thus obtained was very bitter, and, on being allowed to evaporate spontaneously, yielded an amorphous substance, having the appearance of gelatin, which was the principle in question. (See A. J. P., xxii, 89.) A yellow coloring substance called ilexanthin, and a peculiar acid called ilicic acid, were obtained by F. Moldenhauer. Ilicic alcohol, $C_{30}H_{50}O$, was separated by Personne from birdlime and found to be identical with a-amyrin. (C. R. S. B., 1908, 862.) Ilexanthin is obtained in the following manner. The leaves are exhausted with alcohol, the alcohol is distilled off, and the residue set aside for several days. A sediment forms, which is separated from the mother liquor, treated with ether to remove the chlorophyll, and then purified by repeated solution in alcohol and crystallization. The composition of ilexanthin is $C_{17}H_{22}O_{11}$. It crystallizes in yellow needles, which change color at 185° C. (366° F.), melt at 198° 0. (388° F.), and at 214° 0. (417° F.) boil with decomposition, and are not sublimable. It is insoluble in ether, but soluble in alcohol. In cold water it is almost insoluble; but hot water dissolves it freely, and deposits it in crystals on cooling. The berries are about the size of a pea, red and bitter, and are said to be purgative, emetic, and diuretic. Ten or twelve of them will usually act on the bowels, and sometimes excite vomiting. Their expressed juice has been used in jaundice.

Ilex opaca Ait., or American holly, is a middling-sized evergreen tree, growing throughout the Atlantic section of the United States, and especially abundant in New Jersey. It is so similar to the European plant that it has been by some writers considered as the same species. The berries, examined by D. P. Pancoast, were found to contain tannin, pectin, two crystallizable organic principles, and salts of potassium, calcium, and magnesium. One of the crystallizable principles was inodorous and tasteless, the ether inodorous but intensely bitter. The latter was obtained by evaporating a tincture to syrupy consistence, alkalizing with potassium carbonate and, extracting with ether. The ether was allowed to evaporate spontaneously when crystals of the bitter principle were deposited. This is probably pure ilicin. (A. J. P., xxviii, 314.) Walter A. Smith (A. J. P., 1887, 1668) obtained a resin soluble in alcohol by the ether extraction, and in the portion of this soluble in water he obtained evidences of a glucoside. This species is said to possess the same medicinal properties as $I.$ aquifolium $L$.

$I.$ paraguariensis A. St. Hill ($I$. Mate $St.$-Hilaire) yields the celebrated Paraguay tea, or Mate, so extensively consumed as a beverage in the interior of South America. It is a small tree or shrub growing wild along the streams in Paraguay, and also cultivated for the sake of its leaves, which are the part used. These are stripped from each plant every two or three years. The period of their collection extends from December to August, sometimes beginning earlier but never continuing later. Companies are formed who penetrate far into the forest at a distance from the settlements, and devote a long time to the collection and preparation of the leaves. These are first dried by exposure to heat, and are then reduced to powder more or less fine, which is kept for several months protected from moisture, and then packed in sacks and delivered to commerce. (A. Demersay, Ann. Ther., 1868, 72; see also Pharm. Rec., May, 1891.)
They have a balsamic odor and bitter taste, and are usually at first disagreeable to the palate. They have a pleasant and corroborant effect upon the stomach, but, when largely taken, cause purging and vomiting. They are used in the form of infusion, which is prepared from the entire leaves as we prepare tea; or, under the name of cha mate, a fine powder is put in a cup of hot water by the drinker, and after a moment's stirring, the fluid is sucked up by means of a tube expanded below, and pierced with fine holes, so as to strain out the powder. They contain, besides other substances, a peculiar tannin and the alkaloid caffeine in variable amount. Some fresh leaves of Ilex Paraguariensis grown in the Cambridge Botanical Gardens were found by A. H. Alien, after drying at 100° C. (212° F.), to contain: insoluble matter, 57.94 per cent.; tannin, by lead acetate method, 15.62; tannin, by cupric acetate method, 15.66; caffeine, 1.13; total ash, 6.14; soluble ash, 3.56. (Com. Org. Anal., 2d ed., iii. Part II, 527.) Some elaborate proximate analyses of mate are also published by Theodore Peckolt. (P. J. , (3), xiv, 121.) The consumption of mate, or yerba, in South America is enormous. Although largely produced in the Argentine Republic, tons are annually shipped to countries in South America. For an interesting account of the method of preparation, and an elaborate analysis, see P. J. , vol. xiv, 1017.

The Ilex vomitoria Ait. is a handsome evergreen shrub, growing in our Southern States, and especially abundant along the southern coast of Florida. Analysis of its leaves by Venable (A. J. P., 1885, 390) gave 7.39 per cent. of tannic acid and 0.27 per cent. of caffeine. Smith (A. J. P., xlv, 217) found 0.011 per cent. of volatile oil and 0.122 per cent. of caffeine. It is the cassena of the North Carolina Indiana, who formerly employed a decoction made from the toasted leaves, called black drink, or Yaupon, both as a medicine and as a drink of etiquette at their councils. It acts as an emetic. The leaves of the Ilex Dahoon L., or Dahoon holly, have similar properties, and are also said to have entered into the composition of the black drink.

**Illicium.** U. S. 1890. Star-Anise—"The fruit of Illicium verum Hooker filius (Fam. Magnoliaccae)." U. S., 1890. Of the genus Illicium, seven species are recognized, of which two are found on the Atlantic coast of Southern North America, two in Hindostan, and three in China and Japan. Many of the species are possessed of aromatic properties.

The tree yielding star-anise is indigenous to Southeastern Asia and extensively cultivated in subtropical countries. The fruit is chiefly used in the manufacture of a volatile oil which resembles the official oil of anise. The fruit consists of usually 8 boat-shaped follicles or carpels arranged around a central axis. The carpels have an acute summit and taper to a nearly straight beak; externally, they are reddish-brown and somewhat wrinkled; the inner surface is smooth and shiny and encloses a single smooth seed. The odor and taste is aromatic, resembling anise, and this serves to distinguish them from the fruits of the Japanese star-anise which are also known as "Shikimmi fruits" or "Skimmi fruits." The latter being obtained from Illicium religiosum Sieb. et Zucc., a tree which is extensively cultivated in the groves of the Buddhist Temples in Japan.

I. floridanum Ell., poison bay, sweet laurel, a small evergreen tree or shrub with
oblong-lanceolate, acuminate leaves, which grows westward from Florida along the coast bounding the Gulf of Mexico, has its bark, leaves, and probably also seed vessels endowed with a spicy odor and taste, analogous to those of anise. Another species, I. parviflorum Vent. (I. anisatum Bartr., not L.), a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavor closely resembling that of sassafras root. A decoction of the seeds is said to produce violent gastro-intestinal irritation, followed by motor and sensory paralysis, with convulsions and death if the dose has been sufficient. E. Barial (Revue Gen. de Clin., Oct., 1889) states that he has obtained a poisonous glucoside from the kernel. H. C. C. Maisch (A. J. P., 1885, 280) obtained from the leaves a crystalline alkaloid to which the bitter taste is due, tannin, and a resin. In the root bark and capsules he found volatile oil and a crystalline principle, melting at 100° C. (212° F.), insoluble in alcohol and ether, but soluble in chloroform, and neutral to test paper.

Star-anise was examined by C. E. Schlegel (A. J. P., 1885, p. 426), who found a saponin in the aqueous extract; in the alcoholic extract, a crystalline principle of a strong musk-like odor, which did not show alkaloid or glucosidal reactions, and oil of star-anise.

I. religiosum Sieb., or shikimi, of India, is very poisonous, causing vomiting and epileptiform convulsions, with dilated pupil and exceedingly cyanosed countenance; in it has been found by J. F. Eykman (P. J., xi, 1046) a crystalline principle, for which the name of shikimine or sikimin has been proposed.

Eykman (P. J., 1885, p. 985) has shown that in the essential oil of the fruit of Illicium religiosum, safrol is found, accompanied by eugenol. On the other hand, the chief constituent of the oil of I. verum is anethol. The constituents of low boiling-point in star-anise oil, consisting of terpenes essentially, have been reported upon by the chemists of Schimmel & Co. (Schim. Rep., April, 1893). They find dextro-pinene, boiling at 157° to 163° C. (314.6°-325.4° F.), and laevo-phellandrene, boiling at from 170° to 175° C. (338°-347° F.). The medicinal properties of the oil of star-anise are similar to those of oil of anise. Sikimin is not used in medicine. Sikimin is violently poisonous, belonging to the group of convulsants of which picrotoxin is the type. Plugge and Schutte associate in this group—Dioscorine, the alkaloid of Dioscorea hirsuta; cicutoxin, from Cicutia virosa L.; coriamyrtin, a glucoside of Coriaria myrtifolia L.; digitaliresin and toxiresin, prepared by Schmiedeberg from digitalin and digitoxin; phytolaccatoxine, the alkaloid of PhytoIacca acinosa; sikimin; oenanthotoxine, the alkaloid obtained from the Oenantherocacata L., by Pohl; isonitroso-anilacetone, an artificial substance prepared by Holleman. (See A. I. P. T., iv, 1897.) See table by Eykman showing constituents of oil of Illicium religiosum compared with those from allied oils in U. S. D., 19th ed., p. 1526.

**Impatiens.** Impatiens biflora Walt. and I. pallida Nutt. Touch-me-not. Jewel-weed. Balsam-weed.—These two species of Impatiens (Fam. Bal-saminaceae), the former of which is better known commonly as Spotted Touch-me-not and the latter as Pale Touch-me-not, are indigenous, annual, succulent plants growing in low, moist grounds, and flowering from July to September. They may be known by their tender, juicy,
almost transparent stems; by their yellow flowers, which in \textit{I. pallida} are pale and sparingly punctate, and in \textit{I. biflora} are deeper colored and crowded with dark spots, and by their capsules, which burst elastically, and curl up with the slightest pressure. They probably possess properties similar to those of \textit{I. nolitangere} \textit{L.}, of Europe and Asia, which has an acrid burning taste, and, when taken internally, acts as an emetic, cathartic, and diuretic, though considered dangerous, and therefore little used. Ruan of Philadelphia, employed with great advantage, in piles, an ointment made by boiling the American plants, in their recent state, in lard. The flowers may be used for dyeing yellow. The fresh juice is reputed to be efficacious in the treatment of rhus poisoning. The \textit{I. Balsamina} \textit{L.}, or \textit{balsam-weed}, \textit{touch-me-not}, etc., of the gardens resembles the other species in its effects.

\textbf{Imperatoria.} \textit{Imperatoria Ostruthium} (L.) Kch. \textit{Masterwort.} \textit{Rhizoma Imperatoriae}, P. G. \textit{Imperatoire} Fr. \textit{Meisterwurz}, \textit{Kaiserwurz}, G.—An umbelliferous plant, indigenous in Southern Europe. The root has a strong odor, similar to that of angelica, and a pungent, aromatic taste, attended by a flow of saliva, and followed by a growing warmth which remains long in the mouth. E. M. Holmes (P. J., March 17, 1877) noticed this root mixed with aconite in the London market, but this probably arose from carelessness, as masterwort is worth twice as much as aconite. A crystallizable, tasteless principle, called imperatorin, was extracted from the root by Wacken-roder, and Gorup-Besanez found in the root another principle, to which he gave the name of ostruthin. Besides these two crystalline compounds, masterwort contains a volatile oil, composed of a hydrocarbon and an oxygenated compound, probably the aldehyde of angelic acid. (Wagner, J. P. C., Ixii, 283.) J assoy (Ap. Ztg., v, 150) has since investigated the substance ostruthin and gives it the formula \(C_{18}H_{20}O_3\). He states that it does not contain a methoxyl group but a phenol-like hydroxyl. By fusion with potassium hydroxide, it yields along with a carbonaceous residue small amounts of resorcinol and acetic and butyric acids. By the action of bromine in chloroform solution it is changed in the presence of acid sodium carbonate into tribromostruthin, \(C_{18}H_{19}Br_3O_3\). (Schmidt, Pharm. Chem., Bd. ii, 3te Auf., 1510.) Herzog subsequently examined the rhizomes and found a substance identical with oxy peucedanin. (A. Pharm., 1908, 414.) The root of masterwort was formerly used in a wide circle of complaints with so much supposed success as to have gained for it the title of \textit{divinum remedium}. It is, however, merely a stimulant aromatic, which in this country is unknown as a remedy. Its leaves are used as a potherb and to flavor cheese.

\textbf{INFUSUA. U.S.}

\textbf{INFUSIONS}

These are aqueous solutions obtained by treating with water (without the aid of ebullition), vegetable products only partially soluble in that
liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance and macerating the mixture in a tightly closed vessel until the liquid cools. The soluble principles are thus extracted more rapidly, and, as a rule, in a larger proportion, than at a lower temperature. Some principles, moreover, are dissolved in this manner which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable, and this may be effected by placing the vessel near the fire. Cold water is preferred when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case, and in warm weather there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the process of percolation may be advantageously resorted to. The water employed should be free from saline impurities which frequently produce precipitates and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to water pumped from wells or obtained from springs, except when the latter are known to produce water which will not react with any of the constituents of the infusion.

The substance to be acted on should be sliced or bruised, or in the state of powder, but this last condition is seldom requisite, unless when percolation is employed, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases it is sufficient to strain it through fine linen or muslin. When percolation is resorted to, the substance should be more or less finely powdered. The United States Pharmacopoeia furnishes a general formula for infusions, which is to be used when the proportions are not specified. In the U. S. P., 1880, the strength of such infusions was fixed at 10 per cent. Experience has shown, however, that this was too strong for general purposes, and in the U. S. Pharmacopoeia of 1890 and the Eighth and Ninth Revision, 5 per cent. has been chosen as the limit.

**GENERAL FORMULA FOR INFUSIONS, U. S. P. IX.**

"Infusions must be freshly made from the drugs, and, when the strength of Infusions is not otherwise directed, they are to be prepared
by the following general formula: The Drug, coarsely comminuted, fifty grammes [or 1 ounce av., 334 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluid-ounces, 61/2 fluidrachms]. Introduce the substance into a suitable vessel provided with a cover, pour upon it one thousand mils [or 33 fluidounces, 61/2 fluidrachms] of boiling water, cover the vessel tightly, and allow it to stand for half an hour. Then strain with expression, and pass enough water through the strainer to make the Infusion measure one thousand mils [or 33 fluidounes, 61/2 fluidrachms]. If the activity of the Infusion is affected by heat, cold water only should be used. -

"Caution.—The strength of Infusions of potent or very active drugs should be specially directed by the physician." U. S.

Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Brande suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a longer time, but they are more liable to chemical alterations, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.

As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in the patient's home, and the propriety of their introduction into the Pharmacopoeia has been doubted, but it is desirable to have certain fixed standards for the regulation of the medical practitioner, and it is always preferable to direct infusions from the apothecary, for whose guidance official formulas are necessary. Physicians would, indeed, find an advantage in more frequently directing them to be prepared by the pharmacist, instead of leaving their preparation to the carelessness or want of skill of attendants upon the sick. Infusions may be kept during hot weather, and for many months, by straining them while hot, and pouring them at once into bottles provided with accurately ground stoppers. The bottle must be brim-full, the stopper being made to displace its bulk of the fluid. A common bottle with a cork stopper may be used, if the softened cork be forced into the full bottle, tied down, and at once dipped into hot sealing wax. The hotter the liquid and the freer from the air the better will the infusion keep. Sterilization of infusions by heating them to the boiling point, then preserving in bottles which have been kept hot to destroy
germs, and stoppered with sterilized cotton, is effective, particularly if
the bottles have a stopcock near the bottom to draw the infusion when
wanted. Almens has proposed a very efficient method of preserving
infusions. (A. J. P., April, 1875.) It is as follows: The infusion or
decoction is heated for some time in a water bath at 100° C. (212° F.),
and the bottle is then fitted with a tight cork, through which a glass
tube passes lightly filled with cotton wool. The cork has a second
opening, through which a glass tube passes nearly to the bottom of the
bottle; this tube is bent at a sharp angle and has fitted to it a piece of
India rubber tubing, to which a pinchcock is attached, by means of
which the contents may be drawn as wanted. By making very
concentrated infusions, as suggested by Donovan, with a mixture of
three parts of water and one part of alcohol, they may be long kept, and
when used can be diluted with water to the proper strength. Thus, if
made four times as strong as the official infusion, they may be diluted
with three measures of water. The proportion of alcohol would thus be
very small, but it might still be medicinally injurious, and infusions
should not be prepared in this way unless with the cognizance of the
prescriber.

Battley, of London, introduced a set of preparations, which he called
inspissated infusions, the advantages of which are that the virtues are
extracted by cold water, are not injured by heat used in the evaporation,
are in a concentrated state, and are not impaired by time. To prepare
them he macerated the material, coarsely powdered, bruised, or finely
sliced, in twice its weight of cold distilled water, pressing the solid matter
into the liquid repeatedly by a rammer or the hand; then allowed the
liquid to drain out, or expressed it in the case of highly absorbent
substances, and repeated the process, with an amount of water equal to
that which had been separated, until the strength was exhausted. Four
or six hours of maceration were usually sufficient. The infusion is then
to be concentrated by evaporation, at a temperature not exceeding 71.1°
C. (160° F.) to the sp. gr. 1.200, and as much alcohol is to be added as
will make its sp. gr. 1.100. These preparations are very analogous to the
fluidextracts already considered. As a rule, it would probably be
preferable to prepare infusions by the process of percolation.

The inspissated infusions must be diluted when administered. The
presence of alcohol, though in small quantity, would sometimes be a
serious objection. (P. J., x, 129.) Concentrated infusions of the strength
of 50 per cent. were introduced into the British Pharmacopoeia (1898);
they are mostly made by percolation, and were termed "Liquors." This certainly led to confusion in nomenclature, and it is difficult to understand why they were not called concentrated infusions, particularly as then- almost universal use is for making ordinary infusions by diluting with water. They were dropped from the British Pharm. 1914.

**INFUSUM ALSTONIAE. Br.**

**INFUSION OF ALSTONIA**

"Alstonia, bruised, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for half an hour; strain while hot." Br.

See Alstonia. Dose, one-half to one fluidounce (15-30 mils).

**INFUSUM AURANTII. Br.**

**INFUSION OF ORANGE PEEL.**

Tisane d'Ecorce d'Orange, Fr.; Pomeranzenschalenaufguss, G.

"Dried Bitter-Orange Peel, cut small, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

A grateful stomachic.

Dose, from one-half to one fluidounce (15-30 mils).

**INFUSUM AURANTII COMPOSITUM. Br.**

**COMPound INFUSION OF ORANGE PEEL**

Tisane d'Ecorce d'Orange composee, Fr.; Pomeranzen und Citronenschalenaufguss, G.

"Dried Bitter-Orange Peel, cut small, 25 grammes; Lemon Peel, cut small, 10 grammes;

Cloves, bruised, 5 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.
A grateful stomachic in the dose of from one-half to one fluidounce (15-30 mils).

**INFUSUM BUCHU. Br.**

**INFUSION OF BUCHU**

Infusum Diosmae, s. Barosmae; Tisane de Buchu, Fr. Cod.; Buchuaufguss, G.

"Buchu Leaves, freshly broken, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

It has the odor, taste, and medicinal virtues of the leaves, and affords a convenient method of administering the medicine.

Dose, from one to two fluidounces (30-60 mils).

**INFUSUM CALUMBAE. Br.**

**INFUSION OF CALUMBA**

"Calumba Root, cut small, 50 grammes; Distilled Water, cold, 1000 millilitres. Infuse in a covered vessel for half an hour; strain." Br.

The infusion of calumba is likely to spoil very quickly, especially in warm weather. Calumba contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change, but the former is much the more permanent of the two. Hence it is, according to Greenish, that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen which has escaped coagulation. According to these views, the best plan of preparing infusion of calumba is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (A. J. P., xviii, 141; from P. J.) Upon comparing specimens
of the cold and hot infusion, we have not found the results of Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless the plan of preparing the infusion above proposed is probably the best. The infusion of calumba is not colored by salts of iron, and may be conveniently administered in connection with them.

Dose, one fluidounce (30 mils), three or four times a day.

**INFUSUM CARYOPHYLLI. Br.**

**INFUSION OF CLOVES**

Tisane de Girofle, Fr.; Gewirrzenlenken-Infusion, Gewllrznelkenaufguss, G.

"Cloves, bruised, 25 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

The infusion of cloves affords precipitates with lime water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (Phillips.)

Dose, one fluidounce (30 mils).

**INFUSUM CASCARILLAE. Br.**

**INFUSION OF CASCARILLA**

Tisane de Cascarille, Fr.; Kaskarillaaufguss, G.

"Cascarilla, in No. 10 powder, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

This infusion affords precipitates with lime water, infusion of galls, silver nitrate, lead acetate and subacetate, zinc sulphate, and ferrous sulphate.

Dose, one fluidounce (30 mils).

**INFUSUM CHIRATAE. Br.**

**INFUSION OF CHIRETTA**
Tisane de Chirette, Fr.; Chirettaufguss, G.

“Chiretta, cut small, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

Dose, from one-half to one fluidounce (15-30 mils).

INFUSUM GENTIANAE COMPOSITUM. Br.

COMPOUND INFUSION OF GENTIAN

Tisane de Gentiane composee, Fr.; Enzianaufguss, G.

"Gentian Root, thinly sliced, 12.5 grammes; Dried Bitter-Orange Peel, cut small, 12.5 grammes; Lemon Peel, cut small, 25.0 grammes; Distilled Water, boiling, 1000.0 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

The National Formulary IV introduced compound infusion of gentian which differs very slightly from that official in the U. S. P. 1870. (See N.F., Part III.)

It has been the custom with some physicians to prescribe a concentrated infusion made with one-fourth the quantity of menstruum directed by the formula of U. S. P. 1870. This permits the use of a valuable tonic with the presence of but a trifling amount of alcohol. This concentrated preparation keeps well, and it may be diluted with the right quantity of the proper menstruum by the pharmacist to make the infusion of U. S. P. 1870. The use of the alcohol is to assist in dissolving the bitter principle, and at the same time to contribute towards the preservation of the infusion, which, without this addition, is very prone to spoil. The alcohol has, however, been abandoned by the British Pharmacopoeia, and lemon peel substituted.

Dose, one fluidounce (30 mils), repeated three or four times a day.

INFUSUM KRAMERIAE. Br.

INFUSION OF KRAMERIA
Infusion of Rhatany; Tisane de Rathanhia, Fr.; Ratanhia-wurzelaufguss, G.

"Krameria Root, bruised, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

The infusion of rhatany is undoubtedly most efficient when prepared from the root in a state of moderately coarse powder by the mode of percolation with cold water, as directed in the U. S. process of 1870.

Dose, of the infusion, from one to two fluid-ounces (30-60 mils).

INFUSUM QUASSIA. Br.

INFUSION OF QUASSIA

Tisane de Quassie, Fr.; Quassiaaufguss, G.; Infusion de cuasia amarga, Sp.

"Quassia Wood, rasped, 10 grammes; Distilled Water, cold, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain." Br.

Boiling water may be employed when it is desirable to obtain the preparation quickly, but cold water affords a clearer infusion. The fifteen minutes maceration directed in the British Pharmacopoeia, considering that cold water is used, appears to us to be too short for the exhaustion of the wood.

Dose, two fluidounces (60 mils), three or four times a day.

INFUSUM RHEI. Br.

INFUSION OF RHUBARB

Tisane de Rhubarba, Fr.; Rhabarberaufguss, G; Infuso di rabarbaro, It.; Infusion de ruibarbo, Sp.

"Rhubarb, in thin slices, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

In order that the rhubarb may be exhausted, it should be digested with
the water near the source of heat, at a temperature somewhat less than that of boiling water. It is customary to add some aromatic, such as cardamom, fennel seed, or nutmeg, which improves the taste of the infusion and renders it more acceptable to the stomach. One drachm of either of these spices may be digested in connection with the rhubarb.

This infusion may be given as a laxative, and is occasionally used as a vehicle for tonic, antacid, or more active cathartic medicines. The stronger acids and most metallic solutions are incompatible with it.

Dose, one to two fluidounces (30-60 mils).

**INFUSUM ROSAE ACIDUM. Br.**

**ACID INFUSION OF ROSES**

**Infusum Rosae Compositum**, N. F.; Compound Infusion of Rose; Acid Infusion of Rose; Tisane de Rose composee, Fr; Saurer Rosenaufguss, G.

“Red-Rose Petals, dried and broken, 25.0 grammes; Diluted Sulphuric Acid, 12.5 mililitres; Distilled Water, boiling, 1000.0 millilitres. Add the Diluted Sulphuric Acid to the Distilled Water; infuse the Red-Rose Petals in the mixture in a covered vessel for fifteen minutes; strain while hot.” Br.

The formula of the U. S. P. 1870 is preferable to that of the Br. Pharm. on account of the presence of sugar. It is unfortunate, in our opinion, that this elegant infusion was not reinstated at the last revision of the U. S. Pharmacopoeia. We append the formula of the U. S. P. 1870: "Take of Red Rose [dried petals] half a troyounce; Diluted Sulphuric Acid three fluiddrachms; Sugar [refined], in coarse powder, a troyounce and a half; Boiling Water two pints and a half. Pour the Water upon the Rose in a covered glass or porcelain vessel; add the Acid, and macerate for half an hour. Lastly, dissolve the Sugar in the liquid, and strain." U. S. The process for this infusion in the N. F. IV is practically the same. (See Part III.)

The red rose serves little other purpose than to impart a fine red color and a slight rose and astringent flavor to the preparation, which owes its medicinal virtues almost exclusively to the sulphuric acid. According to J. B. Barnes, one part of glycerin added to eight or nine parts of
infusion of rose increases greatly its brightness and transparency. It is refrigerant and astringent, and affords a useful and not unpleasant drink in hemorrhages and colligative sweats. It is much used by British practitioners as a vehicle for saline medicines, particularly magnesium sulphate, the taste of which it serves to cover. It is also employed as a gargle, usually in connection with acids, nitre, alum, or tincture of Cayenne pepper. Dose, two fluidounces (60 mils).

**INFUSUM SCOPARII. Br.**

**INFUSION OF BROOM**

Tisane de Genet a balais, Fr.; Besenginsteraufguss, G.

"Broom Tops, dried and bruised, 100 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

This preparation has been introduced in place of the Decoction of Broom of the British Pharmacopoeia of 1885. Water thoroughly extracts the virtues of broom, and the large quantity of water in each dose aids the diuretic action.

Dose, from one to two fluidounces (30-60 mils).

**INFUSUM SENEGA. Br.**

**INFUSION OF SENEGA**

Tisane de Polygale de Virginie, Fr.; Senegaaufguss, G.

" Senega Root, in No. 10 powder, 50 grammes;

Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for half an hour; strain while hot." Br.

Dose, one fluidounce (30 mils).

**INFUSUM SENNAE. Br.**

**INFUSION OF SENNA**
Senna Tea; Tisane de Sene, Fr.; Sennaaufguss, G.

"Senna Leaves, 100 grammes; Ginger, sliced, 5 grammes; Distilled Water, boiling, 1000 millili-litres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

We prefer the coriander of the U. S. P. 1870 to the ginger of the British. The infusion deposits, on exposure to the air, a yellowish precipitate, which is said to aggravate its griping tendency; it should, therefore, not be made in large quantities. It is customary to prescribe with it manna and some one of the saline cathartics, which increase its efficacy and render it less painful in its operation. (See Infusum Sennae Compositum.) The cold infusion, especially if made by percolation from the coarsely powdered leaves, while probably not inferior in strength to that prepared with boiling water, is said to be less unpleasant to the taste.

Dose, two fluidounces (60 mils).

Off. Prep.—Mistura Sennae Composita, Br.

**INFUSUM SENNAE COMPOSITUM. U. S.**

**COMPOUND INFUSION OF SENNA Inf. Senn. Co.**

Tisane de Sene composee, Fr.; Infusum Sennae Compositum, P. G.; Wiener Trank, Sennaaufguss, G.; Infuso di sena con manna, It.

"Senna, sixty grammes [or 2 ounces av., 51 grains]; Manna, one hundred and twenty grammes [or 4 ounces av., 102 grains]; Magnesium Sulphate, one hundred and twenty grammes [or 4 ounces av., 102 grains]; Fennel, bruised, twenty grammes [or 309 grains]; Water, a sufficient quantity, to make one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. Pour eight hundred mils [or 27 fluid-ounces, 24 minims] of boiling water upon the senna, manna, and fennel contained in a suitable vessel, and allow the mixture to macerate for half an hour. Then strain, express and dissolve the magnesium sulphate in the Infusion, and again strain. Lastly, add enough water through the strainer to make the Infusion measure one thousand mils [or 33 fluidounces, 61/2 fluidrachms]. This preparation must not be dispensed
unless it has been recently prepared." U. S. (See Mistura Sennae Composita, Br.)

This preparation is used in Europe and to some extent in this country. The synonym, "Black Draught" has been deleted from the U. S. P. IX because of the similarity in name to "Black Drop" (Acetum Opii), death having resulted through the confusion in names. The taste is bitter and nauseous and the infusion is now rarely employed.

Dose, four fluidounces (120 mils).

**INFUSUM UVAE URSI. Br.**

**INFUSION OF BEARBERRY**

Tisane d'Uva Ursi, Fr.; Barentraubenblatteraufguss, G.

"Bearberry Leaves, bruised, 50 grammes; Distilled Water, boiling, 1000 millilitres. Infuse in a covered vessel for fifteen minutes; strain while hot." Br.

Dose, from one to two fluidounces (30-60 mils), three or four times a day.

**Insect Powder.** Camomille de Perse, Fr. Persische Bertramblumen, G. Pyrethri Flores.—The unexpanded or partly expanded flower-heads of several species of Chrysanthemum (Fam. Compositae). There are two principal commercial varieties: (1) the Dalmatian insect powder which is obtained from Chrysanthemum cinerariifolium (Trev.) Bocc., a perennial herb indigenous to Dalmatia and cultivated in the United States. (2) The Persian insect powder is obtained from the flowers of C. roseum Web. et Nohr and C. Marschallii Aschers, herbs growing in the Caucasus, Armenia and Northern Persia. The flowers are collected from plants that are from two to six years old, carefully dried and preserved. The most powerful insect powder is obtained from the closed or only partly expanded flowers providing they are properly dried and preserved.

Dalmatian Flowers.—The heads are hemispherical, about 12 mm. in diameter, and consist of a conical torus subtended by a straw-colored involucre and bearing upon the receptacle numerous yellow tubular flowers and a circle of cream-colored ray flowers. The latter are pistillate, the corolla being from 1 to 2 cm. in length, having about 15 delicately veined and 3 short, obtuse or rounded teeth.

Persian Flowers.—The heads are flattened top-shaped; the involucral scales are greenish-brown; the ray florets are reddish-brown or reddish-purple, attaining a length
of 15 mm., being somewhat plicate and having 7 veins. The disc florets are tubular and yellow.

For details as to the special anatomical character of these flowers, see P. J., lxvii, 474; also J. P. C., 1902, xv, 409.

C. cinerariaefolium is now being cultivated on a large scale in California, and as more care is given to the preservation during drying of the color and of the volatile oil than in Dalmatia, the California product which is known by the name of buhach is said to be superior to the foreign drug. (C. D., August, 1889; see also for method of cultivation, Reports of the Fourth U. S. Entomological Commission, 1885, and papers by Seidler, Riedel's Berichte, 1913, and Juttner, Ph. Ztg., 1912, 817.)

The insect powder of commerce varies in color from yellow, yellowish-brown, or brownish-yellow to yellowish-green, the finer qualities verging towards brown and the poorer towards green. Brilliant yellow powder should be viewed with suspicion. On microscopical examination of an insect powder, it will be found to consist of fragments of involucral scales composed of sclerenchyma, perhaps bits of stems composed of collenchymatous cells, pollen grains, fragments of the corolla and of its epidermis and papillae. The absence or scarcity of pollen in the powder shows the absence or scarcity of the flowers in the drug, while the proportion of collenchymatous tissue indicates the proportion of stems. As the activity of the insect powder resides in the flower, specimens containing little of the flowers or much of the stems should be rejected. The powder yielded by the Dalmatian plant can usually be distinguished from Persian insect powder by the following characters. The outer surface and edges of the scales of the Dalmatian flowers contain numerous hairs, consisting of a long cell with attenuated ends placed horizontally upon a one- to three-celled stalk. The Persian flowers are almost entirely glabrous, a white hoariness being found only at and near the base of the scales, and very few hairs near the apex; the hairs are of the same structure as the preceding, only the terminal cell being much longer. Sclerenchymatous cells are much more numerous in the Persian than in the Dalmatian. The so-called Hungarian or Russian daisy, probably a species of the subgenus Leucanthemum, was at one time used as an adulterant. The importance of the adulteration is increased by the fact that the Hungarian daisy appears to be entirely free from insecticidal properties. The Hungarian daisy is distinguished from the true Pyrethrum by the orange-yellow disk florets, by the depression of the involucre, by its prominent dark receptacle, and by the absence of pubescence and pappus. The odor is less pungent than that of the true insect flower, being more like that of matricaria. The difference in odor is more pronounced on infusing in warm water. The Hungarian daisy yields a powder somewhat darker in color than true insect powder. Microscopically, the Hungarian or Russian daisy differs only in the absence from the involucre and stems of the peculiar hairs seen on the scales of the true insect powder, and the presence in their place of certain hairs, consisting of from four to ten cells, and terminating with a much elongated, thin-walled, or inflated cell. There seems to be no recognizable difference between the pollen of the two plants which yield insect powder and of the Hungarian daisy. The presence of quassia, fustic, turmeric, and other adulterants may be made out by the aid of the microscope, and chrome yellow chemically, but the powder of Hungarian daisy cannot be detected.
microscopically. According to George R. Durrant, however, the Hungarian powder yields 10 per cent. of ash, whereas true insect powder yields but 6.5 per cent. F. Dietze, after careful study, found that the best method of valuation of insect powder is based on the amount, appearance and odor of the extract obtainable by the use of petroleum spirits boiling under 55° C. (131° P.). With such menstruum true insect powder affords a bright yellow percolate possessing the odor peculiar to the drug. (See P. J., 1905, 902; also 1906, 891; Ph. Ztg., 1905, 871.)

E. H. Gane, 1910, reports that insect powder is adulterated with ground stems and not ground from flowers only, at it should be. One sample from one of the largest pharmaceutical manufacturing houses was composed wholly of ground stems.

Insect powder does not appear to be actively poisonous to man, though it is said to cause some confusion of mind in those who sleep in close apartments where much of it is used. Upon the insects, however, which are apt to infest the person of man and animals, as well as bedding and sleeping apartments, it acts very destructively, first stupefying and then killing them. It is scattered over the person, upon the beds, about apartments, etc., and is even employed as a dressing for ulcers and wounds to prevent the formation of maggots. It also answers for preserving dried insects and plants in cabinet collections. The powder, exhausted by alcohol, is harmless to insects. The activity of insect powder is due to a toxic principle called pyrethron, and an amber-yellow syrupy substance which is the ester of certain unidentified species. The flowers also contain 0.5 per cent. of a volatile oil and from 4 to 7 per cent. of several resins. (Fujitani, Arch. f. exper. Path. u. Pharmak, 1909, 61, 47, and Chem. Zentralblatt, 1909, 80, ii, 1153.) The ash content varies from 5 per cent. to 8.3 per cent. In a series of experiments, Riley has found that the fumes of the burning powder are very poisonous to insects, and for certain purposes afford a ready mode of application, but that generally an aqueous infusion is the best and cheapest preparation. It is also used now in the form of cones made by making a mass with mucilage of gum arabic, with the addition of a small quantity of potassium nitrate. After drying these are ignited like a fumigating pastille. Twenty-five grains stirred up in two quarts of water were sufficient to kill young cotton worms. The infusion soon spoils. The tincture and the alcoholic extract are both efficient preparations. The tincture (one part to four) has been especially recommended, diluted with ten times its bulk of water, by F. Jager, to keep off vermin from the human body. According to Maisch (A. J. P., 1869, 128), it is capable of causing a vesicular eruption like that produced by the poison ivy.

**Insindiyandiya.**—This substance, a remedy of the Kaffir doctors of South Africa, is a violent poison, and has been shown by E. M. Holmes to be derived from a Bersama, apparently identical with B. abyssinica Fresen. (P. J., Ixxiii, 893.)

**Inula.** N. F. IV (U. S. P. 1890). Inula Elecampane. Aunee, Fr. Alantwurzel, Gr. Enula Campana, It., Sp. U. S. 1890.—"The dried rhizome and roots of Inula Helenium Linne (Fam. Compositae), without the presence of more than 5 per cent. of its stem bases or other foreign matter." N. F. IV.
Inula Helenium is a stout, perennial herb naturalized from Europe and growing along roadides and damp pastures from Nova Scotia to North Carolina and westward as far as Missouri. The rhizome and roots are used in medicine. The N. F. description is as follows: "Rhizome usually split into longitudinal or more or less oblique pieces to which may be attached one or more of the roots; up to 8 cm. in length and 4 cm. in diameter; externally grayish-brown to dark brown, longitudinally wrinkled with occasional buds or stem scars and surmounted at the crown by a portion of the overground stem; inner or cut surface somewhat concave, the edges incised with the overlapping bark, yellowish-brown to grayish-brown, longitudinally striate and more or less fibrous near the cambium zone; fracture short and horny; inner surface light brown and marked by numerous circular or elliptical oleoresinous canals; roots cylindrical and tapering, frequently curved or irregularly curled, up to 13 cm. in length and 1.5 cm. in diameter. Odor aromatic; taste acrid, bitter and pungent. Transverse sections under the microscope show a corky layer of from four to seven rows of broad tabular cells; a cortex of numerous parenchyma cells containing inulin in irregular or fan-shaped masses and a number of large, intercellular, oleoresinous reservoirs arranged in nearly radial rows and forming interrupted circles; woody portion consisting chiefly of parenchyma, a number of tracheae with simple pores of reticulate thickenings and associated occasionally with a few, strongly lignified wood fibers, and oleoresinous reservoirs similar to those occurring in the bark; parenchyma cells in the pith of the rhizome large, containing less inulin than the cells of the wood and bark and separated by large intercellular spaces. The powder is light brown; consisting chiefly of fragments of parenchyma containing inulin and small, irregular, separated masses of inulin; tracheae with simple pores and reticulate thickenings associated occasionally with strongly lignified wood fibers; occasional reddish-brown fragments of the walls of the oleoresinous canals. Inula yields not more than 10 per cent. of ash." N. F. A peculiar principle, resembling starch, was discovered in elecampane by Valentine Rose, of Berlin, in 1804, who named it alantin; but the title inulin, proposed by Thompson, has been generally adopted. It differs from starch in being deposited unchanged from its solution in boiling water when the liquor cools, and in giving a yellowish instead of a blue color with iodine. It has been found in the roots of several other plants. It may be obtained white and pure by precipitating a concentrated decoction with twice its volume of alcohol, dissolving the precipitate in a little distilled water, treating the solution with purified animal charcoal, and again precipitating with alcohol. (A. J. P., xxxi, 69.) It readily dissolves in about three parts of boiling water; the levogyre solution is perfectly clear and fluid, not paste-like, but on cooling deposits nearly all the inulin. Its formula, according to Kiliani (Tollens, Handbuch der Kohlenhydrate, 1888, p. 202), is $3C_{12}H_{20}O_{10} + H_2O$. On prolonged heating with water, more rapidly under the influence of dilute acids, it is changed into levulose and reduces Fehling's solution. As in the case of starch, intermediate products can be obtained before it is completely changed into reducing sugar. Dragendorff obtained by heating with water for ten hours metinulin, and by heating for forty to fifty hours levulin, an optically inactive amorphous substance easily changing into levulose. Tanret, who has since investigated inulin (J. P. C., 27, 449), confirms Kiliani's formula as given above. He finds associated with inulin two closely related principles: pseudo-inulin and inulenin. The first of these, to which the formula $(CeHioOs)$ is $HaO$ is given, forms irregular granules, very soluble in water and weak
alcohol while hot, but only slightly soluble in cold water, and insoluble in cold alcohol; the second is given the formula (C\textsubscript{6}H\textsubscript{10}O\textsubscript{5})\textsubscript{10}.2H\textsubscript{2}O, and forms microscopical needles slightly soluble in cold water and weak alcohol. The amount of inulin varies according to the season, but is most abundant in autumn. Dragendorff obtained from the root in October not less than 44 per cent., but in spring only 19 per cent. A crystallizable substance was long since noticed to collect in the head of the receiver when the elecampane root ia submitted to distillation with water. Similar crystals may also be observed after carefully heating a thin slice of the root, and are even found as a natural efflorescence on the surface of a root that has been long kept. They can be extracted from the root by means of alcohol, and precipitated with water. Kallen (Ber. d. Chem Ges., 1873, 1876) has found that these crystals consist chiefly of the anhydride, C\textsubscript{15}H\textsubscript{20}O\textsubscript{2}, of alantic acid, melting at 66° C. (150.8° F.), and that what was formerly known as helenin was a mixture of these with a liquid, alantol, C\textsubscript{10}H\textsubscript{16}O, boiling at 200° C. (392° F.), the true helenin and alant camphor. The crystals of helenin, C\textsubscript{6}H\textsubscript{8}O, have a bitterish taste, but no odor, and melt at 110° C. (230° F.). The camphor melts at 64° C. (147.2° F.), and in taste and odor is suggestive of peppermint.

Korab (L. L., vol. i, 1885, p. 672) states that helenin is a powerful antiseptic and bactericide, one part in ten thousand of urine being sufficient to arrest putrefaction, and a few drops of a solution of this strength immediately killing the ordinary bacterial organisms, including the tuberde bacillus. He lauds it as antiseptic in surgery and has given it with alleged success internally in doses of one-third to one grain (0.021-0.065 Gm.) in tubercular and catarrhal diarrheas. It is also stated by J. B. Obiol (L. L., April, 1886) to be an efficient local remedy in the treatment of diphtheria. Every four hours the false membrane is to be dusted over with powdered camphor, and then painted with a two per cent. solution of helenin in oil of sweet almond. It is affirmed that when the treatment was commenced on the first day of the patches the cure followed in twenty-four hours. Bockenham (Th.M., 1892, p. 145) asserts that helenin inhibits the growth of tuberde bacilli in the dilution of 1 in 10,000 and it has been employed by various writers in the treatment of pulmonary tuberculosis in doses of from one-sixth to five grains (0.01-0.32 Gm.). Helenin was also given internally. Dose, one and a half grains (0.096 Gm.) to children six years of age.

Elecampane is tonic and gently stimulant, and was employed by the ancients in amenorrhea and other diseases of women, also in phthisis, in dropsies, and in skin affections, in all of which diseases it was probably of no service. It has been given in powder, in the dose of twenty grains to one drachm (1.3-3.9 Gm.), or as a decoction (half ounce to the pint) in doses of one to two fluidounces (30-60 mils).

**IPECACUANHA. U. S. (Br.)**

**IPECAC Ipecac. [Ipecacuanha; radix P. I.]**

"The dried- root of Cephaelis Ipecacuanha (Brotero) A. Richard, known in commerce as Rio Ipecac, or of Cephaelis acuminata Karsten, known
in commerce as Cartagena Ipecac (Fam. Rubiaceae), without the presence or admixture of more than 5 per cent. of stems or other foreign matter and yielding not less than 1.75 per cent. of the ether-soluble alkaloids of Ipecac. "U. S. "Ipecacuanha Root is the dried root of Psychotria Ipecacuanha, Stokes." Br.

Ipecacuanhas Radix, Br., Ipecacuanha Root; Poaya, Braz. Ipecacuanha annele' ou officinale, Fr. Cod.; Racine bresilienne, Fr.; Radix Ipecacuanha, P. G.; Ruhrwurzel, Brechwurzel, Ipecacuanha, G.; Ipecacuana, It.; Ipecacuana (Raiz de), Sp.

The term ipecacuanha, derived from the language of the aborigines of Brazil, has been applied to various emetic roots of South American origin. The botanical character of the ipecac plant of commerce was long unknown. At the present time the plant is well known, but there is considerable conflict regarding the proper botanical name to designate it. The several Pharmacopoeias differ from each other in the generic names used, and hence there may be some confusion. The U. S. Pharmacopoeia wisely retains the generic name Cephaelis, this having been recognized for years in this country. The British Pharmacopoeia uses the generic name Psychotria, which practice has been followed in that country for many years. The Swiss and German Pharmacopoeias follow Ehgler and Pranti, and use the generic name Urugoga. The latter is probably correct, but in view of the unstability of this subject, particularly as other generic names have been proposed and may even supersede all of these it is wise to adhere to the old name Cephaelis, thus causing no confusion.

Cephaelis Ipecacuanha is a small shrubby plant, with a slender root from four to six inches long, marked with annular rugae, simple or somewhat branched, descending obliquely into the ground, and here and there sending forth slender fibrils. The stem is two or three feet long, but, being partly under ground, and often procumbent at the base, usually rises less than a foot in height. It is slender; in the lower portion leafless, smooth, brown or ash-colored, and knotted, with radicles frequently proceeding from the nodes; near the summit, pubescent, green, and furnished with leaves seldom exceeding six in number. These are opposite, petiolate, oblong-obovate, acute, entire, from three to four inches long, from one to two broad, obscurely green and somewhat rough on their upper surface, pale, downy, and veined on the under. At the insertion of each pair of leaves are deciduous stipules, embracing the stem, membranous at the base, and separated above into numerous bristle-like divisions. The flowers are small, white,
each accompanied with a green bract, and collected in a semi-globular head, supported upon a round, solitary, axillary footstalk, and embraced by a monophyllous involucre. The latter being deeply divided into four, sometimes five or six, obovate, pointed segments. The fruit is an ovate, obtuse berry, which is at first purple, but becomes almost black when ripe, and contains two small plano-convex seeds.

Cephaelis tomentosa, of Trinidad, has been studied by Francis Ransom, who finds that it contains emetine, but in too small quantity for commercial purposes. For description of the root, etc., see P. J., xix, p. 258.

The Rio ipecac plant of Brazil flourishes in moist, thick, and shady woods, being most abundant within the limits of the eighth and twenty-second degrees of south latitude. It flowers in January and February, and ripens its fruit in May. The root is active in all seasons, but, as it has to be dried rapidly, collection during the rainy season is relaxed. The native collector, or poayero, seizes all the stems of a clump, loosens them by a zigzag motion, and then, thrusting a pointed stick under the roots, tears up the whole mass. The roots, freed from dirt by shaking, are then dried. The amount gathered daily varies from 8 to 30 pounds, according to skill and locality. Extirpation does not take place, because, as shown by the Edinburgh gardeners McNab and Lindsay, a very small fragment of the root, or even a petiole of a leaf, will rapidly produce a new plant. Weddell, indeed, many years since, stated that the remains of the root, often purposely left in the ground, serve the purpose of propagation, each fragment giving rise to a new plant. Ipecac of commerce comes chiefly from the interior province of Matto-Grosso, upon the upper waters of the Paraguay (from which in some years as much as 450,000 kilos are shipped), although some is said to be gathered near Philadelphia north of Rio Janeiro. The chief places of export are Rio Janeiro, Bahia, and Pemambuco. It is brought to the United States in large bags or bales. The importation into the United States have increased from 78,654 pounds in 1914 to 203,734 pounds in 1916.

UNOFFICIAL VARIETIES OF IPECAC.—From time to time there have been imported into Europe various drugs stated to be ipecac, but differing from the official drug. Of these the most important are White Ipecac; the Larger Striated Ipecac of Planchon (J. P. C., Dec., 1872); and the Lesser Striated Ipecac of Planchon.
Larger Striated Ipecac (Planchon). Violet Striated Ipecac. Ipecac of St. Martha. Ipecac of Carthagena. Striated Elastic Ipecac (Attfield).—This variety of ipecac is generally acknowledged to be the product of Psychotria emetica L., growing in the deep forests of Colombia. The drug occurs in rather long fragments, sometimes 9 or 10 cm., with a thickness of from 5 to 9 mm. The pieces are for the most part almost straight, sometimes sinuous, more rarely tortuous. At distant intervals they are marked by contractions, or circular furrows. Their whole surface is largely striated longitudinally. To their upper part are often attached one or more remaining portions of the stem, distinguished from the root by their much smoother surface. Their color is a grayish-brown, tending sometimes to reddish-brown. Like other ipecacs, they have an outer cortical and a central ligneous portion. The former is soft, so that it may even be penetrated by the nail. It has a horny aspect, and a variable color, passing from whitish, by shades of rose, violaceous, and blackish violet. Its thickness is at least two-thirds of the root, and becomes still greater when this is immersed in water. The central part is yellowish-white. The root has little odor, and a taste scarcely nauseous, sometimes flat, and often sweetish. As to the microscopic characters, the most striking are probably the total absence of the starch granules, and the relatively very small diameter of the vessels in the central part. Chemically this variety is characterized by the presence of 'sugar. It also contains 0.027 per cent. of emetine.

Lesser Striated Ipecac (Planchon). Ipecac des Cotes d'Or (Pelletier). Black Ipecac. Black Striated Ipecac. Striated Brittle Ipecac (Attfield). False Ipecac (Holmes).—It is probably obtained from a species of Richardsonia. It occurs in very short fragments, 2 or 3 cm. long, and 2 or 3 mm. in thickness; some nearly cylindrical, others narrowly fusiform; others again formed of roundish or pyriform segments, somewhat thicker than the preceding, placed end to end. The color is generally of a gray-brown, darker than that of the other kind. The longitudinal striae are fine, and regular on the transverse section. The cortical portion is horny, and its consistence firmer than in the larger kind; the wood is yellowish, and porous. The presence of the starch granules is another of the distinguishing characters of this variety. It contains a larger proportion of emetine than the preceding, yielding, according to the analysis of Pelletier, 9 per cent.

White Ipecac is obtained from Ionidium Ipecacuanha St. Hil. (fam.
Violaceae). It is obtained from Brazil. The root is much branched, free from annulations and of a grayish-white or light brownish-yellow color. The bark is very thin and the wood is light-yellow and porous. It is distinguished by the presence of stone cells and freedom from starch. It contains inulin and no emetine.

According to Pelletier, 100 parts contain 5 of an emetic substance, 35 of gum, 1 of nitrogenous matter, and 37 of lignin. (Histoire abrégée des Drogues simples, i, 514.)

The root of a species of Ionidium growing in Quito has attracted some attention as a remedy in elephantiasis, under the South American name of cuichunchulli. The plant received from Bancroft the name of I. Marcucci; but Hooker found the specimen received from Bancroft to be the I. parviflorum of Ventenat.

Lindley thinks a specimen he received under the same name from Quito to be the I. microphyllum of Humboldt. If useful in elephantiasis, it is so probably by its emeto-purgative action. (See A. J. P., vii, 186.)

Under the same name of East Indian Ipecac there has appeared in the London markets a root of a pale pinkish-brown color, tapering rapidly from the base to the apex, and having annulations much closer than in the true ipecac. It is especially distinguished from the latter root by being evidently monocotyledonous—that is, without the central woody column—the vascular bundles appearing under a pocket lens as a more or less irregular ring of brownish dots. R. A. Cripp obtained from it a minute quantity of an alka-loidal substance, certainly distinct from the alkaloids of ipecac. (P. J., iv.) Ranwez and Campion have also described a false ipecac derived from a monocotyledonous plant, Cryptocoryne spiralis. (Ann. Pharm., i.)

In 1866 the cultivation of ipecac was introduced into India by King, but it was not until twenty years later (1886), when it was found that ipecac flourished in the Straits Settlements equally as well as in the Province of Minas, Brazil, that its cultivation became successful.

Cephaelis acuminata Karsten is the source of the drug of commerce known as Cartagena, Panama, or Savanilla Ipecac. The plant is indigenous to Colombia. The leaves according to Karsten are elliptical, pointed, the stipules being separated, often almost to their base in a
subulate fringe. The root is much larger and the percentage of active constituents is different from that of Rio ipecac. Humboldt considered C. acuminata merely as a different geographical form of C. Ipecacuanha. Owing to the scarcity of Rio ipecac the importations of the Cartagena variety is considerable, at times being the only form obtainable. It was for this reason that it was included in the U. S. Pharmacopoeia. Braun discussed the subject of the cultivation of ipecac (Der Pflanzer, Tanga, i, p. 50) and commented on the available varieties to be selected and the best methods for collecting and treating the drug. Derry states (C. D., lxxx, p. 822) that when established it grows well on virgin soils or where there is a depth of vegetable humus and the situation is moist and shady, but the properties, of the root deteriorate with continued cultivation.

**Properties.**—Rio ipecac is in pieces 2.4 to 4 mm. thick, variously bent and contorted, simple or branched, consisting of an interior slender, light straw-colored, ligneous cord, with a thick, brittle, brownish, finely wrinkled, cortical covering, which presents on its surface a succession of circular, unequal, prominent rings or rugae, separated by very narrow fissures, frequently extending nearly down to the central fiber. This appearance of the surface has given rise to the term annule, or annulated, by which the true ipecac is designated by French pharmacists. The cortex is hard, horny, and semi-transparent, breaks with a resinous fracture, and easily separates from the tougher ligneous fiber, which possesses the medicinal virtues of the root in a much inferior degree. On microscopic examination the very thick bark is seen to be formed of uniform parenchymatous cells, without traces of the medullary rays, which are very distinct in the woody central cylinder. Attached to the root is frequently a smoother and more slender portion, which is the base of the stem, and should be separated before pulverization. Pereira has met, in the English market, with distinct bales composed of these fragments of stems, with occasionally portions of the root attached. Much stress has been laid upon the color of the external surface of the ipecac root, and diversity in this respect has even led to the formation of distinct varieties. Thus, the epidermis is sometimes deep brown or even blackish, sometimes reddish-brown or reddish-gray, and sometimes light gray or ash-colored; hence the varieties of ipepac root which were formerly recognized, the brown, red and gray. It is now known that the color of the root varies according to the circumstances of growth and soil, so that coloration as the basis of classification has been abandoned, and the ipecacs of commerce are
divided according to their geographical sources, into the Brazilian or
Rio Ipecac, the Cartagena or Colombia Ipecac, and the Johore or Indian
Ipecac; of these, the two varieties which are recognized by the U. S.
Pharmacopoeia are described as follows: "Rio Ipecac.—In cylindrical
pieces, curved, and sharply flexuous, occasionally branched, from 3 to
15 cm. in length and from 2.4 to 4 mm. in thickness; externally dark
brown, closely annulated, with thickened, incomplete rings, and usually
exhibiting transverse fissures with vertical sides; fracture of bark short,
of wood tough, bark very thick, light brown, easily separable from the
yellowish-white wood; odor very slight, distinctive, the dust
sternutatory; taste bitter and nauseous, somewhat acrid. Stems
cylindrical, attaining a length of 10 cm. and a thickness of 2 mm., dark
brown, finely longitudinally wrinkled and with a few elliptical scars.
Cartagena Ipecac.—Cylindrical or slenderly fusiform, more or less
tortuous, from 3 to 12 cm. in length and from 4 to 6.5 'mm. in thickness;
externally grayish-brown, the annulations usually not so numerous as
in Rio Ipecac, occasionally transversely fissured and with circular scars
of roots; bark 2 mm. in thickness, dark brown, smooth, somewhat horny,
and easily separable from the light brown wood. Stems attaining a
length of 10 cm. and a thickness of from 2 to 3 mm., cylindrical,
somewhat zigzag, due to the prominent nodes with their elliptical stem-
scars, grayish or dark brown and longitudinally wrinkled; bark thin.
The powder from both varieties of Ipecac is light brown; starch grains
numerous, single or from 2- to 4- or more compound, the individual
grains spherical or polygonal, from 0.003 to 0.017 mm. in diameter;
calcium oxalate in raphides, from 0.015 to 0.04 mm. in length, few;
tracheids with bordered pores and oblique slit-like pores. The stem bark
shows a few, slightly elongated stone cells, from 0.03 to 0.045 mm. in
length with thick lignified walls and simple branching pores. Ipecac
yields not less than 1.8 per cent. nor more than 4.5 per cent. of ash." U.
S.

"In somewhat tortuous pieces seldom more than fifteen centimeters long
or six millimetres thick; from dark brick-red to very dark brown; closely
annulated externally, the annulations not taking the form of narrow
ridges partially encircling the root (distinction from Cartagena
ipecaucuanha). Fracture short, the fractured surface exhibiting a thick
greyish bark and small dense wood. Bark consisting of thin' walled
parenchymatous cells, some containing slender raphides, but most filled
with simple or compound starch grains, the simple seldom exceeding
fifteen microns in length; wood consisting chiefly of tracheids and
containing no vessels or typical medullary rays. In the powdered Root, thin-walled parenchymatous tissue, abundant simple or compound starch grains, the single grains seldom exceeding 15 microns in diameter, acicular calcium oxalate crystals, fragments of brown cork, lignified tracheids and wood-parenchyma; but not more than a very occasional vessel or strongly thickened sclerenchymatous cell. Slight odor; taste bitter. Ash not more than 5 per cent. Yields not less than 2 per cent. of alkaloids when tested by the following process."

(Six pages of painful Ipecac pharmaceutical minutae deleted)

Uses.—Ipecac was employed as an emetic by the natives of Brazil when that country was first settled by the Portuguese, but, though described in the work of Piso, it was not known in Europe until 1672, and did not come into use until some years afterwards. John Helvetius, grandfather of the famous author of that name, having been associated with a merchant who had imported a large quantity of ipecac into Paris, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general attention was drawn to it, and the fortunate physician received from Louis XIV a large sum of money and public honors on the condition that he should make it public.

Ipecac is in large doses emetic, in smaller doses, diaphoretic and expectorant, and in still smaller, stimulant to the stomach, exciting appetite and facilitating digestion. In quantities not quite sufficient to cause vomiting, it produces nausea, and frequently acts on the bowels. As an emetic it is mild, but tolerably certain, and free from corrosive or narcotic properties. The emetic effect seems to be due partly to the local irritant effect of the drug upon the mucous membrane of the stomach, although the experiments of Hatcher show that there is some direct stimulant action upon the vomiting center in the medulla. Of the two alkaloids to which the drug owes its activity it would seem from the experiments of Wild (L. L., 1895, ii, p. 1274) that cephaeline is much more active as an emetic than emetine, although the latter is capable, in sufficient dose, of causing vomiting. Because of the promptness with which the emesis occurs it is scarcely possible for enough of the active principles to be absorbed from the stomach to produce direct systemic effects. When injected subcutaneously or intravenously in large dose, however, the alkaloids act as depressants to the motor side of the spinal cord and probably also to the respiratory center. It would seem that they have some special predilection for the lungs for after toxic doses
alternating areas of pallor and intense hyperemia have been found in the pulmonary tissue.

Originally introduced into Europe as a remedy for dysentery, ipecac for centuries was alternately lauded as a specific and condemned as useless in this disease. In 1911 Vedder (Bull. Manila Med. Soc., March, 1911; also J. A. M. A.; 1914, lxii, p. 501) showed that an infusion of ipecac representing one part of the drug in ten thousand destroyed the viability of the Entamoeba; and that the alkaloid emetine in a one to one-hundred thousand solution had the same effect. He also showed that the drug was possessed of no bactericidal virtues. Since this research reasons for the diversions of opinion as to the usefulness of ipecac are apparent. There are two types of dysentery, one due to a specific amoeba and the other caused by a bacillus. In the latter form of the disease the drug is useless but is probably the most efficacious remedy we possess in the amoebic type of dysentery. The great difficulty in its employment has always been to obviate the emetic effect which sometimes made it almost impossible to get enough of the drug into the intestinal tract to have an effect. In 1912 Rodgers (B. M. J., 1912, i, p. 1424, and ii, p. 405) introduced the hypodermic administration of the alkaloid emetine which has since then become the standard treatment of amoebic dysentery. For this purpose from one to three grains of the emetine hydrochloride (0.065-0.2 Gm.) should be injected daily; preferably divided into two or three doses. The treatment is also of value in the various sequelae of dysentery, such as abscess of the liver, although it does not always produce complete cures. In 1914 Smith and Barrett (J. A. M. A., 1914. lxiii, p. 1746) brought forward evidence that pyorrhea alveolaris, or Rigg’s disease, is due to a specific amoeba, and suggested the use of emetine in its treatment. Their discovery has been confirmed by Bass and Johns (J. A. M. A., 1915. lxiv, p. 553) and others. Smith and Barrett recommended the direct application of a 1 per cent. solution directly to the pus pockets but Bass and Johns prefer the hypodermic administration.

As an emetic ipecac is rarely used merely for the purpose of evacuating the stomach, but when an action upon the portal circulation is desirable, as in the so-called biliousness or acute alcoholism, it is often of service. Many clinicians believe that it has a direct influence upon hepatic secretion, but it is more probable that its effects upon the liver are due simply to its emetic action. By virtue of their nauseating effect small doses of ipecac tend to increase various secretions of the body, thus it is
widely used as a diaphoretic, especially in combination with opium (see Pulvis Ipecacuanhae et Opii) in the early stages of acute coryza and other mild infections. In the same way it acts as an expectorant, and in the early stages of acute bronchitis it is one of the most valuable remedies we possess. Many years ago Trousseau affirmed that ipecac possessed valuable hemostatic powers, especially useful in hemoptysis, but this use of it failed to receive general recognition. The treatment has been revived by Flandin (Press. Med., 1913) and other French clinicians.

As an emetic ipecac may be given in substance in the dose of twenty to thirty grains (1.3-2.0 Gm.), repeated in fifteen to twenty minutes if necessary. As an expectorant the syrup is generally preferred. If ipecac itself is used in dysentery it should be given in doses of five grains every hour combined with opium to prevent vomiting. To obviate the nauseating effect of emetine when given by the mouth, Bass and Johns have used a combination with Lloyd's reagent.

Under the name of riopan, a preparation asserted to contain 50 per cent. of combined cephal-aleine and emetine has been introduced. This is marketed in the form of tablets each containing one-thirtieth of a grain (0.002 Gm.), which is stated to be equivalent to about a grain and a half of ipecac (0.096 Gm.).

Dose, emetic, twenty to thirty grains (1.3-2.0 Gm.); nauseating, two grains (0.13 Gm.); diaphoretic, one grain (0.065 Gm.); stomachic, one-fourth to one-half grain (0.016-0.032 Gm.).

IPOMOEAE RADIX. Br.

ORIZABA J ALAP ROOT [Mexican Scammony Root]

"Orizaba J alap Root is the dried root of Ipomoea orizabensis, Ledanois." Br.

Orizaba Root, Male Jalap, Light, Woody, or Fusiform Jalap; Jalap stalks; Purgo Macho (Mexican).

The genus Ipomoea (Fam. Convolvulaceae) comprises about 300 species of herbs and shrubs, some being erect, others prostrate, but very many climbing. They are remarkable for their showy flowers, as in I. purpurea, the common morning glory of the garden. Many of the species produce large tuberous roots which contain a drastic purgative resin. Orizaba, (also known as light or fusiform) Jalap Root has been recently introduced into the British Pharmacopoeia as a source of scammony resin. The plant yielding it (Ipomoea orizabensis) is indigenous to Mexico and produces a large, fusiform, more or less branching root attaining a length of 5 dm., yellow on its outer surface, milky-white within. The stem is cylindrical, slightly villous and climbing. The leaves are large, petiolate, cordate, acuminate and villous on the veins. The corolla is campanulate and reddish-purple. The capsule is 2-locular and one seeded.

The drug occurs in transverse slices of the root, or in pieces of irregular shape made by vertical section of these slices. The horizontal cut surface is dark from exposure, unequal from the greater shrinking in desiccation of some parts than others, and presents the extremities of numerous fibers, which are often concentrically arranged. Internally the color is grayish, and the texture, though much less compact than that of jalap, is sometimes almost ligneous.

It is officially described as follows: "In irregular, tough, or fibrous pieces of varying size and shape, but often in portions, three to five centimetres wide and two to four centimetres thick, of transverse slices of large roots. Externally greyish-black and wrinkled, internally greyish or brownish. From the transverse surface coarse fibres protrude in irregular concentric circles. Slight odor; taste faintly acrid. Yields to alcohol (90 per cent.) a resin which has the properties enumerated under 'Scammonias Resina.' " Br.
See also under Jalap for further facts concerning these substances.

Ipomoea root has purgative properties similar to those of true jalap, but is less powerful. It is stated (J. P. C., xxiv, 166) that thirty to sixty grains (2.3-3.9 Gm.) are required to act effectively. It is, however, rarely employed and is official only as a source of scammony resin.

**Iron-Wood.** Ostrya virginiana (Mill.) Willd. (O. virginica Willd. Carpinus virginiana Mill.) (Fam. Betulaceae.) —The wood of the hop-hornbean is said to be tonic, antiperiodic, and alterative, and the fluidextract has been used in doses of from a half to one fluidrachm (1.8-3.75 mils) in ague.

**Isatis.** Isatis tinctoria L. Woad. Pastel. (Fam. Cruciferae.)—A biennial plant, indigenous to and cultivated in southern and central Europe to central Asia. The leaves have a fugitive, pungent odor, and an acrid, very persistent taste; they have been used in scorbutic affections, jaundice, and other complaints, but are of no value. They were formerly of importance as a source of indigo. The leaves are prepared by grinding them to a paste, which is made into balls, placed in heaps, and allowed to ferment. When the fermentation is at an end, the mass falls into a coarse powder, which is woad.

**Isopyrum.** Isopyrum thalictroides L. (Fam. Ranunculaceae.)—F. A. Harsten believes he has found two alkaloids, isopyrine and pseudoisopyrine, in the root of this plant, which grows in the forests of middle and southern Europe. (A. J. P., xliv, 453.)

**ISPAGHULA. Br.**

**ISPAGHULA**

"Ispaghula consists of the dried seeds of Plantago ovata, Forsk."

Ispaghue, Spogel Seeds.

Plantago ovata (P. Ispaghula Roxb.) is a herbaceous plant (Fam. Plantaginaceae) growing in India and Persia and extending westward to Spain and the Canary Islands. It is either erect or decumbent and varies in height from 2.5 cm. to 1 dm. The leaves are ovate and either glabrous or shaggy hairy. The flower spikes are either cylindrical or reduced to a globular head. The seeds closely resemble those of other species of Plantago.

They are described as follows: "Seeds boat-shaped, somewhat acute at
one end, from two to three millimetres long and from one to one and a half millimetres wide; pale greyish-brown, with a darker elongated spot on the convex side; on the concave side the hilum covered with the remains of a thin white membrane. In water the testa swells, producing a viscous mucilage. No odor or taste." Br.

The seeds of the Plantago amplexicaulis Cav. are also sold in the Indian bazaars as Ispaghula. They resemble the official seeds, but are of a darker color.

They yield to water a viscid mucilage. They are used in India as a demulcent in dysentery and various intestinal irritations, and are also slightly laxative. On roasting they are said to become astringent, and as such are used for diarrheas, especially of children. By European practitioners they have been chiefly employed in chronic diarrhea. In India they are also used for their demulcent effect in catarrhal conditions, especially of the genito-urinary tract.

Dose from one to two and a half drachms (3.9-9.8 Gm.).

**Off. Prep.**—Decoctum Ispaghulae, Br.

**Ivarancusa.**—The roots of Andropogon Ivarancusa Boiss., now considered to be in large part A. Schoenanthus L. (Fam. Gramineae), a native of Central India. It contains a volatile oil, resin, and a bitter substance, and is stated to be coming into wide vogue on the continent as a diaphoretic drug. It is also used in perfumery.
J acaranda.—Several species of this genus (Fam. Bignoniaceae) are employed in syphilis in Brazil and other portions of South America under the names of caroba, carobinha, etc. Peckolt (A. J. P., 1882, 134) has found in them a crystalline substance, carobin, besides resins and acids, such as carobic and steocarobic acids, and carobon, caroborelinic acid, and caroba balsam. Hesse (Ann. Chem., cclii, 150) found only an aromatic resin, but no alkaloid. The value of the remedy has been asserted in the B. M. J., vol. i, 1885. For further information, consult P. J., 3d series, vols. v, xii, and xiv, and also A. J. P., 1882.

J ALAPA. U. S., Br.

J ALAP J alap.

"The dried tuberous root of Exogonium Purga (Wenderoth) Bentham (Fam. Convolvulaceae), yielding not less than 7 per cent. of the total resins of J alap." U. S. "J alap consists of the dried tubercules of Ipomaea Purga, Hayne." Br.

The precise botanical origin of jalap remained long unknown. It was at first ascribed by Linnaeus to a Mirabilis, and afterwards to a new species of Convolvulus, to which he gave the name of C. J alapa. The correctness of the latter reference was generally admitted, and, as the Ipomoea macrorrhiza of Michaux, growing in Florida and Georgia, was believed to be identical with the C. J alapa of Linnaeus, it was thought that this valuable drug, which had been obtained exclusively from Mexico, might be collected within the limits of the United States; but the error of this opinion was soon demonstrated. John R. Coxe, of Philadelphia, received living roots of jalap from Mexico in 1827, and
succeeded in producing a perfect flowering plant, of which a description was published by Nuttall (Am. J. M. S., Jan., 1830). The same plant has since been cultivated in various parts of Europe, and has been introduced into the Nilgerry Hills of India, where it grows vigorously. J. H. Balfour (Curtis's Bot. Mag., Feb., 1847) maintains that the plant belongs to the genus Exogonium of Choisy, as defined in De Candolle's Prodromus, being distinguished from Ipomoea by its exserted stamens. Bentham and Hooker, however, do not acknowledge the validity of the various genera into which Ipomoea has been broken up by Choisy (Genera Plantarum, ii). Engler and Pranti have restored the genus Exogonium [E. Purga (Wender.) Benth.] for the plant yielding the root called jalap.

The root of Exogonium Purga (Ipomoea Purga Hayne) is a roundish, somewhat pear-shaped tuber, externally blackish, internally white, with long fibers proceeding from its lower part, as well as from the upper root-stalks. A tuber, produced by Coxe, was, in its third year, between two and three inches in diameter. The stem is round, smooth, much disposed to twist, and rises to a considerable height upon neighboring objects, about which it twines. The leaves are petiolate, heart-shaped, entire, smooth, pointed, deeply sinuated at the base and prominently veined on their under surface. The lower leaves are nearly hastate or with diverging angular points. The flowers, which are large and of a lilac-purple color, stand upon peduncles about as long as the petioles. Each peduncle supports two or, more rarely, three flowers. The calyx is without bracts, five-leaved, obtuse, with two of the divisions external. The corolla is funnel-form. The stamens are five in number, with oblong, white, somewhat exserted anthers. The stigma is simple and capitate.

The jalap plant is a native of Mexico, where it is dug during the whole year, and usually dried over the hearths of the Indian huts. It derives its name from the city of Jalapa, in the state of Vera Cruz, in the neighborhood of which it grows, at the height of about 6000 feet above the ocean. The drug is brought from the port of Vera Cruz in bags containing usually between 100 and 200 pounds. The amount of jalap annually invoiced through the Vera Cruz consulate to the United States is about 200,000 pounds. The jalap plant is now successfully cultivated in the government cinchona plantations in India. Analyses of the Indian tubers show that when grown on fresh soil they contain from 16 to 17 per cent. of resin, and that by manuring the percentage is notably
increased, even to 22 per cent. It has also been cultivated in Jamaica, South America and Ceylon. The jalap grows freely in the south of England, but the season is too short for the production of seed by it, although the root has yielded 11.97 per cent. of resin. (P. J., Feb., 1869.) For an account of the cultivation of jalap in Madras, see Am. Drug., 1896,127.

Properties.—Jalap is officially described as follows: " Fusiform, irregularly ovoid or pyri-form, upper end more or less rounded, lower end slightly tapering, the large roots often incised or cut into pieces; from 4 to 15 cm. in length and from 12 to 60 mm. in diameter; externally dark brown, longitudinally wrinkled or furrowed and with numerous lenticels; hard, compact, not fibrous; when broken, internally dark brown, mealy or waxy, bark from 1 to 2 mm. in thickness outer bundles separated from the outer cortical layer by a distinct, brown cambium zone; odor slight but distinctive, smoky; taste somewhat sweet and acrid. The powder is light brown; starch grains numerous, single or 2- to 3-compound, and more or less swollen, ellipsoidal or ovoid with concentric or excentral lamellae and radiating clefts or fissures, from 0.003 to 0.035 mm. in diameter; calcium oxalate in rosette aggregates from 0.01 to 0.035 mm. in diameter; tracheae short, wide, with simple or bordered pores; lactiferous vessels with' yellowish-brown, resinous masses. Jalap yields not more than 6.5 per cent. of ash." U. S.

"Tubercules dark brown, irregularly oblong, napiform or fusiform, three to eight centimetres or more long, the larger being often incised. Hard, compact and heavy; externally wrinkled, and marked with small transverse scars; internally yellowish-grey to dingy brown. In transverse section irregular, dark, concentric lines; examined microscopically numerous compound starch grains, many of which are gelatinised, cluster-crystals of calcium oxalate, and cells containing a resinous emulsion stained yellow by N/10 solution of iodine; in the wood, pitted vessels and traheids. Characteristic odor; taste at first sweet but afterwards acrid and disagreeable. Ash not more than 6.5 per cent. Yields not less than 9 or more than 11 per cent. of resin having the properties of Jalap Resin, when treated by the process described under (Jalapas Resina.) " Br.

Jalap is usually kept by pharmacists in the state of powder, which is of a yellowish-gray color, and when inhaled irritates the nostrils and throat, and provokes sneezing and coughing'. Jalap yields its active
properties partly to water, and completely to diluted alcohol.

"Assay.—Pack 10 Gm. of Jalap, in No. 60 powder, in a cylindrical percolator and extract it with alcohol until the percolate measures 100 mils. Transfer 20 mils of the percolate to a separator, add 20 mils of chloroform, mix the liquids, then add 20 mils of distilled water and shake the mixture thoroughly. When the liquids have completely separated, draw off the chloroform into a tared beaker, wash the contents of the separator by rotating with 5 mils of chloroform and draw it off into the beaker. Evaporate the chloroform solution on a water bath, add about 2 mils of alcohol, again evaporate, and then dry the residue to constant weight at 100° C. (212° F.). The weight will be the amount of total resins from 2 Gm. of Jalap." U.S.

---

Buchner and Herberger supposed that they had discovered a basic substance, which they called jalapin. G. A. Kayser found that the resin of jalap previously discovered by Cadet de Gassicourt consists of two portions, one of which, amounting to seven parts out of ten, is hard and insoluble in ether, the other is soft and soluble in that menstruum. The hard resin he named rhodeoretin, and found to be identical with the jalapin of Buchner and Herberger. By reaction with the alkalies it is converted into an acid, called rhodeoretinic acid. Rhodeoretin is slightly soluble in water, freely so in alcohol, and insoluble in ether, chloroform, or benzene. and the alcoholic solution is precipitated both by ether and water. It is dissolved by solutions of the alkalies, more quickly if heated.

---

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - J-K - Page 4
The Southwest School of Botanical Medicine http://www.swsbm.com
and is not precipitated by acids, having become soluble by conversion into the acid above referred to. It purges violently in the dose of three or four grains, and is supposed to be the active principle of jalap. Mayer confirmed and extended the observations of Kayser. He gave the name of convolvulin to Kayser's rhodeoretin, and stated its formula as $C_{31}H_{50}O_{16}$. This substance is colorless when pure, dissolving easily in ammonia water, and is not reprecipitated by acids, because of its conversion into convolvulinic acid, which is a hydroxide of the glucoside convolvulin. This, on being treated with nitric acid, yields sebacic acid. Convolvulin possesses in a high degree the purgative properties of jalap. A. Kromer (Ph. Z. R., 1894, Nos. 1-7) also made a study of convolvulin. He finds it to be laevo-gyrate, and gives it the formula $C_{61}H_{105}O_{27}$, which was later changed (Die Glykoside, Van Rijn, 1900, p. 391) and is now given by Hoehnel as $C_{54}H_{96}O_{27}$, which is deduced from its analysis and decomposition products; alkalies decompose it into one molecule of volatile methyl ethyl acetic acid, $C_{5}H_{10}O_{2}$, one molecule of purgic acid, $C_{25}H_{46}O_{12}$, and one molecule of convolvulinic acid, $C_{45}H_{80}O_{28}$. (See also A. Pharm., 1901, 373.) This latter is amorphous, yielding a white hygroscopic powder soluble in water and alcohol, insoluble in ether; strong sulphuric acid colors it red or brown-red; by the action of acids one molecule of convolvulinic acid yields five molecules of a glucose and one molecule of convolvulinolic acid, $C_{15}H_{30}O_{3}$, which is insoluble in water, melts at 51.5° C. (124.7° F.), is not colored by sulphuric acid, and is isomeric with jalapinolic acid and scammonolic acid, both of which melt at from 63° to 64° C. (145.4°-147.2° F.). Mayer obtained from Ipomoea orizabensis a resin which he called jalapin, which was afterwards shown by Keller to be identical with the resin of scammony. Mayer's jalapin differs from convolvulin in being soluble in ether. The formula of jalapin, according to Samuelson, is $C_{34}H_{56}O_{16}$. Poleck (A. J. P., 1892, p. 465) continued the investigation of the jalapin from I. orizabensis, and confirmed the identity of it with scammonin, giving it the formula $C_{34}H_{56}O_{16}$. He suggested that the name of jalapin, which is misleading, should be replaced by orizabin. A. F. Stevenson (N. R., 1879, 359) has studied the two resins found in jalap, and furnishes a tabular statement of the differences between the soft resin jalapin and the hard resin convolvulin, which is given in the following table. For the method of obtaining the resin of jalap pure, see Resina Jalapae.

Power and Rogerson report a chemical examination of Ipomoea
purpurea Roth, known as the common morning glory. They conclude that this plant, like many other species of the same genus, contains resins which possess purgative properties, and is thus capable of being used medicinally. (A. J. P., 1908, p. 255.)

Jalap is apt to be attacked by worms, which, however, are said to devour the amylaceous or softer parts, and to leave the resin, so that the worm eaten drug is more powerfully purgative than that which is sound. Thus, out of 397 parts of the former, Henry obtained 72 parts of resin, while from an equal quantity of the latter he procured only 48 parts. Hence, worm eaten jalap should be employed for obtaining the resin, but should not be pulverized, as it would afford a powder of more than the proper strength. The drug is also liable to various adulterations, or fraudulent substitutions, which, however, can usually be detected without difficulty by means of the microscope.

According to Herlant, even in powder it is easy to detect the presence of the root of Mirabilis Jalapa, which is sometimes used as an adulterant to jalap, by the presence of raphides of calcium oxalate.

Tampico Jalap (Purga de Sierra Gorda, Mexican).—This drug closely resembles in appearance, odor, and taste the true jalap, but the tubers are somewhat smaller, more elongated and shrivelled. According to Ambrose Andouard, it is the jalap digité majeur of Guibourt. Through the efforts of Daniel Hanbury, of London, aided by two Prussian officials in Mexico, Hugo Finck, vice-consul at Cordova, and E. Bonecke, consul-general at Mexico, the origin of the drug was traced to the state of Guanajuito, where it grows along the Sierra Gorda, near San Luis de la Paz. In this place it is purchased from the Indians, and conveyed by mules to Tampico, where it enters into commerce. Through the agency of the same gentlemen, Hanbury, after some failures, succeeded in obtaining a living tuber, from which he raised a flourishing plant that proved to be an undescribed species of the genus Ipomoea, differing from I. Purga by its bell-shaped corolla and pendulous flower-buds. To it Hanbury gave the name I. simulans. (A. J. P., July, 1870.) H. Spirgatis, of Konigsberg, obtained a resin by preparing a tincture of the Tampico jalap, evaporating, washing, boiling the residue in water, redissolving in alcohol, and decolorizing by charcoal. He gave it the name of tampicin. Its physical properties are similar to those of the jalap resin. It is brittle, tasteless, inodorous, insoluble in water, soluble in ether and alcohol, and in solution has a feeble acid reaction. By strong alkalies it is changed
into a soluble acid which Spirigatus calls tampicic acid. By the action of
diluted sulphuric, nitric, or hydrochloric acid, it is converted, slowly if
cold, but rapidly with heat, into a peculiar acid called tampicolic, with
sugar. For the mode of preparing these acids, and their properties, the
reader is referred to an article in N. R., July, 1871, p. 50. The melting
point of tampicin is 130° C. (266° F.); its formula is \( \text{C}_{34}\text{H}_{54}\text{O}_{14} \). The
percentage of it yielded by the drug varies from a minimum of 10 per
cent. (Hanbury) to a maximum of 15 per cent. (Umney). Andouard
states that it is purgative.

The average percentage of resin in Jalap has of late years distinctly
lessened; indeed this fact has received official recognition. The U. S. P.,
1890, required 12 per cent., and the French Codex, 1884, 16 to 18 per
cent. Much of the commercial jalap is far below the lowered official
standard, and this appears to be due, not, as believed by Fluckiger, to
the extraction of the resin from the roots in Mexico, but to the fact that
the wild tubers are collected indiscriminately from November to March;
the cultivators of India are very careless in their methods. The lowness
of the U. S. P. standard (7 per cent.) is to be regretted, especially as the
Br. Ph. requires 11 per cent., but it is probably necessary, practically, to
meet the commercial conditions. The German Pharmacopoeia of 1900,
however, requires 9 per cent. From a compilation by M. I. Wilbert (J. A.
Ph. A., 1914, 1286) the range of 173 reported analyses of jalap was from
3.67 per cent. to 21.76 per cent. (For various analyses of commercial
Jalap, see U. S. D., 18th ed., also J. P., lxxii, p. 152.)

A comparison of various methods of assay was made by Dr. P. Seidler
(Ph. Ztg., 1912, No. 2, 15), who recommends the process of the P. G.-V.,
which he says can be still further improved.

The question as to possible substitutes for the official species is also
growing in importance. Fluckiger pointed out that the seeds of the
Ipomoea hederacea (see Kaladana) yield 8 per cent. of resin identical
with that obtained from Ipomoea Purga, and the British Pharmacopoeia
now recognizes Kaladana and its resin. Shimoyama, of Tokio, has
shown that jalap resin can be obtained from the Ipomoea triloba (Phar-
bitis triloba) of Japan. M. K. Hyrano confirms this, and states that the
seeds of the plant have long been used in Japan, under the name of
“kengashi” (For details and method of extracting the resin, see P. J.,
Oct., 1888.)
Jalap should be rejected when it is light, of a whitish color internally, of a dull fracture, spongy, or friable. Powders of calomel and jalap, taken on long voyages to southern climates, are said, when brought back, to have become consolidated, and so far chemically altered as plainly to exhibit globules of mercury. This change is ascribed by Sohaeht and Wackenroder to a fungous growth. (A. Pharm., xxxix, 239.)

Uses.—Jalap is an active cathartic, operating briskly and sometimes painfully upon the bowels, and producing copious watery stools. The aqueous extract purges moderately, without much griping, and is said to increase the flow of urine. The portion not taken up by water gripes severely. The aqueous extract obtained from jalap, previously exhausted by rectified spirit, is said to have no cathartic effect. Jalap was introduced into Europe in the latter part of the sixteenth or the beginning of the seventeenth century, and at one time ranked among the purgative medicines most extensively employed. It is applicable to most cases in which an active cathartic is required, and from its hydragogue powers is especially adapted to the treatment of dropsy. It is generally given in connection with other medicines, which assist or qualify its operation. In dropsical complaints it is usually combined with potassium bitartrate.

The combination of jalap with calomel has long been popular, in the United States, in bilious fever and other complaints attended with congestion of the liver or portal circle. In overdoses jalap may produce dangerous hyperca-tharsis. It is said to purge when applied to a wound. Jalapin when taken internally is probably absorbed, but as yet its presence has never been detected in the urine, and it remains uncertain whether it is eliminated or destroyed. Muller (In. Dis., Dorpat, 1885) found traces of it in the blood, and even in the heart, lungs, and spleen of cats poisoned with it.

The dose of jalap, in powder, is from ten to twenty grains (0.65-1.3 Gm.).

Jambosa Root.—This is the root of Jambosa vulgaris DC., of the Fam. Myrtaceae, which is widely cultivated in the tropics under the name of the rose-apple. It has been found by A. W. Gerrard to contain an oleoresin, besides a crystalline principle, jambosin, C_{10}H_{15}NO_{3}. Lyons has also found in it minute quantities of an alkaloid. The decoction of the bark of the root is used as an astringent in dysentery, gonorrhoea, and leucorrhoea. (P. J. , March, 1884.)

Jambu Assu. Piper Jaborandi.—The root of Piper Jaborandi Veil. (Fam. Piperaceae) is one of the Pipers of Brazil, which is used by the natives as a sudorific, a diuretic, and a febrifuge. It is said to contain an alkaloid and a pungent oleoresin. It has no botanical, and probably no medicinal, relation with Pilocarpus.

Jatropha. Jatropha macrorhiza Benth. Jicama.—This is a euphorbiaceous plant which inhabits Northern Mexico and the adjoining United States. It is a purgative, acting excessively in overdose, and is believed by the Mexicans to be cholagogue. The dose of the fluidextract is stated to be from one-half to two fluidrachma (1.8-7.5 mils).

Jeffersonia. Twinleaf. Rheumatism Root. Jeffersonia diphylla (L.) Pers. Twinleaf. (Fam. Berberidaceae)—This herbaceous perennial is found in woods from New York to Wisconsin, extending southward. The rhizome, which, with the rootlets attached, is the part used, has a brownish-yellow color, and a bitter, acrid taste, which resides in its cortical part, the inner portion being nearly tasteless. E. S. Wayne of Cincinnati, found it to contain albumen, gum, tannic acid, starch, pectin, a fatty resin, hard resin, sugar, lignin, and a peculiar acid principle having acid properties and resembling polygalic acid. The root is said to be emetic in large doses, tonic and expectorant in smaller doses and not unlike senega, as a substitute for which it is sometimes used. (A. J. P., xxvii, 1.) According to Mayer, of New York, the rhizome of this plant contains a small quantity of berberine and a second white alkaloid. The pectin of Wayne he considers to be saponin. (A. J. P., 1863, 99.) A. W. Flexor proved the absence of berberine from the root. (Am. Drug., 1884.) Gordin has since confirmed this view (1902).

Jellies.—The form of jelly is sometimes a convenient method of administering medicines, especially the fixed oils, as cod liver oil, castor oil, resinous juices, etc. The following is a formula recommended by Parrish and William C. Bakes. "Take of the fixed oil or liquid resin a troy-ounce; honey, syrup, each, half a troy ounce; gum arabic, in powder, two drachms; Russian isinglass, forty grams; orange-flower water, six fluidrachms. Dissolve the isinglass, with the aid of heat, in half a fluidounce of the orange-flower water, replacing the water as it evaporates. Triturate the other ingredients, with the remainder of the orange-flower water, into a homogeneous mass in a warmed mortar, then add the hot solution of isinglass, stir the mixture as it cools, and set it aside to gelatinize." (A. J. P., 1861, 4.) Any other aromatic water may be substituted for that of the orange flower, and cinnamon water diluted with an equal measure of pure water would probably better cover the offensive taste. In reference to cod liver oil, the bitter-almond, or cherry-laurel water would be still more effectual, care, however, being taken, in this case, that the water be duly diluted, lest too large a
dose of it be administered.

*J. cinerea* is a tree extending in rich woods from New Brunswick to the mountains of Georgia. The fruit, when half grown, is sometimes made into pickles, and, when ripe, affords in its kernel a grateful article of food. The bark is used for dyeing wool a dark-brown color, though inferior for this purpose to that of the black walnut. It is said to be rubefacient when applied to the skin. The inner bark is the medicinal portion; that of the root, being considered most efficient, was directed by the U. S. P. It should be collected in May or June.

On the living tree, the inner bark, when first uncovered, is of a pure white, which immediately on exposure becomes a fine lemon color, and ultimately changes to deep brown. It has a fibrous texture, and under the title of *Juglans* is described as follows in the N. F. IV:

"In quills, curved strips, or in chips, from 3 to 10 mm. in thickness; of a deep brown color on both surfaces and throughout, except for the faint, intersecting, whitish, radial, and tangential lines shown in the transverse section; outer surface smooth, somewhat warty; inner surface smooth and striate, bearing fragments of thin stringy fiber: fracture short, rather weak, somewhat fibrous. Odor faintly aromatic; taste bitter, astringent, somewhat acrid.

"The powdered drug is dark-brown and, when examined under the microscope, exhibits numerous rosette aggregate crystals of calcium oxalate, up to 0.050 mm. in diameter; simple rounded or occasionally 2- to 4-compound starch grains, the individual grains being up to 0.015 mm. in diameter, sometimes with a cleft through the center; stone cells, some with thick walls, with simple or branching pores, up to 0.10 mm. long and 0.05 mm. wide, sometimes with reddish contents; long thick-walled sclerenchymatous fibers up to 0.03 mm. in width, occasionally associated with crystal fibers, the latter containing prisms of calcium oxalate from 0.01 to 0.05 mm. in length; fragments of parenchyma containing brownish tannin masses and oil; fragments of epidermal tissue composed of polygonal cells having yellowish-brown walls, some with reddish-brown contents. *Juglans* yields not more than 8 per cent. of ash." N. F.

Its medicinal virtues are extracted by boiling water. Bigelow could detect no resin in the bark, and the presence of tannin was not evinced by the test of gelatin, though a brownish-black color was produced by ferrous sulphate. Charles O. Thiebaud found the bark to be destitute of tannic acid and of any vegetable alkaloid, but to contain bitter extractive, oily matter in large proportion, a volatilizable acid, juglandic acid, crystallizing in bright, orange-yellow crystals, and appearing to bear some analogy with chrysophanic acid, another acid crystallizing in tabular, colorless crystals, and a volatile acid. (A. J. P., 1872, 253.) Maisch believes that the juglandic acid of Thiebaud is the nucin of A. Vogel, J. r., found in green walnut peel. (A. J. P., April, 1874, 167.)
D. Truman (A. J. P., 1893, 426) made proximate analyses of the root bark and the trunk bark for comparison. In the trunk bark, instead of the crystallizable juglandic acid, he found an uncrystallizable acid and a crystalline resin. Tanret and Villers isolated from the leaves a carbohydrate, nucite, $C_{6}H_{12}O_{6} + 2H_{2}O$, which fuses at 218° C. (424.4° F.), is not fermentable, and does not reduce Fehling's solution. It has since been shown to be identical with inosite. Tanret also (Jahrerb. f. Pharm., 1876, 198,) thinks that he has obtained an alkaloid from walnut leaves, which he proposes to call juglandine. The European walnut bark yielded glycyrrhizin abundantly to Sestini. J uglon, $C_{10}H_{6}O_{3}$, the characteristic constituent of Juglans regia, has been prepared synthetically by Berthelsen and Semper, and is now recognized as a-oxynaphthoquinone, $C_{10}H_{5}(OH)O_{2}$, as it can be made from dioxynaphthalene by the action of chromic acid mixture. It is in brownish-red, crystalline needles having a faint odor of walnut hulls, and is sternutatory. (Ber. d. Chem. Ges., 1887, 934.) The fluidextract is recognized by the N. F. (see Part III); the extract was official in the U. S. P., 1890.

Extractum Juglandis. U. S. 1890. Extract of Juglans. "Juglans, in No. 30 powder, one thousand grammes [or 35 ounces av., 120 grains]; Diluted Alcohol, a sufficient quantity. Moist the powder with four hundred mils [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until three thousand mils [or 101 fluid-ounces, 212 minims] of tincture are obtained, or the Juglans is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." U. S., 1890.

Butternut is a mild cathartic resembling rhubarb in its action, but less certain. It was much used during our Revolutionary war as an habitual laxative, and was especially esteemed by Rush in the treatment of dysentery and hepatic congestions. Dose of the extract, from five to twenty grains (0.32-1.3 Gm.) ; of the fluidextract, thirty to sixty minims (1.9-3.9 mils).

Several products of Juglans regia L., or common European walnut, are used medicinally in Europe. The hull of the fruit has been employed as a vermifuge from the times of Hippocrates, and has been recommended in syphilis and for old ulcers. The expressed oil of the fruit has been deemed efficacious against the tapeworm, and is also used as a laxative injection. The leaves, long occasionally employed for various purposes in both regular and domestic practice, have been found by Negrier of Angers, in the highest degree efficacious in scrofula. He gave to children a teacupful of a fairly strong infusion, or six grains (0.4 Gm.) of the aqueous extract, or an equivalent dose of a syrup prepared from the extract, two, three, or four times a day, and at the same time applied a strong decoction to the ulcers, and as a collyrium when the eyes were diseased. No injury ever resulted from a long-continued use of the remedy. It appears to act as a moderately aromatic bitter and astringent. (A. G. M., 3e ser., x, 399 and xi, 41.) They are said also to have proved useful as a topical application in
malignant pustule. (Ibid., 5e ser., x, 609.)

Nucitannic Acid.—In the walnut, between the kernel and the shell, is a thin membrane, which closely embraces the cotyledon, called the episperm, which consists of two layers, the inner very thin, colorless, translucent, and perfectly tasteless, the outer coarser, somewhat colored, and of a bitter, disagreeable taste. The latter, examined chemically by T. L. Phipson, was found to contain, among other principles, as gallic and ellagic acid, etc., a new variety of tannic acid, which he proposes to name nucitannic acid or nucitannin, to which the outer membrane chiefly owes its unpleasant taste. It is a glucoside, as when boiled for some hours with diluted hydrochloric acid it splits into glucose and a peculiar red acid substance, which he calls rothic acid, \( C_{14}H_{12}O_7 \), and the properties of which he has pretty thoroughly investigated. (Chem. News, Sept. 3, 1869, p. 116.) For an exhaustive chemical examination of black walnut leaves by Miss L. J. Martin, see A. J. P., 1886, p. 468. The leaves of \( J. \) nigra L. (black walnut), and those of \( J. \) cinerea, probably possess the same properties.

\( J. \) unipersus communis L. is an evergreen shrub, usually small, but sometimes twelve to fifteen feet high, with numerous very close branches, and varying from an erect shrub to a decumbent or even trailing arborescent plant.

The common juniper is a native of Europe and the northern regions of Asia and North America. Northward it becomes a trailing shrub, seldom more than 2 to 4 dm. high, spreading in all directions, throwing out roots from its branches, and forming beds which are often many rods in circumference. The name of \( J. \) depressa has been proposed for this variety. The common juniper flowers in May, but does not ripen its fruit until late in the following year. All parts of the plant contain a volatile oil, which imparts to them a peculiar flavor. The wood has a slight aromatic odor, and was formerly used for fumigation. A terebinthinate juice exudes from the tree and hardens on the bark. This has been erroneously considered as identical with the gum known commercially as sandarach.

The berries, as the fruit is commonly called, were formerly occasionally brought to the Philadelphia market from New Jersey. But, though equal to the European in appearance, they are inferior in strength, and are not much used. The best come from the south of Europe, particularly from Trieste and the Italian ports. They are "nearly globular, about 8 mm. in diameter; externally smooth, shining, black-brown to purplish-black with a blue-gray bloom, at the apex a three-rayed furrow marks the cohesion of the three fleshy bract forming the pericarp; internally loosely fleshy, greenish-brown, containing numerous large schizogenous cavities; seeds three, triangular ovate, hard, brown, with large uneven oil glands on the surface. Odor

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - J-K - Page 12
The Southwest School of Botanical Medicine http://www.swsbm.com
aromatic; taste sweet, pleasant, terebinthinate, slightly bitter.

"Sections, when examined under the microscope, exhibit a pericarp consisting of an epiderm of a single row of rounded polygonal cells filled with a brown granular substance, at the sutures of the bracts these become blunt papillae; a hypodermis of two or three rows or brown-red, collenchymatous cells thickened at the angles; the fleshy portion (mesophyl) composed of loose, irregular parenchyma with large oval canals and traversed by fibro-vascular bundles with areolated fibers; a sclerenchymatous ring of six to eight rows of very thick cells with pitted walls, many enclosing prismatic crystals of calcium oxalate; the seed-testa shows a layer of two to ten rows of stone cells with radial markings on the walls and each enclosing a polygonal crystal of calcium oxalate; endosperm and embryo rich in fat and aleurone. Juniper Berries yield not more than 5 per cent. of ash." N. F.

These properties, as well as their medicinal virtues, they owe chiefly to a volatile oil. (See Oleum Juniperi.) The other constituents, according to Trommsdorff, are resin, sugar, gum, wax, lignin, water, and various saline substances. The proportion of these constituents varies according to the greater or less maturity of the berries. The volatile oil is most abundant in those which have attained their full growth and are still green, or in those which are on the point of ripening. In the latter Trommsdorff found 1 per cent. of the oil. In those perfectly ripe it has been partly changed into resin, and in those quite black, completely so. The berries impart their virtues to water and alcohol. They are very largely consumed in the preparation of gin.

The tops of juniper were formerly directed by the Edinburgh and Dublin Colleges. Their odor is balsamic, their taste resinous and bitterish, and they possess similar virtues with the berries.

Juniper berries are gently stimulant and diuretic, imparting to the urine the odor of violets, and producing occasionally, when largely taken, disagreeable irritation in the urinary passages. They are chiefly used as an adjuvant to more powerful diuretics in dropsical complaints. The infusion is a good preparation. It is made by macerating an ounce of the bruised berries in a pint of boiling water, the whole of which may be taken in the course of twenty-four hours. The fluidextract is recognized by the N. F. (see Part III), but for most purposes the oil is preferable. (See Oleum Juniperi.) Under the trade name of junol there appears on the market a hydroalcoholic extract of juniper berries recommended as a diuretic. Juniper berries are not administered in substance; the dose of the fluid extract is one fluidrachm (3.9 mils) (see Part III).

**Juniperus Virginiana** L. Red Cedar. Cedre de Virginie, Fr. Virginische Ceder, Rothe Ceder, G.—The tops of this plant were formerly included in the Secondary List of the U. S. Pharmacopoeia. The tree is an evergreen of slow growth, seldom very large, although sometimes attaining a height of 25 m.

It grows on dry hills or deep swamps from Maine westward to the Rocky Mountains, from Vermont to the Gulf of Mexico, is most abundant and vigorous in the southern section. The interior wood is of a reddish color, and highly valuable on account of its
great durability. Small excrescences, which are sometimes found on the branches of the tree, are popularly known as cedar apples and used as an anthelmintic in the dose of from ten to twenty grains (0.65-1.3 Gm.) three times a day. The tops have a pleasant odor, and a strong, bitterish, somewhat pungent taste. These properties reside chiefly in a volatile oil, and are readily imparted to alcohol. The leaves, analyzed by Wm. J. Jenks, were found to contain volatile oil, gum, tannic acid, albumen, bitter extractive, resin, chlorophyll, fixed oil, lime, and lignin. (A. J. P., xiv, 235.) They bear a close resemblance to the leaves of Juniperus Sabina L., an European shrub, from which they can be certainly distinguished only by the difference of odor. The oil of red cedar is now an article of commerce; it is used generally in perfumery, and was formerly one of the principal constituents of the popular extract of white rose. (A. J. P., 1877, 186.) It possesses, in a marked degree, the well-known agreeable odor of the red cedar wood. Schimmel describes a volatile oil from Haitian cedar wood which differs from our domestic oil of cedar, only in having a higher specific gravity. (Schim. Rep., 1905, 17.) I. W. Brandel obtained from the leaves of J. Virginiana 0.47 per cent. of volatile oil, sp. gr. 0.913 at 15° C. (59° P.). It had a very pleasant odor. (Proc. A. Ph. A., 1906, 459.) Cedrene camphor, C_{10}H_{26}O=C_{16}H_{24}+H_{2}O, may be obtained by cooling the oil until coagulated, and separating the crystalline portion by expression; the expressed liquid is cedrene, C_{15}H_{24}, which, after rectification and distillation, has the sp. gr. 0.984 at 15° C. (59° P.), boiling at 237° 0. (458.6° P.). Cedrene may also be prepared from the cedrene camphor by the dehydrating action of phosphoric anhydride, PaOc. The resemblance of red cedar to savin is said also to extend to its medicinal properties. It is, however, much less energetic, and has not acquired the confidence of the profession. Externally applied it acts as an irritant, and an ointment, prepared by boiling the fresh leaves for a short time in twice their weight of lard with the addition of a little wax, is employed as a substitute for savin cerate in maintaining a purulent discharge from blistered surfaces. Sometimes the dried leaves in powder are mixed with six times their weight of rosin cerate, and used for a similar purpose. But neither of these preparations is as effectual as the analogous preparation of savin.

The volatile oil, which resembles oil of savin in its medicinal properties, has been used for the purpose of producing abortion, and in some cases has caused death. The symptoms have been burning in the stomach, vomiting, convulsions, coma, and a slow pulse, with evidences of gastro-intestinal inflammation after death. (See S. C. Watt, B. M. S. J., vol. xl.)

Under the name of cedar are known in commerce various trees, some of which do not belong to the genus J uniperus. The wood of J uniperus bermudiana L. is said to be largely used in making pencils. The cedar of Lebanon, Cedrus Libani Barrel, and its two varieties, the African cedar, C. atlantica Manetti, and the Indian cedar or deodar, C. Deodara Loud., are sometimes distilled for oil, and, under the name of libanol. An oil obtained from Cedrus atlantica, Manetti, or satin-wood, has appeared in commerce and is said to be useful in the treatment of blennorrhea, phthisis, bronchitis, and eruptions upon the skin, having properties very similar to those of the oil of santal. It may be given in capsules up to forty-five grains (3 Gm.) per day. In skin eruptions the 25 per cent. ointment made with vaseline has been used. Other trees known as
cedars are the white cedar, Cupressus thyoides L.; the American white cedar, Thuja occidentalis Linn.; the Californian white cedar, Libocedrus decurrens Torr.; the New Zealand cedar, Libocedrus Bidwillii Hook. The Australian red cedar, Cedrela Toona Roxb., and the West India cedar, Cedrela odorata L., belong to an entirely different family, the Meliaceae (Cedrelaceae). The wood of the latter species is used in making cigar boxes, and, according to Schimmel, yields 3 per cent. of a volatile oil, which has a specific gravity of 0.915, boils between 265° and 270° C. (509°-518° F.), and has an optical rotation of 0.053° in a 100 mm. tube. It is said to be a powerful insecticide. (P. J., Aug. 29, 1896, 179.)

KALADANA. Br.

KALADANA [Semen Pharbitidis, Pharbitis Seeds]

"Kaladana consists of the dried seeds of Ipomoea hederacea, J acq." Br.

Closely allied to Ipomoea hederacea is I. muricata, the seeds of which are largely imported into Bombay, from Persia, under the name of tukm-i-nil. The juice of this plant is employed to destroy bedbugs, and the seeds are said to be identical in their medicinal properties with those of the official plant.

Ipomoea hederacea J acq. (I. caerulea Kon.; Pharbites Nil, Choissy) is a twining annual plant belonging to the Convolvulaceae. It has large blue flowers whence the specific name Nil which signifies in Hindustani blue. The leaves are three-lobed and the plant, while common throughout India, is found throughout the tropical regions of both hemispheres. Flickiger found it to contain 8.2 per cent. of resin which corresponded in its various properties to the resin of jalap.

Kaladana seeds are in the form of the segment of a sphere, black, somewhat hairy, weighing from one-half drachm to nearly one drachm.

They are described by the British Pharm., 1914, as follows: "Seeds in the form of a segment of a sphere; usually about five millimetres long, but sometimes much smaller; nearly black. In transverse section, minute dark resin-cells in the plaited cotyledons. Slight odor; taste acrid." Br.

From them is prepared pharbitisin, kaladana resin (Kaladanae Resina, Br.), by digesting the seed with alcohol until exhaustion, and precipitating with distilled water.

UNITED STATES DISPENSATORY - 1918 - Botanicals Only - J-K - Page 15
The Southwest School of Botanical Medicine http://www.swsbm.com
Uses.—Kaladana seeds were used by the Arabian physicians, under the name of Habbun-nil, and have been recommended as a safe and active cathartic by various English physicians resident in India. Their action is probably similar to that of jalap.

Dose, thirty to forty-five grains (2-3 Gm.).

Kalagua.—A study of this South American plant, which has been put upon the market as a specific for tuberculosis, made upon the lower animals by D. H. Bergey, shows that it has no specific influence upon the tubercle bacillus.

Kalmia. Kalmia latifolia L. Laurel. Mountain Laurel. Broad-leafed Laurel. Calico-bush. Spoon-wood. Kalme Fr., G.—This well-known ericaceous evergreen shrub is found from New Brunswick to Florida and from Ohio to Louisiana, being especially abundant on the sides of hills and mountains. It is from 1 to 4 m. in height. The leaves, which are supposed to be possessed of poisonous, narcotic properties, have been found by Charles Bullock to contain gum, tannic acid, resin, chlorophyll, fatty matter, a substance resembling mannite, an acrid principle, wax, extractive albumen, yellow coloring matter, lignin, and salts of potassium, calcium, and iron. (A. J. P., xx, 264.) George W. Kennedy detected the glucoside arbutin in them. (A. J. P., xlvi, 5.) Bourquelot and Fiehtenholz stated that the glucoside that they obtained from the leaves of K. latifolia is identical with the asébotin that Eykman found in Andromeda japonica; both yield a red color with ferric chloride. The leaves are popularly believed to be poisonous to sheep and other small animals, but are said to be eaten with impunity by deer, goats, and grouse. It is also affirmed that severe and fatal poisoning has been produced by eating grouse that have fed upon these leaves. (See 16th ed., U. S. D.) Crawford (Bulletin 121, Bureau of Plant Industry, U. S. Dept. of Agriculture), in experimental investigations, found that laurel caused, either when fed to, or injected into, the lower animals, great salivation, lachrymation and emesis, convulsions, and later paralysis of the extremities, with greatly labored respiration. It is probable, although not proven, that the poisonous principle of this plant is andromedotoxin. The leaves have been used internally in diarrhea and in syphilis, and externally in skin diseases. (See 16th ed., U. S. D.)

It is probable that other species of kalmia, as K. angustifolia L., or sheep-laurel, and K. glauca Ait.; or swamp-laurel, have properties identical with those of K. latifolia. A decoction of the leaves of K. angustifolia is used by the negroes as a wash for ulcerations between the toes.

Kamala. U. S. 1890. Kamala. Glandulae Rottlerae.—The U. S. Pharmacopoeia, under the name of Rottlera, U. S., 1870, Kameela, formerly recognized the glands and hairs from the capsules of Mallotus philippinensis (Lamarck) Muell.-Arg. (Fam. Euphorbiaceae) This tree grows in Abyssinia, Southern Arabia, Hindostan, the East
India Islands, China, and Australia, reaching a height of from fifteen to twenty feet, and yielding a roundish, three-valved, three-locular capsule about the size of a small cherry, thickly covered with a red powder, which is collected in Hindostan by rolling the berries about in large baskets until the freed powder sifts through the open wicker-work.

Kamala, as brought to our market, is a light, finely granular, very mobile powder, of a brownish-red or madder color, with little odor or taste, but producing a slight sense of acridity in the mouth, and feeling gritty under the teeth. (When the grittiness is excessive, the drug has probably been adulterated with earthy matters.) It is inflammable, and flashes almost like gunpowder when dropped into the flame of a candle. It is insoluble in cold and very slightly soluble in boiling water; but alkaline solutions, alcohol, and ether dissolve a large proportion of it, forming a deep red solution, from which water precipitates resinous matter, "imparting a deep red color to alkaline liquids, alcohol, ether, or chloroform, and a pale yellow tinge to boiling water." U. S., 1890. Under the microscope it consists of garnet-red, semi-transparent, roundish, glandular hairs from 0.040 to 0.100 mm. in diameter, and containing numerous red, club-shaped cells and admixed with minute stellate hairs, and the remains of stalks and leaves, the latter of which are easily removed by careful sifting. It has been examined chemically by Thomas Anderson, of Glasgow, and by G. Leube, in Germany. As given by the former, the constituents are, in 100 parts, 78.19 of resinous coloring matter, 7.34 of albumin, 7.14 of cellulose, etc., a trace of volatile oil and volatile coloring matters, 3.84 of ashes, and 3.49 of water. The amount of earthy impurities, chiefly sand, in commercial kamala, varies greatly, sometimes amounting to fifty or even sixty per cent. It can readily be estimated by heating the drug to redness and weighing the residue. The U. S. P., 1890, permitted the presence of "not more than 8 per cent. of ash." Any specimen of kamala containing more than the official percentage of impurity should be rejected. Rusby states that kamala often cornea to this country adulterated. He found one shipment loaded with sand, one with olive stems, one olive stems and sand, and one ground bark. Two samples, 40.8 per cent. acid, 43.4 per cent. ash, were mostly sand. (See also Ph. Rev., 1907, 129; P. J., 1906, 258.) Of the resinous coloring substances, Anderson obtained one in a pure state by allowing a concentrated ethereal solution to stand for two days, draining and pressing in bibulous paper the resulting mass of granular crystals, and purifying them from adhering resin by repeated solution in ether and recrystallization. To this substance he gave the name of rottlerin. It is in the form of minute crystalline plates, of a yellow color and a satin-like luster, insoluble in water, sparingly soluble in cold but more so in boiling alcohol, and readily dissolved by ether, and by alkaline solutions, which assume a dark red color. Perkin (Chem. Soc. Trans., lxiii, p. 975) shows rottlerin to consist of six distinct substances, i.e., rottlerin, isorottlerin, wax, two resins and a coloring substance. The pure rottlerin has the chemical composition C_{33}H_{30}O_{9}. (See also P. Ztg., 1906.) Crude rottlerin, sometimes known as kamalin, melts when heated moderately, and at a higher heat is decomposed, giving off pungent vapors. A. and W. Perkin (Ber. d. Chem. Ges., xix, 3109) and Jawein (Ibid., xx, 182) both stated that rottlerin can be extracted from kamala by the action of carbon disulphide. Jawein gave its fusing point as 200° C. (392° P.), and said that it was easily soluble in hot alcohol and acetic acid. In a later communication, A. G. Perkin (P. J., 1893, 159, 236),
stated that when he extracted it with ether, kamala yielded a dark brownish resinous product from which six distinct substances can be isolated; rottlerin, iso-rottlerin, a wax, and two resins, one of high and one of low melting point, form the principal constituents. There is also present a trace of a yellow crystalline coloring matter melting at from 192°-193° C. (377.6°-379.4° F.). Perkin also found in kamala a small quantity of a sugar soluble in water. Potassium permanganate oxidizes it to oxalic and benzoic acids; nitric acid of 1.5 sp. gr., on the other hand, oxidizes it to oxalic acid, ortho- and para-nitrocinnamic acids, and para-nitrobenzoic acid. The ashes were in the extraordinary proportion of 25.85 per cent., and of the ashes 83.8 per cent. consisted of insoluble silica. Silica probably enters essentially into the constitution of the minute granules, and its presence accounts for their grittiness under the teeth. The active constituent is supposed to be the resin.

Kamala is actively or even violently purgative in full doses, occasionally causing nausea, but seldom vomiting. Kamala has long been used in India against the tape worm, and was first made generally known by C. Mackinnon. (Ind. Ann. Med. Sci., 1854.) Semper (A. E. P. P., 1910, Ixiii. p. 10) has found that kamala has a paralyzing effect on motor nerves and muscles, to which action he believes it owes its tenifuge powers. It is given, without previous preparation of the patient, in the dose of from one to three drachms (3.9-11.6 Gm.), suspended in water, mucilage, or syrup. In the latter dose it sometimes acts violently. The worm is usually expelled at the third or fourth stool. If the first dose fails to operate on the bowels, it may be repeated in four hours, or followed by a dose of castor oil. The tincture (four ounces to eight fluidounces of diluted alcohol) is also said to be efficient in doses of from one to four fluidrachms (3.75-15 mils). As an external remedy, kamala is used by the people of India in various affections of the skin, particularly scabies. William Moore, of Dublin, has employed it successfully in herpetic ringworm. (Dublin Hosp. Gaz., Nov. 15, 1857.) A tenifuge composed of kamala and koussin and known as kamakosin, is in use on the continent.

KAVA RHIZOMA. Br.

KAVA RHIZOME

"Kava Rhizome is the peeled, dried, and divided rhizome of Piper methysticum, Forst. fil." Br. "The dried rhizome and roots of Piper methysticum Forster (Fam. Piperaceae)" N.F.

Kava, N. F.; Methysticum; Kava-kava.

The genus Piper includes a large number of sub-tropical plants, which are mostly shrubs, and rarely herbs or trees. A number of the species are of great economic importance. Piper methysticum is a shrub, several feet high, indigenous to many of the South Sea Islands. The plant has cordate, acuminate leaves and very short axillary spikes of flowers. The
natives prepare a fermented liquor from the upper portion of the rhizome and the base of the stems.

Kava rhizome occurs "in whitish or light brownish-grey irregularly cuboid or roughly wedge-shaped fragments from which the peri-derm has been sliced off; from one to five centimetres thick. In transverse section, usually exhibiting a central dense pith, surrounded by a distinct ring of narrow, radiating, vascular bundles separated by relatively broad, paler, medullary rays. Fracture starchy. Slight agreeable odor; taste pungent and bitter." Br.

The N. F. description is as follows: "Consisting of a large, irregular knotty crown, often 12 cm. or more in diameter, from which proceed numerous, long, cylindrical, tough, nearly simple roots, which tend to fray out into bare, separated fibro-vascular bundles; the crown soft, light, spongy, and granular and very starchy; externally dark-brown or blackish, the crown frequently partly scraped and light brown to light gray; internally white. Odor faint but characteristic; taste aromatic and pungent, slightly bitter, more or less local anaesthesia resulting. The powdered drug, when examined under the microscope, exhibits numerous, simple, or two- to three-compound starch grains, the individual grains being up to 0.045 mm. in diameter, many with radial clefts or triangular fissures at the center; yellow resin and oil cells; narrow sclerenchymatous fibers with thin, strongly-lignified walls; tracheae with scalariform or reticulate markings, up to 0.15 mm. in width; few nearly isodiametric wood parenchyma from the remains of the stem. Kava yields not more than 8 per cent. of ash." N. F.

The pharmacognosy of this drug has been written up by Semenow in Ap. Ztg., 1890, p. 216, and True, Ph. Rev., xiv, No. 2. Powdered Kava consists of numerous starch grains which are either single or 2- to 3-compound, the individual grains having central radial clefts with triangular fissures varying from 0.006 to 0.035 mm. in diameter. The sclerenchymatous fibers have thin walls which are strongly lignified. The tracheae have scalariform or reticulate markings. The oil cells frequently contain a yellowish resin. The drug should not yield more than 8 per cent. of ash.

Goblely isolated from kava root a crystalline principle (analogous to piperin), methysticin, or kavahin, which is without odor and taste, and is probably inert. (J. P. C., Jan., 1860.) It possesses the formula
C\textsubscript{15}H\textsubscript{14}O\textsubscript{5}, and is the methyl ester of p-piperonyl acetic acid, and when purified forms silky, lustrous needles melting at 138° to 139° C. (280.4°-282.2° F.). Kavahin differs from piperin and cubebin in being colored red by hydrochloric acid, the red color fading on exposure to air into a bright yellow, and in being colored by strong sulphuric acid a purplish violet, which passes into green. In 1844 Morson discovered an active principle, kawine. This is a greenish-yellow, strongly aromatic and acrid resin. It was again studied by Cuzaut in 1860, and by Lewin in 1886. This latter investigator separates it into two resins, of which the b-resin is greasy and of a reddish-brown color, appearing in mass almost black. This is less active than the a-resin, which is yellowish-brown, has the characteristic odor of the drug, is freely soluble in alcohol, and placed upon the tongue produces a burning sensation followed by local anesthesia. (A. J. P., 1886, 450.) Yangonin is another glucoside which has been studied by Borsche and Gerhardt. (Riedels Archives, 1914, 50.) A volatile oil has also been found in the root. (J. P. C., March, 1862.) Lavialle (L'Union Pharm., Jan., 1889) claims to have obtained an alkaloid, kavaine. (See also Proc. A. Ph. A., 1897, 564.)

**Uses.**—Under the names of Ava or Kava the natives of the Sandwich Islands have used as an intoxicant a beverage prepared from kava rhizome. The intoxication is wholly unlike that caused by alcohol, being of a silent and drowsy character, accompanied by incoherent dreams, with great loss of muscular power, which is probably due to the action of kava resin upon the spinal cord.

The physiological action of kava and its resin has been investigated by L. Lewin (Piper Methysticum, Berlin, 1886), and David Cerna (T. G., 1891). The phenomena which follow the hypodermic injection of the fluidextract of kava or of a solution of its resin are, anesthesia at the point of injection, followed, after absorption, by general paralysis, due to a direct action on the motor side of the spinal cord; the motor nerves and the muscles remain intact. The local anesthesia is due to a paralysis of the sensory nerve filaments, and when the resin is brought in contact with the mucus membranes there is a burning pain, followed in time by a complete loss of sensibility, which is remarkably permanent, since Lewin found that from six to seven minimis of a solution of kava injected beneath the skin produced a complete loss of sensibility in the surrounding area, which did not pass away for eight days. (D. M. Ztg., Feb., 1886.) The action of the drug upon the circulation is subordinate to its nervous influence, but according to the experiments of Cerna it does
stimulate the heart, although it decreases the number of pulsations by stimulating the inhibitory nerve centers. The same investigator found that at first it stimulates, afterwards depresses, and finally paralyzes the respiratory center. The insolubility and irritant action of kava resin has lessened its use as a practical local anesthetic.

As long ago as 1857 kava root was employed in the treatment of gonorrhea, and there is much testimony to its value both in the acute and the chronic form of the disease, as well as in vaginitis, leucorrhæa, nocturnal incontinence, and similar conditions of the genito-urinary tract.

Under the name of gonosan a twenty per cent. solution of kava resin in oil of sandalwood is used internally in the treatment of gonorrhæa. The advantages claimed for it are that it is much less likely to disturb the stomach than sandalwood oil, that it is locally anesthetic and hence relieves the pain and, apparently, also has some anaphrodisiac action. According to Ganz (All. M. C. Z., 1906, p. 213), while not of itself gonocidal it renders the urine permanently antiseptic and so deprives the gonococci of conditions favorable for their growth. The preparation is marketed in capsules containing 0.3 Gan. of which two to four may be given several times a day. (For the methods of determining kava resins in this and similar preparations, see Ph. Ztg., 1914, 284.)

Dose, of kava rhizome, from fifteen to forty-five grains (1-3 Gm.).

**Kefir.** Kephyr. N. N. R. 1917. (See also Lactic Acid Therapy.)—From time immemorial the Tartars and the Balkan peoples have employed as a food and beverage one or another form of fermented milk. The Tartars prepared from mare's milk a drink known as koumiss or kumys. This is prepared by the action of a peculiar ferment known as kephir (kepir) and called also by the Mohammedans "the prophet's millet." In Western Europe, mare's milk not being available, an imitation of kumys has been made from cow's milk, to which the term "kephir milk " should be applied, limiting the word kumys to the genuine Tartar drink. The Armenians employed a fermented milk, madzonn or matzoon. Giaourdi is a fermented milk prepared in Greece from sheep and goat's milk with an enzyme obtained from fermented figs. The Bulgarians use a fermented milk known as yoghourt (yaowite). The Arabians have a fermented milk called leben.

The kefir grains (or seeds) are white, irregular, roundish bodies about the size of a walnut with a rough, ferruled surface, of gelatinous or, when dried, cartilaginous
consistency. Despite considerable investigation, their composition is not yet definitely settled. They probably contain several micro-organisms as follows: (1) a yeast fungus which Spivak (N. Y. M. J., 1896) believes identical with the ordinary yeast, Saccharomyces cerevisiae, but which Beyerinck believes to be a distinct species, S. Kefir, (2) Bacillus Dispora Caucasica (Kern) or Bacillus Kephir (Sorokin), (3) Bacillus acidi lactici, (4) other bacteria which are probably of little importance to the process of fermentation.

There are a number of directions for preparing kephir milk, varying more or less in the details. The following is a simple one: About 120 grains of kephir grains are softened by soaking over night in a pint bottle full of water. The following morning the water is poured off and the bottle is three-quarters filled with unboiled milk and tightly stoppered. This is kept at a temperature of 20° C. (68° F.) for from one to three days. The milk is strained through cheese doth immediately before use and the residue recovered may be used for fermenting other milk. For various other processes see Kobert (Zeitsch. f. Krankenpflege, 1904, p. 377; Ph. Ztg., 1904, 819 and 1912, 277), Drasler (Med.Klin., 1908), and Spivak (N. Y. M. J., 1896). According to Spivak, the changes in milk during kephirization are as follows: 1. Fat, salts, and water remain unchanged. 2. The quantity of lactose is gradually lessened from 30-50 per mille to 16-30 per mille in the second-day kephir, and to 12-20 per mille in the third-day kephir. 3. Lactic acid is increased from 3.5-8.6 per mille in second-day kephir to 6.3-9.0 in third-day kephir. 4. Alcohol is produced from 5.3-8.0 mille in second-day kephir to 6.0-10.0 in third-day kephir. 5. Carbon dioxide is generated in quantities approximately 10 per cent. 6. A part of the casein—namely, about 10 per cent.—is transformed into acid albumin and peptone, 10 per cent. into hemialbumose, and the rest loses its lime, and therefore becomes more easily digestible.

There is largely sold, under the name of kumys, a spurious drink which is made by fermenting sweetened milk with ordinary yeast. It is a pleasant beverage, but differs in important regards from the true kephir milk. The following formula has been suggested by L. Wolff (A. J. P., 1880, 291): "Grape sugar, half an ounce. Dissolve it in four ounces of water. Dissolve twenty grains of compressed yeast, or well-washed and pressed out brewer's yeast, in two ounces of milk. Mix the two solutions in a quart champagne bottle, which is to be filled with good cow's milk to within two inches of the top. Cork well, se-icure the cork with wire, and place in a cellar or ice chest, where a temperature of 10° C. (50° F.) or less can be maintained, and agitate three times a day. In three or four days the koumys is ready for use, and should not be kept longer than four or five days; it should be drawn only with a champagne tap." A beer bottle with patent stopper may be substituted for the champagne bottle.

The composition of true koumys, according to Stalberg, is given below; other analyses may be found in the J. P. G., 1875, 62.

Koumys of June. In 100 parts, alcohol 1.65, fat 2.05, sugar of milk 2.20, lactic acid 1.15, casein 1.12, salts 0.28, carbonic acid 0.75.

Koumys of September. Carbonic acid 1.86, alcohol 3.23, fat 1.05, lactic acid 2.92, casein and salts 1.21. Stalberg gives the following as the result of an analysis of...
Swiss koumys, made from cow's skimmed milk to which sugar had been added. Alcohol 3.622, lactic acid 0.256, sugar 2.376, albumin 2.099, butter 2.008, mineral salts 0.574, carbonic acid 1.997. Warnikiewicz found in koumys from cow's milk 6.32 per cent. of solid material, casein 3.08, butter 0.22, milk sugar 1.77, salts 0.33, lactic acid 0.62, alcohol 1.23 parts per hundred. (See also König’s Nahrungs- und Genussmittel, 416-419.)

These fermented milks vary in composition with the milk they are prepared from. In the following analyses, the first three columns are taken from A. J. P., 1887; the matzoon analysis is by Uffelmann.

Gordon Sharp (P. J., 1892, 512) stated that the composition of koumys is complex, and that the decomposition which its proteids undergo is closely allied to putrefaction.

Kephr milk is useful either as an accessory or sole food in various conditions of malnutrition. Not only does it offer the nutritive elements of milk in a partially digested form, but it is claimed that the living ferments which are contained in it have an influence in aiding digestion in the alimentary canal, and that it also stimulates the appetite. It first came into Europe as a remedy in pulmonary tuberculosis, but has also been recommended in various forms of dyspepsia, whether functional or organic, in anemia and chlorosis, in rachitis, chronic rheumatism, and other conditions of impaired nutrition. It has also been employed as an infants' food with asserted remarkable results. Its value in phthisis has been extraordinarily lauded by Uroganski. (Wiener Med. Wochens., 1907.)

**Kinkeliba.** Combretum album. (Fam. Combretaceae)—This is the leaf growing in Western Africa which is affirmed to be of great value in the treatment of bilious hematuric malarial fevers. Heckel and Schlagdenhauffen found in the leaves nothing more active than tannin and potassium nitrate. (See Perrot and Lefevre, Travaux du Laboratoire de Mat. Med., p. 67.)

**KINO. U. S., Br.**

**KINO**

"The spontaneously dried juice of Pterocarpus Marsupium Roxburgh (Fam. Leguminosae)." U. S. "Kino is the juice obtained from incisions in the trunk of Pterocarpus Marsupium, Roxb., heated to boiling and evaporated to dryness. Known in commerce as East Indian, Malabar,
Madras, or Cochin kino. “Br.

The term kino was originally applied to a vegetable extract or inspissated juice taken to London from the western coast of Africa, and introduced to the notice of the profession by Fothergill. Vegetable products obtained from various other parts of the world, resembling kino in appearance and properties, afterwards received the same name, and some confusion and uncertainty still exist, in relation to the botanical and commercial history of the drug. We shall first consider the general properties of official kino, then the several varieties.

Properties.—The official description is as follows: "In small, brittle angular fragments, usually considerably less than 15 mm. in diameter, varying in color from dark reddish-brown to reddish-black; when crushed upon a slide and examined under the microscope the angular fragments are more or less translucent with a glass-like, conchoidal surface, the thinner pieces having a yellowish-red or deep brownish-red color, the pieces often being marked by nearly parallel, curved and straight lines; inodorous; taste very astringent; when masticated it colors the saliva somewhat pink. The powder is of a dark brick-red color; upon the addition of water, the sharp angular fragments assume a deep rich-red color and become more or less rounded and separate into innumerable, small, granular particles among which are a large number of rod-shaped bacteria. On mounting powdered Kino in alcohol the fragments at first assume a deep red color, then mostly dissolve, leaving a number of small, colorless granules and indistinguishable, cellular fragments. Kino is only partly soluble in cold water, and not less than 40 per cent. is soluble in boiling water. The latter solution, when cooled and filtered, shows a faintly acid reaction, gives a dark green precipitate with ferric chloride T.S. and a reddish-violet color with alkalies. The yield of alcoholic extractive is not less than 45 per cent. Kino contains not more than 12 per cent. of moisture, and yields not more than 3 per cent. of ash." U. S.

"In small, angular, glistening, opaque, reddish-black, brittle fragments; transparent and ruby-red in thin laminae. Inodorous; taste very astringent. Almost entirely soluble in alcohol (90 per cent.), slowly and incompletely soluble in cold water, not less than 75 per cent. soluble in
boiling water, the solutions being deep red in color. Almost entirely insoluble in ether. An aqueous solution (1 in 20) yields a voluminous reddish precipitate with dilute mineral acids, and, when largely diluted with water, a greenish-black precipitate with T. Sol. of ferric chloride. Ash not more than 2.5 per cent. In India and the Eastern Divisions of the Empire, Butea Gum (Buteae Gummi) may be employed in making the official preparations for which Kino (distinguished in commerce as East Indian, Malabar, Madras, or Cochin kino) is directed to be used."

If in large masses, it may be reduced without difficulty into minute fragments. It is without odor, and has a bitter, highly astringent taste, with a somewhat sweetish after-taste. It burns with little flame, and does not soften with heat. It imparts its virtues and a deep red color to water and alcohol, but is nearly insoluble in ether. Cold water forms with it a clear infusion. Boiling water dissolves it more largely, and the saturated decoction becomes turbid on cooling, and deposits a reddish sediment. The tincture is not disturbed by water. When long kept, it often gelatinizes, and loses its astringency. (See Tinctura Kino.) Kino undoubtedly consists chiefly of a modification of tannic acid or tannin, which has received the name of kino-tannic acid, with extractive, gum, and sometimes probably a little resin, but we need a careful analysis of the different well-ascertained varieties. The aqueous solution is precipitated by gelatin, the soluble salts of iron, silver, lead, and antimony, mercuric chloride, and sulphuric, nitric, and hydrochloric acids. The precipitate with iron is of an olive or greenish-black color. The alkalis favor the solubility of kino in water, but essentially change its nature and destroy its astringency.

1. EAST INDIA KINO. Malabar Kino.—This is the variety at present probably most used and most highly esteemed, and the only one recognized by the British and United States Pharmacopoeias. Its origin was long unknown. It is now ascertained, through the researches of Pereira, Royle, Wight, and others, to be the product of Pterocarpus Marsupium, a lofty tree growing upon the mountains of the Malabar coast of Hindostan. Kino is the juice of the tree extracted through longitudinal incisions in the bark and afterwards dried in the sun. Upon drying it breaks into small fragments, and is put into wooden boxes for exportation. It is collected near Tellicherry, and exported from Bombay. It is sometimes imported into this country directly from the East Indies, but more commonly from London. From a communication in the
of the Asiatic Society of Bengal, by F. Mason, it appears that kino is also collected in the Tenasserim provinces, in Farther India, and has been exported from Maulmain to Europe. It is produced by a tree called Padouck, which Christison recognized from a description furnished to him by Begbie, of Maulmain, as Pterocarpus Marsupium, so that this kino has the same origin as that from Malabar. Pterocarpus indicus, of the Mauritius Islands, where it is known as sang-dragon, also yields a red kino to commerce.

When kino is boiled in water, the decoction deposits, on cooling, a bright red substance, and a similar deposition takes place when a cold filtered aqueous solution is long exposed with a broad surface to the air. According to Hennig, kino consists of tannic acid about 40 per cent, with a trace of gallic acid, kinoic acid, pectin, ulmic acid, and inorganic salts, with excess of earthy bases. (See A. J. P., xv, 544.) C. Etti obtained a new constituent, kinoin, by extracting kino with ether. He finally adopted the following method as more practicable. One part of gum kino is added to 2 parts of boiling diluted (1 to 5) hydrochloric acid. Kino-red immediately separates as a soft mass, becoming gradually solid on cooling, while the kinoin, mixed with a small quantity of kino-red, remains in solution. The solid residue is once more boiled with water, the liquids are united and shaken with ether. The ethereal solution, on evaporation, leaves a crystalline reddish residue, which is dissolved in hot water, on the cooling of which tolerably pure crystals of kinoin are obtained. By continued recrystallization they are obtained colorless. Their formula is $C_{14}H_{12}O_6$, and kino-red is the anhydride of this:

$$2C_{14}H_{12}O_6 + H_2O = C_{28}H_{22}O_{11}$$

This kino-red heated to 160° to 170° C. (320°-338° F.), parts with a molecule of water and yields a lower anhydride, $C_{28}H_{20}O_{10}$. Both anhydrides are precipitated by gelatin, but kinoin itself is not. When heated with hydrochloric acid to 120° to 130° C. (248°-266° F.), kinoin yields methyl chloride, gallic acid, and catechol, and hence probably has the constitution of a guaiacol or methyl-catechol gallate. Kino contains about 1.5 per cent. of kinoin. (Ber. d. Chem. Ges.; N. R., Feb., 1897.) Kremel found Malabar kino, Butea gum, eucalyptus kino, and the kino from Coccoloba uvifera to be free from Etti’s kinoin, but to contain a body acquiring, like kinoin, a red color with ferric chloride, which proved to be pyrocatechuic acid; this was present either alone or mixed
with gallic acid. (A. J. P., 1883, 267.) Some doubt was also thrown upon
the value of Etti’s conclusions by White (P. J., 1903, p. 676), who failed
to find several of the constituents reported by Etti. The true chemistry of
kino may therefore be considered to be in a somewhat doubtful state.
This is probably due to the fact that many different drugs have
appeared in commerce under that name. Kino contains in its natural
condition an oxidizing enzyme or oxidase which is the cause of the
gelatinization which takes place in preparations of this drug. This
enzyme can be destroyed by heat and advantage is taken of this fact in
making Tinctura Kino (which see). In an examination made by David
Hooper of ten varieties of East Indian kino, the proportion of tannic acid
was found, after thoroughly drying the kino, to vary from 80 to 97 per
cent. of the whole mass. (Agricultural Ledger of India, No. 11, 1901.)

It is said that catechu, broken into small fragments, has sometimes been
sold as kino. Genuine kino is sometimes substituted by the extract of
krameria. The latter is more brittle and dissolves, more quickly in water.

2. WEST INDIA OR JAMAICA KINO.—This is believed to be the
product of the Coccoloba uvifera L., or sea-side grape. It grows in the
West Indies and neighboring parts of the continent. The kino is said to
be obtained by evaporating a decoction of the wood and bark, which are
very astringent.

Although it has been many years since any large quantity appeared in
our markets, it may occasionally be met. It is contained in large gourds,
into which it was evidently poured while in a liquid or semi-liquid state,
and then allowed to harden. When taken from the gourd it breaks into
fragments of various sizes, upon an average about as large as a
hazelnut, and having some tendency to the rectangular form. The
consistence of these fragments is uniform, their surface smooth and
shining, and their color a dark reddish-brown approaching to black.
They are, however, neither so glistening nor so black as the East India
kino. In mass they are quite opaque, but in thin splinters are
translucent and of a ruby redness. They are readily broken by the
fingers into smaller fragments, are easily pulverized, and yield a dull-
reddish powder, considerably lighter colored than that of the East
Indian variety. The West India kino is without odor, and has a very
astringent, bitterish taste, with a scarcely observable sweetish after-
taste. It adheres to the teeth when chewed, although rather less than
the East Indian variety, and colors the saliva red. The solubility of
Jamaica kino was very carefully examined by Robert Bridges, who found that cold water dissolved 89 per cent., and alcohol 94 per cent. The portion dissolved by alcohol and not by water was probably of a resinous nature, as it appeared to be viscid, and very much impeded the filtration of the aqueous solution. Considering the nature of this substance, the form of kino in which it was found is probably, like that from the East Indies, an inspissated juice. Guibourt, who states that Jamaica kino is but slightly dissolved by cold water, must have operated on a different product.

3. SOUTH AMERICAN KINO. Caraccas Kino.—In 1839, an astringent extract was described which had been introduced into our market, derived from Caraccas, and known by that name to the druggists. It is probably the same as that described by Guibourt, in the last edition of his History of Drugs, as the kino of Colombia. As imported, this variety of kino is in large masses, some weighing several pounds, covered with thin leaves, or exhibiting marks of leaves upon their unbroken surface, externally very dark, and internally of a deep reddish-brown or dark port-wine color. Some of the masses are very impure, containing pieces of bark, wood, leaves, etc.; others are more homogeneous, and almost free from impurities. The masses are broken up by means of a mill so as to resemble East India kino, from which, however, this variety differs in being more irregular, less sharply angular, more powdery, and less black. In appearance, taste, odor and other sensible properties this kino closely resembles the West India variety. It is not improbable that they are derived from the same plant, and there is no difficulty in supposing that this may be the Coccoloba uvifera, as that tree grows as well upon the continent as in the islands. South American kino was found by Bridges to yield 93.5 per cent. to cold water, and 93 per cent. to alcohol; so that, while it has almost the same solubility as Jamaica kino in alcohol, it is somewhat more soluble in cold water. The aqueous solution in this case was not embarrased by the adhesive matter which impeded the filtration in the former variety, and the want of a minute proportion of resinous matter in the South American kino is the only apparent difference between the two drugs.

4. AFRICAN KINO.—The original kino employed by Fothergill was known to be the product of a tree growing in Senegal, and upon the banks of the Gambia, on the western coast of Africa, but the precise character of the tree was not ascertained until a specimen, sent home by Muugo Park during his last journey, enabled the English botanists to
decide that it was the Pterocarpus erinaceus of Lamarck and Poiret. A particular account of Pterocarpus erinaceus and its concrete juice, with a figure, by W. F. Daniell, is contained in the P. J. for August, 1854 (vol. xiv, p. 55). The importation of African kino has long ceased. In 1896, however, a consignment of African kino reached London. It was examined by E. M. Holmes, who stated that it was evidently yielded by P. erinaceus. (C. D., 1896, 226.) It is said to be still used by the Portuguese of Angola, under the name of Sangue de Drago. As described by Fothergill, the African kino, for which he proposed the name of gummi rubrum astringens Gambinense, was in lumps of about the size of those of gum Senegal or dragon’s blood, and so similar in appearance to the latter that a good judge might easily be deceived. These lumps were hard, brittle, opaque, and almost black, but minute fragments were reddish and transparent like garnet. The drug was inodorous, of a strongly astringent and sweetish taste, and soluble in water to the extent of about five or six parts out of seven, forming a deep red astringent infusion. There can be little doubt that this variety of kino is a concrete juice, which exudes either spontaneously or from wounds in the bark, and hardens in the air. (Med. Obs. and Inq., i, 358.)

MACARANGA KINO is obtained from Macaranga Roxburghii Wright, of the Deccan peninsula. It occurs in the form of odorless, tasteless tears or irregular masses. The tears have fibrous fractures and when immersed in water yield unravelling fibers giving the appearance of a sea anemone. According to Hooper, this kino yields from 6 to 15 per cent. of a peculiar tannin and is closely allied to Butea kino, from which it is distinguished by fibrous tears and the fact that it contains so much gum which swells without dissolving in water. (P. J., lxvi, 616.)

MYRISTICA KINO.—There has been produced in Southern India a kino consisting of (Smaller or larger angular pieces, of deep garnet color, in thin fragments, and having the general characteristics of Malabar kino; according to E. Schaer, it is a product of Myristica malabarica, of M. fragrans, and probably of other species of the genus. In all important respects these kinos are said to correspond with Malabar kino, but to be distinguishable by containing crystals of calcium tartrate. Myristica Kino is probably a distinctive product from the so-called Syndai varnish, a rich red fluid obtained from the Myristica gibbosa Hook. f., and employed in Assam as a varnish. This varnish is highly astringent and after exposure becomes perfectly impervious, the changes being due to the presence of a ferment or enzyme. As has been shown by D. Hooper
Syndai varnish, if kept in corked bottles, gelatinizes in a few weeks. Edmund White made an investigation into the cause of the gelatinization of tincture of kino (P. J., May, 1903), from which it appeared that this phenomenon was due to the presence in the kino of an enzyme belonging to the oxydases, and this enzyme was subsequently isolated by David Hooper from the fresh juice of Myristica gibbosa. (Proc. A. Ph. A., 1903, 733.) It is believed by White that this enzyme may be eliminated from the official as well as other kinos by a judicious method of collection, and considers it probable that the following one, adopted by J. Q. F. Marshall and described in the "Agricultural Ledger" (1900, No. 11, 381), will accomplish this: "A longitudinal cut is made with an axe or knife, called acha katti, through the bark of the trees, down to the cambium, about 1 1/2 feet long, and side outs are made to lead into this. A bamboo tube is then fixed at the bottom of the main incision in order to catch the juice. In the course of about twenty-four hours the flow of gum ceases and the bamboo is taken down. When several of these bamboo cups are nearly full they are taken to headquarters and emptied into a large cauldron and the juice boiled. During the boiling, the impurities, consisting of pieces of bark, wood and leaves, rise to the surface and are skimmed off. When sufficiently concentrated to the consistence of a thick extract it is exposed to the sun, in thin layers, in shallow vessels until it is dry enough to crumble to pieces. The kino is then weighed and packed away in wooden cases." (P. J., 1903, 702.)

Botany or Blue Mountain kino is obtained from Angophora lanceolata Cav. Colombo kino is obtained from a number of species of Angophora. Hooper (P. J., 1908, xxvii, 161) reports the occurrence of three new astringent plant juices or kinos. They are derived from Jatropha Curcas, from South Salem; Xylia doldbriformis, from Burma; and Parkia insignis ("Myauk-ta-nyæ"), also from Burma.

Uses.—Kino is powerfully astringent, and in this country is much used for the suppression of morbid discharges. In diarrhea, not attended with febrile excitement or inflammation, it is often an excellent adjunct to opium and the absorbent medicines, and is a favorite addition to chalk mixture. It is also used in chronic dysentery when astringents are admissible; in leucorrhœa and diabetes; and in passive hemorrhages, particularly those from the uterus and the intestines. The infusion may be made by pouring eight fluidounces of boiling water on two drachms of the extract, and straining when cool; aromatics may be added, if
deemed advisable. The dose of this infusion is a fluidounce (30 mils). The proportion of alcohol in the tincture renders it frequently an unsuitable preparation.

Dose, eight to thirty grains (0.5-2.0 Gm.).

**KINO EUCALYPTI. Br.**

**EUCALYPTUS KINO [Eucalyptus Gum Red Gum]**

"Eucalyptus Kino is an exudation from the stem of various species of Eucalyptus." Br.

Eucalypti Gummi, Br. 1898; Australian Kino.

Eucalyptus kino is prepared from a number of species of Eucalyptus, but most of the commercial article is prepared from E. rostrata, a tree which is very abundant in Western Australia. This tree received its name from the rastrate character of the opercula. Masses of kino are sometimes found in cavities between the wood and the bark, this being due to the evaporation of the sap in these places. It is usually obtained by incising the trees and collecting the exuding liquid which is then dried in the sun. It has been stated that five hundred pounds of the kino are sometimes yielded in a single year by one tree, but this seems to be a great exaggeration. Occasionally the juice reaches England unevaporated. Kino juice has a fine deep red color, a slightly aromatic odor, and a decidedly astringent taste, and on evaporation yields a genuine kino in varying amount. It must not be confounded with the so-called Liquid Kino, or apple tree juice, which is obtained from incisions in the Angophora intermedia or narrow-leaved apple tree of Australia. This varies from the consistency and colorless-ness of water to an orange brown or reddish-brown liquid as thick as molasses. It contains catechin and tannie acid, and is said to be especially employed for the purposes of tanning nets.

**Properties.**—Australian kino usually occurs in dark, reddish-brown (not reddish-black) masses or grains, which when sufficiently thin may
be translucent and garnet-like. This form of kino is at the present time very largely used and while similar to the official or East Indian Kino in physical and therapeutical properties has not in solution the tendency to gelatinize. For further information concerning it the reader is referred to an elaborate paper on it by J. H. Maiden, in P. J. , Oct., 1889; also A. J. P., 1897, 1.

“In very dark reddish-brown grains or small masses. Thin fragments transparent and ruby-red, or garnet-red. Inodorous; taste astringent. Tough and adhering to the teeth when chewed. Not less than 80 per cent. soluble in water, Almost entirely soluble in alcohol (90 per cent.)." Br.

Eucalyptus kino contains catechin, pyro-catechin and kinoin, and in some specimens a volatile oil, giving a slightly aromatic odor to the drug, which is especially developed by hydrochloric acid. J. H. Maiden (A. J. P., 1895, 575) states that Australian kino contains eudesmin and aromadendrin. The former of these when purified exists as a pure white mass with a luster resembling spermaceti. It is soluble in hot water, but crystallizes out again on cooling. It is soluble in alcohol, ether, acetic ether, and chloroform, but not in benzene, petroleum spirit, or carbon disulphide. It is dissolved by sulphuric acid with a dark color changing to purple, by nitric acid with a beautiful yellow color. Its formula is given as $C_{26}H_{30}O_8$, and its melting point as 99° C. (210.2° F.). The second substance was also obtained crystallized from boiling water, and melted at 162° C. (323.6° F.). No analysis has been made of it.

**Uses.**—It does not equal kino in astringency. It is used for diarrheas of relaxation, and other affections for which kino has been employed, and is also largely employed as the basis of lozenges and gargles for the relief of relaxed conditions of the pharynx.

Dose, from five to twenty grains (0.3-1.3 Ghn.).

**Off. Prep.**—Trochiscus Kino Eucalypti, Br.

**Kola.** N. F. IV. Cola. Kola Nuts. Semen (Nuces) Colae. Noix de Cola, Noix de Gourou, Cafedu Soudan, Fr. Kolanus, G.—It is described by the N. F. as "the dried cotyledons of several species of Cola Schott and Endlicher (Fam. Sterculiaceae), yielding not less than 1.5 per cent. of caffeine." N. F. The official drug is obtained chiefly from the large African tree Cola Acuminata R. Br., which is extensively cultivated in various portions of the tropical world for its seeds. The latter, under their Guinea name, or the
Soudan name of guru nuts, are extensively employed as a caffeinic stimulant in Africa and other portions of the world. Six hundred tons of them are said to be sent yearly to Brazil for the use of the negroes, who, it is affirmed, also employ the seeds of Sterculia Chica A. St.-Hill. and S. striata A. St.-Hill. Three varieties of kola nuts are said to be the product of Cola acuminata. The most valuable, the kola of Sakhala, is the largest, and is of a white color. The kola of Kassi, of Sierra, and of Toute, is of medium size, red or white. The kola of Maninian is small and red. Of this white kola there are two varieties, one whitish, resembling the kola of Sakhala but smaller; the other more or less rose-colored and larger. The kola nut itself consists of the cotyledons which are irregularly plano-convex, broadly oval, or approaching circular in outline, from 2.5 to 5 cm. in length, or triquetrous; heavy, hard and tough; brown with the outer surfaces slightly wrinkled, the inner surfaces lighter and smoother; edges slightly incurved and sharp. Odorless; taste slightly astringent. The powdered drug is reddish-brown and, when examined under the microscope, exhibits numerous starch grains, some of which show alteration, the normal grains up to 0.045 mm. in diameter, the smaller ellipsoidal or spherical, the larger ellipsoidal or irregularly oblong and occasionally with a protuberance on one side; many of the larger grains show lamellae and a circular point of origin of growth or a fissure through the center, and a distinct cross when examined with the polarizing microscope; parenchyma cells numerous, about 0.065 mm. in diameter, with reddish-brown walls.

Assay.—" Introduce 6 Gm. of Kola, in No. 60 powder, into a flask and add 120 mils of chloroform and 6 mils of ammonia water. Stopper the flask, shake it frequently for half an hour, then let it stand four hours. Again shake the flask vigorously and, when the drug has settled, filter the liquid rapidly through a pledget of purified cotton and collect 100 mils of the filtrate, representing 5 Gm. of Kola. Evaporate the clear filtrate to dryness and dissolve the residue in 5 mils of weak sulphuric acid with the aid of a gentle heat. When the liquid has cooled, filter it into a separator and wash the container and filter with several small portions of distilled water. Now add ammonia water until the liquid is distinctly alkaline to litmus and shake out the alkaloid with successive portions of chloroform until completely extracted, as shown by testing with iodine T.S. Evaporate the united chloroform solutions and dry the residue to constant weight at 80° C. (176° F.). The weight is the amount of caffeine from 5 Gm. of Kola. Kola yields not more than 3 per cent. of ash." N. F.

Daniell (P. J., 1865) was the first to show that kola nuts contained caffeine. Subsequently an elaborate analysis yielded to Attfield 2 1/3 per cent. of caffeine from the nut. Schuchardt summarizes the results of his chemical analyses as follows: 1. Martinique nuts contained 1.06 per cent. caffeine; 2, Ceylon, 1.39 per cent.; 3, Gaboon, 1.47 per cent.; 4, Tropical West African coast. Sierra Leone, 1.69 per cent.; 5, Tropical West Africa, interior, 1.61 per cent. The chemical studies of Parke, Davis & Co. show that as found in American commerce these nuts contain from 0.72 to 2.02 per cent. of caffeine. Heckel and Schlagenhaufen (A. J. P., 1884) give theobromine 0.023 per cent., caffeine 2.35 per cent., tannin 1.62 per cent., as the result of their analyses. The researches of Knebel (A. J. P., 1892, 190), confirmed by Hilger (Ibid., 568), show that fresh kola nuts probably contain no caffeine, but a glucoside, kolanin,, which yields by its decomposition caffeine, glucose, and kola-red
Betaine is also stated to be present. The glucoside is decomposed by a ferment present in the nuts, and therefore readily yields the caffeine as a decomposition product. Schweitzer (1895) confirmed the results of Knebel and Hilger, and proposed for kolanin the formula \( C_{12}H_{15}N_4O_{21} \). Knox and Prescott (Proc. A. Ph. A., 1896, 136), after an investigation, assert that the kola ferment does not assist in the liberation of caffeine, but attribute the presence of caffeine to the action of heat and moisture; they also give the name of kolatannin or kola-tannic to the tannin of kola nuts, and propose a method of assay. (Proc. A. Ph. A., 1897, 131.) For Carlo's method of assay, see P. J., 1896, 289. Goris (P. J., 1906, lxxvi, p. 261) has separated from the kola nut a basic glucoside to which he gives the name of kolatine.

Travellers in Africa assert that the fresh kola nuts have a stimulant action which is not explicable on the ground of their caffeine content. But as they appear in European commerce their action is undistinguishable from that of the other caffeinic drugs. The experiments of Mosso (A. I. B., xix) seem to demonstrate conclusively the inertness of kola-red.

Kola is about equivalent to guarana, tea, coffee, etc., and may be substituted for them. In dose of one hundred and fifty grains (9.8 Gm.) a day, A. Hudson (T. G., ii) has found the nuts to act decisively in cardiac weakness.
